AGRICULTURAL SOCIETY OF NIGERIA

LIST OF PAST PRESIDENTS

Professor A. Oyenuga	-	(1962 – 1964)
Chief T.S.B. Aribisala	-	(1964 – 1967)
Chief B.S. Oloruntola	-	(1967 – 1969)
Professor L.K. Okpeke	-	(1969 – 1970)
Chief E.C. Ogor	-	(1970 – 1972)
Chief Ndaeyo	-	(1972 – 1973)
Chief C.O. Oranyeli	-	(1973 – 1977)
Dr. B.E. Onochei	-	(1977 – 1979)
Professor I.B. Olugbemi	-	(1979 – 1984)
Professor B.N. Okigbo	-	(1984 – 1988)
Dr. L.S.O. Ene	-	(1988 – 1993)
Sir Tunji Akiniyi	-	(1993 – 1998)
Dr. L.C. Igbokwe	-	(1998 – 2002)
Dr. E.D. Imolehin	-	(2002 – 2006)
Dr. C.O. Okonkwo	-	(2006 – 2010)
Professor I.U. Abubakar	-	(2010 – 2014)

AGRICULTURAL SOCIETY OF NIGERIA

ABSTRACT
The study analysed the determinants of occupational choice among fishermen in the Riverie areas of Ilaje and Ese-odo Local Government Areas of Ondo State, Nigeria. Multistage random sampling technique was employed in the collection of data from one hundred and forty four fisher men from the study area through the use of a structured questionnaire. Data were analyzed using descriptive statistics of frequency counts and percentages. The results indicated that fishermen were mostly male (77.8%), married (75.5%) between the age of 30 and 39 (40-43%). The result also indicated that majority inherited fishing as family business (92.40%), to earn a living (90.30%), ready market for fish (90.30%) and involvement of less skill (86.80%) as the determinants of fishing as an occupation among the respondents while constraints faced in fishing industry include difficult access to credit (93.80%), lack of government assistance (93.10%), weed interference (92.40%) and unpredictable weather (90.30%). The study recommended that young people should be encouraged the more to go into fishing as this will increase food security as well as creating employment among other things. Government and other stakeholders should come to the aid of the fishermen in mitigating the constraints faced by the fishermen.
Key words: analysis, fishermen, gender, occupation, riverie

INTRODUCTION
Nigeria is a maritime country with tremendous aquatic and fisheries resources that make significant contributions to livelihood, food security and the overall economy of the nation. The country's fresh water and marine fisheries resources are enormous and offered tremendous opportunities for fish production through capture and culture fisheries. The freshwater bodies comprised of seasonal and perennial rivers, lakes reservoirs and dams, estimated at about 14 million hectares (Ipinjolu *et al*, 2014). Furthermore, the coastal waters, comprising of the creeks, lagoons and estuaries, have been estimated at about 37, 934km^2. (FDF, 2008). Capture fisheries involve the harvesting of naturally existing stocks of wild fish. This can be done either by small scale/artisanal fishers or by industrial/ commercial trawlers. In artisanal fisheries, production is achieved by individual or by small groups by the use of labour intensive gear (Anene *et al*, 2010). Characteristically, artisanal fishers operate from dug out, wooden carries that are more often than not unmotorised (Coates 2000). FAO (2005) has identified and opined that Nigeria is one of the countries in the West African region with great potentials to attain sustainable fish production since the country is blessed with large coastlines comprising lagoons, estuaries, wetland and series of interconnecting creeks. Fishing is a traditional activity involving the hunting and gathering of aquatic products for food. Fish and marine products include freshwater and ocean fish, shellfish, ocean mammals and seaweed as well as plankton. Economically, fish provides an important source of food and income for both men and women and fishing has an important social and cultural position in reverie communities. However, the tradition of fishing has been transformed over several decades of human civilization to become a resource extraction industry spanning the entire globe. Man first learned to catch fishes in traps and nets. These fishing activities were limited at first to the lakes and rivers, but as men improved on the boats and fishing technologies, they ventured into sheltered coastal areas, river mouths and eventually farther out on to the continental shelves, relatively shallow ocean plains between the land and the deeper ocean areas (Olubanjo *et al*., 2007).
Fisheries resources overexploitation and Coastal environmental degradation must be seen as vital issues in the long-run management and sustainability agenda of many developing countries if the contribution of the sector to real GDP and the welfare condition of the people in the coastal areas are to be maintained (Acqual and Abunyuwah 2011). This study therefore analysed the determinants of occupational choice among fishermen in the Riverie areas of Ilaje and Ese-odo Local Government Areas of Ondo State, Nigeria. Specifically, the objectives of the study are to: (i) examine the socio- economic characteristics of the respondents (ii) analyse the factors that determines the choice of fishing as an occupation (iii) describe the constraints militating against the respondents' operations in the study area.

METHODOLOGY
Study area
The study was carried out in Ilaje and Ese – Odo local government areas of Ondo State, Nigeria. About 80% of the study area is covered with water, Swamp and flood plains with a coastline of 80km long. This makes Ondo State qualify as a maritime state and makes it rank among the highest artisanal fish producers in the country.

Method of selection of respondents and data collection

Multistage random sampling technique was used to draw samples for the study. Two of the three local government areas that are predominately fishing communities were selected out of the eighteen local government areas (LGAs) in the State. Secondly, six fishing communities were selected from each of the two LGAs earlier chosen to give a total of 12 fishing communities covered in the study. Subsequently, 12 fishers were randomly selected from each of the 12 communities, to constitute a total of 144 respondents.

Data for the study were collected from fishers using interview schedules that were administered to the selected respondents with the assistance of trained enumerators that were fluent in the local dialects of the respondents. Data collected include personal characteristics such as gender, age and marital status, etc as well as constraints they face in their occupation. Data from the survey were analyzed using descriptive analysis such as frequency counts and percentages.

RESULTS AND DISCUSSION

Socio – economic characteristics of the fishermen in the study area

In Table 1, findings show that majority of the fishermen 77.8% were male and married (75.7%). The dominance of male in the profession could be attributed to the drudgery nature of fishing. Generally, males are physically stronger than their female counterparts and so the use of some fishing gear such as trawl and cast net are better operated by males, leaving out their female counterparts in fishing. Age distribution of fishermen between 30 – 39 years was the highest (40.3%). The implication is that young men dominate the occupation. This could mean that fishing in the study area is majorly engaged by those who are physically strong to be able withstand the stress and drudgery associated with it, thus increased productivity. Faridi and Gilani (2012) in a similar study in Pakistain reported the involvement of more male in fishing as well as joing the occupation at an early stage in life. This study corroborates with theirs. Majority (75.7%) of the respondents were married. By implication, majority of the respondents are responsible family members who are likely to spend their profits on their family.

Socio-economic factors influencing the choice of fishing as an occupation

Table 2 showed that 92.4% inherited fishing as a family business, 90.3% were in fishing to earn a living. Furthermore, 90.3% indicated available ready market for fish while 86.8% indicated that fishing involves less skill. Fishing as an occupation may have sustained their livelihoods for so many generations; therefore, the choice of fishing as an occupation is plausible. The result corroborated Acquah and Abunyuwah (2011) who reported that 87.8% of respondents are involved in fishing as a family business in their study.

Constraints faced by fishermen in their operations

Table 3 shows constraints faced in the fishing industry. Majority, (93.8%) indicated difficulties in accessing credit, 93.1% indicated lack of government assistance, while 92.4% indicated weed interference and unpredictable weather 90.3%. In a similar study, Adeokun *et al* (2006) indicated lack of credit as one of the major constraints faced by the fishermen.

CONCLUSION AND RECOMMENDATIONS

The study had shown some of the factors that influence people in the study area into choosing fishing as an occupation as well as the constraints faced by the fishermen. It is therefore; recommended that young people should be encouraged the more to go into fishing as this will increase food security as well as creating employment among other things. Government and other stakeholders should come to the aid of the fishermen in mitigating the constraints faced by the fishermen.

ABSTRACT

The study examined the socio-economic determinants of yam output in Imo State, Nigeria. Multistage random sampling technique was used in selecting 120 yam farmers for the study. Data collected was analysed using descriptive statistics such as frequency, percentage and multiple regression. The results showed that farming experience, age of farmers, amount of capital invested, farm size and labour use level were strong determinants of yam output, explaining 73.6% of the total variation in yam output at 1.0 percent probability level. Findings revealed that the major problems affecting yam production in Imo Sate were scarcity and high cost of planting materials, inadequate capital, high cost of input, storage and poor road network. It is therefore recommended that increase in investment capital is needed for yam production.

Keywords: Yam production, output, socio-economic and Imo State

INTRODUCTION

Yam (Discorea spp) is a crop of immense importance in Nigeria. It is one of the staple foods, a good source of income and serves other social and cultural purposes (Nwoko *et al*., 2000). Annual production of yam in the country is estimated at 37.8 million tonnes (FAO, 2013). Nigeria is the largest producer of yam in the world and there is need for increasing production to satisfy domestic and export demand for yams (Okonkwo, 2011). Production of yam in the country had not been able to meet its demand especially in Imo State. This is due to the fact that the edible part of yam is used as its planting material (Ikeorgu *et al* (2010) and also as a result of challenges faced by farmers due to some of their socio-economic variables in yam production (Njoku *et al*., 2008). Hence scarcity of planting material and hindrances of some socio-economic variables of farmers are among the constraints in yam production. Therefore there is need to ascertain those socio-economic variables that affects yam production in the study area. The objectives of this study were to determine the socio-economic variables that influence yam output in Imo State; and to identify the problems of yam farmers.

METHODOLOGY

The study was conducted in Imo State. Imo state is located in the South-Eastern geo-political zone of the Nigeria, occupying the area between the lower River Niger and upper and middle Imo River. Imo State is bounded by the states of Anambra in the north, Abia in the east and Rivers in the south (Imo ADP, 2001). Imo State has an estimated area of 5,150 square kilometres. The state has 21 local government areas with three agricultural zones as Orlu, Okigwe and Owerri. Farming is the predominant occupation of the people. The area is favourable for the production of yam, cassava, cocoyam, maize, okro and other vegetables. In each of the three State's Agricultural Zones, two blocks were randomly selected and in each of the blocks, two circles were randomly selected. Ten yam farmers were randomly selected in each of the selected circles giving a total of 120 farmers. Primary data was collected through oral interview and structured questionnaire. Data was analyzed using descriptive statistics like frequency table, percentage, and multiple regression. The multiple regression model was specified implicitly as follows:

$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, ei)$

Where:

Y = Output of Yam (tonnes/ha)
x_1 = Age of the farmer (years)
x_2 = Level of education (years spent in school)
x_3 = Marital status (Dummy variable; 1 = married, 0 = single)
x_4 = Years of farming experience
x_5 = Farm size (ha)
x_6 = Amount invested (₦)
x_7 = Labour use (mandays)

e = Error term.

The multiple regression was run in four functional forms: Linear, Semi-log, Double log and Exponential forms. The Double-log equation was chosen based on econometric and statistical reasons such as the number of regression coefficients that were significant, R^2 value, the significant level of F-ratio and agreement with a priori expectations.

RESULTS AND DISCUSSION

Estimation of Socio-economic Factors of Yam Output

Table 1 showed that five variables were statistically significant in the socio-economic determinants of yam output. The variables were farming experience, age of farmer, amount invested, farm size and labour use level. Farming experience has positive and significant relationship with yam output of the farmers. This indicates that with more farming experience, a farmer can become more or less averse to the risk involved in yam production. It also implies that experienced farmers are willing to explore their environment to boost their productivity (Obinne, 2007). Age of farmer has a significant positive effect on yam output. This shows that, older farmers had more yam outputs and are more productive than the younger ones. This result could be explained given the fact that older farmers have gained more experience in farming. Amount invested in yam production has positive and significant relationship with output. This indicates that as farmers invest more money in yam production the yam output increases. Farm size has positive significant relationship with yam output. This implies that as the farmer increases his farm size for yam production that will equally increase his output. Results in Table 1 also showed that labour use level had positive and significant relationship with yam output. This indicates that as farmers engage more labour in yam production, there will be a corresponding increase in yam output. This finding agrees with that of Yisehak (2008) that increase in labour enhances output and farm productivity.

Problems of Yam Production

Table 2 shows that the major problems affecting yam production in Imo Sate were scarcity and high cost of planting material (91.7%), high cost of input (81.7%), inadequate capital (75%), storage (62.5%) and poor road network (45%). This result revealed that scarcity/high cost of planting is a very serious challenge in yam production. This agrees with Ikeorgu *et al* (2010) that scarcity and/or high cost of healthy seed yams are the greatest constraints in yam production in Nigeria.

CONCLUSION

The results of this study have shown that farming experience, age of farmer, amount invested, farm size and labour use level were the socio-economic variables that positively and significantly affect yam output. The major problems affecting yam production in Imo Sate were scarcity and high cost of planting material, high cost of input, inadequate capital, storage and poor road network. It is therefore recommended that increase in investment capital is needed for yam production.

ABSTRACT
The study assessed the factors influencing adoption of yam minisett technology in Ebonyi State, Nigeria with the following objectives: describe socio-economic characteristics of yam farmers in the study area; identify sources of information on yam minisett production technologies available to farmers in the study area; determine the factors that influence the adoption of yam minisett technology in the study area; and identify the constraints militating against the adoption of minisett technology by the yam farmers in the study area. A multistage random sampling technique was adopted in the selection of blocks, circles and yam farmers. First 4 blocks were randomly selected from each of the three zones to give a total of twelve (12) blocks. From the selected blocks, five (5) circles each were randomly selected to give a total of sixty (60) circles. Finally, two (2) yam farmers were randomly selected from the selected circles to give a total of one hundred and twenty yam farmers. Percentages, means, frequency distribution, regression analysis were used for the analysis of the data. Majority (69.17%) of the farmers received information on the technology and was aware of the technology; the study also established that there is significant relationship between farmers' social-economic characteristics and adoption level. The coefficient of the tobit regression model shows that farm income and contact with ADPs were positive and statistically significant at 1% level. The coefficient of gender, age, household size and farming experience were negatively related to the level of adoption of yam minisett technology and were statistically significant at 1% and at 5% respectively. Therefore, for the full potential of minisett technology to be realized in the study area constraints to yam minisett technology has been identified in this study, integration of farmers practices into yam minisett packages are very necessary since bases of research is to transfer the findings to the end users.
Keywords: adoption, technology, yam minisett, Ebonyi

INTRODUCTION

Yam is referred to as the "king" of all crops in Nigeria because of its monetary value per unit weight compared to food crops (Orkwor, 1998). This indicates that the crop could contribute to export earnings should production increase. However, one of the most critical constraints to increasing production is scarcity and high cost of healthy seed yams (NRCRI, 2004). In Nigeria, yams contribute significantly to the national economy and income by providing employment to many rural dwellers (Asumugha *et al*., 2010) and cheap carbohydrate staple food for over 80 percent of the populace (Nwachukwu, 2008). Seventy (70.0%) of the population live in rural areas where farming is their primary occupation (Okuneye, 2002; NPC, 2006; Nwachukwu, 2009). Majority of the farmers in rural areas produce yam and other food crops for their own consumption and income because their living standards are low arising from low agricultural productivity (Onyenweaku, 1991). Yam production in Nigeria has been observed to be more financially rewarding enterprise than groundnut, rubber and cotton production irrespective of its enormous constraints (Idaclaba, 2004).

According to Onwuka (2012), yam is one of Nigerians leading root crops, both in terms of land under cultivation, and value of production. Seed yams constitute over 33.0% of the cost outlay in yam production with small whole tubers of about 100-300 grams used as planting materials in production of about 1,000 grams weight of ware yam (Orkwor *et al.*, 1998).

Nigeria like other underdeveloped countries is still facing a persistent food shortage problem. Seed yams are the most important input required for yam production. The scarcity and high cost of planting materials constitute major constraints to yam production in Nigeria, especially Ebonyi State. Seed yams constitute as much as 40% of the total cost of production. As a result of the unavailability/high cost of seed yams, many yam farmers have resorted to planting their yam farm with any yam material they can lay their hands on which may be low yielding. Consequently the traditional yam barns that were once the prides of the rural yam producing communities in Ebonyi State have now disappeared.

Since the development of Minisett technique in the late 1970's, the level of awareness and adoption as a commercial production practice for seed yam is still very low (Okoro, 2008).

Otoo *et al*., (2008), observed a low rate of adoption of yam minisett technology as a result of high degree of risk, small size of minisett and other extraneous factors making them vulnerable when planted in the field and other socio – economic characteristics of farmers in spite the effort made by the Food and Agriculture Organization (FAO) through the root and tuber improvement and marketing programme to promote the adoption of this technology.

The study therefore, has the following objectives and they ate to: examine the various sources of yam minisett technology recommendation used by farmers in the study area; estimate the factors that influence the adoption of seed yam technology by farmers in the study area; and describe the constraints faced by farmers in yam minisett technology in the study area.

METHODOLOGY

The study was conducted in Ebonyi State. The State is located in the South Eastern geo-political zone of Nigeria. The State has a population of 2.3 million people and a land mass of 5,9300km^2 (NPC, 2006). The state shares boundary with Cross River State on the East, Enugu State on the West, Benue State on the North, Abia State on the South. Ebonyi State lies between latitudes $5^0 10^1$N and $6^0 35^1$ North of the equator and longitudes $7^0 10^1$E and $8^0 5^1$E of the Greenwich Meridian. The state has three agricultural zones in Ebonyi State are Ebonyi North, Ebonyi Central and Ebonyi South. It is a leading producer of rice and yam in South Eastern Nigeria. The state is also endowed with artisanal fishing practices because of rivers, streams, lakes and flood plains prevalent in the state, thereby making fishing a revenue earner for the state.

Sampling Technique

A multistage random sampling technique was adopted in the selection of blocks, circles and yam farmers. First 4 blocks were randomly selected from each of the three zones to give a total of twelve (12) blocks. From the selected blocks, five (5) circles each were randomly selected to give a total of sixty (60) circles. Finally, two (2) yam farmers were randomly selected from the selected circles to give a total of one hundred (120) yam farmers in Ebonyi State.

Data Collection and Analysis

Primary data were collected by the use of questionnaires in eliciting information from the participating farmers. Inferential and Descriptive statistics were used for the data analysis. The factors that influence the adoption of yam minisett technology packages by farmers were determined using tobit regression analysis.

Since the level of adoption of yam minisett technology packages, cannot be negative (the threshold is zero) the dependent variable can be written using an index function approach in accordance with Onyenweaku *et al*., (2010).

$Ii = B^T X + ei$... (1)

$Yi = O$ if $Ii = T$... (2)

$Yi = I$ if $I > T$.. (3)

Where;

Y represents a limited dependent variable, which simultaneously measures the decision to adopt the technologies and intensity of adoption.

I^x is an underlying latent variable that indexes adoption.

T is an observed threshold level

X is the vector of independent variables affecting adoption.

βi is a vector of parameters to be estimated

ei = error term.

If the non variable T becomes a continuous function of the independent variables and O otherwise for the generated case, the value of log likelihood function is stated explicitly as;

$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, + ei)$

Where:

Y = level of adoption of technologies (measured by numbers of adoption scores of the respondents)

X_1= Gender (Male = 0, Female = 1)
X_2 = Age (in years)
X_3 = Educational status (measured by the number of years of farmer spent in school)
X_4 = Household size (numbers)
X_5 = Farming experience (years)
X_6 = Farm size (hectares)
X_7 = Farm income (₦)
X_8 = Contact with ADP extension officers (Yes=1, No=0)
ei = Error term

RESULTS AND DISCUSSION

Sources of Information Available to Farmers

The distribution of respondents by sources of information on yam minisett technology available to them is presented in Table 1.

The results showed that the major sources of information on yam minisett technique to farmers were the ADPs (66.67%). About 12.5% of the farmers received their own information from the research institute and 5.83% from radio/television and cooperative society respectively. This implies that majority of the farmers got their information from the ADPs, this agrees with Bolarinwa and Oladeji, (2009) who also reported the ADPs as a good source of information on yam minisett technology to the farmers in Osun, Oyo and Kwara States of Nigeria.

Socioeconomic factors influencing the Level of Adoption of Yam Minisett Technology among Farmers in Ebonyi State

The socioeconomic factors influencing the level of adoption of the minisett technology among the farmers in the study area is presented in the Table 2. The result indicates a chi-square value of 9527.69 and was significant at 1% level. This implies a good fit for the regression model used for the analysis.

The coefficient of the Tobit regression model shows that the coefficient of farm income and contact with ADPs were positive and statistically significant at 1% level to the level of adoption of yam minisett technology. This implies that farmers with higher income are more likely to adopt the minisett technology as well as farmers that had regular contact with ADPs extension agents. The coefficient of gender, age, and household size were negatively related to the level of adoption of yam minisett technology and were statistically significant at 1% and at 5% respectively. This implies that more males are likely to adopt the minisett technology in the study area than females. The coefficient of age was significant at 1% but inversely related to the level of adoption. This implies that the older the farmer, the lower the level of adoption, this further explains that youths are likely to adopt the minisett technology than aged farmers. Hartley (2003) stressed that respondents within productive age were likely to adopt innovations better because they are still active and dynamic against the ones that are of age. These factors could be as a result of the low adoption rate of yam minisett technology in the study area. FAO, (1997) asserted that farmers adopted only those practices they have been familiar with and which are in line with existing practices. This study also agrees with Bolarinwa and Olajide (2009) and Tiamiyu *et al.*, (2010) who reported similar trend in their work on adoption of yam minisetts and NERICA rice production technologies respectively.

CONCLUSION

Farmers in the study area received information on ministt technology majorly from ADPs. However, gender, age, household size, farm size, farm income and contact with ADPs were the socio-economic factors influencing the adoption of yam minisett technology in the study area. Therefore, the ADPs/extension agents should be empowered by the government to reach out to farmers with the full package of the technology.

ABSTRACT
The study was conducted to examine the determinants of fish production in Ikot Ekpene Local Government Area of Akwa Ibom state. The data used for the study were collected from 80 fish farmers randomly selected from the study area. .Descriptive statistics (tables and percentages) and multiple regression analysis were the tools of analysis adopted. The major findings of the study were that fish production was mostly practiced by men, with 75.5% between 31-50 years of age, 68.75% were married and 92.5% having formal education. Most of the respondent (63.75%) had above 15 years production experience and 48. 75% relying on inherited farmlands. Stock density, quantity of feed used, labour, educational level and farming experience were found to have significant effect on fish production. High cost of feed, unavailability of quality fingerlings, poor access to credit and poor storage facilities were major constraints to fish production in the study areas. The study recommended the establishment of modern fishery hatcheries and feed mill by the government in the area to reduce cost of production and increase farmers productivity.

INTRODUCTION
Fish farming or culture which is an aspect of aquaculture is an integral component of the overall agricultural production system in Nigeria. The major species cultured in Nigeria include tilapias, catfish and carp; however the African catfish *Clariasgariepinus* is the most farmed (*Agbede et al., 2003*). Fish and fish products constitute more than 60% of the total protein intake in adults especially in rural areas (Adekoya, 2004). FAO (2003) indicates that fish is very important in nutrition, as it provides vital nutrients and source of animal protein especially to the poor who are unable to purchase other more expensive sources such as beef, pork or chicken.
Nigeria has over 14 million hectares of inland water surface, out of which about 1.75 million are available and suitable for aquaculture (FAO, 2006). Olaoye *et al* (2013) reported that, aquaculture is predominantly an extensive land based system, practiced at subsistence levels in fresh waters in Nigeria. Commercial farming is yet to become widespread (Fagbenro, 2005). At present, most fish farmers operate small-scale farms ranging from homestead concrete ponds (25-40 meters) to small earth ponds (0.02-0.2 hectares).
In spite of the great potentials of fish farming in Nigeria, Nigeria is still unable to bridge the gap in the short fall between total domestic fish production and the total domestic demand. In Nigeria, total domestic fish production is far less than the total domestic demand. According to Zango-Daura (2000), as cited by Rahji *et al* (2001) the country requires 750,000 tons of fish annually while domestic production amounted to 350,000 tons. Importation is thus often used to bridge the fish supply-demand gap. FDF (2008) reported that the quantity of fish imported in Nigeria increased from 557, 884.00 tons to 739,666.12 tons between 2000 and 2007. The amount of foreign exchange on fish importation also increased from ₦ 48.3 billion in 2000 to ₦ 115.88 billion in 2007. In 2008, 681 metric tons was imported into the country. This constitutes a huge avoidable drain of Nigeria's scare foreign exchange.
FAO recommended minimum fish consumption rate of 12.5 Kilograms per head yearly to satisfy basic protein needs (Zango-Daura, 2000). For Nigeria to meet this recommendation, policy actions geared towards improving domestic productions by providing solution to factors militating against aquaculture in the country are required. It is against this background that this study was undertaken to determine the factors affecting fish production in the study area to encourage participation

METHODOLOGY
The study was conducted in Ikot Ekpene Local Government of Akwa Ibom State. The area is located between latitude 5^0 10' and 5^0 30' North of the Equator and longitude 7^0 30' and 7^0 45'.The local government is bordered on the East and North by Obot Akara Local Government Area on the west by Essien Udim Local Government Area and on the South by Abak and Uyo Local Government Areas of the State. The annual precipitation ranges from 200- 300mm per annum. This rainfall regime received in most parts of the State encourages farming throughout the year. There are available local feedstuffs that could be compounded for fish feed. The area has a total land mass of 305km^2 and population of over 145,077 people (NPC 2006) in five clans and 91 villages.
Data Collection: Data was collected by the use of structured questionnaire administered to fish farmers in the study area. Multi-stage random sampling technique was used to select towns, villages and respondents. Firstly, four clans (Utu EdemUsung, IkotObongErong, Ifuho and IkotAbia Idem) were randomly selected out of the five

(5) clans in the area. In the second stage, two (2) villages were randomly selected from each of the clans. Lastly, ten (10) farmers were randomly selected from each of the selected villages. This gave a total of eighty respondents. **Analysis procedure:** Descriptive statistics (Tables and percentages)was used to analyze socio-economic characteristics of the respondents. Multiple regression analysis was used to determine the factors that affect output of fish farmers. The multiple regression model is stated thus: $Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, ei)$. Four functional forms of the model are explicitly represented as follows: Linear: $Y = a+b_1X_1+b_2 X_2+b_3X_3+b_4\log X_4$-----+ei; Semi Log: $Y=a+b_1\log X_1+b_2\log X_2+b_3\log X_3+b_4\log x_4$-----+ei; Double Log:Log Y= $a+b_1X_1+b_2X_2+b_3 X_3 +b_4 \log X_4$ -----+e. Where Y= Output of fish produced (kg); bo = constant; b1-b7 = coefficients to be estimated; X_1 = Age of the farmer (years); X_2=Stock Density (number of fish per period size); X_3 = Feed used (kg); X_4=Labour (Md); X_5= Educational Level (in years); X_6=Farming Experience (years); X_7= Gender and ei = error term.

RESULTS AND DISCUSSION

Table 1shows the socio- economic characteristics of the respondents. The table indicated that 85% of the respondents were males. This indicates that fish farming is a male dominated activity. Result is in consonance with Oladoja *et al* (2008) who assert that fish farming is a male dominated activity. Majority (72.5%) of the farmers fall between the ages of 31-50 years, indicating that most of them are within the economically active population and therefore constitute a good labour force for fishery enterprise with the expectation that they would be good managers of limited available resources (Amazan *et al*,2000). Married people participated more (68.75%) in fish farming than singles, Divorced, Widows and widowers. Oladoja *et al* (2008) asserted that marriage confers some level of responsibility and commitment on individual who are married. About 92.5% of respondents acquired formal education. Education increases the farmers' production through evaluation and adoption of new production techniques (Amazan and Olayemi, 2000). Data on production experience shows that 63.75% of farmers have above ten years production experience and are expected to have acquired skill in fish farming and should have better approaches to fish farming business. Daramola and Olorunfemi (2004) reported that farmers count more on their farming experience than educational attainments in order to increase their efficiency. About 40% of respondents used both family and hired labour in production.

Table 2 shows result of regression estimates of the determinants of fish production in the study area. Semi- log functional form was chosen the lead equation based on the high R^2 estimate, number of significant variables and agreement with a priori expectation. The R^2– value of 0.636 implies that about 63.6% of the variation observed in fish production was explained by the independent variables included in the model, while the remaining percentage was due to error term. F-value 2.501 was also highly statistically significant at 1% probability level indicating goodness of fit of the model. Coefficients of stock density(X_2), feed used (X_3), labour (X_4), educational level of the farmer (X_5) and farming experience (X_6) had positive signs and were significant at 5% level of probability. This implies that a one unit increase in any of these variables will result to an increase in output by a corresponding coefficient of the variable. Result is in line with a priori expectations and supports findings of Olawumi *et al* (2010).

Information on production constraints was presented in Table 3. High cost of quality fish feed and unavailability of quality fingerlings were the major problems that affected fish farming in the study area. Most feed used by the farmers were brought in from other states and were formulated. This increased the cost of feed. There were few hatcheries that produce fingerlings in the L.G.A. Some fingerlings were brought from outside the area at a high cost. Insufficient capital and poor storage facilities were reported by 82.5% and 85% respectively. Most of the farmers source their credit from their personal savings, local money lenders, friends and relatives. Banks are often reluctant to deal in agricultural credit because of inherit risk and prospect of loss of investment. Preservation problems create seasonality scarcity and price instability. Finding is consistent with Adedeji and Owoigbe, (2005) who also observed preservation and marketing to be major problems in fish marketing and distribution in Nigeria. These problems constitute hindrance to farmers and invariably lead to increase in production cost and generally reduced their revenue.

CONCLUSION AND RECOMMENDATIONS

Stock density, quantity and quality of feed used, labour, education level and farming experiences were found to have positive and significant effect on fish production. High cost of feed, unavailability of quality fingerlings, insufficient capital and poor storage facilities were the major problems of fish production in the study area. Based on findings of the study, the following recommendations were made.

1. There is need for establishment of modern fishery hatcheries by the government in the area for supply of quality fingerlings
2. Government and private investors should establish feed mill in the area to reduce the cost of feed.
3. Credits should be made available to farmers through Micro-finance banks, Agricultural cooperative banks and other government agencies at reduced interest rate.
4. Provision of good storage facilities where the perishable fish can be stored. This will also help in stabilizing the price of fish in the area.

ABSTRACT
This study examined the effects of land tenure systems on technical efficiency of farmers in Nigeria using stochastic frontier model. The data were obtained from 1381 farmers that cut across 36 states in Nigeria. The data were extracted from General Household Survey (GHS 2013). The results showed that the average technical efficiencies of farmers operating under communal, purchase and leasehold land tenure systems were 89.36%, 3.48% and 7.16% respectively. The results also showed that. Farm size, fertilizer were responsible for inefficiencies among the farmers
Keywords: Land tenure systems, technical efficiency, stochastic frontier, Nigeria

INTRODUCTION

Nigeria is the largest country in West Africa and the most populous country in Africa. It is eight most populous country in the world with a population of over 160 million (NPC, 2006).At present the nation is still grossly an agrarian society. About 60% of the workforce is employed in the agricultural sector, which largely dominated by the subsistence non-commercial farming. Several land tenure systems had been operated in various regions of Nigeria from the colonial era to the promulgation of the Land use Act in 1978. The pre-colonial LandSystem in Nigeria is characterized by appropriation and adjudication by might of warfare, occupation and rulership in which princes and religious adventurist carved out dominion for their followers and communities. Community and warlords had great influence in the administration of the land for communal living, farming and grazing purposes. In the Northern part, as the predominantly nomadic Fulani rare their cattle over large expanse of Land they found settlement and markets (as they move) without defining boundaries for any group of communities or settlements (Mabogunkeand Oguntoyinbo, 1997, Adedeji2006). In Southern Nigeria, land was held by the community, village or family,particularly extended lineage with individual having only usufructuary rights by virtue of their membership of the group.

The introduction of freehold in the Southern states and the consequence economics development resulted in land becoming an economics commodity and the evolvement of many and varied interest of rights in land. Subsequently, ownership of Land especially in urban areas becoming a great economic venture and speculators made it very difficult for other Land users and even various government and their agencies to acquire Land for development purposes (Atilola, Fajemirokkun 1979).

In an attempt to halt the contrasting land tenure system, the country and the attendant litigations, fraudulent practice, and difficulties being experienced by various governments in accessing Land for public good that the Federal Military Government promulgated the Land use Decree (now Act) of 1979. The philosophy of the Act is encapsulated in the preamble,which goes thus: "whereas it is in the public interest that the rights of all Nigerians to the land of Nigeria be asserted and preserve by law and whereas it is also in the public interest that the right of all Nigerians to use and enjoy Land in Nigeria and the natural fruit thereof in sufficient quantity to enable them to provide for sustenance of themselves and their families should be assured, protected and preserved" (Federal Republic of Nigeria, 1978).

The Land use Act with all its potentials and promises to transform the land tenure system in the country did not work as intended for various technical, institutional and social reasons and lack of sincerity and political will on the part of various government to implement the Act (Fabiyi 1978a)

The philosophy of the Land use Act that all Land belong to the state and should be held in trust by the governor for the people, and that undeveloped Land has no value, constitute a great obstacle to the development of the dynamic market Land economy and therefore needs surgical review for the current initiatives of unlocking the commercial potential of Land in Nigeria to be realized. It is the current dysfunctional nature of Land administration dynamics in Nigeria and concerns arising from its unproductive nature as noted here in call for the need to provide a better strategy that make Land administration work and provide benefits to all citizens in Nigeria. Emanuel *et al* (2014), Bugri (2008), Ubink and Quan (2008) observed that economic development will be stagnated in countries and societies where land tenure systems did not evolve properly to accommodate changes in agriculture, industry and services. It is against this background that the study was set out to estimate the effect of land tenure system on the farmers' level of technical efficiency in the country.

METHODOLOGY

The present study employed stochastic frontier analysis to examine the effects of land tenure system on the technical efficiency of farmers in Nigeria. The analysis involves three in first, the parameter of the production function are estimated simultaneously with that of an inefficiency model, in which inefficiency effects are specified as a function of variables such as land tenure system and other socio economic characteristic of the farmers.

$$L_n y = f(x_{ij}, \beta)^{e(\phi - n_i)}, U = \phi_i - \eta_i and i = 1,2,3...N; \; j = 1,2...j ....(1)$$

Where Iny denotes the output of the ith farm

X_{ij}(i = 1,2,….N; j= 1,2….j) represent a(1 ∗ K)

Vector of inputs and β is (K X I) vector of the unknown parameters to be estimated. Equation (1) is linearized by taking the natural logarithm of both sides and manipulating the relevant terms to give

$$\ln Y = \alpha = \sum_{j=i}^{j} \beta \ln x_j = \phi_i - \eta_{i,} u_i = \phi - \eta_i ....(2)$$

here ϕ is the systematic random error that accounts for measurement error and other factors that are not under the control of household and η_i denotes the asymmetric non-negative random error component that measures technical inefficiency effects. The systematic random error variable ϕ is assumed to be independently and identically distributed with zero mean and variance σ^2 (Coelli, 1995). The non-negative variable η_i is assumed to be independently and identically distributed with zero mean and truncation (at zero from below) of the N ($\sigma^2\eta_i$) distribution (Coelli, 1995). Moreover ϕ and η_i are assumed to be independent of each other and also independent of the input, X_j. The variance parameter of the model are parameterized as in (3)

$\sigma^2 = \sigma^2\phi + \sigma^2\eta, \gamma = \sigma^2\eta/\sigma^2\mu$ and $0 \leq \gamma \leq 1$ …………(3)

The technical efficiency of farm denote by TE_i can be estimated as

$$TE_i = \frac{R_i}{R_i^*} = \frac{f}{f} \frac{(x_{j,} \beta)^{e(\phi - \eta)}}{(x_{j,} \beta)^{e(\phi_j)}} = \quad \ell^{-\eta_i} \text{ (so that } 0 \leq \gamma \leq 1 \text{ ....(4)}$$

RESULTS AND DISCUSSION

The choice of truncated was based on variance (σ_r) which is 229.0842 for truncated and 3.40699 for half normal distribution. Also the likelihood for normal is less than that of truncated distribution-1460.0806 and -1459.0516.The decision rules is that the distribution with small variance and higher likelihood will be the lead equation

The variance δ^2 and γ (gamma) are 229.084 and 0.999.This can be interpreted that 99% of the variation in output among farmers in Nigeria are due to the difference in technical efficiency for the distribution. They are significant at 1% level, the sigma square δ^2 indicates the goodness of fit and correctness of the distribution form, assumed that the systematic influences that are un-explained by the production.

Fertilizer was significant at 1% and positively correlated with farm size. The coefficient of 0.509246 indicated that 1% increase in fertilizer would increase the farm output by 49% in Nigeria. The result was in agreement with Donkoh *et al*.(2013), who observed a positive relationship. The findings concur with those by Everson and Mwabu (1998) that demonstrated positive and significant relationship between fertilizer used and productivity. Farm size was significant at 1% level and positively related to output. This indicates that percentage increase in farmsize will increase productivity by 0.2734.

The coefficient of farm size (B_3) was found to be positive and significant at 1% level. The result is in line with the findings from Okike's (2000) study of farmers in the savanna zone of Nigeria reported farm size to be significant and positive for low-population-high market domain. The result could mean that it is possible to expand farming activity in the study area.

Statistically, the magnitude of the coefficient of farm size shows that output is inelastic to land or farm size. If the farm size is increased by 1%,output level will improve by less than proportionate (by margin of 2.72%).This means that there is still some scope for increasing output per plot by expanding farm land.

Fertilizer (β_1).The production elasticity of output with respect to quantity of fertilizer is 0.50925.By increasing the quantity of fertilizer by 1%, output level will improve by margin of 5.091%.The estimated coefficient is highly significant at 1% level. The finding is variant with the report by Winrock (1992), which showed a non significant contribution of the livestock manure and crops residues in semi-arid sub-Saharan. Though not certain, it may be possible that non separation of fertilizer into their different forms e.g crop residue, livestock manure, inorganic fertilizer etc) account for the difference in the findings of this study and as reported by Winrock (1992).

Coefficient of labour was not significant and had a negative sign. Labour is expressed as person-days and is the summation of family labour and hired labour. It is expected that labour will positively influence the level of output. This is in contrast with Okike, (2000), and Awoyemi, (2000) that shows the importance of labour in farming, particularly in developing countries where mechanization is only common in big commercial farms.

The result of technical mean scores of land tenure system (Figure 1) revealed that purchases are more technically efficient (0.667) than communal (0.298) and leasehold (0.521). Those, who rented were more likely to invest in short term land improvement measures, since they would benefit in the short run. Farmers who rent lands have to make little effort to break even and pay for their rent charges. The farmland owners had acquired their land through the family marriage inheritance or as gift. This confirms that most of the land belonged to family (particularly the family head). This implies that, when a man dies and his properties including farmland are inherited by his next of kin. The law of inheritance is central to most small-holder farmers and this relates to problems stemming from land partition and fragmentation. To this end, Fabiyi (1978) has advocated the formulation of cooperatives by the farmers so as to enjoy the economies of large scale production. According to Idowu (1990) reported FAO 1969 that the tenure arrangement affect agricultural productivity in many ways. Leasing is also common practice under this system that is the landlord (lessor) conveys or allows to be conveyed, his right of use and possession of land to tenant (lessee) for a definite period of time, during which a certain amount is paid (Famoriyo, 1979)

CONCLUSION

The study examined the effect of land tenure system on the resource use productivity and technical efficiency in Nigeria. Various level of efficiency were tested under various land tenure system and concluded that farmer are technically inefficient in Nigeria. However, farm size and fertilizer tends to influence production efficiency in Nigeria. Higher inefficiency is associated with the socio-economic characteristics of the respondents. Farm size , fertilizer are major production factors that influence agricultural productivity in Nigeria It is therefore worthy to mention that the recommendation of land reform committee in Nigeria should be follow to the letter to enhance adequate distribution of land to serious minded famers; this will promote efficiency in Nigeria agricultural sector.

COST AND RETURNS OF MARKETING POULTRY FEED (TOP FEED) IN AFIKPO EBONYI STATE, NIGERIA

M.U. Agunannah & B.A. Essien

Department of Agricultural Technology, Akanu Ibiam Federal Polytechnic Unwana, Afikpo, Ebonyi State
Email: agumike4real@yahoo.com

ABSTRACT
The study was to assess the cost and returns of marketing poultry feed in Afikpo, Ebonyi State. Data for this study were collected from activities of poultry feed marketers for the year 2015. The data were collected using structured questionnaire. Twenty (20) feed marketers purposively selected, were administered with questionnaires. Data collected were on socio-economic characteristics, cost and returns, and problems associated with feed marketing. Percentages were used to describe the socio-economic variables and problems associated with feed marketing. While marketing margin analysis were used to determine market performance. Major findings revealed that majority of respondents (75%) were male and literate (35% and 40% respectively). While over 40% have between 6 – 10 years marketing experience. The percentage marketing margin for starter, grower and finisher mash were 12.72, 16.67 and 9.26 respectively. This indicates that, marketers obtained 12.72%, 16.67% and 9.26% of the final sales which was paid by the consumer. Major problems faced were inadequate capital, high cost of transportation and feed spoilage. The study recommends provision of soft loans to marketers, storage facilities and periodic road maintenance to ease vehicular movement.
Keywords: Cost, Returns, poultry feed, marketing, market margin.

INTRODUCTION

Nigeria with a population of over 140 million people is Africa's most populous country and agriculture is the centre of activity of her people (Ugwu, 2009). The poultry industry is currently one of the most important agribusiness enterprise that has a great potential for providing additional income to our farming community and educated unemployed persons of the rural areas through creating self employment opportunities (Ahmed and Hamid, 1992). The value of the annual output of the commercial poultry sector was estimated at about N170billion naira (Adene and Oguntade, 2006), hence poultry production is one of the important subsectors in the Nigerian economy (Rahman and Yakubu, 2005).

In addition to its contribution to the Gross Domestic Product (GDP) and provision of employment opportunities, poultry production is a major source of protein in the country (Ohajianya *et al*, 2013). Poultry is found to be one of the most nutritious and most complete food known to man as it provides a means by which rapid transformation of animal protein intake can be achieved (Murtala *et al*., 2004).

Despite the nutritive value of poultry meat, its production in the country is grossly inadequate as reflected in the wide gap between demand and supply of the product. This could be attributed to numerous problems that poultry farmers in Nigeria are facing. These problems include low capital base, inefficient management, diseases, poor housing, poor quality of day old chicks (DOC), and high cost of feeds (Alabi and Isah, 2002, Bamgbose *et al*., 1998).

Poultry feed is a kind of balanced livestock feed which aid proper development of chicks and pullets and hence used for feeding the domesticated birds such as chickens, turkeys, ducks, geese, etc that serve as a source of eggs and meat (FAO, 2012). It is a major component of any livestock production enterprise as it accounts for an average of 60 – 70 percent of cost of production (Taiwo, 1989; Mafimisebi, 2002; Unang, 2003 and FAO (2012).

The commercial poultry sector in Nigeria is feed dependent and requires about 1.87 million tones of feed per annum (Adene and Oguntede, 2006). Current high prices of poultry feed coupled with occasional scarcity calls for improvement in the efficiency of producing and marketing poultry feeds.

Recently, there has been a surge in poultry business especially in Afikpo, Afikpo North Local Government Area, of Ebonyi State. This is due to government agricultural support programmes which encourages civil servants and others to go into agriculture coupled with the recent ban on importation of frozen chicken in Nigeria by Federal Government. Despite government intervention programmes, the production output of this industry has been hampered by insufficient, irregular and lack of adequate feed supply (Okonkwo, 2013).

Markets and marketing activities are very essential for the distribution of poultry feed to the final consumers. Poultry feed marketing is a crucial human invention. It embraces the activities engaged in order to satisfy the economic needs and wants of the people. Hence,feed marketing encompasses all business activities which direct the smooth flow of feed between producers, wholesalers, retailers, and consumers so as to accomplish the producer's objectives (Girei *et al*; 2013). According to Rewoldt (1977), marketing can better be described as those activities involved in getting goods and services from the producers to the consumers. As the economy grows agricultural marketing will become more and more complex and its efficiency will depend on the managers of the marketing system who themselves must be well informed about what is takes to have efficient marketing system. Since poultry feed accounts for about 60 – 70% of the cost of commercial poultry production, an assessment of the cost and returns of poultry feed marketing in the study area.

i. What are the socio-economic characteristics of poultry feed marketers?
ii. What were the cost and returns associated with poultry feed marketing?
iii. What were the constraints associated with poultry feed marketing?

METHODOLOGY

The study was carried out in Afikpo, Ebonyi State. Afikpo has a land mass of 164sqkm, with an estimated population of 156,611 based on 2006 census. It lies between latitude $5^0 89^1$N and longitude $7^0 94^1$E (NPC, 2006). Their predominant occupation is farming which encompasses fishing, cropping and farming, the inhabitants also engage in various other occupations such as civil service, trading and commerce. The population of the study was made up of all the poultry feed marketers in the area. Twenty (20) poultry feed marketers were purposively chosen because they constitute major marketers. The study made use of primary data. Primary data were obtained from poultry feed marketers with the use of structured questionnaires.

Both descriptive (frequency, percentage and mean) and inferential statistics (Marketing margin and percentage market margin) were used for analyzing the data generated from the study. Marketing margin analysis was used to measure market performance of the feed marketers. Adekanye (1988), defined marketing margin as the difference between the price consumers pay and the price the producer get.

$$MM = CP - MP$$

$$\%MM = \frac{CP - MP}{CP}$$

Where:

MM	=	Market Margin
%MM	=	percentage Market margin
CP	=	Consumer Price
MP	-	Market Price

RESULTS AND DISCUSSION

Cost – Returns Analysis of Poultry Feed Marketing

Table 2 presents the cost and returns associated with feed marketing. Marketing margin and percentage market margin was used respectively to determine profit and market performance. The result showed that the market margin for 1 bag of poultry feed sold, for starter, grower and finisher were N200, N270 and N120 respectively. While the percentage market margin was 12.72, 16.67 and 9.26 for starter, grower and finisher respectively. This means that for every bag of poultry feed sold, 12.7%, 16.67% and 9.26% is what accrues to the marketers, while the remaining 87.28%, 83.33% and 90.74% goes to the producer.

Constraints Associated with Poultry Feed Marketing

Constraints associated with poultry feed marketing in the study area during the period under review includes; capital, transportation, price fluctuation, and spoilage.

Analysis as shown in Table 3 revealed that 40% of the respondents indicated inadequate capital as their major problem. According to Maianguwan, (2013), insufficient access to capital forces the poor to engage in less productive farm and non-farm enterprises, thus forgoing income. Similarly, about 25% of them reported high transport cost. While others complained of price fluctuations which accounted for 20%, with spoilage constituting 15%.

CONCLUSION

Despite the various constraints experienced in the study area, poultry feed marketing was identified as a profitable venture. However, the profit margin can be improved if consideration is geared towards addressing all the identified constraints that tends to increase the marketing cost and thereby causing losses to the trader. High transportation cost, inadequate capital, price fluctuation and spoilage of feeds were identified as problems faced by the marketers.

The study recommends that government and other lending agencies should do more and assist the marketers with accessible and affordable soft loan in order to reduce the problem of inadequate capital. High transport fares and bad roads should be address in order to improve, sustain and make the business more attractive.

Table 1: Analysis of Marketing Margin for poultry feed (1 bag)

Starter Mash	Amount (₦)	Growers Mash	Amount (₦)	Finisher Mash	Amount (₦)
Cost of feed	2,400	Cost of feed	2,000	Cost of feed	2,450
Transport Cost	100	Transport Cost	100	Transport Cost	100
Cost of Loading	10	Cost of Loading	10	Cost of Loading	10
Cost of off loading	10	Cost of off loading	10	Cost of off loading	10
Security Cost	5	Security Cost	5	Security Cost	5

ABSTRACT
Economics of okra marketing in Ivo Local Government Area in Ebonyi State was studied. Percentage response, marketing margin and marketing efficiency were used to address the objectives. The result showed that marketers were inefficient in marketing margin but efficient in marketing efficiency. The major constraints to okra marketing for the marketers were multiplicity of okra sellers, commission agent and credit problems. Therefore, there are needs to improve marketers' access to credit provision of improved storage facilities and control the activities of commission agents by government.

Keyword: Economics, Okra, Marketing

INTRODUCTION
Agricultural marketing according to Arene, (2002) include all those legal, physical and economic services that make it possible for produce to get to consumer at the price agreeable to producers and consumers for the change of ownership and possession. Marketing occupies a significant position in an exchange economy, especially in areas where increasing commercial activities and high rate of urbanization exist (Essien and Essien, 2010).Okra is rich in vitamins A. B and C, 86% moisture, 9.7% carbohydrate, 2.2% protein, 10% Fibre, 0.2% Fats and 0.9% Ash . Anuebunwa, (2004); reported that immature okra pod is used for human consumption, treatment of ulcer, salad dressing, as substitute for coffee and matured types is stored for next season planting material (Tiamiyu *et al*, 2010). Apart from dietary importance, okra provides employment for different categories of people in the areas of production, processing and marketing (Eke *et al*, 2005). The marketing of okra is limited by high cost of transportation, seasonality of supply, inadequate credit facilities, price fluctuation and perishability of the commodity (Anuebunwa; 2006).In spite of the importance of okra in the study area, no significant studies had been carried out in the activities surrounding the marketing in the area. The specific objectives were to determine the marketing margin and efficiency of okra marketers and to identify the constraints of the marketers

MATERIALS AND METHODS
Ivo Local Government Area (LGA) of Ebonyi State, Nigeria was the study area and located between Latitude $5^1 – 55^0$, $6^1 – 55^0$ North of equator and Longitude $7^1 – 31^0$, $7^1 – 46^{0-}$ East Greenish Meridian. The annual rainfall is 1200 – 1600mm and the relative humidity of 88%. The LGA has many towns, villages and markets. The data needed to carry out this project were obtained through the use of primary sources. The primary source was collected through the use of structured questionnaires and oral interview administered to the respondents (Wholesalers and Retailers). Multi-stage random sampling technique was used to select markets and marketers. In the first stage, a random selection of two markets Eke Ishiagu and Ngwo Agharagu Market out of the three markets. In the second stage, from each market 25 wholesalers and 25 retailers were randomly selected. A total of 100 respondents were selected. The part of objective (i) and (ii) were captured using descriptive statistic such as percentage. Objective (i) was captured using marketing margin.

$$\text{Wholesaler Marketing Margin} = \frac{Selling\ Price - Purchase\ Price}{Selling} \ldots\ldots\ldots\ldots\ldots \quad (1)$$

$$\text{Retailers Marketing Margin} = \frac{Selling\ Price - Purchase\ Price}{Selling} \ldots\ldots\ldots\ldots\ldots \quad .(2)$$

The Objective (ii) was addressed marketing efficiency

$$\text{Wholesaler Marketing Efficiency} = \frac{Marketing\ Benefit\ X\ 100}{Marketing\ Cost} \ldots\ldots\ldots\ldots\ldots \ (3)$$

$$\text{Retailers Marketing Efficiency} = \frac{Marketing\ Benefit\ X\ 100}{Marketing\ Cost} \ldots\ldots\ldots\ldots\ldots (4)$$

RESULTS AND DISCUSSION

Table 1 shows that wholesalers had selling price of ₦93, 600 while the retailers ₦78,400. The purchasing price of the wholesalers and retailers is ₦69, 900 and ₦58, 900 respectively. The wholesalers and retailers had marketing margin of 0.25 each. This implies that both wholesalers and retailers were inefficient since the value is less than 1. Marketing efficiency is marketing benefit divided by the marketing cost multiply by 100. The marketing benefit is selling price minus purchasing price which is equal to ₦23, 700 and ₦19, 500 for wholesalers and retailers respectively as contained in Table 2. Table 2 shows that the total marketing cost was ₦59, 980 for wholesalers and ₦25, 280 for retailers. Among the cost items considered wholesalers showed that transportation was the highest (26.00%). This finding is in line with Tiamiyu (2009) who reported that high transportation cost could be associated with poor road network in most rural areas.

For the retailers, material cost (48.42%) was the highest. Materials which include baskets, basins, and bags are limited in supply compared to demand. However, the marketing efficiency is 39.51% for wholesalers and 77.14% for retailers. This implies that both wholesalers and retailers of okra marketing were efficient in the study area.

Table 3 revealed that multiplicity of okra sellers was the highest (100%) constraint for wholesalers and retailers respectively. This is because of the law of supply which states that; the more the number of suppliers, the lower the price of goods. Okeke, (1986); agrees with this assertion. Bulkiness of okra affects its transportation. This was reported by 96% and 80% of wholesalers and retailers respectively. Furthermore, 90% of respondents, (both wholesalers and retailers) reported on poor access to credit. Credit is needed to offset marketing costs Nwaru, (2004) made a similar assertion.

The problem of commission agents was complained by 56% of the wholesalers and 20% of the retailers. Their financial extortions increased marketing costs, subsequently causing reduction in profit (Okeke, 1986).

CONCLUSION AND RECOMMENDATIONS

The study concluded that okra marketers had high marketing margin but very low marketing efficiency. Also, multiplicity of okra sellers, nature of okra, poor access to credit were the major constraints to okra marketing. The result of marketing margin was inefficient while marketing efficiency were efficient for both wholesalers and retailers. Based on the results, the following recommendations were proffered; there is need to improve marketer's access to credit and an improved storage facility to reduce post harvest loses. There is need to checkmate the excesses of commission agent fee by the appropriate authority.

Table 1: Distribution of Respondent According to Marketing Margin

Items	**Values**	
	Wholesalers (N)	**Retailers (N)**
Selling price	93, 600	78, 400
Purchasing price	69, 900	58, 900
Marketing margin value	0.25%	0.25%

ABSTRACT
This study examined the income of Fadama programme among root and tuber crop farmers in central States of Nigeria. A multi-stage sampling procedure was used to select 934 farmers with 427 respondents from programme participants and 507 respondents from the non-participants. Primary data were collected on socioeconomic variables, (age, and educational level, farm size, farming experience and non-farming activities of the respondents); input – output of participants and non-participants using structured questionnaires and interview schedules. Data collected were analyzed using net farm income analysis. The result of net farm income (NFI) for Fadama III root and tuber crop participants and non-participants before programme intervention is ₦268,195.04 /Ha and ₦287,768.09 /Ha respectively before the programme intervention, while the net farm income after the programme intervention is ₦639,584.75,584.75 and ₦511,515.40/Ha for participants and non-participants respectively. The change in income is 50% and 38% for participants and non-participants respectively while the change in net farm income (NFI) was 58% and 44% for participants and non-participants respectively. Z-statistics analysis shows that the income of Fadama III programme participants is significantly different from the non-participants. The problems encountered by the farmers in the study area are high cost of input, limited finances, bad roads, low produce prices, inadequate fixed inputs, poor marketing practices, high cost of labour, poor storage facilities, and non-availability of water and shortage of fertilizer. The study recommends that farmers should be advised through the Agricultural Development Programme of Benue, Kogi and Plateau States on how to allocate and the use of their resources in other to enhance their net farm income, there is the need for the National Orientation Agencies at both federal and state level should embark on vigorous enlightenment programme , farmers are encouraged to form cooperative societies to enhance bulk purchase of input which will reduce input cost and ensure timely supply of same, high costs of inputs were identified as a problem in root and tuber crop production and there is the need for policy makers to pursue opportunities for regional cooperation in international input procurement and to facilitate privatization and competition in input distribution.
Key words: Income, Fadama III programme, root and tuber crops, Participants, Central States, Nigeria.

INTRODUCTION
In Nigeria, despite agricultural policies and strategies, food insecurity remains a fundamental challenge (.Machethe, 2004). For instance, although agriculture remains a key component of the Nigerian economy, contributing about 37% of GDP and employing about 70% of the active population, it receives less than 10% of the annual budgetary allocations (Adebayo and Okunneye, 2005). As a result, the agricultural sector has significantly underperformed given its vast potential (Machethe, 2004). Consequently, Nigerian agriculture has failed to supply sufficient food in quantity and quality to feed the constantly growing population. Therefore, the level of food insecurity in Nigeria has continued to increase steadily since the 1980s.Raising agricultural productivity, reducing food insecurity and poverty is an important policy goal for concerned government since agriculture plays a major role in the economy of many developing countries, as it is a significant source of nourishment for citizens and a means of livelihood for the most vulnerable members of this country (Adewuyi, 2002). Increasing agricultural productivity requires one or more of the following; an increase in output and input with output increasing proportionately more than inputs; an increase in output while inputs remain the same; a decrease in both inputs and output with input decreasing more; or decreasing input while output remains the same (Adewuyi, 2006; Oni *et al*, 2011) Increasing inputs in order to expand output involves raising both the quality and quantity of inputs, examples of which will include the mechanization of agricultural processes, use of high yield varieties of crop seeds or planting materials, use of fertilizers, irrigation in areas where rainfall is inadequate, and the use of agrochemicals such as herbicides and pesticides.

Although, concerted efforts have been made by past and present governments of Nigeria towards improving agricultural productivity and production efficiency and in alleviating poverty among the rural farmers, millions of people in Nigeria are still poor and hungry (Simonyan, 2008). Hence, the role of increased efficiency and productivity of root and tuber crop farms is no longer debatable but a great necessity in order to reverse the low technical, economic and allocative efficiency of small farms in Nigeria, since root and tuber crops (e.g. cassava, yam and irish potato) have the potential for bridging the food gap, as they have been discovered from research that famine rarely occur where these crops are widely grown (Simonyan, 2008).

METHODOLOGY

The study was conducted in north central geo-political zone or the middle belt region of Nigeria. It is made up of Benue, Kwara, Kogi, Nassarawa, Niger and Plateau states and Federal capital territory. The temperature throughout the year in the area ranges from 28°C – 34°C and the annual rainfall varies from 1500mm to 1200mm. Ethnically, Benue State is dominated by Tiv, followed by Idoma, Igala, Yoruba, Egbira, Nupe and Bassa form the main ethnic groups in Kogi State. Plateau State is dominated by Beroms in the northern zone, the Magavhus in the central and the Taroks in the southern zone. It is situated between latitude 110 20'. The zone has a population of 17 million (NPC, 2006), with a projected population of 22.3 million (2015) . A multi-stage sampling technique was used for this study. In the first stage, three states namely; Benue, Kogi and Plateau States under the Fadama III root and tuber crop programme were purposively selected from the states in the central state based on the targeted root and tuber crops adopted for the National Fadama Development Project. In the second stage, four local government areas were purposively selected from Benue state agricultural zones with at least one from each zone, three local government areas from Kogi state with one each agricultural zone and one local government area was purposively selected from northern agricultural zone being the zone where irish potato is grown. In the third stage, from the sample frame, 10% representing a total of 427 and 507 of the participants and non-participants were randomly selected. Primary and secondary data was collected from participants and non-participants of Fadama III root and tuber crop scheme in the study area were used for this study. Primary data was collected from participants of Fadama III programme and non-participants involved in root and tuber crop production through interview method using questionnaire, which was administered on the two groups of respondents' socioeconomic, demographic and institutional characteristics and participants and non-participants output and inputs used in root and tuber crop production and associated sales of output. Secondary data in the form of base line and end line data on the income of the programme participants and non-participants obtained from Fadama III programme coordinating offices in Makurdi, Lokoja and Jos were also used for this study.

Analytical Techniques

Net farm income measures the return to unpaid family labour, operator's land, labour, capital and management Olukosi and Erhabor (2008). It is notationally represented as Net Farm Income (NFI).

NFI $=\sum P_y - \sum P_X - \sum P_K$ ………….…………………………………………… (1)

Where:

NFI = Net Farm Income (₦/hectare)

$\sum$ = Summation sign

$P =$ Unit price

$y =$ Output

X= Input (Variable)

K= Input (fixed)

The fixed cost is the depreciation for farm tools used by the farmer (hoes cutlasses, wheel barrows and knapsack sprayers). The straight line method of depreciation was used to calculate the rate of depreciation. This method of depreciation assumes that an asset loses value at a constant rate. Depreciation by this method is the difference between the purchase price (P) and the salvage value (S) divided by the number of years of the life of the asset (n).

Note: % change in income = $\frac{Income\ After - Income\ Before}{Income\ After} \times 100$ ……………………… (2)

% change in Net Farm Income (NFI) $=\frac{NFI\ After - NFI\ Before}{NFI\ After}$ ………………….. (3)

The fixed cost is the depreciation for farm tools used by the farmer (hoes cutlasses, wheel barrows and knapsack sprayers). The straight line method of depreciation was used to calculate the rate of depreciation. This method of depreciation assumes that an asset loses value at a constant rate. Depreciation by this method is the difference between the purchase price (P) and the salvage value (S) divided by the number of years of the life of the asset (n).

Z – **Statistic**: The Z statistic was used to test for the significance of income between the Fadama III root and tuber crop participants and non-participants

Where:

Z = the value of the statistic, Y_1 = mean of the annual crop production by the programme participants, Y_2 = mean of the annual crop production by the non-participants, S_1 = variance of the annual crop production by the programme participants, S_2 = variance of the annual crop production by the non- participants, N_1 = number of participants, N_2 = number of non-participants.

$$Z = \frac{Y_1 - Y_2}{\sqrt{\frac{S_{12} + S_{22}}{n_1 + n_2}}} \text{.......................................} (4)$$

Where:

$\bar{X}$ and $\bar{Y}$= two paired sample of beneficiary and non-beneficiary income respectively.

n = sample size

n – 1= degree of freedom

RESULTS AND DISCUSSION

The result of net farm income analysis in Table 1 below shows that the total cost of production per hectare of participants and non-participants root and tuber crop before Fadama III programme intervention was ₦113, 087.65/Ha and ₦117,614.73/Ha respectively while the total cost after the Fadama III programme for the participants and non-participants was ₦128, 233.30 and ₦137,756.57/Ha respectively. The total revenue/ha before the programme intervention is ₦381, 282.69/Ha and ₦405, 382.82/Ha while the total revenue/ha after the programme was ₦767, 818.05 and ₦649, 271.97/Ha for participants and non-participants respectively. The total revenue before the programme obtained by the non-participants was higher than that of the participants while the total revenue obtained by the participants was higher than that of the non-participants after the programme. The change in total revenue was 50.34% and 37.56% for participants and non-participants respectively. The net farm income (NFI) for Fadama III root and tuber crop participants and non-participants was before the programme is ₦268,195.04 /Ha and ₦287,768.09 /Ha respectively, while the net farm income after the programme is ₦639,584.75 and ₦511,515.40/Ha for participants and non-participants respectively. The result indicates that root and tuber crop production is profitable in the study area. This is in agreement with the work of (Ajayi, 2014) titled comparative economic study of mixed and sole cassava cropping systems in Nigeria. The change in net farm income (NFI) is 58.34% and 43.74% for participants and non-participants respectively. This percentage is however lower than the 134% and 52% respectively for participants and non-participants obtained by (Simonyan, 2008) in her findings titled ‗impact assessment of Fadama II project on income and productivity of beneficiary farmers in Kaduna State, Nigeria. The return on investment for Fadama III root and tuber crop scheme participants and non-participants before programme intervention is ₦2.37 and ₦2.44 respectively while the return on investment after programme intervention is ₦4.98 and ₦3.71 programme participants and non-participants respectively. The interpretation of this result for Fadama III participants is that for every ₦1.00 invested, ₦2.37k is their profit while for the non-participants, for every ₦1.00 invested, ₦4.98k is their profit before the programme intervention while for every ₦1.00, ₦4.98 and ₦3.71 is their profit for the programme participants and non-participants respectively after the programme intervention. The higher difference in net farm income of participants over that of non-participants may be attributed to the increase in farm output realized by the participants after the Fadama III programme. Participant‘s profitability index is higher because they may have been taught better farming techniques which had impacted on their yield and revenue. The result of the Z-test shows that the income of Fadama III root and tuber crop participants is significantly different from that of the non-participants.

CONCLUSION AND RECOMMENDATIONS

From the findings of this study, it is concluded that root and tuber production under the Fadama III production was profitable and the participants earned more naira to everyone naira invested in it root and tuber production. Its income is significantly different from that of the non-participants. It is recommended that policy makers to pursue opportunities for regional cooperation in international input procurement and to facilitate privatization and competition in input distribution.

ABSTRACT

The study analyzed the differences in performance among cocoyam farmers in Ezeagu LGA in Enugu State, Nigeria. The study obtained data from 120 (60 cooperators and 60 non cooperators) respondents using a multi-stage randomized sampling techniques. The study described the socio-economic characteristics of the cocoyam farmers. Majority of the cocoyam farmers were still young and active (21-30) and (41-50), educated, married with large household sizes. The results show that marketing margin (₦154.800) and marketing efficiency (394.318%) of the cooperators were higher than those of the non-cooperators (127,000) marketing margin and ((238.889%) marketing efficiency. This study therefore recommends more awareness on the importance of cooperative membership to the rural farmers by the government and cooperative societies through extension services.

Keywords: Cooperators, Performance, Cocoyam, Farmers

INTRODUCTION

Cocoyam originated from Asia and about forty (40) species are mostly grown in West Africa (Asumugha and Mbanasor, 2002).Cocoyam, both *Xanthosoma* species and *Colocasia* species belong to the family (Aracea). Cocoyam is a stem tuber that is widely cultivated in the tropical regions of the world and is a well-known food plant which has a long history of cultivation with Nigeria being the largest producer in the world and accounting for about 40.0% of the total world output (Ademiluyi, 2013) Cocoyam contributes significantly to carbohydrate content of the diet of individuals in developing countries, and provides edible starchy storage corms. According to Opera (2002), cocoyam though less important than other tropical root such as yam, cassava and sweet potato, yet a staple food in most part of tropics and sub tropic. It contains calcium, phosphorus, vitamins A and B. Despite the economic importance of cocoyam as a source of food in most parts of the tropics and sub tropic, there is still limited information on their cultivation which perhaps contributes to the scarcity of cocoyam in the market (Ekpo *et al.*, 2001). Cooperative can be defined as a social enterprise or organization created voluntarily by members with the full support and assistance from members in order to cater for the economic needs and interests of the members. The idea was to pull members economic resources together to ease their access to finance, other socio-economic resources and easy marketability of their produce. The basis for instituting a cooperative organization includes common business interest, location, professional goals and objectives, need for social interaction on common interest, exploitation of common resources through group strategy. The simplest and most basic benefit of cooperative societies is the creation of an avenue for members to borrow money and obtain loans with minimal interest to meet their business and social needs and serves as an avenue for savings and easy access to marketing of their produce. It is a powerful instrument that ensures that loans are adequately and timely available to members Akpan (2005). However, In Nigeria, farmers face many problems including high transaction costs which prohibit their access to better-paying markets and worsen their poverty level. Lack of information on prices and linkages between farmers and other market actors, credit constraints and other market imperfections are some of the problems faced by cocoyam farmers. They have been selling their crops at a low price through intermediaries who have taken advantage of market imperfection for their own benefits (Mensah *et al.*, 2012). To overcome these constraints, cooperative societies were formed by farmers. Most studies on cocoyam had been done in the areas of production, nutrient constituent, yields and suitable soils. Therefore, this study aims at investigated performance differentials amongst cocoyam farmers in Ezeagu LGA Enugu State, Nigeria

METHODOLOGY

The study was carried out in Ezeagu Local Government Area of Enugu State. It is one of the seventeen Local Government Areas of the state. Ezeagu is bounded in the North by Uzo-uwani in the south by Orji-River in the West by Udi and in the East by Anambra State. It comprises twenty one communities and these are: Olo, Amagu-Umuolokpa, Iwollo, Oghe, Okpogho, Ihionyia, Akama, Imezi-Owa, Aguobu-owa, Mgbagbu-owa, Awha-Ndiagu, Awha-Imezi, Umana-Ndiagu, Umaana-Ndiuno, Obeleagu-Umana, Obinuofia-Ndiuno, Aguobu-Umunba, Isingwu-umuana and Umualor. It is located at the south-west part of Enugu state. It has a humid hot air temperature. The Local Government Area is inhabited by Igbo people with a population of about 169,718 people and landmass of about 633sqkm (633km^2). The soil is mainly sandy-loam and the vegetation is a thick rainforest. About 85% of the entire population of Ezeagu is engaged in Agricultural activities like crop production, processing, marketing to animal husbandry. A multi-stage sampling technique was used to select 120 cocoyam respondents from Ezeagu Local Government Area, Enugu State. The first stage involved purposive selection of five communities from the twenty-one communities listed and the five communities were; Aguobu-Owa, Mgbagbu-Owa, Imezi-Owa, Akama, Umana-Ndiagu. These five communities were purposively selected because they produce cocoyam in good quantities. The second stage involved random selection of six villages each from the five communities. Finally, four respondents, two (2) cooperative cocoyam farmers and two (2) non-cooperative cocoyam farmers were randomly selected from each of the thirty villages, giving a sub total of 60 cooperative cocoyam farmers and 60 non cooperative cocoyam farmers with a grand total of 120 respondents. Primary method of data collection was adopted for the study. The primary data was obtained through a well-structured questionnaire. The analytical techniques include descriptive statistical techniques such as frequency distribution, mean and percentage. Marketing efficiency and marketing margin were used as performance indices to determine the marketing performance of both the cooperator and non-cooperators.

Marketing efficiency was estimated using the Shepherd's index formula developed by Shepherd (1965) the formula is given by: $ME\ INDEX = \frac{GM}{MC} - 1$

Where: ME = Marketing Efficiency index , GM = Gross marketing margin in Naira

MC = Total marketing cost in Naira. The higher the ratio, implies the higher the marketing efficiency and vice versa. The net marketing margin accruing to the retailer of cocoyam is the difference between the gross marketing margin and the total marketing costs.

RESULTS AND DISCUSSION

The result in Table 2.0 show that majority of the cooperators (53.33%) were males while majority of the non-co-operators (73%) were females respectively. Generally, this implies that many cocoyam farmers in the study area were interested in membership of cooperative societies which definitely enhanced their profits. They must have been benefiting from shared resources like obtaining farm inputs and finances together. Some researchers concluded that the ratio of female-to-male performance in terms of capacity utilization, revenue and annual investment spending indicates that women and men are influenced by many of the same variables when making entrepreneurial decisions (Vossenberg,2013and Ogunleye,2005). The results shows that 3.33% and 6.66% of the cooperators and the non-cooperators had age brackets of 21-30 years while 10.00% and 46.67% had age brackets of 31-40years . About 53.33% and 36.67% of the cooperators and non –cooperators had age brackets of 41-50years respectively. This result shows that majority of the cocoyam farmers were still young and active. This implies that they can pursue business activities aggressively (Ike, 2012). According to Oloruntoba (2000), Age is very important in Job performance. The results show that about 70% of the cooperators attended secondary education. While about 46% attended both secondary and tertiary education for the non-cooperators The percentage of the cooperators that attended secondary education is an indication of the positive influence of education on the cooperators. Amara *et al* (1999) noted that schooling is a crucial factor in the adoption of innovation and technology. Education has also been shown to enhance the skills and experience needed for business (Akanji, 2002; Kuzilwa, 2005).

The results in Table 2.0 show that the purchase price per kg of cocoyam among the cooperators was ₦40.866 and ₦65.667 for the non cooperators. There were no wide margin between the selling price (₦195.667) for cooperators and non cooperators (₦192.667). This could be due to the fact that, to certain extent, some characteristics of perfect competition market exist. For instance, the commodities could be homogenous, you have many buyers and sellers and perhaps some access to market information.

The marketing margin (₦154.800) for the cooperators was greater by 17.95% compared to the marketing margin for non cooperators (₦127.000). The reason for a higher marketing margin for the cooperators could be attributed to the fact that the cooperators had more access to resources like finance and other imputs, resulting from their association. On the other hand, the non-cooperators probably could not access such resources because individual find it difficult to access farm inputs especially from the government. Results show that the marketing efficiency for cooperators was 394.318% compared to their non-cooperators counterpart (238.889%). This shows that the cooperators were more efficient than their non-cooperator counterparts in the study area.

CONCLUSION

The study analyzed the performance differentials among cocoyam farmers in Ezeagu LGA, Enugu state, Nigeria. The results show that about 70% of the cooperators attended secondary education while about 46% attended both secondary and tertiary education for the non-cooperators. The percentage of the cooperators that attended secondary education is an indication of the positive influence of education on the cooperators. The results show that 3.33% and 6.66% of the cooperators and the non-cooperators had age brackets of 21-30 years while 10.00% and 46.67% had age brackets of 31-40years. About 53.33% and 36.67% of the cooperators and non –cooperators had age brackets of 41-50years respectively. The marketing margin (₦154.800) for the cooperators was greater than the marketing margin of non cooperators (₦127.000). Results show that the marketing efficiency for cooperators was 394.318% compared to their non-cooperators counterpart (238.889%).

ABSTRACT

This work estimated the impact of government spending on agricultural output and economic growth of Nigeria. The objectives of the study are to analyze government allocation to agriculture for the period under study and determine the effect of government allocation to agriculture on economic growth. Data used for the study were obtained from CBN and NBS (National Bureau of Statistics) from 1981 to 2012. Descriptive statistics (line graph) and regression analysis was used to analyse the data. The Durbin-Watson statistic was used to test for autocorrelation among the independent variables and the dependent variable. The results showed that government allocation to agriculture within the period under study was discouraging, but had a significant effect on the output of the agricultural sector. From the regression analysis, Agricultural Credit Guarantee Scheme Fund (ACGSF) was significant and positively related to GDP while average annual rainfall was also significant but had a negative relationship to GDP. Government should be more proactive in insisting on the private sector, especially, the financial sector to set aside funds annually for agricultural financing to compliment government efforts.

Keywords: Government spending, agricultural output, economic growth, Nigeria, Allocation

INTRODUCTION

Agriculture is a key sector in the Nigerian economy. Its importance is particularly glaring in a developing economy like Nigeria where land and labour resources are relatively abundant and the industrial sector is poorly developed (Tamuno, 2006). The contribution of agriculture to overall development especially in developing countries like Nigeria include provision of increased food supplies, provision of gainful employment, provision of capital and capital formation, increasing foreign exchange for development and increasing rural welfare. The agricultural sector's contribution to economic growth and sustained rural development remains to be fully exploited (FMARD, 2006). The contribution of agriculture to GDP was 64% in 1960, declined to 35% in 1988, and presently, the agricultural sector in Nigeria contributes less than 30% to GDP, with crop production accounting for an estimated 85% of this total, livestock 10%, with forestry and fisheries contributing the remaining 5% (Awotide and Akerele, 2010). Mejeha and Nnanna (2010) attributed this declaring trend of agricultural production to inefficient traditional practice by smallholder farmers. However, the facts remains that government precisely the commercial banks have not come to grapple with the problem because much has not been felt in the area of credits to agriculture. The accusation was that government prefers granting credit to commerce or trading to agriculture and where the credit was allowed, the interest payable seems outrageous with some tight securities, which place restrictions and scare many prospective farmers (Ebere *et al*., 2014).

Farm credits are however important means for improving farm capital investment in Nigeria, with which there may be no progress in the agricultural sector to adequately fulfill its expected roles or millennium development goals (Musa *et al*., 2010)..Not until recently, government seriously thought and attempted to mobilize potential savings for the rural farmers. Commercial banks themselves have given little attention to the approval of loans to farmers for fear of defaults. Where credits are received from other sources apart from government and commercial lending, the interest rates have been too high. These reported high interest rates are stark realities to the peasant farmers.

Objectives of the study

1. analyze government allocation to agriculture for the period under study
2. determine the effect of government allocation to agriculture on economic growth

METHODOLOGY

Method of data collection: Secondary data used for the study were obtained from Central bank of Nigeria (CBN) Statistical Bulletins, National Bureau of Statistics (NBS) annual abstract of statistics, and Food and Agricultural Organization (FAO) Statistical Year Books.

Methods of Data Analysis

Objective 1 was achieved with a line graph which gave a graphical presentation of the trend of government expenditure on agriculture for the period under study. To realize objective 2, a multiple regression model was specified, and estimated through an ordinary least square (OLS) procedure.

Model Specification

The implicit form of the model was specified as follows:

GDP = f(GDPA,RIR,ACGS,GEA,AAR,t) (1)

The four functional forms of the model were specified in the explicit form as follows:

Linear: $GDP = Bo + b_1GDPA + b_2RIR + b_3ACGS + b_4GEA + b_5AAR + t + Ui$ (2)

Exponential: $LogGDP = Bo + b_1GDPA + b_2RIR + b_3ACGS + b_4GEA + b_5AAR + t + Ui$ (3)

Semi-log: $GDP = Bo + b_1logGDPA + b_2logRIR + b_3logACGS + b_4logGEA + b_5logAAR + logt + Ui$ (4)

Double log: $LogGDP = Bo + b_1logGDPA + b_2logRIR + b_3logACGS + b_4logGEA + b_5logAAR + logt + Ui$

(5)

Where,

GDP = Gross Domestic Product (1981-2012) in Naira
GDPA = Gross Domestic Product of Agriculture (1981-2012) in Naira
AOP = Agricultural Output (1981-2012) in Naira
RIR = Real Interest Rate (1981-2012) in Naira
GEA = government expenditure in agriculture (1981-2012) in Naira
CRE = volume of credit to the agricultural sector, under the Agricultural Credit Guarantee Scheme (1981-2012) in Naira
AAR = annual average rainfall for the country (1981- 2012) in mm
t = time (in years)
B_0 = constant term
$b_1 – b_5$ = parameters to be estimated
Ui = stochastic error term

RESULTS AND DISCUSSION

In Fig.1 it can be seen that recorded government expenditure to the agricultural sector did not really reflect the output from the sector. This agrees with Mogues *et al.,* (2008) that public spending in the agricultural sector is astronomically low. According to them, less than 2 percent of total federal expenditure was allotted to agriculture during 2001 to 2005; far lower than spending in other key sectors such as education, health, and water, contrasting dramatically with the sector's importance in Nigeria's economy and the policy emphasis on diversifying from oil-based economy, and also far below the 10 percent goal set by African leaders in the 2003 Maputo agreement. A lot of arguments have been put forward on whether government spending can boost economic growth. Although this work's focuses is on the agricultural sector financing through public instruments, Eboh *et al.,* (2012) are of the opinion that financial economists and policy makers are divided on whether government spending helps or hinders economic growth and stability. According to them, proponents of more government spending opine that government programs provide valuable public goods such as education, health, roads and other infrastructural facilities. To boost agricultural production and enhance its contribution to the country's Gross Domestic Product (GDP), a lot more has to be done in the area of increasing allocation and expenditure to the agricultural sector.

Agricultural GDP, government expenditure in agricultural sector, and real interest rates were not significant at levels tested. The non-significance of these variables on total GDP can be attributed to the apparent neglect of the agricultural sector through irresponsive policies towards the macroeconomic variables that directly impact on the agricultural sector. The Agricultural Credit Guarantee Scheme Fund (ACGSF) was significant and had a positive relationship with GDP. Its impact on the GDP is shown by its regression coefficient of 0.516 that is significant at 1%, indicating that if the amount of money guaranteed under the scheme is increased by a unit of its measure, total GDP will increase by the value of the coefficient. This is in consonance with Ebere *et al*., 2014 where it was found out that Agricultural Credit Guarantee Scheme Fund (ACGSF) was positively related to economic growth. A negative coefficient was obtained for average annual rainfall which was significant at 1%. This is contrary to a priori expectations, given that increased rainfall would lead to improved agricultural production. However, given that agricultural output did not have a significant effect on total output, this result may stand. Agriculture in Nigeria is highly seasonal and rain-fed, and adequate rainfall should positively relate to output from the agricultural sector. However, the relationship between agricultural GDP and total GDP has not been determined. That relationship, when established, will give support or disregard this result.

CONCLUSION

From the study, it was observed that government spending and allocation to agriculture is below what can boost the agricultural sector for commercial production. The Agricultural Credit Guarantee Scheme Fund has helped in sustaining the agricultural sector. However, the contribution of agriculture to total GDP decreased over the period studied. The study further reveals that in spite of poor investment in the agricultural sector, yet it has potentials to contribute about 73% of total GDP. This is presumed to be the contributions of small holder-farmers who constitute about 80% of the farming population in Nigeria. Government is therefore called upon to reinforce its efforts in increasing budgetary allocation for agriculture as this can support rural farmers in the acquisition of farm inputs and credit facilities this can help to boost agricultural productivity.

DETERMINANTS OF FERTILIZER USE INTENSITY AMONG SELECTED ARABLE CROP FARMERS IN IKWUANO LOCAL GOVERNMENT AREA, ABIA STATE, NIGERIA

E.I. Offor., K. C Igwe & U. C Joseph

Department of Agricultural Economics, Michael Okpara University of Agriculture, Umudike, P. O. box 2, MOUAU Post Office, Umudike, Abia State, Nigeria
offorevelyn53@gmail.com

ABSTRACT
The study analyzed determinants of fertilizer use intensity among arable crop farmers in Ikwuano Local Government Area of Abia State, Nigeria. Primary data were obtained from 10 arable crop farmers randomly sampled from 8 villages which gave a total of 80 farmers. Descriptive statistics and multivariate linear regression analysis were used to analyze data collected. The result showed that the fertilizer use in the study area was moderately high due to enormous demand on the limited land. Age, gender, educational level, household size and price of fertilizer were the significant factors that influenced fertilizer use intensity among the arable crop farmers. The study recommends that government and policy makers invest on increased knowledge and skill of farmers through avenues such as field days, extension agents contact with farmers or any other capacity building mechanism. Rural credit should be emphasized in order to mobilize savings and maximize the availability of credit to the farmer and to facilitate the distribution and uses of fertilizers, the agro-services centers should be opened in the rural areas. In addition, mechanism should be put in place to ensure that the subsidized fertilizer reaches the right target at the subsidized price. Fertilizer records at state and local government level over the years could be scrutinized to ensure and instill a sense of accountability and determine the true fertilizer situation at the levels.

Keywords: ***socioeconomic, fertilizer, use intensity, arable crop, farmers, government***

INTRODUCTION

Soil, which is the top most part of the earth, is an essential resource for mankind particularly; agricultural activities are carried out intensively on soil. The level of crop yield depends largely on the fertility of a given soil. According to Oguwole *et al.*, (2002), the inability to incorporate soil improvement technique into farming practices degrades the soil. It does not only frustrate efforts at achieving higher productivity but also undermine the carrying capacity of the environment to sustain the welfare of humans. It is obvious that environmental sustainability and sustainable agriculture brings about wellbeing of the people, particularly the rural dwellers whose basic survival are Hinged upon by environmental dynamics. The environment in its various conceptualization includes the social, physical, economic, political and policy environment (Adebayor, 2006). As a matter of fact, this environmental component has impact on the welfare of resource-poor rural farmers. Consistent depletion of soil nutrients in several rural farming communities has prompted the unavoidable reliance on chemical fertilizers in order to sustain crop production. The use of chemical fertilizers have made significant contribution to increase production largely. Akpoko, (2004) noted that traditional bush fallow system as well as inaccessibility to other soil improvement techniques like organic manure, mulching, zero tillage, minimum tillage have been sustainable hence make the use of organic fertilizer popular. Although organic fertilizer has impacted greatly on crop yield hence its wide spread. Inorganic fertilizer has become a major source of soil nutrient improvement for many farmers, but its high cost made it inaccessible. These have resulted to low level of production among framers. Halley (1992) had noted that many Nigerian soils have no sufficient qualities of nutrient necessary for high yield in crops. Therefore fertilizer is the key to rapid improvement in agricultural production and productivity (Husain, 1987).

In recent times, there is an increase in the awareness of the use of chemical fertilizers in order to augment for the depleted soil nutrients and sustain soil fertility for crop yield. This has led the government to increase a budgetary commitment to fertilizer procurement. However, procurement of chemical (organic fertilizer) by government is just a subset of the fertilizer-rural farmer-livelihood matrix. Accessibility of rural farmers to the procured fertilizer is the most important issue. Okoji and Ayichi, (2000) opined that the major bottlenecks to fertilizer accessibility are inadequate physical infrastructure, absence of well-organized rural institutions to handle input-distribution, political interference, fraudulent practices by staff of ministry and local government directly involved in fertilizer distribution and delay in procurement due to cumbersome procedure and bureaucratic process in decision making. These have affected the availability and usage of chemical fertilizers. Hence the main objective of the study is to examine fertilizer use intensity among arable crop farmers in Ikwuano Local Government Area of Abia state, Nigeria, using the fertilizer use intensity (FUI) adopted from Maingwa *et al*. (2007) and Olayide *et al*. (2009) in estimating the determinants of fertilizer use intensity.

METHODOLOGY

The study was conducted in Ikwuano LGA of Abia State, Nigeria. The main occupation of the people is farming. The major crops cultivated are cassava, melon, yam, maize, rice vegetables and cocoa which is an important cash crop. A simple random sampling technique was used to select 8 communities from the LGA. Thereafter 10 respondents each were selected randomly from the 8 communities to give a total of 80 arable crop farmers for the study. The arable crop farmers in the study area cultivate crops either solely or mixed cropping. In specific terms, the socio-economics was realized using percentages and tables, the fertilizer use intensity was achieved using the fertilizer use intensity (FUI) adopted from Maiangwa (2007) and Olayide (2009) stated thus

$$FUI = \frac{\text{Quantity of fertility used by the farmer measured in Kg}}{\text{Area of land cultivated by the farmer measured in hectare}}$$

The determinants of fertilizer use intensity were realized using multivariate linear regression analysis. The model is stated thus:

$FUI = B_1Age + B_2GEN + B_3EDU + B_4HHS + B_5LANS + B_6PRD + B_7OUT + B_8PANI + U_i$

Where FUI = Fertilizer use intensity, X_iAGE = Age of farmers (in years), X_2GEN = Gender of a farmer (1 = male, 0= female), X_3EDU = level of education (years), X_4HHS = Household size of farmers, X_5LAN = Land size cultivated by farmers (in hectares), X_6PRD = Perceived price of fertilizer by farmers (1 = high price, 0 = low price), X_7OUT = Output of fertilizer (in Naira (₦)), X_8PANI = Poultry owner (1 = owned poultry enterprise, 0 = otherwise) and U = error term

RESULTS AND DISCUSSION

Socioeconomics characteristics of the fertilizer users in the study area

The average farmer in the study area had a mean age of 43years, implying to be in active age, which could be positively related to farming and the adoption of new technologies like fertilizer usage. This is in line with the study of Nwaiwu *et al.* (2004) who work on problems and prospects of large scale plantain banana marketers production in Abia State show that the farmers were at their middle age of 46 years. This active age group usually undertake decision that concerns resource allocation in their venture across all Endeavour.. The male dominated the female counterparts in the use of fertilizer with a percentage of 80 to 20 respectively. This is as expected because the farm lands are usually owned by the men. The farmers in the study area were literate with a mean value of 11.8year. This implies that most of the farmers spend about 12years acquiring formal education. The level of education will reflect their technology adoption level positively. The arable crop farmers in the study area had a mean value of 0.43hectare of land. This implies that, they are smallholder farmers. The result is similar to the findings of Nwaiwu *et al* (2004), who observed that plantain/banana farmers in Abia State are smallholder with a mean value of 1.4hectares and therefore they are limited in capital, scope of operations and production. The arable crop farmers in the study area had a mean income of N76,487 per annum. This implies low income level of the farmers. This could be the reason why they could not have savings that could be reinvested into their farm business, hence appear to operate in a somewhat vicious cycle of poverty. The findings showed that 85% of the farmers use fertilizers representing more than half of the sampled farmers and this implies that the farmers adopted the use of fertilizers in the study area. Only about 50% of the sampled farmers do not use fertilizers.

Level of Fertilizer Use by Sampled Farmers

Table 2 showed that 52.6% of the arable crop farmers use a minimum of 50kg fertilizer. The mean value obtained was 88.9kg. This implies that the level of fertilizer usage in the study area was moderately high indicating high demand for fertilizer because fertilizer is one the important technologies used in increasing food production (Obiesesan *et al*., 2013).

Determinants of Fertilizer Use Intensity among Arable Crop Farmers

From Table 3:,Age of the arable crop farmers was significant at 1% level and had a positive relationship with fertilizer use intensity (FUI).This implies that a unit increase in the age of the farmers increases the fertilizer use intensity by 0.4867.It also means that older farmers use more fertilizer than younger farmers. This is in line with the findings of Ugwuja *et al.*, (2011).The variable gender was significant at 1% level but inversely related to fertilizer use intensity. This indicated that a unit change in the gender of the farmers will change the fertilizer use intensity by 0.137. This showed that majority of the farmers were female, as females tend to be involved in cultural practices during farming. Education level was significant at 1% level and was positively related to FUI, indicating that higher educational level influenced higher fertilizer use. This is in agreement with (Ugwuja *et al*., 2011) who reported that education correlates positively with adoption of improved practices. This is expected since most of the farmers in the study were educated The coefficient of Household size was significant at 10% level and had positive relationship with FUI. This implies that, the higher the number of the household size of the family, the higher the use of fertilizer. This conformed to *a priori* expectation because higher household members would require more food and this would mean more fertilizer use to grow more crops. Price of fertilizer was significant at 10% level and was positively related to FUI. This implies that a unit increase in price of fertilizer would increase the use of fertilizer by 0.077. This is contrary to apriori expectation. It is plausible however because fertilizer is an essential commodity to these farmers and as demand for fertilizer increases, its prices also increases but would not stop farmers from using them. This is contrary to the work done by Obisesan (2013) who reported that farmers use more fertilizer when the price of fertilizer is low than when the price is high. The R^2 value was 0.906 indicating that about 90.6% of total variation in the dependent variable was explained by the exogenous variables in the model. The F-ratio was also significant at 1% level. This indicated the goodness of fit of the model.

CONCLUSION

It is concluded that arable crop farmers in the study area were at their active age, literate, had mean income of about N76,487 and showed high use of fertilizer despite its high cost. Age, education and household size were significant factors that had positive relationship with fertilizer use intensity while high cost of fertilizer, limited access to credit and inadequate supply of fertilizer were the constraints to fertilizer use by farmers. Therefore, it is recommended that government and other policy makers should initiate capacity building programme to increase knowledge and skill of farmers through avenues such as field days, extension agents contact with farmers;emphasize rural credit mobilization to boost farmers savings and maximize the availability of credit to farmers; establish functional agro-services centers near to rural areas as sources of fertilizer supply to farmers, by this government can monitor the distribution and uses of fertilizer and ensure that subsidized fertilizer reach the farmers that need them at subsidized price.Fertilizer record at state and local government level over the years should be scrutinized to ensure and instill a sense of accountability and determine the true fertilizer situation at these levels.

ABSTRACT
This study analyzed the profitability of cassava processing among the rural households in the South East, Nigeria. Data used for the study were obtained from 120 respondents using a multistage random sampling technique. The data was analyzed using descriptive statistics and cost and returns analysis. The cost and returns analysis showed that he estimated total cost was ₦250, 465 while the estimated total revenue was ₦544,490.94 for the garri enterprise. Result of the analysis showed a gross margin of ₦326, 814.53/tonne and an estimated Net Income (NI) of ₦294, 025.19. Furthermore, the estimated profitability index (PI) of 0.5400 implies that for every ₦1.00 earned as revenue, 54 Kobos were returned as net income. Hence, the cassava processing enterprise was profitable. The rate of return on investment (ROI) was calculated as a percentage ratio of the Net Income to the Total Cost (TC). The estimated ROI for the garri enterprise was 117.39. This implies that the garri enterprise made more than double the amount on every ₦1.00 invested. However, cassava processing have some constraints, prominent among which are; inadequate capital, high cost of transportation, high input price, high interest rate and high cost of labour . Provision of credit support to investors in cassava processing not only as agricultural loans but as part of small and medium scale enterprises (SMEs) development grant, to expand their capacities, adopt new technologies / innovations, improve scale of operation and income is recommended.
Keywords: Profitability, Cassava processing, Rural Households, Cost and Returns

INTRODUCTION
Cassava (manihot esculenta) variously designated as Manioc, Tapioca or Yucca has been acknowledged as one of the most popular staple crops in the African diet (Nweke *et al*., 2002). Its production is characterized by small scale producers who use old varieties and traditional production technologies which largely accounts for low yield. The South Eastern region accounts for about 20 percent of the total cassava output in the country with Abia, Enugu and Imo states producing a total of 634 metric tonnes, 2599 metric tonnes and 2315metric tonnes of the crop annually (NBS, 2007). The crop is produced in many forms both in the fresh and processed forms, starting from the producers through myriads of processors to the end users. Acceptance of cassava as a low cost food in urban centres and as a source of steady income for rural households will depend on how it can be processed into a safe form (Bokanga, 1995). It also depends on how far it can be presented to urban consumers in an attractive form at prices which are competitive with those of wheat, cereal and yam . If cassava can be processed in a more efficient manner, it stands to gain in domestic demand as well as a potential export. However, the lack of appropriate and affordable technologies (especially for use by farmers and processors), a weak private sector (especially, intermediary processors and bulking agents that link small scale producers and processors with end user industries), trade policies, consumer preferences and policy volatility threaten this transition (Porter, 1980). In addition, if producers could harvest cassava and process them into staple commodities (such as garri) that could be stored for several months, they would earn high profits during the periods of scarcity. The acquisition of even simple processing, equipment is an investment which the majority of the small scale cassava processors cannot afford. Consequently, poor credit facilities and high interest rate make such investments risky and financially unattractive and hinder the development of the economic potential of the crop. More so, the inability to analyse effectively the cost benefit returns from the activity, coupled with poor access to productive inputs according to Oyewole and Philip (2006) stagnate expansion and investment opportunities. Therefore, this study analysed the cost and returns for cassava processing into garri and identified the constraints militating against the enterprise in South East, Nigeria.

METHODOLOGY
The study was done in South Eastern part of Nigeria. The zone lies between latitude 6º and 9ºE and 4º and 7ºN longitude and has a total land mass of 10, 952, 400ha with over 16 million people (NPC, 2006). Cassava production is a common business in this zone, usually processed into different forms like garri, fufu, abacha, flour, chips and starch A multi- stage sampling technique was used to randomly select 120 processors from four Local Government Areas in three states (Abia, Enugu and Imo).. Data were collected from primary sources with the use of structured questionnaire designed in line with the objective of the study. Data collected were analyzed using budgetary techniques and descriptive statistics. Descriptive statistics used include percentages and frequencies.

Budgetary technique was used to estimate the gross margin, profitability index, rate of return on investment, operating expenses ratio, net income and benefit-cost ratio. The Gross Margin technique was given thus:

$$GM = GR - TVC \quad \text{.....(1)}$$

Where; GM = Gross Margin in naira per kg
GR = Gross Revenue in naira
TVC = Total Variable Cost in naira

The result of the budgetary analysis was used to obtain the following ratios;

PI = Profitability Index = NI / TR ....(2)

RRI = Rate of Return on Investment $= \frac{NI}{TC} \times \frac{100}{1}$ ....(3)

OR = Operating expenses ratio $= \frac{TVC}{TR}$ ....(4)

Where; NI = Net Income
TR = Total Revenue
TC = Total Cost
TFC = Total Fixed cost
TVC = Total Variable Cost

RESULTS AND DISCUSSION

Profitability Analysis of Cassava processing

The budgetary technique was used to analyze the profitability of cassava processing into garri, while BC ratio, profitability index and rate of return on investment were calculated. The result of the analysis is presented in Table 1.

Findings showed that the cost incurred in cassava processing included cost of raw materials (cassava tubers, firewood, fuel, water, bags, palm oil etc), labour (peeling, washing, grating (soaking, drying, sieving, frying etc), and cost of depreciated assets. An average of 2730.63kg of cassava was processes into garri and this accounted for 29.17 percent of TVC and 25.35 percent of TC. Labour cost accounted for 37.84 percent of TVC and 32.89 percent of TC while other raw material inputs accounted for 32.99 percent of TVC and 28.67 percent of TC. The remaining 13.09 percent of the TC were accounted for by other inputs. The estimated total cost was ₦250,465 while the estimated total revenue was ₦544,490.94 for the garri enterprise. Result of the analysis showed a gross margin of ₦326, 814.53/tonne and an estimated Net Income (NI) of ₦294, 025.19. Furthermore, the estimated profitability index (PI) of 0.5400 implies that 54 percent of total revenue generated constituted Net Income for the garri enterprise and for every ₦1.00 earned as revenue, 54 Kobos were returned as net income. Hence, the cassava processing enterprise was profitable. The rate of return on investment (ROI) was calculated as a percentage ratio of the Net Income to the Total Cost (TC). ROI ratio in this study was used to estimate earnings per ₦1.00 investment. The estimated ROI for the garri enterprise was 117.39. This implies that the garri enterprise made more than double the amount on every ₦1.00 invested. This could also be seen in the estimated Benefit-Cost ratio for the enterprise. For every N1.00 spent, there was a return of N1.17 (2.17:1.0) for the garri enterprise. This confirms the findings of Ehinmowo *et al.* (2015) that the processing of cassava is profitable, returning a BCR of between 1.75 and 2.24 in Southwestern, Nigeria. Operating Ratio (OR) is a profitability indicator which measures percentage of variable cost per N1.00 sale. The OR for the enterprise was 0.40 (40%). This result indicates that for every N1.00 sale/revenue, the percentage of variable costs was 40 percent. This could be attributed to the prices and quantities of the inputs of variable cost items used in the production process.

Constraints to Garri Production

Garri production in the study area is faced with numerous challenges affecting its productivity which can also result to various levels of inefficiencies. The problems associated with garri production in the study area include inadequate capital, high cost of labour, high cost of transportation, lack of processing and storage equipments among others. Findings from Table 2 showed that inadequate capital, high cost of transportation, high input price, high interest rate as well as high cost of labour were the major constraints faced by the processors. The result showed that 65 percent of the respondents ranked first in terms of problems faced in garri production. Capital serves as the major back bone in any business enterprise. High cost of transportation and high input prices ranked second and third respectively.

CONCLUSION

Based on the findings, the enterprises were profitable at varying levels with garri and abacha enterprises returning more than double the amount invested in them. while problems such as high cost of labour, lack of basic amenities, inconsistent government policies and high cost of processing were among the major problems faced by the processors. Provision of credit support to investors in cassava processing not only as agricultural loans but as part of small and medium scale enterprises (SMEs) development grant, to expand their capacities, adopt new technologies / innovations, improve scale of operation and income is recommended. The amount of credit used by the processors in most of the cases had significant effects on their performance. Therefore the relevance of credit in strengthening the processors is fundamental.

AGRIBUSINESSES ENTERPRISES: A ROADMAP TO SELF-RELIANCE AND SUSTAINABLE ECONOMIC DEVELOPMENT

B.N. Ajakemo

Department of Laboratory Technology
Federal Polytechnic, Oko
Email: just4babygirl@gmail.com

ABSTRACT

Presently the economic situation in Nigeria is deplorable and has manifested in the exchange rate of dollars high level of unemployment, double digit rate of inflation. More than 25 states in the federation cannot even pay workers salaries. There is so much hunger in the land. A discussion on agribusiness enterprises as a road map to self reliance and sustainable economic development is therefore a welcome idea to the present issue of economic diversification in Nigeria. Agribusiness enterprise is a collective business activities that are performed from farm to fork and involves processing, packaging, production, marketing and so on. Its objectives and benefits to the nation were highlighted in this study. Notable considerations in moving forward include integration of agribusiness enterprises into policy formulation agenda, technological innovations in various areas of agriculture, organization of seminars and trainings for farmers and so on. The study, however, is of the opinion that government should promote policies and programmes to energize agribusiness in the country.

Keywords: Agribusiness, enterprise, roadmap, sustainable, self-reliance, economic, development

INTRODUCTION

Nigerian government over the year, that is since after the discovering of crude oil in Nigeria, have relied so much on income from crude oil than on agricultural produce. This is one of the major reasons why almost all agricultural programmes established to resuscitate the economic condition of Nigerians, failed to be fruitful. Presently the economic situation in Nigeria is deplorable and has manifested in the exchange rate of dollar, high level of unemployment, double digit rate of inflation. Today many state governments are unable to pay their workers salaries and the resultant effect of this is acute poverty and hunger in the society. This however calls for the need for economic diversification in Nigeria, and it has been found out that one of the basic ways of doing this is through establishment and development of various agribusiness enterprises in the different communities in Nigeria.

Agribusiness enterprising involves complex business activities that are performed from farm to fork, that involves processing, packaging, production, marketing and so on. There are several objectives for establishment of agribusiness ventures in any nation and all of them aimed at making the country to be self-reliance. Its importance to the Nigerian society, when actually adopted, as has been found out, would not only create wealth, but will also make individuals, farmers and Nigerian society as a whole to be self-reliant.

The objectives of this study therefore were:

i. to give an overview of agribusiness(es);

ii. evaluate self-reliance and economic development through agribusiness(es);

iii. examines the roadmap to sustainable economic development through agribusiness ventures;

METHODOLOGY

The major sources of information presented in this study were obtained from conference papers, journal publications, magazines, books of proceedings and textbooks.

Overview of Agribusiness Enterprises

Agribusiness is any type of business involved in agricultural production. This finding however, goes in line with the definition given by the free dictionary (2016), where agribusiness is defined as a large scale farming. This definition was also similar to the definition given by Wikipedia (2016), where agribusiness was defined as the business of agricultural production. According to Wikipedia (2016), the term "agribusiness" was coined in 1957 by Goldberg and Davis. It includes agro-chemicals, breeding, forestry projects, horticulture, livestock farming, crop production, (farming and contract farming), distribution, farm machinery, processing, and seed supply, as well as marketing and retail sales.

According to the Department of Agriculture, Jomo Kenyatta University of Agriculture and Technology (2016), agribusiness is the business of food, agricultural commodity and fiber production and the technology necessary to change raw materials (a commodity) or an idea into a new product or business for the world's consumers. This however, shows that agribusiness is a complex enterprise that integrates agricultural production, processing, packaging, distribution and marketing activities (APO, 2003). APO (2003) goes on to state that agribusinesses entail greater risk that simple farming and require specific skills and experience.

On the other hand, agribusiness is also seen as the collective business activities that are performed from farm to fork (FAO, 2016). It covers the supply of agricultural inputs, the production and transformation of agricultural products and their products to final consumers. Agribusinesses include firms that are involved in production of plants and animals. Its approach involves examining farming problems in a new and more compressive setting. The major benefit of this approach is the release of workers (farm manpowers) from agriculture to employment in new non-farm operations (Encyclopedia, 2016).

Objectives for Agribusiness Enterprise Development in Nigeria

According to ATC (2016) the major objectives for agribusiness enterprise development are:

- To enable farmers develop positive attitudes towards agribusinesses.
- Enable farmers determine real market demand for their agricultural produce.
- Sensitize farmers about the value chain(s) of their chosen agribusiness enterprise(s) and the possibilities of value addition.
- To determine current skills and knowledge that farmers possess, to establish the gap and suggest possible ways of acquiring such skill and knowledge to close the gaps.
- Assist farmers learn how to scan internal and external business environmental factors.
- Sensitize farmers on profitability and risk analysis regarding agribusiness enterprises.
- Highlight requirements for starting up and budgeting for agribusiness enterprises.
- Sensitize farmers on how they can mobilize resources for their agribusiness enterprises.

Roadmap to Sustainable Economic Development through Agribusiness Enterprises

Having looked at the concept of self-reliance, economic development and agribusiness enterprises, it is also necessary to look at various ways of promoting agribusiness enterprises for self reliance and sustainable economic development in Nigeria. Some of the ways are:

Policy Formulation: Agribusiness enterprises should be considered in policy formulation in Nigeria and policies formulated should always be in favour of such enterprises. There should be an adequate interaction between the rural community development officers and professionals in agricultural policy formulation, programme implementation and evaluation for rural areas in Nigeria, in any areas of need before they are established and implemented (Ajakemo, 2015).

Technological Innovation: There should be on the farm technological development in order to solve some problems encountered on the farm. Use of electronic gadgets for making animals in the farm is a example. There should also be some innovations in various areas of agriculture such as in the use of milking machines, animal breeding practices, irrigation and drainage system etc. Some of the technologies when introduced should be tested, trailed before being adopted for use by man.

Research and Development: Government should invest large sum of money on research and development institutions. This will help to improve agricultural productivity and profitability.

Development of Business Skills: Development of business skills could be achieved among farmers and youths through seminars and trainings. Such training should be designated to empower small holder individual farmers and farm groups with the basic entrepreneurial skills to enable them identify and select feasible agricultural enterprises to engage in within their locality.

Re-establishment and Development of co-operative Societies: Rural farmers, families and individuals should be encouraged to establish and develop the already existing co-operative societies in their localities. This medium will help them to take up one or more agricultural ventures especially medium scaled enterprises easily. Such medium will not only help them to assist themselves financially, it will also help to attract the government to help them financially where need be.

CONCLUSION

Having assessed agribusiness as roadmap to economic prosperity, the study has identified a number of factors as possible panacea to the economic downturn. In the light of the foregoing, the study recommends that government should promote policies and programmes to energize agribusiness in the country.

DETERMINANTS OF INVESTMENT BEHAVIOUR AMONG SMALLHOLDER PIG FARMERS: IMPLICATIONS FOR IMPROVING THE FARMING SYSTEMS OF ABIA STATE, NIGERIA

[1]N.C. Onyemauwa, [2]I.N. Nwachukwu, [1]H.N. Anyaegbunam & [1]N.U. Uchechukwu

[1]National Root Crops Research Institute, Umudike, Abia State, Nigeria

ABSTRACT
Over the years, pig farming has emerged as an effective enterprise and can be a reliable one due to certain attributes of pigs and the Nigeria production system. Pigs are known to be prolific producers realizing twenty to thirty (20-30) piglets from 2½ litter per year. Its ability under efficient management and balanced nutrition to reach slaughter weight of about 80 to 90kg in about 7 to 8 months makes it one of the most efficient feed converters. The demand for pork in Abia State has remained higher than supply as most shops that deal on processed pork are always running short of supply due to excess demand. Inadequate supply of feed has been one of the problems militating against pig production in Nigeria. The study examined the determinants of investment behavior among smallholder pig farmers in Abia State. A total of 120 farmers were purposively selected using a well structured questionnaire, information sought were on the socio –economic characteristics and other quantitative variables of interest. Descriptive statistics such as percentages, mean, frequencies and multiple regression model were used in analyzing the data. The results of the analysis revealed that Age and interest rate were significant and negatively related to investment while farm profit, farming experience, farm income and depreciation were significant and positively related to investment. it was recommended that government should adjust their monitory policy to bring about reduction in interest rate so that farmers can have access to loan at cheaper and affordable rate. This will encourage farmers to invest more in pig farming, thereby boosting the farming system through diversification of enterprises and improved income generation.
Keywords; Determinants, Investment, Pig Farmers

INTRODUCTION
Agriculture in Nigeria is practiced at subsistent level and its characterized by numerous farmers operating several scattered small and fragmented land using traditional methods such as lands rotation, bush burning and crude implements (Odoemenen *et al*, 2013).
According to OLuwepo,(2012); majority of the rural populace in Nigeria either depend entirely on farming and farming activities for survival and generation of income, or depend on other non farming activities to supplement their main sources of income. The validity of this statement becomes evident when it is realized that over 90.0% of the countries local food production comes from small farms which are usually not more than 10 hectares in size, while at least 60% of the population earn their living from these small farms. It could then be seen that most farmers have limited resources, a factor that limits their production outputs, income and investment.
Investment in agriculture is highly dependent on credit factors and other variables. Some of the factors according to Foster, (1996) are internal to the firm and others are a function of the economic environment. Managers can influence agricultural investments to some extents by developing strategies to effect variability, products divergent, amount of product innovations, input price variability, and fixed cost. Investments are being made in agriculture to improve the quality of rural assets and enhance productivity. The ability, willingness and opportunity of household to save and invest overtime can therefore significantly influence the rate and sustainability of capital and accumulation and economic growth in developing countries (Oluwakemi, 2012).
Over the years, pig farming has emerged as an effective enterprise and can be a reliable one due to certain attributes of pigs and the Nigeria production system. Pigs are known to be prolific producers realizing twenty to thirty (20-30) piglets from 2½ litters per year. Its ability under efficient management and balanced nutrition to reach slaughter weight of about 80 to 90kg in about 7 to 8months makes it one of the most efficient feed converters. The production of pigs in an economically viable livestock system, therefore calls for the provision of nutritionally balanced ration. This however, represents 50 to 83% of the production cost in a commercial pig enterprise (Tewe and Adesehinwa, 1995).
The demand for pork in Abia State has remained higher than supply as most shops that deal on processed pork are always running short of supply due to excess demand. Inadequate supply of feed has been one of the problems militating against pig production in Nigeria due to high cost of feed ingredients (Ngoka, 1979). Therefore this study is expected to provide relevant information that would encourage individual (farmer) not only those that are already in piggery, but also new entrants to venture into pig farming. The broad objective of the study was to

access the determinants of investment behavior among smallholder pig farmers in Abia State and to examine the socio-economic characteristics of farmers in the study area

METHODOLOGY

The study was conducted in Abia State of Nigeria. Abia State belongs to one of the states in the South –eastern Nigeria. The population according to the 2006 Census was about 2833999 comprising 1,434,193 males and 1399,086 females (NPC, 2006).Abia State is divided into 167 local Government Areas. The State shares common boundary with Rivers State in the South, Imo State in the west, Ebonyi and Enugu States in the North and Akwa Ibom and Cross River in the East. There are (3) Agricultural Zones namely Aba, Ohafia and Umuahia. The people of the state are mostly farmers. Farmers grow major crops such as Maize, Yam, Cassava, Rice, Vegetable etc, Livestock e.g. Goat, Pigs, Sheep, etc and Plantations, such as oil palm production, cocoa plantation and rubber.
Multistage sampling techniques was employed for the study, three local Government areas were selected from each of the (3) agricultural Zones, four communities were selected in the Second stage from the Local Governments given a total of Twelve communities. The last stage was a selection of 10 respondents from each of the communities. 120 respondents were employed and their represented the sample size for the study. Primary data were collected using a well structured questionnaire. Analysis was carried out using descriptive statistics such as tables, frequencies, percentages, mean and multiple regression model.

To estimate the determinants of investment the following model was specified in line with Ezeh (2007).
Where $Q=X_1, X_2$……………………….X_9+ei.
Q= Amount Invested (N `
X_1= Age of Farmer (Yrs)
X_2 = Cost of Variable Input
X_3 = Farm profits (N)
X_4 = Education of Farmers (Yrs)
X_5 = Household Size (No)
X_6 = Farming Experience (Yrs)
X_7 = Farm Income (N)
X_8 = Interest Rate (%)
X_9 = Depreciation (N)
ei = Error Term

RESULTS AND DISCUSSION

The Functional forms of multiple regression model namely linear, exponential, semi log and double log were tried and the semi log regression model was chosen as the lead equation based on the value of R^2 (coefficient of multiple determinations), F-Statistics, the number and degree of significant variables. The R^2 is 0.853 shows that 85.3% of the variation in the dependent variable was accounted for by the independent variables included in the model. Age and interest rate were significant and negatively related to investment while farm profit, farming experience, farm income and depreciation were significant and positively related to investment.

The results in Table 1 depicts that, Age had a negative coefficient and significant at 1% probability level, indicating that as the age of the respondent increased, investment decreased , the implication is that as the farmer gets older it could be constrained by energy and the greater the level of constraints it could face. As such, the less time he has to attend to his farm; this also affects his level of investment in the farm. Interest rate was significant at 1% risk level and negatively related to investment indicating that as interest rate increased, amount invested decreased. this could be due to the fact that interest rate which is the cost on borrowed funds increased, the burden of borrowing and the greater the burden of borrowers on the amount of money borrowed, the less the amount they borrow from lending institution, the less their investment. According to Aluko,(1987),increased interest rate will lead to under investment or low investment. Farm profit was significant at 5% risk level also and positively related to investment, indicating that as farm profit increased, investment also increased and vice versa. Under normal condition increased farm profit could be as a result of the maximization of economic benefits. Higher rates of maximizing economic benefits lead to availability of fund for investment in the farm investment. Farming experience was also significant at 1% probability level and positively related to investment. Increase in farming experience could be an indication of the practical knowledge which has been acquired by the farmer Olomola (1988). In line with a prior expectation, farm income had a positive coefficient and was statistically significant at 1% level of probability. The results revealed that the higher the income the farmer realizes from his farm, the greater his level of farm investment. This result consolidates the findings of Ezeh (2004) who obtained a similar outcome Depreciation was significant at 1% probability level and positively related to investment, indicating that the more depreciation value increased, the more investment. This implies that the effort by the farmer to keep the fixed assets in good working condition has a long run effect on his farm business, although the reverse is the case in the short run.

CONCLUSION

The study was carried out to analyze the determinants of investment behavior among pig farmers with a view to enhance the farming systems of Abia State. The results revealed that Age and interest rate were significant and negatively related to investment while farm profit, farming experience, farm income and depreciation were significant and positively related to investment. It was recommended that government should adjust their monitory policy to bring about reduction in interest rate so that farmers can have access to loan at cheaper and affordable rate. This will encourage farmers to invest more in pig farming, thereby boosting the farming system through diversification of enterprises and improved income generation.

CONSTRAINTS MILITATING AGAINST PRODUCTION AND COMMERCIALIZATION OF COCOYAM IN ABIA STATE

S.C. Uko, Okoye B.C. & J.O. Onyemma

National Root Crops Research Institutes Umudike
E-mail: ukochijioke@yahoo.com

ABSTRACT
The study examined the determinants of production and commercialization of Cocoyam in Abia State. The specific objectives include to; determine the socio-economic characteristics of Cocoyam Farmers, examine the factors that affect cocoyam production, categorize the farmers based on the level of commercialization, identify the constraints in cocoyam Production and Commercialization. The study was carried out in Abia State. Multistage random sampling technique was used in selecting the respondents. The data collected were analyzed using descriptive statistics, ordinary least square method and commercialization index as detailed below. The result indicates that female household heads (76.7%) dominated farming in the area. Many (48.9%) of cocoyam farmers are married. The farmers are educated. About 52.2% attended secondary schools while 21.1 % attended tertiary education. Highest farming experience ranged between 11 to 20 years (45.6%) and the majority of the respondents are aged between 51 to 60 years (46.7%). Cocoyam farmers are moderately oriented towards market production (42.1%). Marketing problems (81.1%), low soil fertility (80.0%), high incidence of pest and disease infestation (74.4%), small farm size (72.2%) high cost of inorganic fertilizer (72.2%), difficulty in obtaining credit facilities (61.1%) and poor access to good roads for transportation (60.0%), in the order listed, are identified as the constraints to cocoyam production and commercialization by the respondents.
Keywords: Commercialization, cocoyam, constraints, Abia State

INTRODUCTION
Nigeria is an agrarian nation but still face an ever increasing food crisis as the level of food production is yet to keep pace with demand. There is worsening food insecurity, even with massive food importation as evidence by rising food import bill (Okoye, et al 2008). Akan Sunmi (2009). Nigeria faces acute food shortage and its accompanying ravaging malnutrition. Though endowed with vast expanse or arable land for crop production report still shows that Nigeria cannot produce food crops her population requires and thus being depending of food-importation to meet her domestic demands (Adepeju and Awodumuiyila, 2008). Cocoyam is an important staple in Nigeria and rank third in importance after cassava and yam among the root and tuber crops cultivated and consumed Echebiri 2004, Okoye, Asumugha, Okezie, Tanko and Onyenweaku, (2008).
It is the most widely grown crop in both western and eastern region of Nigeria in terms of area cultivated and number of producer and it is not only a major source of food but also income especially in the rural area (Oguniyi, 2008). Nigeria is the world leading producer of cocoyam with an estimated 3.5 million metric tones in 2003. This was about 40% of the world cocoyam production (Eze and Okorji, 2003). As a food crop cocoyam has some inherent characteristic, which make it attractive to consumers in Nigeria. It has a multiplicity of end uses; for example, it can be used for making starch, flour, soup, confectionaries and so on.

METHODOLOGY
Study Area
The study was carried out in Abia State, South-Eastern Nigeria. The state is located between longitudes 5° and 7° East of the Greenwich meridian and attitude 5° and 7° North of the equator. Abia State is in rainforest belt with a temperature range of 21°c to 28°c and high humidity. The state occupies about 5,834 square kilometres, is bounded on the north and north east by the states of Anambra, Enugu and Ebonyi. To the west of Abia is lmo state, to the east and south east are Cross River State and Akwa lbom State and to the South is River State. The Southern part of the state lies within the riverine part of Nigeria. It is low-lying with a heavy rainfall of about 2400mm/year especially intense between the months of April through October. The rest of the state is moderately high plain. The major soil types commonly found in these areas includes clay soil, loamy soil, sandy soil and sandy loam soil. The population of Abia State as reported by National population Commission 'NPC' (2006) is 2.4 million people; mainly Christians with more than 85% of the population engaged in farming as main source of livelihood. It has 17 administrative local government area divided into three (3) agricultural zones namely: Zone, Umuahia, Isiala Ngwa, Ohafia, it is suitable for livestock rearing, production of cash crops such as oil palm, cocoa, kola nut and food crops such as yam, cassava, cocoyam, plantain etc.

Sampling Procedure
Multistage random sampling technique was used in selecting the respondents. Two local government areas were randomly selected from each of the three agricultural zones making six local government areas. From each of the six local government areas, one community was selected making six communities with the assistance of key

informants, the list and location of cocoyam farmers in each community was compiled from which the sample for the study was drawn. Fifteen (15), farmers were sampled from each of the six communities across the state totaling 90 cocoyam farmers in all.

Method of Data Collection

Data was collected through the primary source by the use of well structured questionnaire that were administered to cocoyam farmers. The questionnaire was used to obtain information on the socio-economic characteristics and other quantitative variable such as size of cocoyam farm cultivated, labour input used, expenses on planting materials, fertilizer and fixed capital inputs.

Data was collected through visits, personal interviews and direct observations, on the production of cocoyam planting season by the researcher. These will help to facilitate the correct interpretation of questions and proper recording of responses.

RESULTS AND DISCUSSION

The socioeconomic characteristics of the respondents are presented in Table 4.1 and the results show that the farmers are predominantly married, literate and middle aged female farmers with relatively high farming experience. In terms of constraints, marketing problems alongside low soil fertility cum high incidence of pests/diseases were reported to be the major problems militating against commercialization.

RECOMMENDATIONS

It is recommended that the level of education and experience of cocoyam farmers be increased through awareness campaigns and dissemination of research information and findings of research institutes through extension services, television and radio programs.

Table 4.1: Socioeconomic Characteristics of the Respondents

Socioeconomic characteristics		Frequency	Percentages

ABSTRACT
The study analyzed the effect of NDRE-REP on the poverty status of agribusiness entrepreneurs in Abia State. A purposive sampling technique was used to select 60 beneficiaries and 60 non beneficiaries of NDE-REP in the state. Data were collected through personal interviews, focus group discussions and well-structured questionnaire. The data was analyzed by means of descriptive statistics such as frequency tables, percentages and Tobit regression analysis. The coefficients of membership of cooperatives and farm size have an indirect relationship with poverty intensity at 5% level of probability each and business experience and age at 10% level each. The coefficient of beneficiaries of NDE-REP had an indirect relationship with poverty intensity at 1% level. The coefficients of native of community and household size had a direct relationship with poverty intensity at 10% and 5% level of probability.The results therefore call for policies aimed at land reforms by allocating more land especially to the youths, formation of cooperatives and sustaining the NDE-REP programme to improve the welfare of the farmers and poverty reduction.
Keywords: NDE-REP, Poverty Status and Agribusiness Entrepreneurs

INTRODUCTION

Poverty is a global phenomenon which threatens the survival of mankind. Majority of the poor people live in the rural areas. The poverty situation in the country has reached such a monumental crisis that it has become a great concern to the government at all levels (Ogunlela andOgwumike 2006).It has been observed that one of the principal causes of poverty in the country is unemployment resulting from joblessness and under-employment. The rate of unemployment has been on the increase in the last few years. For example, the labour forces sample survey conducted by the National Bureau of Statistics (2010) indicated an increase from 14.7% in March 2008 and 19.7% in 2009.

A number of government programme have been put in place to improve basic services. Such as infrastructure, housing facilities, access to credit, and provision of farm inputs and creating employment for the rural population. Such programmes includes; farm settlement scheme, River Basin Development Authorities (RBOA), Agricultural Development Programme (ADP), Better Life Programme and NDE-REP etc, all these were established by different administrations in the country to address various manifestation of poverty such as unemployment, lack of access to credit and rural and gender dimension of poverty. (Ogwumike, 2002).The National Directorate of Employment (NDE) is a skill formation and credit granting scheme, with consequences on alliterating Agribusiness entrepreneurship development. NDE-REP was targeted towards alleviation of poverty in rural areas which is based on that of engagement of Agribusiness entrepreneur skills. (Mbam et.al, 2010). Therefore, the objective of this study was to determine the effect of National Directorate of Employment-Rural Employment Promotion (NDE-REP) on poverty status of agribusiness entrepreneurs in Abia State.

METHODOLOGY

The study was carried out in Abia State. Abia State is one of the South-East Geo-political Zone of Nigeria. the state is made of 17 local government areas with the capital in Umuahia. It lies between longitude 4°45 and 0.6°17 North and Latitude 07^0 .00 and 08^0 10 East bounded by Imo State on the West, Ebonyi and Enugu State, on the North, Cross River and AkwaIbom State on the East, Rivers State on the South. The major occupation of the people is agriculture due to the rich soil, which stretches from yam, cocoyam, plantain, rice, vegetables, okro, maize etc, (NPC, 2006).

A multi-stage sampling procedure was used for the study. In the first stage, the three zones of the state were selected based on the evidence of NDE-REP consistency since the last 5 years. In the second stage, one local government areas were purposively selected also from each zone given a total number of three local governments. In the third stage two communities from each local government where NDE-REP has taken place were selected given a total number of six communities. A total of 60 beneficiaries were randomly` selected through the help of local governments officials of NDE in each local government and 60 non beneficiaries were also selected through the aid of Extension Agents of ADP given a sample size of 120 respondents.Data was analyzed by means of descriptive statistics such as frequency tables, percentages and Tobit regression analysis. The descriptive statistics was used to analyze variables like the socio-economic characteristics of the respondents, Tobit regression was used to analyze the determinants of poverty status among entrepreneurs in the study area.

RESULTS AND DISCUSSION

Table 1 shows the socio-economic characteristics of the respondent, which indicates that monthly income of the beneficiaries wasN45,119.29 while monthly income of non-beneficiaries N31,135.35. This implies that the beneficiaries earned higher income than the non-beneficiaries. The result also shows that majority of the beneficiaries belong to cooperatives societies (62.50%) compared to (40%) for the non-beneficiaries. This institutions help to address gender inequalities by mobilizing savings from members, donor agencies, NGOs and development agencies to develop member's business. The beneficiaries and non-beneficiaries had an average farm size of about 1.07 and 1.3ha respectively. This implies that they are small-holder farmers. The average years of business experience was 10 and 11 years for the beneficiaries and non-beneficiaries respectively. This indicates they have long years of business experience. The beneficiaries and non-beneficiaries had a household size of 5 and 8 persons respectively. This indicates that large household sizes have correlation with food insecurity, especially when the head of the family is engaged in agriculture as the main source of income and livelihood.
The results in Table 2 show the Tobit regression estimates of the determinants of poverty status among entrepreneurs in the study area. The result shows that the coefficient of household size was positive and significant at 5% level. This implies that any increase in household size will lead to increase in poverty intensity among the respondents.The coefficient of business experience was negative and significant at 10% level. This implies that increase in business experience will decrease the poverty intensity of the respondents. The coefficient of membership of cooperatives was also negative and significant at 10% level. This implies that respondents who are members of cooperatives have a decreased probability of staying below the poverty line than their counterparts who are not members.The coefficient of farm size was negative and significant at 5% level. This implies that any increase in farm size will lead to a corresponding decrease in the poverty intensity of the respondents with more output leading to more income and reduction in poverty among them. The coefficient of beneficiaries of NDE-REP has a lower probability of stay below the poverty line than non-beneficiaries. Being beneficiaries decreased the poverty line of the respondents.

Table 1: Average statistics of the respondents

Variable	Beneficiaries	Non beneficiaries	Pooled
Age	38.28	37.35	37.82

CONCLUSION

The study analyzed the effect NDE-REP on poverty status of agribusiness entrepreneurs in Abia State. Important variables related to poverty status include age, household size, business experience, membership of cooperatives, native of community and form size. Therefore there is need for policies aimed at land reforms by allocating more land especially to the youths for agribusiness activities, encouraging the formation of cooperatives and sustaining the NDE-REP programme by bringing it closer to the people and introduction of adequate practical's to aid training.

ABSTRACT
This study was designed to examine rural credit and production efficiency among yam farmers in Isiukwuato Local Government Area of Abia State. The objectives of the study were to describe the socio-economic characteristics of credit-users and non-credit users in yam production and to determine the relative technical efficiency among them. A purposive sampling of ten yam producing villages in the study was done. A list of yam farmers who obtained credit from the two banks and cooperative societies was obtained. Six credit users were randomly selected from the ten village and six non-credit users were also randomly selected from the ten villages. Descriptive statistics was used to analyze the socio-economic characteristic of the yam farmers. However, regression analysis using additive multiplicative dummy variable approach was used to analyze the technical efficiency of the yam farmers. Cobb-Douglas functional form was chosen as the lead equation for technical efficiency because it had a high R^2 of 63%. Farm size(X_2), value of fertilizer (X_3) value of other inputs (X_4) and Dummy for labour (X_1D) were statistically significant at 5percent level. The credit users and the non-credit users operated under the existing technology and were factor biased or non-neutral in their production function. On the basis of the findings, government should ensure that agricultural credit facilities and incentives are given to yam farmers. Policies that will enhance acquisition of large farm size by credit-users should be formulated and implemented.

Key words: Rural credit, Technical efficiency, Production efficiency.

INTRODUCTION
Rural development is a process of not only increasing the level of per capita income in the rural sector, but also the standard of living of the rural population. With adequate financial capital, farmers can become more efficient in their resource allocation and uses (Eze, 2006). According to Okigbo (1981), it is generally acknowledged that the availability of financial capital is a pre-requisite for increased production and rapid economic development of any nation. It follows therefore that banks have a vital role to play in making vast financial resources available for financing and promoting crop production such as yam.

Inadequate credit facilities have long been identified as one of the major constraints to agricultural production in Nigeria. (Nwajiuba, 2000). A number of agricultural policies have been adopted by the Nigerian government in an effort to provide credit facilities to farmers. The policies emphasize the need to make credit available to farmers through formal and non-formal credit institutions so as to boost agricultural production.

Nigeria is by far the world's largest producer of yams, accounting for over 70-76 percent of the world production (Oluwatusin and Shitu, 2014).According to Akoroda and Hahn (1995), the production of yam in Nigeria is grossly inadequate and cannot meet the ever increasing demand for it under the present level of input use. One of the major factors that contribute immensely to this fallout in the productivity of yam over the years is the problem of production inefficiency. This is so as production efficiency is directly related to increase in production. Efficiency is concerned with the relative performance of the processes used in transferring given inputs to outputs.

Yam can be grown in nearly all tropical countries provided water is not a limiting factor. In Nigeria it is grown within the coastal region up to latitude 12^0N and corresponds to the rainforest, wood savanna and southern savanna belt. This is the region where the annual rainfall exceeds 800mm in amount and 4months in duration (Ike and Inoni, 2006).

The main objective of the study was to determine the impact of rural credit on production efficiency of yam farmers in Isuikwuato Local Government Area of Abia State, Nigeria. However, the specific objectives were:

- To describe the socio-economic characteristics of borrowers and non-borrowers among yam farmers.
- To determine the relative technical efficiency among users of rural credit.

METHODOLOGY
The Data
The data used in this study were primary data collected through cost-route approach by means of structured questionnaire from a sample of one hundred and twenty yam farmers in Isuikwuato Local Government Area of Abia State. A purposive sampling of ten yam producing villages was selected from the area. (Acha, Ozara, Ezere, Ahaba, Ovim, Ndundu, Akpukpa, Nvurunvu, Isunabo, and Achara).

A list of yam farmers who obtained credit from the two main banks in the area (Access Bank, PLC and Uturu Community Bank PLC) during the 2012 farming season were obtained from the banks, and corporative societies. Six credit users were randomly selected from the ten villages giving a total of sixty yam credit users. Six non-credit users were also randomly selected from the ten villages, giving a total of sixty non-credit users.

Data Analysis

The addictive multiplicative dummy variable approach was used to determine technical efficiency of the yam farmers.

The production function is implicitly specified as follows:

$Y=f(X_1, X_2, X_3, X_4, X_5, D, X_1D, X_2D, X_3D, X_4D, X_5D, ei)$ …….. (1)

Explicitly, the log linear Cobb-Douglas functional form is:

$LnY = LnA_0 + B_0D + A_1LnX_1 + B_1DLnX_1 + A_2LnX_2 + B_2DLnX_2 + A_3LnX_3 + B_3DLnX_3 + A_4LnX_4 + B_4DLnX_4 + A_5LnX_5 + B_5DLnX_5 + ei$ ………. (2)

Where in equation (1) and (2):

Ln = the natural logarithm

Y = Value of all output (₦)

A_0 = the intercept or constant term

B_0 = co-efficient of the intercept shift dummy or neutral technical efficiency parameter.

D = dummy variable which takes the value of unity for credit users and zero otherwise.

X_1D, X_2D, X_3D, X_4D, X_5D are the slope shift dummies for:

X_1 = Labour input (manday)

X_2 = Farm size (Hectare)

X_3 = Value of fertilizer used (₦)

X_4 = Value of other production inputs like seeds, cost of agrochemicals, planting materials (₦).

X_5 = Value of capital services used with the production period such as farm machinery, implements and tools

e_i = Error term

RESULTS AND DISCUSSION

1. Socio-economic characteristics of Respondents

a. Age of farmers:

For the non-credit users, 28% of the farmers were of the 26-35years age bracket, 8% were between 56 and 65 years old. For the credit-users, 42% were of the 36-45years age bracket and 3% were between 66 and 75years old.

b. Educational Level

For the non-credit users, 87% had formal education and 13% had no formal education. For the credit-users, 83% had formal education but 17% had no formal education.

c. Household Size.

For the non-credit users, 77% had a household size of 5-8, 3% had a household size of 11-15. In the credit-users, 78% had a household size of 5-8 and 3% had a household size of 11-15.

d. Years of Experience in Yam Farming

For the non-credit users, 27% had 5-15 years of experience in yam production while 8% had over 50years of experience in yam production. For the credit–users, 42% had 5-15years experience while 3% had over 50years experience in yam production.

e. Farm Size.

For non-credit user, 68% of the farmers had farm size of 0.1-1 hectare and 32% had farm size of 1.1-2 hectares. For credit users, 53% had farm size of 1.1-2 hectares and 13% had farm size of 3.1-4 hectares.

From the Table1, the intercept dummy for the two groups of farmers was not significant this implies that the two groups of farmers were equally technically efficient in yam production.

However, the slope shift dummy for labour was statistically significant at 1 percent indicating that the credit users and the non-credit users were factor biased or non-neutral in their production function. The slope shift dummy for labour was positive, which shows a higher level of use intensity for labour by the credit users.

The result indicated that the Linear form fitted the data for credit users with 66% of the total variation in the value of output accounted for by the explanatory variables. The value of output was significantly influenced by the labour, farm size and other production inputs at 5% probability level. This implies that one additional unit of labour will reduce the value of output by N326.50. White one hectare increase in farm size will increase the value of yam production by N55,781.24 and one Additional unit of other productive input will lead to #1,229.00 increase in the value of output of yam. The value of fertilizer used and the depreciated capital input were not significant.

The result of the estimated function for non-credit users in Table2 indicates that the double log production function was the best fit and explains 55% of the variation in yam output in the study area.

The coefficients of labour and other inputs were positive and statistically significant at 5% Level. However, the coefficient of fertilizer was negative but statistically significant at 5% Level this implies that a unit increase in labour will increase the value of output of yam by N512.00; a unit increase in other production inputs will increase production of yam by N470.00

CONCLUSION

The main objective of this study was to determine the impact of rural credit on the production efficiency of yam farmers in Isuikwuato local government area of Abia state, Nigeria.28% of the non-credit user farmers were of the credit user farmers were of the 26-35 years age bracket while 42% of the credit-users were between 36 and 45 years old. 87% of the non –credit user farmers had formal education, but 83% of the credit users had formal education .77% of the non –credit user farmers had a family size of 5-8 27% of non –credit users farmers had 5-15 years of experience in yam production. 68% of the non –credit users had a farm size of 0.1-1 hectare, while 53% of the credit users had farm size of 1.1-2 hectares.

Cobb –Douglas functional form was chosen as the lead equation for technical efficiency because it had a higher R^2 of 63%. Farm size (X_2), value of fertilized (X_3), value of other inputs (X_4) and dummy for labour (X_1D) were statistically significant at 5 percent level.

ABSTRACT
Rehabilitation is any method or activity that can improve the performance of existing trees. Rehabilitation of cocoa trees involves pruning and other activities, removing all diseased and pest-infected pods, dead and diseased branches, mistletoes, chupons, controlling weeds and disease, and pest control. This study describes socio-economic characteristics of the respondents and also to identify various operations and cost involved in carried out cocoa rehabilitation techniques. The study was carried out ldanre local Government Area (LGAs) of Ondo state. Primary data were used through the use of well structured questionnaire. Multi-stage systematic sampling techniques were used to select three villages from ldanre local Government Area .Descriptive statistics were the analytical tools used for the analysis of the study data which includes frequency and percentages distribution. A total of 53 respondents were enumerated during the study .The result from study area shows that majority of the respondents spent average ₦8000 on labour for clearing their farm while 32.1% of the respondent spent average of ₦3000 on labour per hectares for removal of mistletoes. However, 64.2% spent average of ₦5000 per hectare to procure fungicides while (83%) of the respondent spent average of ₦5000 to procure fertilizer that is used for cocoa production. Majority (73.6%) of respondent has knowledge about cocoa rehabilitation techniques. Finally, the major problem encountered by respondent was high price of input with (62.2%). Farmers should always be encourage to carried out rehabilitation techniques in all cocoa producing states which will bring existing trees into better production .
Keywords: cocoa, rehabilitation, cost, techniques, descriptive

INTRODUCTION

The centrality of agriculture to the development of developing economics is now beyond dispute. A vast body of knowledge has assigned a phenomenal role to agriculture in the early stages of industrialization in west and central Africa, agriculture has continued to play a dominant role in the provision of food, raw materials for industries, employment for the majority and foreign earning ,which are used in financing development activities particularly the permanent crops .Permanent crop otherwise known as perennial tree crops are long term crops that occupy the field planted for a long period of time and largely harvested every year and do not have to be replanted for several years after each harvest. ln the last 40 years ,permanent crops ,notably cocoa ,coffee, oil palm and rubber, have dominated the export agriculture (Nkamleu, Nyemeck and Gockowski,2010). Rehabilitation entails factors such as planting materials, cultural practices (weeding and pest control), plant propagation management and the economics of rehabilitation.

There are many defined and undefined factors that affect cocoa production rehabilitation in Nigeria and adequate and concise attention is not to be given to these factors. Cocoa farmers in Nigeria are not going out of cocoa production due to its less profitability and productivity. Many factors that affect cocoa production rehabilitation includes high cost of venturing into vegetative propagation and multiplication of cocoa, lack of technical know-how or illiteracy on the part of the farmer, insensitivity of government to agriculture and cocoa production, use of unselected seedlings or less improved seedlings for planting and no adequate or proper management of cocoa trees. These factors among others contribute to the less productivity and profitability of cocoa production in Nigeria.

Rehabilitation is any method or activity that can bring existing trees into better production. Rehabilitation of cocoa trees involves pruning of cocoa and shade trees, removing all diseased and pest-infected pods, dead and diseased branches, mistletoes, chupons, controlling weeds and disease, and pest control. Rehabilitation may also involve cleaning out all unwanted materials from the cocoa farm and adding fertilizer or organic matter to renew soil nutrients in order to improve the production of old cocoa trees.

Objectives

i. identify various operations and cost involved in carried out cocoa rehabilitation technique In the study area and;

ii. identify the problem which cocoa farmers are facing in the study area**.**

METHODOLOGY

The study was carried out in ldanre, Ondo state, Nigeria. The state is situated in the south western geo-political zone of Nigeria. Ondo State has a vast area of arable land, which is predominantly known for agricultural activities which is the main of economic livelihood (Adegeye, 2003).The inhabitants of Ondo State grow a wide variety of tree crops which produce fruit ,leaves ,timber and other useful products. Ondo State is the main of cocoa producing area of the country, at present. It supplies more than 65 percent of Nigeria's cocoa exports. Other producing states in Nigeria are Ekiti, Oyo, Ogun, Osun, Edo, Kogi, Kwara, Taraba, Imo, and Cross River State . Idanre is a Local Government Area in Ondo State, Nigeria. Its headquarters are in the town of Owena. It has an area of 1,914 km² and a population of 129,024 at the 2006 census. Idanre local government was created in 1991 from old Idanre/ Ifedore Local Government. It has landmarks of about 428km and shares boundaries with Ile-Oluji / Okeigbo, Ondo East, Odigbo, Akure South/ North and Edo-State.The primary data were carried out through the use of well-structured questionnaires, which were administered at the farm level among the cocoa farmers in the study area.A multi-stage systematic sampling technique was followed to draw the study sample of 53 respondents.

RESULTS AND DISCUSSION

Results presented in Table 2 shows the cost spent on labour for the following operations. It can be deduced from the study that 86.8% of the respondent spent average of ₦8000 on labour used in clearing their land while majority (77.4%) of the respondent spent average of ₦3000 on labour used in fertilizer application for their farm operations .Furthermore, chemical used for farm operations by the respondents show that 45.3% of the respondents spent average of ₦3000 on labour been chemical used on their farm while 26.4% spent ₦2000 on labour for pruning of unwanted branches which cost ranges between ₦2300, ₦2400, ₦2500, ₦2700, ₦3000, ₦3500. It can also be deduced from study that 32.1% of the respondent spent ₦3000 on labour per hectare for removal of mistletoes while 79.2% of the respondent spent average of ₦3000 on labour for insecticides application.

However, 64.2% of the respondents spent average of ₦5000 per hectare in procuring fungicides while 66.0% of the respondents spent ₦2300 in procuring herbicides. The result from finding shows that 47.2% of the respondents spent ₦1500 been cost used in procuring cutlass. Majority (79.2%) of respondent spent ₦1000 to procure harvesting hook while 49.1% of the respondents spent average of ₦15000 to procure knapsack sprayer and 83.0% of the respondents spent average of ₦5000 to procure fertilizer that is used for cocoa production.

Table 3 shows rehabilitation techniques and problem faced by respondent in the study area. It can be deduced from the study that 64.2% of the respondents weed their farm two times throughout the farm season while 20.8% weed their farm three times. Majorly (73.6%) of the respondents have knowledge about the cocoa rehabilitation techniques and 22.7% of the respondents does not have knowledge about rehabilitation techniques.

However, 49.1% of the respondents replant their cocoa while 39.6% of the respondents used coppicing as their rehabilitation techniques while 11.3% of the respondents also used budding on generated chupons. Majority of the respondents have problems of mistletoes in reducing cocoa yields in study area while 3.8% of the respondents have the problem of moss in reducing cocoa yield, 1.9% have problems of reducing cocoa yields through rodents and climber. Table 2 shows that 62.2% of the respondents have problems in obtaining farm inputs while 43.4% does not have problems in obtaining farm inputs.

Table 2 shows problem encountered by respondents in the study area, Majority (62.2%) of the respondents have problem with high price of farm inputs while 11.3% of the respondents have problem for both scarcity and high price and unavailability of farm inputs while 15.1% the respondent have problem with Untimeliness supply of farm inputs. Table 2 also shows that majority (96.2%) of the respondents used plantain as shade crop for cocoa production while 3.8% of the respondents used banana as shade crop for cocoa; which means respondents used plantain as crop shade in the study area. Finally, 62.3% of the respondents have problem with illegal felling of trees on farm while 37.1% does not have problems with trees felling.

CONCLUSION AND RECOMMENDATIONS

Based on the result of this research, the following policy measures which will assist cocoa farmers in Ondo State are recommended tha farmers should always be encourage to carried out rehabilitation techniques in all cocoa producing states which will bring existing trees into better production and government should reduce the high cost of input especially the chemicals which are used to control weed, disease and pest.

Table 1: Cost Spend on Labour for the Following Operations.

Clearing Cost(₦)	**Frequency**	**Percentages**

APPLICATION OF THE LOGIT MODEL TO DECISION ON FARMERS' ADOPTION OF IMPROVED CASSAVA VARIETIES IN AKWA IBOM STATE, NIGERIA

C.A. Nwigwe[1]*, C.O. Osuagwu[2], N.E. Udo[3] & E.C. Anumihe[4]

Department of Agricultural Extension and Management, Imo State Polytechnic, Umuagwo
akuchius@yahoo.com

ABSTRACT
The study aimed at estimating and explaining the parameters of the adoption process of the disease-resistant new improved cassava varieties, by farmers in AkwaIbom State. The main purpose for the development of the varieties is to increase the yield of cassava, which is a famine-reserve crop and rural staple food in Nigeria. Like any other innovation, improved cassava varieties must endure a phase of dissemination. Innovators and policy makers need knowledge of the expected rate of adoption. In this study, a conceptual framework was developed for the decision to adopt or not to adopt and econometric analyses of the diffusion process are presented, using Logistic regression model. To increase the rate of adoption in the study area, emphasis should be on the availability of the improved cassava stems to the farmers.
Keywords: Cassava, farmers, adoption, decision, logit model, Akwa Ibom.

INTRODUCTION
There has been much discussion on the need to increase productivity and sustainability in agriculture through adoption of modern agricultural production technologies (Adesina and Baidu, 1995; Akudugu*et al.*, 2012; Chilot*et al.*, 1996; Polson and Spencer, 1992; Nkonya*etal.*, 1997; Beshir*et al.*, 2012 etc). Increasing agricultural productivity is critical to meet expected rising demand and, as such, it is imperative to investigate the factors that influence farmers' decisions on modern technology adoption (Challa, 2013). Agricultural technologies include all kinds of improved techniques and practices which affect the growth of agricultural output (Jain *et al.*,2009). In the opinion of Loevinsohn *et al.*, (2013), the most common areas of technology development and promotion for crops include new varieties and management regimes; soil as well as soil fertility management; weed and pest management; irrigation and water management. By virtue of improved input/output relationships, new technology tend to raise output and reduces the average cost of production, which in turn, results in substantial gains in income (Challa, 2013). In fact, adoption of improved technologies is believed to be a major factor in the success of the green revolution experienced by Asian countries (Ravallion and Chen, 2004; Kasirye, 2010). On the other hand, non-adopters can hardly maintain their marginal livelihood with socio-economic stagnation, leading to deprivation (Jain *et al.*, 2009).
Quite a large number of studies have investigated the influence of various socio-economic, cultural and political factors on the willingness of farmers to use new technologies (Strauss *et al.*, 1991; Polson and Spencer, 1992; Adesina and Zinnah, 1993; Akudugu et al., 2012).
In many of the adoption behavior studies, the dependent variable is constrained to lie between 0 and 1 and the models used were exponential functions while univariate and multivariate logit and probit models, including their modified forms have been used extensively to study the adoption behavior of farmers and consumers. Shekya and Flinn (1985) have recommended probit model for functional forms with limited dependent variables that are continuous between 0 and 1 and logit models for discrete dependent variables.In this study, the responses recorded are discreet (mutually exclusive and exhaustive) and therefore, a univariatelogit model was developed to analyze the adoption behavior of farmers to improved cassava varieties. The logit model, which is based on cumulative logistic probability functions, is computationally easier to use than other types of models and it also has the advantage to predict the probability of farmers adopting the technology.

Methodology
Study Area
The study area was Akwa Ibom State and it has 6 agricultural zones namely Oron, Abak, Ikot Ekpene, Etinan, Eket and Uyo which have very high potential for agriculture. A total of 120 farmers were selected, using a multi-stage random sampling technique across the zones.

Logit model: The logit model was used and it assumes that the underlying stimulus (Ii) is a random variable which predicts the probability of "improved cassava varieties" adoption:

$$Pi = \frac{e^{Ii}}{I+e^{Ii}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Conceptually, the behavioural model used to examine factors including "new cassava varieties" adoption is given by:

$Y_{i\,=\,g}(Li)$……………………………………………………………………………….(2)

I_i=$bo + \Sigma_{bj} X_{ji}$…………………………………………………………………….(3)

WhereY_i is the observed response for thei^{th} observation ($i.e,$ the binary variable, Y_i = 1 for an adopter, Y_i = 0 for non-adopter). $I_i$is an underlying stimulus index for the i^{th}observation. (Generally, there is a critical threshold $\{I_i^*\}$ for each farmer, if $I_i < I_i^*$, the farmer is observed to be non-adopter and if$I_i \geq I_i^*$, the farmer is observed to be adopter); g is the functional relationship between the field observation (Y_i) and the stimulus index (I_i) which determines the probability of the "improved cassava varieties" adoption).

$I = 1, 2, \ldots\ldots\ldots, m$ are observationson variables for the adoption model; m is the sample size; X_{ji} is the j^{th}explanatory variables for thei^{th} observation and $j = 1, 2, 3, \ldots\ldots\ldots, n; bj$ is an unknown parameter; $j = 0, 1, 2, \ldots\ldots\ldots, n,$ where n is the total number of the explanatory variables.

Empirical model specification: The data in which the empirical model is based were drawn from a sample size of one hundred and twenty smallholder farmers in AkwaIbom State, using a multi-stage random sampling technique. Structured questionnaire was used to solicit information from the respondents. The dependent variable is measured by dichotomous variable: farmers who used the technology or still using the technology were categorized as adopters while those not using were non-adopters. The definitions and measurement of variables as well as sample characteristics are presented in Table 1. The variables included in the logit model are: age, educational level, farming experience, access to improved varieties, access to credit, farm distance, frequency of extension contact with farmers, and $ei,$ the random disturbance.

Past studies have shown that the age of the farmers is related to adoption decision. Younger farmers have been found to be knowledgeable about new practices and at the same time, willing to take risk (Polson and Spencer, 1992; Bultena and Hoiberg, 1983; Gould *et al.*, 1989; Challa and Tilahun, 2014).Following the earlier empirical findings, the maintained hypothesis is that age is negatively related to adoption. Years of experience ($i.e.$when the farmer had his own farm) are distinguished from farming experience. The latter is not relevant for empirical model since most farmers judged their total experience as starting from the first day that they started going out with their parents to farm. What is important is the experience since the farmer became a decision maker on his own field (Mueller and Jansen, 1988). Farm size represented by farm area has been shown to be positively related to adoption decision (Akinola, 1987; Norris and Batie, 1987), therefore, it is hypothesized that the sign is positive. Contact with extension agents is expected to be positively related based on the innovation-diffusion theory. Such contact, that is, exposing farmers to information can stimulate adoption (Polson and Spencer, 1992; Voh, 1982; Kebede*et al.*, 1990). Years of experience in farming are related to the ability of the farmer to obtain; process and use information relevant to farming. A positive relationship is hypothesized between this variable and the probability of new improved varieties of cassava stems adoption.

RESULTS AND DISCUSSION

Empirical result: A summary of the socio-economic characteristics of the sampled respondents in the study area reveals that actual mean estimates obtained for variables did not show much variation (Table 2). Most of the farmers were still within the productive age. Majority (71.4 percent) in the area are young and energetic male farmers with high literacy levels. Access to the new cassava varieties was found to be 44 percent. The study further revealed that farmers usually look upon the extension agents to provide information and farm inputs. About 75 percent established that extension agents within their locality were the primary source of information on the improved cassava varieties but since there was scarcity of the improved cassava cuttings, adoption sometimes become difficult. This may have affected adoption rate in the study area.

Rate of adoption: The rate of adoption is the relative speed with which members of a social system adopt an innovation. It is measured as the number of individuals who adopt a new technology within a specified period. In measuring the rate of adoption of the improved cassava varieties, the proportion of farm land (proxy) related to cassava planting to the proportion of cassava cuttings received from the extension agents was used as criteria. The rate of adoption for the state was found to be 38.5 percent.

Logit regression analysis, using shazam software package shows that most of the coefficients are not consistent with hypothesized relationships and their tests of significance help to indicate their importance in explaining adoption decisions of the farmers. The parameter estimates for the model was evaluated at 5% level of significance. Logit estimates for the survey location (Table 3) revealed that apart from age, years of farming experience and farm size were found not statistically significant in explaining improved cassava variety adoption; education, contact with extension agents, access to cassava stems (cuttings) and distance to farm were statistically significant at 5% level. The positive sign and significance of the extension contact variable implies that extension is an important factor that will promote farmers' adoption of improved cassava varieties in the study area.

The study revealed that the main source of technology is through extension personnel. The non-availability could be attributed to non-accessibility in terms of quantity and time. Farm size though not statistically significant has a negative correlation with adoption. This sign is contrary to a priori expectation and implies that an inverse relationship exist between the farm size and adoption. The result further confirmed that increase in farm size might not after all lead to adoption of the technology. This result is consistent with findings from India and Bangladesh (Ahmed, 1981; Onyewaku and Mbuba, 1991). Farmers' age and education (though significant) were found to be negatively and positively related to adoption behavior respectively. These two parameters are consistent with our a priori expectation. The implication of these findings is that a younger farmer with better education has the tendency to take risk and adopt the technology.

The empirical model can be used to draw economic implication for the new improved cassava varieties improvement strategies in the state. The estimated model was used to predict probability of the improved cassava variety adoption:

I_i = -0.178 – 0.298 +2.627 – 0.679 – 3.395 – 1.054 + 0.624 – 1.75

The probability that a farmer will adopt the technology is given by:

$$P_i = [\frac{e^{-1.75}}{1+e^{-1.75}}] = 0.78$$

or 78 percent. The result shows that there is 78 percent chances that a farmer would adopt the improved cassava varieties, all other things being equal.

CONCLUSION

This paper showed that education, contact with extension agents, access to improved cassava varieties are significant variables that influence farmers' improved cassava variety adoption and use decisions. The results demonstrated further that for the technology to be successful, government and research institutes in charge of improved cassava variety distribution must ensure cassava cuttings availability in the right quantity and appropriate time. This provides a justification for government policies aimed at providing adequate infrastructure and institutional arrangements that will enhance the procurement and distribution of the improved cassava varieties. Technical guidance in the form of extension training will also enhance adoption of the technology.

Table 1: Definition of variables in the empirical model

Dependent variable	
Yi	Farmer adoption decision which takes the value of 1 if he is adopting and 0, otherwise.
Independent variable	
Age (X_1)	Age of the farmers, measured in years
Education (X_2)	Farmers' education level: 1 if he is able to read and 0, otherwise.
Farm size (X_3)	Farm size represented by farm area, measured in hectare.
Experience (X_4)	Farmers' farming experience, measured in years.
Extension (X_5)	Contact with extension agents, measured by the frequency of contact or participation at cooperative meetings
Farm distance (X_6)	Distance between homesteads to farm, measured in kilometer.
Access to improved cassava stems (X_7)	Access to cassava stems is measured in kilometer

ABSTRACT
A survey was conducted to investigate the socio-economic characteristics, farm holding capacity and groundnut digging operations employed by groundnut farmers in some selected Local Government Areas of Kano State Nigeria. A multi-stage random sampling technique was used to select 72 respondents for the study and the data was analyzed by the use of descriptive statistics. The results revealed that, majority (62.5%) were above 40 years while 26.40% of them were of the age bracket of 36-40 years constituting about 94.4% of the respondents. The result of this study showed that 93.1% of the respondents were married and about 40.3% have household size of 6-10 persons, 27.8% of them have household size of 11-15 people, 48.60% have no formal education while 51.4% have acquired one form of formal education or the other. The result further showed that, 88.9% were predominantly farmers having farming as their primary occupation and majority (52.80%) of them had farming experience above 20 years. 94.4% of the respondent were small scale groundnut farmers with groundnut farmland between 0.1-5.99 hectares and a mean of 2.2 hectares. Majority (90.3%) of the respondents use animal traction in their farming operations, 88.9% of them used cattle as draught animal in the study area. Most (93.1%) used hired labour, 98.6% of them dig their groundnut manually and 100% of the respondents pay for groundnut digging operation. It was recommended that, government agencies and NGOs should assist groundnut farmers in the study area in sourcing small scale groundnut digger to increase their productivity and link farmers with financial institutions where they can assess soft loan.
Keywords: Farming holding, capacity, Groundnut, Nigeria, Kano State

INTRODUCTION

Groundnut (*Arachis hypogaea L.*) is one of the world's most popular leguminous crops cultivated throughout the tropical and subtropical area where annual precipitation is within the range of 1000-1200 mm for optimum growth of crop. The crop is grown in nearly 100 countries and the most leading producers of groundnut are China, India, Nigeria, U.S.A, Senegal, Indonesia and Sudan (Garba *et al*, 2002). The total world output of the crop in 2012 was 40.1 million metric tons out of which Nigeria accounted for 3.1 million metric tons (USDA, 2012). Groundnut has high economic and nutritional potentials and is an important cash crop for peasant farmers in poor tropical countries (Garba *et al*, 2002). In Africa, groundnut production has been estimated at about 4.6 million tons with Senegal, Nigeria, Zaire and Sudan being the largest producers and an annual estimation placed Nigerian production of unshelled nut at about 2.6 million metric tons from a land area of approximately 2.5million hectares (Attanda and Adinoyi, 2016). Beside, providing food for man and livestock, groundnut can be an important source of much of the needed foreign exchange for the country (Ashley, 1993). In Nigeria, groundnut is produced in almost all the northern states. The leading producing states include Niger, Kano, Sokoto, Kastina, Kaduna, Adamawa, Yobe, Plateau, Borno, Taraba, Gombe and Nassaraw (Attanda and Adinoyi 2016). Despite its importance, the crop is still not sufficient due to some problem which hinders its productivity, this problem is attributed to rapid urbanization, fragmented farm lands, pod loss during harvesting, low per capital income, poor storage, inadequate transportation and marketing facilities as well as non-challent attitude to agriculture among others Gulati (2000). Kuye *et al*, (2004) further noted that, small operators in Nigerian agricultural sector face pure competition both at production and marketing stages.

The objectives of the study were to:

i. Determine the socio-economic characteristics of the respondents
ii. To ascertain the holding capacity of groundnut farmers in the study area and
iii. To identify the digging operations employed by groundnut farmers in the study area

METHODOLOGY

Study Area

Kano State is located in North-Western Nigeria with Coordinates: 11°30′N and 8°30′8.5°E, the State has been a commercial and agricultural state, which is known for the production of groundnut. It has more than 18,684 square kilometers (7,214 sq mi) of cultivable land and is the most extensively irrigated state in the country. It has 44 local government areas in 3 senatorial districts Adinoyi (2016).

Data Collection

A multi-stage random sampling technique was employed to select respondents for the study. In stage one, all the three senatorial districts was considered for the study, in stage two, two local government areas were randomly selected from each senatorial district, the local government areas selected were Gezawa and Dawakin Kudu from Kano central, Dambata and Tofa in Kano north as well as Bebeji and Ajingi in Kano south. In stage three, twelve farmers were randomly selected from each local government area. In all, a total number of seventy two (72) farmers were used for the study. The Data collected was analyzed using a simple descriptive statistic.

RESULTS AND DISCUSSIONS

Socio-Economic Characteristics of the Respondents

The results obtained from the study as depicted in Table 1 reveals that, majority (62.5%) were above 40 years while 26.40% of them were of the age bracket of 36-40 years. Also, male farmers dominated groundnut production constituting about 94.4% of the respondents. This reveals that, more men were engaged in groundnut farming than women due to its economic and commercial value to provide income for the up-keep of the family, this is in line with the study of Girei *et al*, (2013) which showed that, in Africa, when a crop is perceived as commercial, men are more likely to take over from women. Also, the result of this study shows that 93.1% of the respondents were married. This implies that married people are more involved in farming activities in the study area than the single and other categories. This implies that being married tends to provide family labour for groundnut production and less money is spent on hired labour. The study also reveals that, 40.3% of the respondents have household size of 6-10 persons, while 27.8% of the farmers are of household size of 11-15 people. The result also shows that 48.60% of the respondents have no formal education while 51.4% have acquired one form of formal education or the other which is a vital component in technology adoption in agricultural mechanization. The result further shows that, 88.9% are predominantly farmers having farming as their primary occupation while, 20.80% had petty trading as their secondary occupation. Majority (52.80%) of them had farming experience above 20 years.

Table 2: shows that the majority (30.6%) of the farmer had up to 11 years of groundnut farming experience while the remaining 69.40% had groundnut farming experience of 12 years and above. The research also revealed that 61.1% of the respondents are small to medium scale farmers having 0.1-5.99 and 6.0-9.99 hectare of farm land respectively. It was discovered from the result that 94.4% of the respondents interviewed were farming groundnut at small scale level with groundnut farm land of between 0.1-5.99 hectares and a mean of 2.2 hectares and this agrees with the findings of Lowder *et al*, (2015). Majority (23.6%) of the groundnut farmers in the study area had groundnut yield between 10-20 bags per year. It was found out that 25.0% of the farmers spent between ₦5, 000 to ₦9, 000 (five thousand to nine thousand Naira) per year per hectare on groundnut digging operation.

The result in Table 3 revealed that, majority of the respondents (90.3%) use animal traction in their farming operations. About 88.9% of them used cattle as draught animal in the study area while majority (90.30%) of the farmers used draught animal for ridging, 66.70% used their drought animal for weeding operation, and 68.1% for transportation. Most of the respondents (93.1%) used hired labour in farming operation. The result revealed that 98.6% of the respondents dig their groundnut manually using hoe while 100% of the respondents pay for their groundnut digging operation. This result is in line with the finding of Paul *et al*, (2013) states that digging and lifting operations or harvesting, are among the most time and labor-intensive operations associated with groundnut production. When plants are ready for harvest, rural smallholders traditionally dig their crop using a hoe to sever the tap root and lift the groundnut plant by hand. 97.2% of the smallholders surveyed reported harvesting their crop using this method which takes one or two weeks for both husband and wife to complete lifting an acre of groundnut farm.

CONCLUSION AND RECOMMENDATIONS

The results of the study showed that majority of the respondents fall within the active age, most of them were found to be small holder farmers and manually dig their groundnut using hoe. They also employ the use of draught animals (Cow) in carrying out ridging, weeding and transportation operations.

Based on the outcome of the study, it is therefore recommended that government agencies and NGO's should assist groundnut farmers in the study area in getting small scale groundnut harvesting machine like animal drawn groundnut digger since they used animal traction in some of their farm operations, a simple animal draw groundnut digger would be suitable for small groundnut farm holders because it would require minimum investment in acquiring the machinery, and this require less problem of repair and maintenance with technical known how and this will eventually lead to reduction in cost, maximize time and increase productivity of groundnut farmers. Also, since majority of the respondents in the study area are small scale groundnut farmers, it will be worthwhile to link them with financial institutions where they can assess soft loan to boost their production.

ABSTRACT
The study examined the factors influencing income generating activities by rural women in Ogo-Oluwa Local Government Area of Oyo State. A well structured questionnaire was used to obtain relevant information from respondents. a total of 90 respondents constitute the sample size, which were selected through simple random sampling technique. The study revealed that 68.9% of the respondents were within the age range of 30-49 years.71.1% had one form of education or the other, 69% of the respondents are married and 41.1had 4-6household size. The major occupation of the respondents is farming with 56.7% had 5-20 years of experience in their income generating activities. The study also revealed multiple responses of various factors influencing their choice of income generating activities such as past experience (90%) personal interest (83.3%) and capital (60%) are of great magnitude. It is therefore recommended that compulsory and free education, capital, and capacity building should be provided for rural women in the study area by different levels of government and non-governmental organization to improve on their income generating activities and quality of food to the household.
Keywords; Factors, income, activities, rural women

INTRODUCTION

Women have moved from traditional roles of being housewives and providing labour on their husband's farm only, to also own farm of their own (FAO, 2011). Most of the activities which women engaged in their livelihood strategies are not defined as 'economically active employment in national account systems, yet are crucial to the wellbeing of household members (FAO, 2010). Much of women work is also under valued because it is typically under remunerated and often confined to the domestic or household realm such as caring for children, the elderly and the ill, collecting water and fuel for cooking and heat, and maintaining households and preparing food are the responsibilities which are mostly taken up by women and girls (Fontana, 2010).

Women comprise 50 per cent of the world's total population, perform two-third of the world's work hours, receive 10 per cent of world's income and own less than one per cent of total assets (Elkhalil, 2014). Women are 70% of the world's poor and 70% of agricultural labor in developing countries. Women provide between 60 and 80 per cent of the food for household consumption (World Bank, 2014). Women's contribution to agricultural production varies from country to country, crop to crop and task to task (Marilee, 2012). On the basis of available evidence and statistics, the role of women in agricultural production in Nigeria cannot be trivialized. They perform crucial roles in the domestic and economic life of the society. Rural and national development can hardly be achieved with the neglect of this important and substantial segment of the society (Kishor, 2012).

There has been an increased concern for developing the skills of women. Many factors can contribute to the socio-economic development of women such as land, technology, credit, and employment, etc. in their choice of income generating activities. Of these various factors, access to credit constitutes the crucial input for their ability to earn an income, leading to an increase in their status and autonomy (Rajasekhar, 2010). Therefore, the objective of the study is to determine factors influencing income generating activities of rural women in Ogo-Oluwa Local Government Area of Oyo State.

METHODOLOGY

The study was carried out in Ogo-Oluwa Local Government Area of Oyo State. The simple random sampling technique was used in selecting respondents. The data for this study was obtained from primary source. Questionnaire was the main instrument for data collection. It was however complimented with interview schedule. The questionnaire comprises of demographic characteristics (age, marital status, educational level, household size, etc,) and the factors that influence their choice of income generating activities (gender differential, past experience, capital, etc,). The study covered the whole of Ogo-Oluwa Local Government. A total of 90 household respondents were selected. Data generated for this study were analysed using descriptive statistics such as frequency distribution, percentage, mean.

RESULTS AND DISCUSSION

The results in table 1 show the age grouping of the respondents. Most of the women farmers (68.9%) falls between the age 30-49 years thus could be regarded as middle age ,while 4.4.% fall between 60-69. It shows that more than half of the respondents (69 %) are married while 1 % is divorced. This implies that most rural women have additional responsibilities to carry out (FAO, 2011). The greater proportion of the household size is between 4-6 (41.1%). This can be attributed to increase in awareness and sensitization of rural people of benefits of family planning by government agencies (like primary health care centres and extension agent). Table also indicates that majority (71.1%) has one form of education or the other while only 28.9% of the respondents did not have any form of education. It shows that most of the respondents (55.5%) are farmers while about 44.5 % of the respondents engaged in non-farming activities, this is consistent with Marilee (2012) who revealed that women's contribution to agricultural production varies from country to country, crop to crop and task to task.

Table 2 shows the factors influencing respondents in their choice of income generating activities. It shows that the major influencing factors are the past experience (90%) in their chosen activities, personal interest (83.3%) and availability of initial capital (60%). It is followed by inherited (37.8%), taste of people in their areas (24.4%), demand of the people and gender differential (23.3%), their husband decision (18.9%), socio-cultural factor (10%) and educational status (7.8%). This result is also in line with Rajasekhar (2010) who revealed that many factors can contribute to the socio-economic development of women such as land, technology, credit, and employment, past experience, etc, in their choice of income generating activities.

CONCLUSION

Based on the findings of this study, it can be concluded that rural women play a significant role in agricultural activities through their income generating activities to ensure household food security which cover both agricultural and non-agricultural activities in addition to their domestic responsibilities. Majority of the rural women engaged in farming activities as their primary occupation while they engaged in non-agricultural activities to complement their income. It is therefore recommended that compulsory and free education, capital, and capacity building should be provided for rural women in the study area by different levels of government and non-governmental organization to improve on their income generating activities and quality of food to the household.

ANALYSIS OF AGRICULTURAL CREDIT ON FARMERS PRODUCTIVITY IN UYO LOCAL GOVERNMENT AREA OF AKWA IBOM STATE, NIGERIA

C.R. Okezie & E.E. Akaka

Department of Agribusiness and Management
Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
Coresponding author: rosynma2003@gmail.com

ABSTRACT
The study was conducted in Akwa Ibom State, Nigeria to determine the effects of agricultural credit on farmers productivity in the study area. Multistage random sampling technique was used in the study. Primary data was collected through a well-structured questionnaire and analyzed with OLS multiple regression model. The result of the study indicated that out of the nine (9) variables fitted in the model, seven (7) were significant. The significant variables included level of education, credit source, experience, farm size, amount approved, interest and household size as the major factors affecting the productivity of farmers. The coefficient of multiple determinations for the lead equation R^2 was 0.82, was highly significant at 1% probability level, indicating that 82%of the variation in farmers productivity (income) were significantly explained by the variables investigated in the study. F – ratio value of 42.48 is statistically significant at 1%. This implies goodness of fit in the model. The study indicates that farmers would benefit more from farm credit if policies are made to improve availability of more credit and accessible financial institutions.

Keywords: credit, productivity, agricultural credit, Akwa Ibom

INTRODUCTION

Agriculture is a major contributor to Nigeria's Gross Domestic products (GDP) and small – scale farmers play a dominants role in this contribution (Rabji *et al*, 2009) but their productivity and growth are hindered by limited access to credit facilities (Odoemenem *et al*, 2010). There seem to be general consensus that the provision of credit to farmers and other agricultural related business will improve the agricultural sector of the Nigerian economy as agricultural credit is expected to play a critical role in agricultural development (Duong and Izumida, 2002). It was in recognition of the downward trend that was observed in agricultural productivity that the federal Government of Nigeria at various periods put in place credit policies and established credit institutions and schemes that could facilitate the flow of agricultural credit to farmers (Adegeye *et al.*, 1985). Among such schemes are; the Nigeria Agricultural and co – operative and Rural Development Bank (now known as the Nigerian Agricultural co – operative and Rural Development Bank) established in November 1972, the establishment of rural branches of rural branches of commercial banks throughout the country following a mandatory federal Government Policy direction in 1976. Agricultural credit enhances productivity and promotes standard of living by breaking vicious cycle of poverty of small scale farmer. Adegeye *et al* (1985) described agricultural credit as the process of obtaining control over the use of money, goods and services in the present in exchange for a promise to repay at a future date. Olaitan (2006) noted that countries witnessing declining agricultural production at the same time it is faced with an increasing population. Iheancho *et al* (2006) suggested that the lack of finance to the agriculture sector has caused a decline in agriculture production and agribusiness. According to the CBN (2007), about 65 percent of Nigerian's economically active population lacks access to formal financial service, hence the continuous effects by government to address the issue. The situation raises the need for an enquiry into the performance of the credit finance provided, that is the effects it has on creating access to finance, increasing productivity and ultimately delivering on intended objectives.

METHODOLOGY

Study Area

The research was conducted in Uyo Local Government Area of Akwa Ibom State,Nigeria. Akwa Ibom is a state in Nigeria named after the Qua – Iboe River. It is located in the coastal south – southern part of the country, lying between latitudes 4^0321 and 5^0331 north and longitudes 7^0251 and 8^0251 East. The state is bordered on the east by Cross River State, on the west by Rivers State and Abia State, on the south by the Atlantic Ocean and the southern most top of cross River State. It has a population of about 3.9 million people, though comparatively small in land mass, it is rich in a couple of mineral resources such as; crude oil, natural gas, limestone, gold, salt, coal, silver, to mention but just a few.

Sampling Technique

Multistage random sampling technique was adopted in the study. First stage was the purposive selection of Uyo Local Government Area because of predominance of farmers in the area. Second stage was the random selection of five communities' out of the nineteen communities, which are Oku, Anna, Offot, Uyo Itam and Ikono Uyo. In

the last stage, twenty farmers each were selected from the five communities each by random sampling to make a total of one hundred farmers (sample size).
Primary source of data were collected through the use of a well-structured questionnaire. Data were analyzed with the use of descriptive statistics like tables and frequencies and multiple regression analysis method was used to determine the effect of credit utilization on farmers output and income and the model specification is stated below.

Y = Income(₦)
X_1 = Age (years)
X_2 = Education (years spent in school)
X_3 = Credit source (formal = 1, informal = 0)
X_4 = Farming experience (years)
X_5 = farm size (hectares)
X_6 = Amount of credit received (₦)
X_7 = Interest charge (yes = 1, No = 0)
X_8 = household size (numbers)
X_9 = grace period (yes = 1, No = 0)
U = Error terms

RESULTS AND DISCUSSION

The result from Table 1 shows the determinants of income. The double log functional form was chosen as the lead equation for the study. This is due to its R^2 value, number of significant variables, significance of F- ratio and conformity to apriori expectations. From the double-log functional form, out of the nine (9) variables fitted in the model, seven (7) were significant. The significant variables included level of education, credit source, experience, farm size, amount received, interest and household size.
Farm size, amount received and interest were statistically significant at 1% and positively related to the dependent variable (income). This implies that as this variables increase, the income of the farmers also increases.
Experience was significant at 10% and directly related to the dependent variable (income). This implies that as the farmers grow older in farming, their income tend to increase.
Education, credit source and household size were statistically significant at 5%, 10% and 10% respectively and are inversely related to the dependent variables (income). This implies that as those variables increases, the dependent variable (income) reduces though this against a priori expectation. The coefficient of multiple determination for the lead equation R^2 was 0.82 was highly significant at 1% probability level, indicating that 82%of the variation in farmers productivity (income) were significantly explained by the variables investigated in the study. This therefore means that 18% of the variation was lost due to error or variable not accounted for.
F – ratio value of 42.48 is statistically significant at 1%. This implies goodness of fit in the model.

CONCLUSION AND RECOMMENDATIONS

The study indicates that farmers would benefit more from farm credit if policies are made. To improve upon the existing condition; availability of more and accessible financial institutions, release of loans, literacy programmes as such would enhance their socio-economic status.

DETERMINANTS OF LABOUR SUPPLY AND OUTPUT OF CASSAVA FARMERS IN EBONYI STATE, NIGERIA

D.C. Nwaogu, R.N. Echebiri & J. Eluu

Department of Agricultural Economics, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria ***danielchinedu32@gmail.com***

ABSTRACT

This study was carried out in Afikpo North L.G.A of Ebonyi State. The major aim was to examine the factors responsible for labour supply and productivity among cassava farmers in the study area. Farm level and relevant household variables were used for the data analysis. The findings show a relatively aging population of predominantly men. The Cobb Douglas function for labour supply factors showed a 67.3% variation in labour supply as a result of supply related variables included in the model. Variables household size and wages were all significant and positively related to labour supply at 5% and 1% respectively while farm size and farm income were significant at 1% and 5% respectively but negatively related to labour supply. Similarly, 77% variation in the cassava output was explained by the changes in the independent variables included in the model. The result showed that farm size was positively related to cassava output at 1% level of significance. Farming experience showed a 1% positive significance level implying that farmers would get more output from their cassava farms as they got more experience. Based on the findings of this research, it was recommended that Government at all levels should empower rural cassava farmers through the provision of farm loans, adequate supply of improved farm inputs (seeds and fertilizers) that are early-maturing and disease-resistant. Farmers on their own should form cooperatives which would make access to loans very easy and convenient and as such, lending institutions should be willing to assist rural farmers meet their food production target by ensuring timely disbursement of loans and at affordable interest rates too.

Keywords: Labour supply, output, determinants, cassava

INTRODUCTION

Cassava (*Manihot esculenta crantz*) belongs to the family *Euphorbiacaea*, and originated in Latin America and it is now cultivated in all parts of the world. In Africa, about 600 million people are dependent on cassava for food (International Fund for Agricultural Development (IFAD) 2013). Nigeria is the largest producer of cassava in the world with a population figure of 52.4mt and it is one of the world's most important food crops with an annual output of over 34 million tonnes of tuberous roots (Asogwa *et al*. 2013). Nigeria's production accounts for 19% of the world output and 34% of Africa's output, it also plays a principal role in the nation's food economy (Agwu *et al.,* 2007). Cassava is the chief source of dietary food energy for the majority of the people living in the lowland tropics and much of the sub- humid tropics of west and central African (Tsegia *et al*., 2002; Cited by Echebiri and Edaba, 2008). At present, a wide range of traditional cassava forms (such as garri, fufu, starch, lafun, abacha etc) are produced for human consumption (Kormawa *et al.*, 2003). Cassava products are used in various forms for human consumption, livestock feed and manufacturing of industrial products (Ene, 1992).

According to Nweke *et al.* (2002), eighty percent (80%) of Nigerians in the rural areas eat a cassava meal at least once a day and hence it plays a major role in the country's food security. As a crop whose by-products have a wide array of uses, cassava is the most important food crop for Nigeria by production quantity next to yam, which is the most important food crop by value (FAOSTAT, 2012).

Despite an increase in production in recent times, cassava production has suffered a considerable shortage in labour supply even with adequate provision of other production inputs. Agricultural production especially in the tropics and sub-saharan Africa is essentially manual and labour intensive, involving the use of rudimentary equipment-mainly simple tools and equipment such as hoes and cutlasses. Government at the national, state and LGA levels, have attempted to ease the labour constraint and stimulate expansion of farms through tractor hiring services but the tractors are either inaccessible to the poor who need them most or in a state of disrepair. According to the World Bank report (2009), labour productivity in Nigeria is persistently low.

Studies of the labour supply have concentrated on the developed countries. Also, most of these studies emphasized the determinants of the size of the labour supply and the pattern of labour participation placing emphasis on the personnel, gender, household and labour market characteristics, and some relevant demographic factors such as fertility, urbanization and migration. Similarly, use of work oxen is difficult because of tsetse fly infestation and the nature of the soil. Considerably, efforts in terms of family and hired labour are needed to clear land, prepare it for planting. Family labour which is mostly used as hired labour is expensive because of migration of able body young men and women to the cities in search of other higher paid and attractive jobs or education, leaving an aging farm labour force.

Moreover, mechanization of farming activities such as land clearing and preparation will be difficult in the cassava producing area because of heavy rainfall and the dominance of trees and shrubs. This study therefore is an attempt to examine the labour supply condition of cassava producers in Afikpo, Ebonyi state.

METHODOLOGY

Study Area

This work was carried out in Afikpo North L.G.A of Ebonyi State. The L.G.A is situated in the southern part of the state, bounded to the North by Akpoha, west by Okposi L.G.A, south by Ubeyi L.G.A and east by Abbi in Cross River state. The study areas span an area approximately 164 square kilometers (164 sq. km). Afikpo North is hilly and lies in trough of a syncline of undulating sandstone. The inhabitants are mainly peasant farmers. Data used for this work was collected with the aid of questionnaires from the study area. Such data included the socio-economic characteristics of the cassava farmers, their labour supply data, farm size and other farm related variables.

Data Analysis and Model Specification

The data collected for this study were analyzed with the use of simple descriptive tools like frequencies tables and percentages. Other econometric tools like Cobb Douglas function, multiple regression were also used.

The Cobb-Douglas stochastic production frontier function is explicitly specified as:

$Ln\ Y = \beta_0 + \beta_1 In\ X_2 + \beta_2 In\ X_2 + \beta_3 In\ X_3 + \beta_4 In\ X_4 + v_1 - \mu_1$

Where

Y= Total Labour Supply (Man days); X_1=Household size; X_2= Farm size (Hectares);X_3= Wages (₦); X_4= Farm Income (₦)

The multiple regression model is implicitly stated as;

$Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + b_7X_7 + b_8X_8 + U$

Where

Y= Total cassava output (measured in naira); X_1=Farm size (Hectares); X_2=Farming Experience (Years); X_3=Fertilizer input (₦); X_4 = Distance to farm site (Km); X_5 = Number of Extension visits/year; X_6=Credit value (₦); X_7=Household size; B_0=Intercept; $b_{1-}b_8$ = Coefficients of the estimated parameters; U=Stochastic error term

RESULTS AND DISCUSSION

Socio-Economic Characteristics of the Cassava Farmers

The result shows that 75% of the respondents were males and 25% females implying that cassava farming households predominantly carried out by males with moderate house sizes of 4 to 6 persons. Result further shows that land acquired by inheritance accounted for about 50% of all the land used for farming in the study area. This indicates that the traditional ownership of land was still in vogue as the farmers would have refused to sell their land on the grounds of native beliefs. This kind of land tenure system stems from the kinship practice still observed in most communities of the south-eastern part of Nigeria.

Factors Affecting Labour Supply to Cassava Farmers in the Study Area

The result of factors affecting labour supply to the cassava farmers are presented in Table 1. Four explanatory variables were included and regressed against the data for labour supply measured by the total man days of labour during the farming season. The R^2 value of 67.3% means that 67.3% variation in labour supply was accounted for by changes in the independent variables included in the model.

Household size positively affected labour supply to cassava farmers at 5% level of significance in the study area. It implies that households will give out labour to those in need of it provided that the household is large enough such that the loss of a labourer would not reduce the required labour needed to carryout farm operations in the household owned farms. The findings of this work also showed that wages positively affected labour supply at 1%. This means that households would release more labour to the market provided that buyers paid reasonable amount of wages. These wages in-turn would increase household income. This is obtainable only when the wages received for a labourer given out is more than the cost of hiring a labourer to do the same task. This assumption holds for imperfect labour markets with some elements of wage discrimination.

Farm income had a negative relationship with labour supply to cassava farmers in the study area at 5% level of significance. This implies that as farm income increased, households were reluctant to supply labour. This is may be so since the income from farm was enough to meet other necessary family consumption needs. It could also be that the household labour force increased farm output at an optimal level such that a loss in one labourer will lead to a larger marginal decline in output.

Determinants of farm output of cassava farmers

The multiple regression was used to analyze the determinants of cassava farmers' productivity in the study area. The lead (linear) equation was chosen based on the number of significant explanatory variables, value of R^2 and the signs of the coefficients as they conform to *a priori* expectation. The results are presented in Table 2.

The result showed that 77% of variation in cassava output was explained by the variables included in the model. Farm size was positively related to cassava output at 1% level of significance. This conforms to *a priori* expectation and simply means that as farm size increased, cassava output increased as well. It is worthy to note that farm size is the major determinant of farm output because farmers in the rural areas are not yet receptive to modern technologies due to low income. Such technology that encourages land use intensification would definitely increase farm output even with limited farm size but this is not the case in the study area where farmers depended solely on crude implements and output only increased with land area.
Farming experience showed a 1% positive significant relationship with cassava output. This implies that farmers would get more output from their cassava farms as they got more experience. This result is in concordance with economic theory. Experience is an important variable which enables farmers to make certain innovative and market driven decisions such as adoption of modern farm practices and use of improved inputs. Experienced farmers are also able to overcome certain production challenges and farm intricacies, thus, losses through ignorance and adoption or continuous utilization of obsolete practices are avoided.
Fertilizer usage influenced cassava output positively at 5% level of significance. This indicates that cassava output will increase with an increase in fertilizer application. This statement meets *a priori* expectation. The coefficient of fertilizer at 0.3 means that for every 1kg increase in fertilizer application, farm output will increase by 0.3. It is therefore obvious that increasing farm output would require that farmers increase fertilizer usage. However, it should stated that excessive use of fertilizer on farmlands can damage the soil fertility by destroying the soil living organisms responsible for soil aeration and other desirable soil qualities. Application also should be dependent on the type of cassava, soil nutrient requirement and under the best and most suitable application technique.
The distance farmers travelled to their farms from their homes had a negative toll on cassava productivity at 10% significance. The implication of this is that as farmers located their farms farther away from their residential areas, farm output decreased. The reason for this decline may stem from the number of household members willing to trek long distances for the purpose of farming. It may also be as a result of loss of strength through walking. In such cases, the farmers get tired and may either become completely worn-out to do any meaningful farm work and thus reduce efficiency as a result of drudgery and fatigue.
A 10% significant positive relationship existed between the number of extension visits witnessed by cassava farmers and their output. This means that farm output will increase with the frequency of extension visits. During extension visits, farmers are informed of current farm management practices, new and available technologies, better farm decisions and others. Household size had an unexpected negative relationship with cassava output at 10% meaning that farm output will decrease as household size increases. This finding does not corroborate *a priori* expectation and may have arisen from the fact that many of the farming households had a large dependency ratio, thus limiting the available labour for increased output.

CONCLUSION AND RECOMMENDATIONS

The determinants of labour supply, utilization and farm productivity as studied by this work showed that both farmers' socio-economic characteristics and other economic and land tenure-related variables had strong influences on the labour market of cassava farmers as well as their productivity level in the study area. The study also revealed that labour supply was highly inelastic, i.e. an increase in wage rate increased labour supply by a large margin. This is because of the relative availability of labour in the study area. Based on the findings of the study, farmers are encouraged to expand their productive capacity to make food abundant in supply as to meet the ever-growing demand for food in the study area; community Labour unions should ensure a uniform wage rate for different categories of labourers. Government at all levels should on their own part empower rural cassava farmers through the provision of farm loans, adequate supply of improved farm inputs (seeds and fertilizers) that are early-maturing and disease-resistant. Farmers on their own should form cooperatives which would make access to loans very easy and convenient and as such, lending institutions should be willing to assist rural farmers meet their food production target by ensuring timely disbursement of loans and at affordable interest rates too.

COST-BENEFIT ANALYSIS OF WEED CONTROL METHODS ON COWPEA PRODUCTION

B.T. Mohammed, A.F. Abdulquadri & J.K. Omisore

National Centre for Agricultural Mechanization (NCAM) Km.20 Ilorin-Lokoja Highway
P.M.B 1525, Ilorin Kwara State
bolarindemohammed@yahoo.com

ABSTRACT
This study is aimed at evaluating the cost-benefit analysis of selected weed control methods in cowpea production in research farm of the National Centre for Agricultural Mechanization (NCAM), Ilorin, in the 2014 and 2015 planting seasons. Five treatments, included weeding with rotary cultivator (mounted on a tractor), hoe-weeding at 3 and 6 weeks after planting (WAP), pre-emergence herbicide application (Galex at 5litres/ha), post-emergence herbicide application of fusilade (2 litres/ha) followed by scepter (1 litre/ha) and a no-weeding check. All the treatments were laid out in a randomized complete block design with four replications. Cowpea yield was best under pre-emergence weed control at 490.0kg/ha and 605.5 kg/ha while no weeding control had the poorest yield between 313.8 and 338.9 kg/ha in both years (2014 and 2015). Also the highest profit (₦137,400:00 and ₦184,160:00) was obtained under the pre-emergence weed control while the lowest profit (₦94,140:00 and ₦108,448:00)was obtained in No-weeding control plot in both years. The highest cost benefit ratio (CBR) of 26.1 in 2014 and 30.5 in 2015 were recorded with rotary cultivator plot followed by pre-emergence with CBR of 15.3 and 20.1 while the lowest CBR of 3.9 and 4.3 respectively were recorded for hand weeding in both years.
Keywords: Cowpea, Cost-benefit analysis, Treatments, NCAM

INTRODUCTION

Recent statistics shows that about 7.56 million tons of cowpea were produced annually on about 12.76 million hectares of land (IITA, 2013). The need to provide food in the right quantity, quality and at affordable costs remains a priority in most of the developing countries, where the bulk of agricultural production is largely in the hands of peasant farmers. Constraints faced by this category of farmers include the use of poor plant genetic materials and inadequate protection practices (Williams, 2006).

Weeds are a permanent constraint to crop productivity in agriculture and they are plants which compete for nutrient, space and light and they exert lots of harmful effects by reducing the quality as well as quantity of crops if the weed population is left uncontrolled (KavalinusKaite and Bobinas, 2006). Because weeds interfere with mankind's efficient use of the natural environments that have been disturbed, weed control is basic to the use of those environments for food, fiber, shelter and recreation. Weed control reefers to those actions that seek to restrict the spread of weeds and destroy or reduce their population in a given location (Akobundu, 1987). Weed control is a required input in most crop production ventures.

Weed management is the ability to manipulate weeds so that they do not seriously interfere with mankind's efficient use of their environment. In relation to agricultural activities weed management refers to how weeds are manipulated so that they do not interfere with the growth, development and economic yield of crops and animals. The major components of weed management are preventive weed control, cultural control, biological control and chemical weed control.

Cowpea (Vigna unguiculata L.) sown in summer season is infested by a number of weed species that competes with the crop right from germination to harvest, affecting the crop yield adversely (Yadav *et al*, 1998). Therefore in order to enhance crop yield and its effects on soil fertility, control of weeds during peak periods is very important. Weed density, type of weeds, their persistence and crop management practices determine the magnitude of yield loss. Yield loss in cowpea due to weeds was 12.7-60.0 % (Li *et al*, 2004). There is no single method to controlling weeds of all forms; different kinds of social, economic and environmental factors influence the choice of control method to be used. Although conventional methods like hand weeding and herbicide application are effective in weed control but they are uneconomical due to higher cost of labour and hazardous effects to the environment (Cheema *et al*., 2003). Also in general, herbicides are effective only against some weed species, but results in serious infestation of other weeds. The suggestion that integrated weed management can be useful to provide better weed control measures should further be assessed. In view of these, a study was designed to evaluate different weed control methods under rain-fed cowpea production.

The objective of this study was therefore to analyze the cost-benefit of several weed control techniques on the performance of cowpea.

MATERIALS AND METHODS

Field experiment was carried out at the Research farm of the National Centre for Agricultural Mechanization, Ilorin, located on Longitude 4°30' East and latitude 8°26' North, in the 2014 and 2015 planting seasons. Land preparation was done using conventional tillage of ploughing followed by harrowing after about one week

interval. Field was thereafter demarcated into plots. Planting of cowpea seeds was done by hand with a spacing of 75cm x 15cm and 2 seeds per hole. The cowpea variety planted was Ife brown. Five treatments which included weeding with rotary cultivator (mounted on a tractor), hoe-weeding at 3 and 6 weeks after planting (WAP), pre-emergence herbicide application (Galex at 5litres/ha), post-emergence herbicide application of fusilade (2 litres/ha) followed by scepter (1 litre/ha) and a no-weeding check. The treatments were laid out in a randomized complete block design with four replications.
Weed cover scores of the plots were obtained after hoe weeding and when all the weed control methods have been applied to the treatments on the field. Crop vigour score was obtained 8WAP, when all weeding techniques on the treatments had been completed. At maturity 20 plants per plot were taken randomly to study the effects of the weed control methods on plant height, number of pods per plant, number of seeds per plant and weight of 1000 seeds. Grain yield in kg per hectare was also measured. The results were subjected to analysis of variance and means separated using the least significant difference method.

RESULTS AND DISCUSSION

The tables below showed the yield difference per hectare recorded by the different treatments account for the variation observed in value of output/ha (total revenue) in both years. The value of Total Revenue (TR) for different weed control methods varies from rotary cultivator to no weeding control with pre-emergence weed control having the highest revenue of ₦137,400 and ₦184,160 for year 2014 and 2015 respectively followed by post-emergence weed control, rotary cultivator, hand weeding and no-weeding (₦110,310 - ₦158,702, ₦108,830 - ₦148,250, ₦98,150 - ₦140,656 and ₦94,140 - ₦108,448). This conformed with that of Chikoye *et al.* 2005 and Omovbude and Udensi, 2013 who noted that chemical control is a better alternative to manual weeding because it is cheaper, faster and gives better weed control. The highest cost benefit ratio (CBR) of 26.1 in 2014 and 30.5 in 2015 were recorded with rotary cultivator plot followed by pre-emergence with CBR of 15.3 and 20.1 while the lowest CBR of 3.9 and 4.3 respectively were recorded for hand weeding in both years.

CONCLUSION

Cowpea productivity was enhanced through application of herbicides by reducing weed infestation. This interplay in the net revenue recorded in the seasons in the study area.

ABSTRACT

The study assessed the participation in rural development projects in Umuahia South Local Government Area of Abia State: the Fadama III project experience. Personal characteristics of the respondents were described, level of participation ascertained and factors influencing their participation in the project were determined. A multi-stage simple random sampling technique was adopted to select respondents for the study. Frequencies, percentages and regression analysis were used to analyze data collected. About 37.78 percent of the respondents were in the ages of 38 and 47 years, while majority of them were female. There were more married respondents with household size of 2 and 6 members representing 58.89 percent and 63.33 percent respectively. Secondary education was observed as their level of formal education with informal form of occupation representing 35.56 percent and 57.78 percent respectively. Respondents' level of participation was rated low. Personal characteristic like age, sex, martial status, household size were highly significant at 1 percent and level of formal education was also significant at 5 percent and positively related to their participation except occupation. The hypothesis of significant relationship was accepted. It was recommended, for proper education and awareness to be created on the benefits and sustainability of the project, before the beneficiaries are allowed to assess the grant and hence implement/execute the project.

Key words: Participation, Rural development project, Fadama III project.

INTRODUCTION

In Nigeria, implementation of rural development projects has been impeded as observed by the centre-down approach in which the rural people were not involved in project conception, planning and monitoring which often led to failure and abandonment of many valuable projects. Of recent, infrastructural approach to development remains a vital instrument to reach and assist poor communities in the developing countries (UN, 2005). Development interventions in the past have tended to focus on resource and knowledge transfer to beneficiary communities through the stale centre-down approach (Creighton, 2005). Having realized the weakness of this approach, it has paved way for the adoption of the 'bottom-up' approach to development. Since the 1970's, there have been deliberate government efforts towards mobilizing the people for rural development. The integrated rural development, river basin development authorities, community development and institutional strategies constitute integral parts of concerted efforts geared towards socioeconomic transformation at the grass-roots.

However, inspite of the clamour for 'bottom-up' approach to rural development, project beneficiaries are still being deprived of participating in the identification, planning, implementation, monitoring, and evaluation of projects that are meant to improve their welfare (Akpomunie, 2010). Even when an element of 'participation' is built into projects, it is often largely in terms of local investment of labour and not necessarily participating in decision-making. Beneficiary communities are only informed after plans have been made and this is done through formal meetings where the officers justify their plans but modification is not considered (Thwala, 2010).

The World Bank is one of the main institutional players of development projects in developing countries. Over the years, the World Bank has been involved in various identifiable key projects in Nigeria. Fadama development project is one of the those key projects of World Bank aimed at sustainably increasing the living standard of rural poor farmers, the vulnerable in the society and the physically challenged. It is an agricultural-based development project targeted at the rural communities to able them improve their living standard. Fadama project came into Nigeria in 1992, but Abia State keyed into this project in 2008.

Despite great expectations and hope that Fadama project will sustainably put food on the tables of benefiting communities and the Local Government Area, the impact of the project is not that visible and yet to be felt, hence the study. Specifically, personal characteristics of the beneficiaries were described, level of participation assessed and personal characteristics influencing participation in the project was determined. Hypothesis of significant relationship between personal characteristics and participation in the project was also tested.

METHODOLOGY

The study area was Umuahia South Local Government Area of Abia State. All the Fadama Community Associations (FCAs) in the area formed population for the study. A multi-stage simple random sampling technique was used to select respondents for the study. At first stage, three (3) FCAs were drawn from all the FCAs in the study area. At second stage, three (3) Fadama Users group (FUG) were drawn from the FCAs selected at the stage one. At third stage, ten (10) members were drawn each from the FUGs selected at stage two. Those selected formed respondents for the study. Data for the study was collected with the aid of questionnaire and interview of respondents. Percentages, frequencies and regression analysis were used to analyze data collected. The concept of participation was achieved through Chapin social participation scale of 1939. The participation components were weighted as follows:

Attendance to meeting -1, committee membership -2, financial contribution -3 and office holding -4. In this study, level of participation was measured based on the degree of involvement specified as follows: score 0 for non participation, score 1-5 for low level of participation and score 6-10 for high level of participation.

RESULTS AND DISCUSSION

Result from Table 1 showed that about 37.78 percent were in the ages of 38 and 47 years with majority (56.67%) been female. About 58.89 were married while household size ranged between 2 and 6 members representing 63.33%. Secondary education was observed to be their level of formal education while informal occupation was their means of livelihood representing 35.5% and 57.78% respectively.

From Table 2, it was observed that there was low level of participation from the respondents sampled. This was attributed to poor awareness and education of the beneficiaries by the facilitators of the project before they were allowed to access the grant. The low level of participation reflects the lack of total acceptance of the project, hence the non-sustainability of the project in the study area.

The coefficients of sex, age, household size and marital status were highly significant but at 1% and positively related to respondents participation in the project while level of formal education was significant at 5% and positively related to participation. This result is in agreement with earlier result of Udoka 2007 who found that coefficients of age, sex and household size were key factors in determining participation in development projects. Occupation was not significant and hence not discussed. The hypothesis of positive relationship between personal characteristics and participation was accepted.

CONCLUSION

It was concluded that majority of the respondents were adult with ages between 38 and 47years while more female participated in the project. There were more married respondents while their household size ranged between 2 and 6 members. Secondary education was their level of formal education while informal occupation was the means of livelihood of the respondents. It was also concluded that there was low level of participation in the project leading to non-sustainability of the project and its attendant effect. Personal characteristics play an important role in influencing respondents' participation excepting occupation. There was positive relationship between participation in the project and personal characteristics of the respondents. It was recommended to sufficiently educate the beneficiaries on the benefits and workings of the project before they are allowed access the grant, this will ensure sustainability and full participation in the project.

ABSTRACT
The study was carried out in Abia State, Nigeria to estimate the cost and returns to cassava based mix cropping system. The multi-stage stratified random sampling technique was used in selecting a sample of 100 respondents from the area. Data were collected using a well-structured questionnaire. The data collected was analyzed using descriptive statistics and farm budget technique. The result of the analysis show that the net returns to cassava/yam/maize/melon crop mixture was N142, 667.28, while the returns per naira invested by the farmer were ₦0.48k. The cassava varieties cultivated are TME 419, TMS 30572, TMS 30555, TMS 4(2) 1425, TMS 98/002, NR 8083, NR 8082, NR 84292, NR 8212, Nwaibibi, 98/0581 and yellow root cassava. The study recommended the practice of mixed cropping as a food security strategy and income generating venture.
Keywords: Net Returns, Cassava-based, mix cropping

INTRODUCTION

Cassava is one of the world's most important food crops, with annual global production at approximately 276 million metric tons (MT) in 2013. According to Nteranya and Adiel (2015), supported by Obasi *et al*, (2015), The top producing countries globally in 2013 were: Nigeria (accounting for 19% of the total), Thailand (11%), Indonesia (9%), Brazil (8%) and Democratic Republic of Congo (6%). It is a major source of dietary food energy for the entire populace living in the lowland tropics and much of the sub-humid tropics of West and Central Africa (Echebiri and Edaba, 2008).

Nigeria is currently the largest cassava producer in the world with estimated annual production of about 40 million metric tonnes. About 90% of this is however, consumed as food. Presently, cassava is primarily produced for food especially in the form of *gari*, *lafun* and *fufu* with little or no use in the agribusiness sector as an industrial raw material. But the crop can be processed into several secondary products of industrial market value. These products include chips, pellets, flour, adhesives, alcohol, and starch, which are vital raw materials in the livestock, feed, alcohol/ethanol, textile, confectionery, food and soft drinks industries. They are also tradable in the international market. Cassava (*Manihot esculentum*) is a very important staple root crop in Nigeria.

Although Nigeria is the world's largest producer of cassava, production is largely by small scale illiterate and conservative farmers who cultivate the soil with rudimentary implements. The demand for cassava in developing countries is estimated to grow at 2% annually for food and 1.6% per year for feed, while total production is projected to reach 16.8million tons by 2020 based on current production rate (Mailumo *et al*., 2012). In addition, improvements in the cropping system will also boost productivity as well as enhance the net returns from the enterprise. Fakoyode *et al*., (2008), observed that though cassava when cultivated as the sole crop result in high output, the greatest disadvantage of sole cropping is that in instances of pest and disease outbreaks, the farmer usually loses a significant part of his crop and sometimes loses all.

In South East of Nigeria, there are essentially two types of cropping patterns involving cassava-based (cassava, maize, melon) and yam-based (yam, cassava, maize and melon). Other crops that may be found in this crop association are Okra, groundnut, cocoyam, pepper, cucumba, and garden egg. The main reason for these crop combinations in the farmer's field is that it is used as a food security initiative in most communities. The key to increasing agricultural output in most developing countries is improving the productivity of farmers, which cannot be achieved without markets that would effectively bind the increasingly specialized activities of thousands of widely dispersed producers into an integrated national economy. Thus, an efficient and responsive cropping system is an indispensable component of the development process (Egbetokun and Omonona, 2012). This study therefore estimated the cost and returns of cropping systems involving cassava in the study area.

METHODOLOGY

The study was conducted in Abia State of Nigeria. The state lies within approximately latitude $4^0 40`$ and $6^0 14`$ North and longitude $7^0 10`$ and 8^0 east and covers a land areas of about 5,243.7sq km which is approximately 5.8% of the total land area of Nigeria. Abia state is characterized by three agricultural zones; name Aba south, Umuahia and Ohafia areas. The main crops grown in the area include cassava, cocoyam, yam, maize, melon, okra and vegetables. A multi – stage random sampling technique was employed in the selection of the respondents for the study. The existing three agricultural zones in the state namely Abia south, Umuahia and Ohafia were used. Also, a random selection of two local government areas from each agricultural zone was done. In the third stage, ten communities were randomly selected from each of the local government areas earlier selected; then a village was randomly selected from each of the communities. Lastly, four farmers were randomly selected from each of the four selected villages. This gave a sample size of 100 respondents.

Data were collected using structured questionnaire. The variables on which data were collected include the production practices of farmers, cultivars of cassava planted in the area, size of farm land cultivated, quantity of inputs used, labour availability, revenue derived from non-farm sources, prices of inputs used and outputs produced, quantity of output produced, and expenditure on farm inputs used. The prices of inputs used and outputs produced were based on the prevailing market prices in the study area during the 2015 cropping season. The prices are as specified: land rent at N1,196.72 per plot; labour wage rate at N1,500 per man-day; cassava cuttings at N500 per bundle; fertilizer at N96 per kilogram (or N4,800 per 50 kg bag); capital at N1.00 ; output price at N12.50 per kilogram (Obasi *et al*, 2015). The period of the research covered the 2015 cropping season. Data were analyzed using descriptive statistical tools, gross margin analysis and net returns model. The estimates are stated below:

$GM = TR - TVC$

$\pi = GM - TFC$

Where,

GM = Gross margin

Π = Profit

TVC = Total variable cost

TFC = Total fixed cost

TR = Total revenue

The net return model is specified as:

$NR = TR\text{-}TC$

$NR = \sum_{j}^{n} = 1\ TVP_i - \{TVC_j + TFC_i\}$

$\sum_{j}^{n} = 1\ P_jQ_j - \sum_{j}^{m} = 1\ \{\sum_{k=1}^{z} P_kX_k + \sum_{l=1}^{z} P_lF_l\}$

Where:

TVP = Total Value of Production

FC = Fixed Cost

j = jth respondent

n = number of respondents

Pj = Price of jth respondent's output

Qj = Output of jth respondent

Pk = Price of the Kth variable input

Xk = Variable inputs

m = number of variable inputs

PL = Price of the Lth fixed input

FL = Fixed input

z = number of fixed inputs

Straight line method was used to depreciate the capital input. The model is specified as follows:

D = (P – S) N...

Where

D = Annual depreciation

P = Purchase Price

S = Salvage or scrap value

N = Economic life span of asset

The revenue generated through the sale of cassava stems, roots and other crop mixtures was estimated, and the difference between the revenue generated and the cost incurred was also calculated.

RESULTS AND DISCUSSION

Net Returns to Cassava Cropping Systems (Cassava/Yam/Maize/Melon Cropping Systms)

The income and expenditure analysis for cassava/yam/maize/melon; cassava/yam/maize/okra and cassava/yam/maize/vegetables mix cropping. The net farm income was N144, 876.58. The return per naira invested was N0.48k. This result indicates that cassava/yam/maize/melon mix cropping has both the highest net return per naira invested. The cropping system is therefore ranked first among all the cropping systems practiced by farmers.

The income and expenditure analysis for cassava/yam/maize/melon shows total revenue of N480, 000 and a total cost of production of N357, 912.16. The total variable cost and total fixed cost were N111, 844. 73 and N35, 939.69 respectively. The total variable cost on farm inputs are; planting materials (N52,744.73 or 21%) and fertilizer (N43,200 or 16%), land preparation (N36,000 or 17%) and weeding (N12,000 or 10%) respectively. The return per naira invested was N1.48 The result suggests that the mix cropping is profitable.

CONCLUSION

The result of this study suggests policies aimed at promoting cassava based cropping systems by providing cassava farmers with necessary inputs especially fertilizers, good road transportation network. However, farmers should be encouraged by extension workers to form associations that would enable them pull their resources together, raise loans and purchase the needed facilities so as to tap the potentials inherent in cassava enterprise. Conclusion is that the mixtures are profitable and farmers are encouraged to practice it for food security and income.

Table 1: Income and expenditure analysis for Cassava/Yam/Maize/Melon crop mixture

Item	Quantity	Unit Price (N)	Value (N)/ha
Cassava tubers	15 tonnes	12,500	187,500

ABSTRACT
The study assessed the impact of menace of Fulani herdsmen on cassava production in Abia State, Nigeria. Multi-stage purposive sampling technique was used to select five Local Government Areas (Ohafia, Umuahia North, Umunneochi, Ikwuano and Bende L.G.As) and one community from each of the selected LGAs with twenty respondents drawn. This gave a sample of one hundred respondents. Data and information were elicited from the respondents using structured questionnaire sets. Descriptive statistics were employed in the analysis of data and the results show the activities of Fulani herdsmen had moderate impact on their economy (3.13) through the destruction of crops and reduction in crop yield as well as their environment (3.36) through environmental pollution, fertilization of the farm, land degradation and erosion. The study concluded by recommending that federal and state governments should discreetly implement the grazing reserve policy and also takes necessary actions to curb the menace of the Fulani-herdsmen in the area.
Keywords: Herdmen, Fulani, menace, cassava production

INTRODUCTION

Cattle rearing by Fulani-herdsmen have contributed to the economy of the South-East and the country at large. The place of Fulani herdsmen is inevitably important as they have sustained the production and sales of meat in markets across the country. Despite their undisputable importance to the country's economy, recently their activities in the South-East and the country as a whole threaten the life and existence of those living within their areas of grazing, especially in the rural areas. There is virtually no community in the South-East where you will not find the Fulani herdsmen but the most disturbing to people especially farmers is the way they kill, maim and allow their cattle to destroy farm crops wherever they set their feet. According to Nkwopara et al., (2015), the activities of these herdsmen in some communities in Abia State have become a source of major concern to the people. This is as a result of the repeated destruction of crops and farmlands in rural communities in the state. The most annoying aspect is that the herdsmen challenge them when they are confronted.

Haro and Dayo (2005) opined that one of the major causes of the conflict is that most times the Fulani herdsmen lead their herds into the farms during growing season while these cattle eat or trample on the crops thereby destroying the farm. Tonah (2006) asserted that the reasons for the increasing farmer-herder conflicts include the southward movement of pastoral herds into the humid and sub-humid zones, coupled with the successful control of the menace posed by disease, the extensive availability of veterinary medicine and expansion of farming activities into areas that served as pasture land before now. Other sources of conflict according to Gbehe (2009) are the pursuit of access to a variety of limited resources which includes grasslands, water for animals, rival claims to land, and so on.

METHODOLOGY

The study area was carried out in Abia state, Nigeria. Multi-stage purposive sampling technique was used to select five L.G.As (Ohafia, Umuahia North, Umunneochi, Ikwuano and Bende L.G.As) and one community from each of the selected LGAs. The LGAs selected were the ones that have experienced destruction by Fulani herdsmen. Twenty respondents were randomly selected from each of the selected communities giving a total of 100 respondents.

A well structured questionnaire was used to elicit information from the respondents. Data collected were analyzed using descriptive statistic like percentages, means and a 5-point Likert scale rating.

RESULTS AND DISCUSSION

Table 1 revealed that the respondents perceived that the activities of Fulani herdsmen had moderate impact on their economy (3.13) through the destruction of crops and reduction in crop yield as well as their environment (3.36) through environmental pollution, fertilization of the farm, land degradation and erosion. Furthermore, it had high impact on their social lives (4.21) through conflict, obstruction of traffic, loss of lives and destruction of property.

Results in Table 2 showed that respondents' perceived that the menace of Fulani herdsmen in the study area has reduced the amount invested into cassava production (3.35) for fear of losing their investments as well discouraged farmers from going to the farm for cassava cultivation (3.20).

Table 3 indicated that the major problems associated with tackling the conflict between Fulani herdsmen and farmers in the study area are governments' inability to implement the grazing reserve policy (3.27), inability of security personnel to take adequate actions (4.42), increased rate of unemployment (3.25), high rate of poverty (3.50) and illiteracy (3.01).

CONCLUSION

The activities of Fulani-herdsmen in the Abia state and South-east in general is a major obstruction to the development of agriculture and the nation's economy. Therefore the study recommends federal and state governments should discreetly implement the grazing reserve policy and also take necessary actions to curb the menace of the Fulani-herdsmen in the area.

ABSTRACT

This study assessed the effect of microcredit on poverty reduction among rural non-farm households in North-East, Nigeria. Multi-stage random and purposive sampling techniques were employed to select 200 non-farm households who constituted the sample size. Primary data used for the study were sourced with the aid of structured questionnaire which was administered to the respondents. Data collected were analysed using both descriptive and inferential statistics. The result showed that non-farm households accessed credit from both formal and informal credit sources, however, bulk of micro-credit was obtained from informal/unorganized sector. The study observed that out of the mean of ₦366,180 applied for by nonfarm households, ₦265,815 representing 72.6% was disbursed to them. Prior to acquisition of microcredit, the rural households earned a mean annual income of ₦254,580, however, a year after microcredit acquisition, it rose by 29.4% (₦106,025.04) to ₦360,605.04. Moreso, the findings indicated 38.0% of nonfarm households were poor. The poverty depth of 0.30 and poverty severity of 0.26 was obtained for the households. The regression analysis on the effect of microcredit on the income of the non-farm households revealed that the coefficient of income was positive and statistically significant at 1% probability. The effect of microcredit on the poverty profile of non-farm households revealed that microcredit exerts negative influence on poverty status of non-farm households in the study area. The study recommends: the establishment of robust rural credit scheme in rural areas; and institution of policy framework that will enable poor rural households without appropriate collateral to access funds for farm and non-farm activities.

Keywords: Microcredit, Poverty Reduction, Rural Nonfarm Households, Northeast Nigeria.

INTRODUCTION

Nigeria occupies a total land mass of 923,766 square kilometers and has over 74 million hectares of arable land. She has a projected population of 162.47 million in 2011 and active workforce of 56.6% (15 – 64 years of age) (Mimiko, 2011); yet Nigeria is among the 25 poorest countries in the world with up to 70% of her population being poor (UNDP, 2000). This level of poverty in the country is attributed to inadequate economic productivity and growth. In the quest to overcome poverty rural households engage in economic diversification activities such as nonfarm activities. Diversification is a sure way of reducing the risk of income variances while improving household income (Fuller, 1990).

Capital resource such as finance is one of the principal factors of production. In support of this, Ezike (1999) contended that finance is the sixth sense that makes other senses to function effectively. Access to finance is a crucial motivation for agricultural and non-agricultural productivity. Non-farm enterprises in rural areas require unhindered access to credit to boost their economic activities. This is predicated on the fact that credit serves as the engine that drives other factors of production to attain higher level of growth. The birth of microfinance of which micro-credit is a subset component represents a flexible structures and systems by which a wide range of financial and enterprise development services are offered to micro-entrepreneurs in an affordable and convenient manner. Thus, microcredit is one of the mantras of contemporary development initiatives all over the world.

The introduction of microcredit in Nigeria was based on the failure of the top-bottom formal financial institutions to address the credit needs of the rural poor households, thereby constraining the processes of investing for livelihood enhancement among the rural entrepreneurs. This credit gap created by formal financial institutions to give credit to rural entrepreneurs is filled by the micro-finance institutions. Despite the existence of several microcredit institutions such as microfinance, cooperative societies, Bank of Agriculture, money lenders etc, Northeast, Nigeria is still regarded as the zone with the highest rate of poverty in Nigeria (NBS, 2012). It is against this backdrop that this study assessed the effect of microcredit on poverty reduction among rural nonfarm households in Northeast, Nigeria. To achieve this, the following specific objectives were set out: analyse the sources and utilization of micro-credit by the rural non-farm households; determine the effect of micro-credit on the income of non-farm households in the area; and determine the effect of micro-credit on the poverty profile of rural non-farm households in the study area. The study also tested the hypothesis that microcredit has no significant effect on poverty profile of the rural nonfarm households.

METHODOLOGY

This study was carried out in Northeast, Nigeria. North East Geo-political zone is made up of six (6) states, namely: Adamawa, Taraba, Bauchi, Gombe, Borno and Yobe. It has a population of 18,984,299 million people and a land mass of 274,548.1 km^3. The study employed multistage random and purposive sampling techniques in the selection of 200 rural nonfarm households. The first stage involved the purposive selection of four (4) States out of the six States in the North East zones. This was informed by the need to select only those states with relative peace because of activities of Boko Haram in this zone. In the second stage, five local government areas were randomly selected from each of the four states, to give a total of twenty (20) LGAs. In the third stage, two wards from each local government area were randomly selected to give a total of forty (40) wards. In each of the wards, five (5) were selected purposively, thus, a total of two hundred (200) rural non-farm households were sampled for the study. Data for the study were collected using interviewers schedule based on structured questionnaire. Descriptive statistics was used to analyze objectives (i) and (ii) while objective (ii) was further subjected to FGT index analysis, and objective (iii) was achieved using simple regression. Finally, objective (iv) was achieved with the aid of logit regression. F-test, Z-test was used to test the hypotheses.

Model Specification

The Foster, Greer and Thorbecke (FGT) Index

The Foster, Greer and Thorbecke (FGT) index was used to determine the threshold which was used to categorize the level of poverty among non-farm households in the study area. The FGT index was computed with the aid of this formula stated below:

$$P\alpha = \frac{1}{n}\sum_{i=1}^{H}\left(\frac{Z-Y}{Z}\right)^{\alpha} \text{ .... (i)}$$

Where: Z = poverty line
N = total Sample
H = the number of poor (below poverty line).
Y = average household monthly *per capita* expenditure
α = poverty index which takes value of 0, 1 and 2

Simple Regression Model

The simple regression model used to determine the effect of micro-credit on the income of non-farm households in the study area is explicitly stated as:

i. Model for nonfarm households:

$Y = \alpha + \beta X + et$ ………………………………. (ii)

Where:
Y = Amount of microcredit acquired by the nonfarm households (naira)
X = Income of nonfarm households (naira)
α = Constant/ intercept
β = Coefficient
et = Stochastic error term

RESULTS AND DISCUSSION

Sources and Utilization of Micro-Credit by Rural Non-farm Households

Basically, credit can be secured either from formal or informal sources. The result of the analysis is presented in Table 1. The result in Table 1 shows that rural non-farm households accessed micro-credit in the study area from both formal and informal credit sources. However, the bulk of micro-credit obtained by the respondents was higher from informal/unorganized sector. The inform sources of microcredit accessed by the non-farm were money lender (63.0%), rotatory club (isusu/adasu) (62.5%) and friends and relatives (44.0%). On the formal credit source, the most available sources for nonfarm households include: cooperative society (38.5%) and commercial bank (23.0%). This is an indication that the rural non-farm households depend more on informal credit sector for microcredit procurement and this have serious implication for their investment level, considering the exorbitant interest rate inherent in the informal credit institution. However, the high access to informal credit may be attributed to the ease with which clients approach the credit principals. This is in consonant with the findings of Mohieldin and Write (2000), who identified the major sources of informal credit for rural households to into family, friends, money lenders and savings from and off-farm income. Similar report has been credited to Akinbode, Salami and Ojo (2014).

From the result in Table 2, it was observed that although 37.5% of the non-farm household applied for above N300,000, most (45.0%) of them obtained between ₦150,001 – ₦300,000. More so, the mean amount applied was ₦366,100 out of which about 72.6% representing N265,815 was disbursed to them. Overall, the level of access to micro-credit in terms of amount disbursed to the rural non-farm households in the study area is general low, considering the current economic reality in the country. This finding is in line with that of Okonkwo (2010), who argued that demand for microcredit by rural households is hardly met. This is mostly due to their poor state and the fear of high loan default.

The result in Table 3 shows that nonfarm households utilized the acquired credit for investment in various economic non-farm activities. It was observed that the rural households utilized the acquired microcredit to start-up and expand their petty trade (69.0%), procurement of mini equipment and tools for artisanal works (mason, carpentry, mechanics, black smith) (54.5%), procurement of raw materials for manufacturing firms (46.0%) and non-farm labour (43.5%). This suggests that rural households used acquired credit to invest in economic ventures as against the popular opinion that such credit is diverted for family and personal purposes.

Determination of Household's Poverty Status

The relative poverty index (RPI) approach was used for determination of poverty status of non-farm households in the study area. The RPI was computed as 2/3 of the monthly mean *per capita* expenditure. Based on the mean *per capita* expenditures of ₦18,375.4 for non-farm households, the RPI was determined to be ₦12,250.3. Consequently, any household with monthly expenditure below the poverty line (i.e. ₦12,250.3) were classified as poor while those with expenditures of (₦12,250.3 and above) were classified as non-poor. Expenditure is known to play a very important role in the poverty level of household because it reflects the true level of actual income. Hence, expenditure is more preferable to income since incidental inflows like remittances and gifts, which do not occur regularly, are part of household income. The result of the analysis is presented in Table 4.

The result in Table 4 shows the FGT poverty indices among the surveyed rural nonfarm households. The poverty indicators were consistently high among the rural households. For example, the head count ratio value of 0.38 was recorded among the nonfarm households in the study area. This implies that about 40% of rural nonfarm households were poor (i.e living below the World Bank minimum per capita daily expenditure of $1.25 (₦400.00)). On the poverty depth, 0.30 was recorded among the rural nonfarm households, suggesting that an average household requires to mobilize up to 30% of $1.25 (₦400.00) per day for each household member to be able to escape poverty. The poverty severity shows 0.26, indicating the seriousness of poverty in the study area; because the closer this value is to one (1), the more serious the poverty in the area. The high proportion of poor households in the study area calls for urgent poverty policy intervention programmes for poverty alleviation in the area. This may not be unconnected with fact that poverty is largely a rural phenomenon (Pinstrup-Anderson, Lorch, and Rose, 2001).

Effect of Microcredit on the Income of Rural Non-Farm Households

Simple regression analysis was also used to determine the effect of microcredit obtained by the non-farm households on their income in the study area. The summary of the findings is presented in Table 6.

The regression result in Table 5 shows that the coefficient of determination (R^2) was 0.954 or 95.4%, indicating that 95.4% of total change observed in the income of non-farm households was attributable to variation on the amount of microcredit obtained by the non-farm household. The very high value of F-ratio (4122.951) and the low value of standard error of the estimate (22.823636) signify the goodness of fit of the model. The Durbin-Watson value was 2.010 indicates absence of autocorrelation in the model. The overall model was statistically significant ($P < 0.05$), implying that microcredit exerts significant influence on the income of non-farm households in the study area. The coefficient of income of the non-farm households was positively signed and statistically significant at 1%. This implies that procurement of microcredit will enhance income generation of the non-farm households. Additionally, acquisition of micro-credit caused 41.3% effects on income of the non-farm households in the study area. The very high level of significance at 1% level, suggests that microcredit is an important predictor of income generation among non-farm households in the study area.

Effect of Microcredit on Poverty Profile of Non-Farm Households in the Study Area

The result of the logit regression analysis is presented in Table 6. From the result in Table 7, it was observed that the coefficient of microcredit obtained was negatively signed as well as statistically insignificant. This means that increase in supply of microcredit can lead to decrease in poverty profile among non-farm households by 0.004 and vice versa. The overall logit model was moderately adequate as indicated by the values of Pearson Goodness-of-Fit (34.295) and the 2 Log likelihood (251.813). However, the overall model was statistically insignificant ($P > 1.000$); implying that microcredit does not exerts positive influence on poverty profile of the non-farm households in the study area. This may be explained by the small size of credit available to the non-farm households in the area.

Test of Hypothesis

The null hypothesis which stated that the microcredit has no significant effect on poverty profile of the rural nonfarm households was tested using the values of Cox & Snell R^2 (0.019) and Nagelkerke (0.026) as presented in Table 6 above. These values indicated that microcredit has poor effect on poverty profile of the nonfarm households in the study area. Consequently, the null hypothesis was accepted that the microcredit has no significant effect on poverty profile of the nonfarm households in the study area.

CONCLUSION

The study concludes that microcredit acquisition significantly contributed to the income generation of rural nonfarm households. This implies that microcredit is a veritable tool for enhancing income generation among nonfarm households in rural communities of Nigeria. However, the study found that microcredit exerts negative influence on poverty status of rural non-farm households in the study area. This apparently was due to the meagre size and volume of credit supplied to the households, which was majorly between ₦50,001 – ₦150,000. This range of credit is grossly inadequate to impact meaningfully on the poverty profile of rural households in the study area. Based on this the study recommends the establishment of robust rural credit scheme in rural areas; and institution of policy framework that will enable poor rural households without appropriate collateral to access funds for farm and non-farm activities.

SOCIO-ECONOMIC FACTORS AFFECTING AGRICULTURAL TECHNOLOGIES ADOPTION AMONG FARMERS IN ABAKALIKI LOCAL GOVERNMENT AREA OF EBONYI STATE, NIGERIA

B.N. Mbam & A.N. Ezeh

Department of Agricultural Economics, Management and Extension, Ebonyi State University, Abakaliki, Ebonyi State, Nigeria
Email of corresponding author: ***bonnymbam@yahoo.com***

ABSTRACT
The study analyzed the socio-economic factors affecting agricultural technology adoption among farmers in Abakaliki Local Government Area of Ebonyi state. Multistage random sampling technique was used to select a total of 120 respondents and primary data which was used for the study were collected through the use of structured questionnaire. Objective I was realized using descriptive statistics while objective ii was actualized with the aid of multiple regression analysis. The result of the analysis showed that majority (65%) of farmers were male, 65% of the respondents were married with an average household size of 9 persons and a mean age of 46 years. Most of the respondents (84.2%) had a formal education with a mean farming experience of 17 years and also with a mean annual farm income of ₦185, 000.00. Also, the study showed that the socio-economic characteristics of the farmers have significant influence on technologies adoption as was shown by the coefficients of multiple determinations (R^2) of the socio-economic variables which was 0.748. Based on the findings, the study recommended that farmers should be encouraged to engage into full time farming and improvement in their productive base in order enhance the adoption of agricultural technologies in the area.
Keywords: Socio-economic, Agricultural Technologies, Adoption, Farmers

INTRODUCTION
The importance of technology to agricultural development especially in less developed countries is widely recognized. This is predicated on the observed impact of technology and its potential and actual contributions to development of agriculture. In developing countries like Nigeria where the greater proportion of its population lives in the rural areas, agricultural technologies can provide a potential means of increasing production, rise in income as well as the standard of living of farmers (Ani, 2002). Kassapu (1999) defined agricultural technology as the application of knowledge to the solution of practical problems to meet the basic needs of mankind in their daily life in terms of energy, food, housing, health, clothing, transportation.
According to Agwu (2004), there are number of factors that influence the extent of adoption of agricultural technologies such as characteristics or attributes of technology, the adopters or clientele, which is the object of change agent and the socio- economic, biological and physical environment in which the technology take place. Among these factors the socio-economic attributes of farmers have great influence on adoption of appropriate technologies needed for optimum farm outputs and productivities. For instance, socio-economic factors determine the number of technological package to be adopted at a particular time irrespective of other influencing factors. Thus, annual farm income, total annual income, farm size and educational status were positively related to adoption while age and household size had inverse relationship with technologies adoption (Mbam, 2016). Also, the personal characteristics of the farmers such as age, sex, experience and educational status have strong influence on the level of technologies adopted by farmers in order to enhance farm outputs and productivities. For example, the willingness to adopt a technology may change with age and experience (CIMMYT 1993). Thus, as older farmers may be less willing to invest in technologies that only pay off in the longer term (Feder and Umali 1993), younger farmers who may be more educated or be more open to trying out new technologies often modify their perceptions of the riskiness of new technologies over time as they acquire more information on new improved technologies (Marra et al 2003).
Although a number of studies have been conducted across the globe on agricultural technology adoption, there seems to be dearth of knowledge on the socio-economic factors that affect agricultural technologies adoption, especially among farmers in the study area. In a bid to proffer solution to the above problem, the study described the socio-economic characteristics of the farmers and as well as analyzed the effects of the socio-economic characteristics of the farmers on the levels of adoption of agricultural technologies in the area.

METHODOLOGY
The study area was Abakaliki, Local Government Area (L.G.A) which has seven (8) autonomous communities with its headquarters at Nkaliki. The L.G.A. covers a mass area of 106km^2 and total population of 285,758 people (NPC, 2006). Geographically, the area lies within longitude 80^{0}E and latitude 40^0 N and South west and north east trade wind that prevail in the area. The annual rainfall of the area ranged between 1500-2000 mm and the temperature ranged between 23.9ºc to 25.7ºc per annum. The area is bounded in the north, west and south by

Ebonyi, Ezza south and Ezza north L.G.As respectively and in the east by Obubra L.G.A of Cross River state. The inhabitants of the area are predominantly farmers and as such engaged in crop, livestock and fish production. Multistage random sampling technique was used in selecting the respondents for the study and primary data collected through the use of well structured questionnaires were analyzed using descriptive and inferential statistics. Objective i was realized using descriptive statistics while objective ii was actualized using multiple regression analysis.

RESULTS AND DISCUSSION

Socio-Economic Characteristics of the Respondents

The result of the analysis (Table 1) showed that majority (87.2%) of the respondents was between 31-60 years of age with a mean age of 46 years. This implied that the majority of the farmers were within their productive and active age of farming and this is within the age defined as economic active age (30-60) (FAO, 2000). Also, the result showed that most (65%) of the respondents were male indicating that more males were into farming in the area. This finding is in line with Madugu and Bzugu (2012) who opined that for agricultural sector of the economy to be in its optimum level, there must be preponderate of male in farming. Equally, the result showed there was active participation of married people in agricultural activities as was indicated by the majority (65%) of the respondents that were married. This is justified as Agbom (2012) reported that more married farmers were involved in adoption of agricultural technology in Oyi Local Government Area of Anambra state. The household size of the respondents with mean household size of 9 persons implied that the farmers had chances of getting family labor for use in their farm and this would have increased the size of land cultivated. The study showed that majority (84.2%) of the farmers had acquired various levels of education. This justified the importance education in the adoption of agricultural technologies and this in consonance with the findings of Feder and Umali (1993) that adoption of new technologies was positively correlated with the farmer's level of education. Again, it was found that the average farming experience of the farmers was 17 years implying that the farmers have acquired reasonable years of experience as a result of farming activities in the area and this favored adoption of innovations. This is in consonance with the findings of Marra *et al*. (2003) that in addition to schooling, farmers will also benefit from the skills to use the technologies that may be acquired through long time experiences.

Furthermore, the result showed that majority (51.7%) of the respondents had a mean annual farm income of N185, 000.00 which is an indication that the farmers earned little or low income from farming activities. This corroborated Mbam (2016) who found that income level is an important factor in determining farmers' decision to adopt agricultural technologies. The study also showed that majority (72.5%) of the respondents was into full-time farming and with a mean farm size of 5 hectares. This implied that the respondents were small to medium holder farmers and this may have affected the adoption of agricultural technologies in the area thus, justifying the report by Gabre-Madhin *et al.*, (2001) that large commercial farmers adopted new high-yielding maize varieties more rapidly than small-holder farmers.

Effects of the Socio-economic Characteristics of the Farmers on the Level of Adoption of Agricultural Technologies

A multiple regression analysis was used to determine the effect of the socio-economic characteristics of the farmers on the level of adoption of agricultural technologies (Table 3). The result showed that the coefficient of multiple determinations (R^2) was 0.748 or 74.8%, signifying that 74.8% of total variation observed was explained by the explanatory variables i.e. socio economic characteristics (x_1-x_9) included in the model. Specifically, the coefficient of age (x_1) was statistically significant and positively related to the adoption level of agricultural technologies. This implies that the older a farmer is, the more receptive he will be to adoption of agricultural technologies. This conformed to findings of Onumadu and Osahon (2014) that the age was one of the socio-economic determinants of adoption of improved rice technology. The coefficient of marital status (x_3) was positive and statistically significant indicating that marital status will bring about increase in adoption level of agricultural technologies. This conforms to the *a priori* expectation as married couples are constantly engaged in economic activities such as farming in order to meet-up with their family needs (Baumüller, 2012).

The coefficient of household size (x_4) was statistically significant but negatively related to the adoption level of agricultural technologies implying that a decrease in household size will lead to increase in the adoption of agricultural technologies thus conforming to the a priori expectation. The coefficient of educational level (x_5) was statistically significant and positively related to the adoption levels, implying that the more educated a farmer is, the higher his level of technologies adoption. Farming experience (x_7) was positive and statistically significant, implying that years of experience influence positively the adoption of technologies. This corroborated Alarima, Adamu , Masunaga and Wakatsuki (2012) who found that years of experience influenced the adoption of new rice technologies. The coefficient of the farm size (x_9) was statistically significant and positively related to technologies adoption level. This implies that the higher the farm size, the higher the number of technological package a farmer will adopt and this was justifiable as (Mbam, 2015) found that farmers with large farm size have comparative advantage than those with smaller farm size as it concerns the adoption of technologies.

CONCLUSION AND RECOMMENDATIONS

The study found that socio-economic characteristics of the farmers such as age, marital status, household size, educational status, farming experience and farm size affect significantly the adoption of technologies needed for enhanced farms' outputs and productivities. Based on the findings, the study recommended that farmers should encouraged to engage into full time farming in order enhance the adoption of agricultural technologies. Also, farmers' productive base should be improved in order to increase the adoption of more agricultural technologies in the area.

ABSTRACT

Household food consumption pattern in Nigeria is a growing challenge as reflected in the rise in the general price level. The impact of this hardship in the current dispensation in the country may not be equally felt by all socio-economic groups. This is because the wherewithal for meeting essential food requirements may vary from one income group to the other. This, therefore, calls for the need to examine the extent of the variation in consumption expenditure among income groups. This study examined food consumption expenditure in Uyo Metropolis, Akwa Ibom State, Nigeria using data collected from 179 households through stratified sampling. Findings revealed that majority of the respondents were wage earners. Food expenditure was found to be highest in self employed/wage earners households while per caput food expenditure was highest in the self employed households. The self employed households were found to earn the highest monthly income. Educationally, household heads who have attended university or its equivalent spent the highest amount (N41,075.71) on food. About 68% of the households in the study were found to be low income households. Income, household size and households' level of education were found to have great influence on household food consumption expenditure.

INTRODUCTION

Food consumption is a topical issue in Nigeria, not only because it is related to poverty and food security, but because it is highly correlated with living standards and household resources. Essentially, the demand for food depends on population and the dietary habit per capita and daily calorie intake of the people. If this is particularly biting in a developing country where food expenditures account for a relatively large share of household income, it is more excruciating in Nigeria as a mono-culture economy where massive oil wealth of the 1970s led to the neglect of the entire agricultural sector. This worsened the problem of food shortages and Government's responded with massive importation of food products to meet domestic demand. Imports increased from ₦756.5 million in 1970 to ₦12, 839.6 million in 1981. This high import bills, not only aggravated the food crises, it exacted on the foreign reserves of the country (Ayantoye, 2009).

To solve the fundamental problems of food shortages and consumption, government embarked on multi-dimensional policies, programmes and projects spurred-on by large incomes from oil exports.

In spite of all these efforts, statistics and reports point to insufficient food supply for the teeming Nigerian population. According to Kormawa (1999), per capita growth of production of major foods in Nigeria has not been sufficient to satisfy the demands of an increasing population. This has created a gulf between national food supply and demand. The wide food supply–demand gap is compounded by high inflation rate. This, according to CBN, (2012) has manifested as increases in prices of food, beverages, housing, water, electricity, and transport among others. Though, it is said that the rural Nigerian communities still adhered to traditional food habits that are related to socio-economic status, production, distribution, utilization and household size (Okeke, 1996), the high inflation rate has direct negative consequence on the food purchase ability of the populace (Mohammad and Omotosho, 2010).

Empirical studies on food consumption expenditure and pattern abound (Cunningham, Cuningham and Saigo, 2005; and Obayelu, Okoruwa and Oni, 2009). However, it is the work by Olarinde and Kuponinyi (2005) that reported on the dynamic (ever changing) household food consumption patterns in Nigeria with its attendance effect on expenditure. Uyo as the state capital and a commercial nerve city in Akwa Ibom State could not be an exception. However, in spite of these changes, and the growth of Uyo as a State Capital, there has not been any recent empirical study to assess what factors influence food consumption expenditure in the area. The present study is intended to bridge this information and knowledge gap. Specifically, it intends to examine the influence of socio-economic characteristics on household food consumption expenditure in Uyo metropolis

METHODOLOGY

The Study Area: The study was conducted in Uyo Metropolis, Akwa Ibom State. Uyo is the capital of Akwa Ibom State. It is located on latitude 05º3ʺN and longitude 07º57ʺE. It is bordered on the south by Ekpe Atai and Nsit Ibom Local Government Areas, on the West by Abak Local Government, on the North by Ikono and Itu Local Government Areas and on the East by Uruan Local Government Area respectively. It has an estimated population of 309,573 (National Population Commission, NPC, 2006). It is a commercial nerve centre of the entire

Akwa Ibom State. Inhabitants of Uyo Metropolis are workers in public and private institutions and firms. Others are engaged in trading, craft making and transportation business.
Stratified sampling method was employed in the study. The study area was stratified into cells based on features/characteristics usually associated with low, medium and high density settlements. Due to non-availability of sampling frame, selection of compounds from which households were chosen was done through "random-walk" method. One household was selected in each compound for detailed study. A total of 60 respondents were selected from high, medium and low income earners areas of Uyo metropolis respectively. This gave a total sample size of one hundred and eighty (180). Out of 180 households, 179 supplied complete data that were used in the analysis while the remaining one (1) was discarded because of incomplete information.

Methods of Data Analysis: To analyze the socio-economic characteristics of the households and how they affect consumption expenditure in Uyo metropolis, descriptive statistics namely mean and percentages were used.

RESULTS AND DISCUSSION

Household (Hh) Socio-economic Characteristics and Food Expenditure

Table1 presents sampled households classified by occupation of the household head. The result reveals that 42.78 percent were wage earners, 32.78 percent were both wage earners and self-employed and 24.44 percent were household heads that were only self-employed. The wage earners group was made up of public servants, civil servants, professionals, Bankers, company workers as well as administrators. The self-employed households had the least average household size of 5 persons while the wage earning households had an average household size of 6 persons. The result also reveal that the self-employed and wage earning households spend the highest on food of ₦48,747.54 (27.11%) per month while their per caput food expenditure amounted to ₦6,673.09. Moreover, the wage earning households spend the least amount on food as well as the per caput food expenditure per month. In view of this, the self-employed households had the highest amount of income and the per caput income that accrues to the household which was ₦187,954.55 and ₦31,807.69 respectively.
Household size characteristic assessed in this study area was noted to vary directly with both income and expenditure. The Table shows that average household size of 4 persons had 46.93% of the household's sampled persons while only 2.23% have average household size of 17 persons. The results reveal a tendency towards small family size in the study area. This is in line with Obayelu, Okoruwa, and Oni, (2009) study of urban households in Kogi and Kwara State as well as Usharani and Reddy (2004) in Hyderabad, India. The current trend can be attributed to awareness created by government and such non state actors like Society for Family Health in controlling birth rate. Another reason could be high rate of inflation in the State. This may have made keeping and maintaining large family size rather hard and difficult. Average household size in the study area was six (6) persons.
Table 3, presents the educational level of household Heads. The result shows that percentage food expenditure decreases as income per household increases with the level of education attainment. This may not be unconnected with adoption of family planning measures by the learned. The result conforms to the *apriori* expectation. This correlation is reflected in the income per household, per caput income as well as the per caput food expenditure. The finding is similar to those of Yeong-Sheng (2012) in Malaysia.
Table 4 present the average monthly income by income group. The result shows that an observable pattern in the result is that, the higher the household income, the larger the size of the household, and also the food expenditure per household as well as the income per caput. Finally, the result reveals that the low income household spend 51.74 percent of their income on food, the middle income households allocate 26.19 percent of their disposable income on food whereas, the high income household allotted only 13.69 percent of their disposable income on food. This is in line with Umoh (1994) and Yeong-Sheng (2012) in Malaysia.

CONCLUSION AND RECOMMENDATION

This study examined food consumption expenditure in households in Uyo Metropolis, Akwa Ibom State, Nigeria. It was found that almost a half of the respondents were wage earners. Food expenditure was found to be highest in self-employed/wage earners households while per caput food expenditure was highest in the self-employed households. The self-employed households were found to earn the highest monthly income. Educationally, household heads who have attended university or its equivalent spent the highest amount (N41,075.71) on food followed by those with NCE and ND while those who have only primary education spent the least amount (N19,609.49) on food per month. Only 68% of the households in the study were found to be low income households. Income, household size and households' level of education were found to have serious influence on household food consumption expenditure. This also shows that large incomes have the tendency of households to consume good quality food items and procure other basic necessities in life.
In order to improve income in Uyo Metropolis, employment should be provided for the labour force so that unemployment can be relatively reduced. Qualitative education and apprenticeship training of the population should be embarked upon by government and developmental agencies in order to enhance the employment of the

generality of the masses. Also, the current minimum wage rate should be increased. To substantially improve the quality of life in the metropolis, there must be a concerted effort to get those who are not educated to be educated to a higher level. This is because; the likelihood of securing a higher paid job tends to increase with the level of educational attainment. It also increases the tendency of the population to adopt new practices that can lead to a rise in income generation.

Table 1: Distribution of Households Heads by Occupation and Food Expenses per month

Occupation	Percentage of total Household	Average Household Size	Food expenditure per Household (₦)	Monthly per caput food expenses (₦)	Monthly Income per Household (₦)	Monthly per caput income (₦)
Self employed	24.44	5.00	40,300.79 (21.44%)	6,820.13	187,954.55	31,807.69
Wage earners	42.78	6.00	38,939.26 (26.19%)	6,434.17	148,643.63	24,610.92

Corresponding email:amarachiobinna2015@gmail.com

ABSTRACT
Yam, a tropical crop in the genus Dioscorea*, has as many as 600 species out of which six are economically important staple species. In Nigeria, in many yam-producing areas, it is said that "yam is food and food is yam". However, the economic production of yam in Nigeria is substantially short and cannot meet the growing demand at its present level of use. Yam is grown on free draining, sandy and fertile soil, after clearing the first fallow. Land is prepared in the form of mound or ridge or heap of 1 metre (3 ft 3 in) height. The yams recommended for such soil conditions in Nigeria are white yam or white guinea yam (Discorea rotundata) and water yam or yellow yam (Discorea alata). Planting is done by seed yam or cut setts from ware tubers. Its cultivation is very profitable despite high costs of production and price fluctuations in the markets . An average profit per yam seed, average harvest and storage in Nigeria, was calculated at over US$13, 000 per hectare harvested .Households demand for yam consumption is very high in Sub-Saharan Africa. Nutritionally, yam is a major staple food consumption, providing food for millions of people in the West Africa. It is eaten in different forms such as fufu , boiled, fried and roasted . This root and tuber place in the diet of smallholder farmers cannot be ignored. It contributes over 200 dietary calories per capita per day for over 150 million people in West Africa. Yam tubers are sold on cash and carry basis and prices based on perceived size and quality of tubers. There is normally no grading system in place and a lack of formal contacts and arrangements between farmers and traders. From district markets yam tubers are transported to major urban centres such as Lagos for sale at larger urban markets. This review indicates that lack of finance, inadequate modern farm inputs, storage and processing, and high cost of labour, appeared to be the major constraints to yam production in Nigeria. In order to improve yam production, the government of Nigeria should provide a conducive environment and invest heavily in yam cultivation by providing farm tools to small holder farmers at subsidized rates.*
Keywords: Yam, Economics, Production, Nigeria.

INTRODUCTION

Yam is in the class of roots and tubers that is a staple of the Nigerian and West African diet, which provides some 200 calories of energy per capita daily. In Nigeria, in many yam-producing areas, it is said that "yam is food and food is yam". However, the production of yam in Nigeria is substantially short and cannot meet the growing demand at its present level of use. It also has an important social status in gatherings and religious functions, which is assessed by the size of yam holdings one possesses.(Ayannwuyi *et al.*,2007).According to the Food and Agricultural Organization report, in 1985, Nigeria produced 18.3 million tonnes of yam from 1.5 million hectares, representing 73.8 percent of total yam production in Africa.(Aidoo, 2009).According to 2008 figures, yam production in Nigeria has nearly doubled since 1985, with Nigeria producing 35.017 million metric tonnes with value equivalent of US$5.654 billion (Babaleye,2003). In perspective, the world's second and third largest producers of yams, Côte d'Ivoire and Ghana, only produced 6.9 and 4.8 million tonnes of yams in 2008 respectively. According to the International Institute of Tropical Agriculture, Nigeria accounted for about 70 percent of the world production amounting to 17 million tonnes from land area 2,837,000 hectares under yam cultivation.(Asante *et al*.,2007). Yam, a tropical crop in the genus *Dioscorea*, has as many as 600 species out of which six are economically important staple species. These are: *Dioscorea rotundata* (white guinea yam), *Dioscorea alata* (yellow yam), *Dioscorea bulbifera* (aerial yam), *Dioscorea esculant* (Chinese yam) and *Dioscorea dumetorum* (trifoliate yam). Out of these, *Dioscorea rotundata* (white yam) and *Dioscorea alata* (water yam) are the most common species in Nigeria. Yams are grown in the coastal region in rain forests, wood savanna and southern savanna habitats (Grunert *et al*., 2005).

The major producers of yam in Nigeria are Niger State, Abia State, Nassarawa State and Benue State. The problems of yam marketers include poor storage facilities, poor marketing strategy, and problem of income and culture of the people. As the campaign for household food security gains momentum all over the world, and some extreme hunger and poverty must be eradicated by year 2015, yams are some of the food crops whose production has got to be emphasized. Yams, being an important food crop for at least 60 million people in West Africa, it is therefore necessary to lower its production cost and scale up its production through an efficient use of its production resources (Babaleye, 2005). It is thus important that the profitability of its production be assessed. It is obvious that there is a potential for the increase in its production and much can be done to derive foreign exchange from its export. In spite of this, little or no study has been conducted to assess the profitability of yam production among small scale farmers. The objective of this review is to analyse the status of production and marketing of yam in Nigeria.

Cultivation Practises

Yam is grown on free draining, sandy and fertile soil, after clearing the first fallow. Land is prepared in the form of mound or ridge or heap of 1 metre (3 ft 3 in) height. The yams recommended for such soil conditions in Nigeria are white yam or white guinea yam *(Discorea rotundata)* and water yam or yellow yam *(Discorea alata)*. Planting is done by seed yam or cut setts from ware tubers. One day before planting, the tubers have to be subjected to treatment with wood ash or a fungicide (thiabendazole) to prevent damage to the soils. The setts are planted at an interval of 15–20 centimetres (5.9–7.9 in) with the cut face facing up. Mulching is essential during October–November with dry grass or plant debris weighed down with balls of mud. Dosage of fertilizer application, as essential, is decided after chemical analysis of the soil samples. Manual weeding by hoeing is done three or four times depending on the rate of weed growth. Two Stakes, each of 2 metres (6 ft 7 in) height are used for staking the plants to vine over it; one for two plants with the other used for bracing with the adjacent stakes. Sorghum stovers are also used for this purpose in the savannah land. Pest and disease control is addressed by cultural control and chemical methods; the pests which affect the plant are nematodes suchas root knot *Meloidogyne* spp. and yam nematode *(Scutellonema bradys)*, and insects such as yam shoot beetle, yam tuber beetle and crickets. Weeding of the field is essential and maintaining a 2–3 metres (6 ft 7 in–9 ft 10 in) weed free border around the field is to be ensured. Disease resistant [cultivars] are normally recommended for use. Harvesting is done before the vines become dry and soil becomes dry and hard. Generally, a yield of 10–15 tonnes per ha for white yam and 16–25 tonnes for water yam are obtained by following prescribed management practices. The harvested yams are stored by tying them with ropes. They have a shelf life of about 5 months. Warehouses where they are stored should be made rodent proof with a metal base and wire netting. Rotten buds and sprouted buds should be removed. Although it is grown widely in Nigeria, the area where it is grown most is the Benue State (land area of 802,295 km^2) one of the states in Benue valley of Nigeria where the labour-intensive practices are still the norm and the land holdings are small. In this state especially among Tiv people, the size of the yam farm or the tonnage of yams produced becomes the social status of that farmer. Because of high level of yam production in the State of Benue, Benue State is crowned as the Nigerian Bread Basket. Yams are planted on mounds rather than flat slopes depending on the hydromorphic nature of the soils which are generally of loose soil suitable to grow roots and tuber crops.(Bolinks *et al*.,2005While yam production issues have been stressed on agronomical practices, a research study carried out on the economic efficiency of this crop grown in this region with small farm holdings, which is labour-intensive, reveals that land, labour and material (fertilizers and chemicals), credit and extension services inputs have a significant bearing on the yield of yam in the region.

Socioeconomic Importance of Yam Production

Yams are among major cash and most consumed food crops West African countries (GTZ, 1999) like Nigeria (Babaleye, 2003; National Bureau of Statistics, 2012). Its cultivation is very profitable despite high costs of production and price fluctuations in the markets (IITA, 2013; Izekor and lumese, 2010). An average profit per yam seed, aer harvest and storage in Nigeria was calculated at over US$13, 000 per hectare harvested (IITA, 2013). Households demand for yam consumption is very high in Sub-Saharan Africa. Nutritionally, yam is a major staple food consumption, providing food for millions of people in the West Africa. It is eaten in diff erent forms such as fufu (the so-called poundo yam and Amala in Nigeria), boiled, fried and roasted (Aidoo, 2009; IITA, 2009). This root and tuber place in the diet of smallholder farmers cannot be ignored. It contributes over 200 dietary calories per capita per day for over 150 million people in West Africa (Babaleye, 2003). Yams have over 21% dietary fi bre and are rich in carbohydrates, vitamin C, potassium, manganese and other essential minerals (IITA, 2009). Many yam belt areas in Nigeria continuously proclaimed "yam is food and food is yam" (Maikasuwa and Ala, 2013). Some family rural dwellers, where yams are grown, eat it all day round. Arguably, yams are the only available food especially during the harvesting season. However, the primary research carried by LSMS-ISA (Living Standards Measurement Study- Integrated Surveys on Agriculture) in Nigeria showed that the consumption patterns of yams differ from the poor and rich people.

Relatively, richer households were found to be consuming more yams, but selling less harvested than poorer households. Poorer households consumed fewer yams, arguably because they heavily depended on yam for income than their richer counterparts who have other sources of earning (National Bureau of Statistics, 2012). Yam plays signifi cant roles in the social-cultural activities in Sub-Saharan Africa such as Nigeria and Ghana. For instance, some households used it during marriage and fertility ceremonies. More so, the festival takes place yearly to celebrate its harvest,and other social ceremonies (IITA, 2013; Izekor and Olumese, 2010; Bamire and Amujoyegbe, 2005; Aidoo, 2009). In Nigeria just like in many sub-Saharan African countries, agriculture is the largest employer of labour.

Yam Marketing in Nigeria

Yam tubers are sold on cash and carry basis and prices based on perceived size and quality of tubers. There is normally no grading system in place and a lack of formal contacts and arrangements between farmers and traders. From district markets yam tubers are transported to major urban centres such as Lagos for sale at larger urban markets. There are a number of different types of trader involved in the purchase and sale of yam tubers. Rural assemblers and local wholesalers (also known as shed owners in some states) purchase yam from local farmers to sell on to individual consumers but principally to larger urban traders (wholesalers) who visit district markets. The local wholesalers serve as collection centres for farmers. Buying agents normally facilitate sales from farmers to larger wholesalers and charge a commissioning fee to local wholesalers (Grunert *et al* ,2005). Local wholesalers sell on behalf of the farmers and also receive a service charge from bulk buyers (urban wholesalers). In some cases this fee is in the order of N200.00 to N300.00 per 100 tubers transacted. The larger-scale urban wholesalers often travel to origin to organise purchase of yam, perhaps travelling weekly or more frequently. Nigeria is the world's largest yam producer, contributing approximately two thirds of the global production. In Nigeria, there is a high demand for yam in terms of consumption (Bamire *et al*,2005). Yam is however, prepared in various ways such as boiled, roasted, fried or mashed as done with mashed potatoes or processed into powder for puddings or for other meals. The back of the yam is also used as feed for livestock; therefore all parts of it are useful. 'Yam tubers however, consist of about 21% dietary fiber and are rich incarbohydrates, vitamin c and essential minerals and are also low in fat' (IITA, 2012).It provides a reference point for improvements in services and the business environment. It is a vehicle for pro-poor initiatives and for linking small businesses with the market. Value chains reside at the core of high-impact and sustainable initiatives focused on improving productivity, competitiveness, and entrepreneurship, (Bolinks *et al* 2005).

CONCLUSION

Yam products have some socioeconomic importance in Nigeria. For instance, some households used it during marriage and fertility ceremonies. They also celebrate its harvest and used it for other social ceremonies. Yams are among the most major cash and food crops in the country. Lack of finance, inadequate modern farm inputs, storage and processing, and high cost of labour, appeared to be the major constraints to yam production in Nigeria. In order to improve yam production, the government of Nigeria should provide a conducive environment and invest heavily in yam cultivation by providing farm tools to smallholder farmers at subsidized rates. In addition, the government should provide more loans to farmers at zero or low-interest rate. Yam processing industries should be created for sustainable cultivation and higher productivity. Possibly, this will go a long way in accelerating yam products for the betterment of smallholder farmers and traders, thus partly ensuring food security in the country.

Table 1: Annual yam production in the world and Nigeria, (1961-2012)

Yams element	Area	1961	1980	1990	2000	2010	2012

ABSTRACT
The study aimed at examining determinants of loan repayment among cassava farmers in Imo State. It adopted simple random sampling technique in the selection of 152 cassava farmers as respondents. Data were generated by use of questionnaire. Data were analyzed using descriptive statistics and Tobit model. The study results showed that educational attainment, experience in loan use, household size and net farm income significantly influenced loan repayment performance of cassava farmers. The study recommended that financing institutions should take the afore-mentioned determinants seriously in their lending business.
Keywords: Determinants; Loan; Performance; Tobit model

INTRODUCTION
Agricultural lending involves giving out credit in cash or kind to farmers for the purpose of farm production (Abott & Makeham, 1979; Ojiakor &Ogbukwa, 2012). The principles of economics and finance have shown that by using other people's funds along with his own, an investor is most likely to improve his business significantly than if he had to depend solely on his equity (Lot, 1998; Pandey, 2010). As this rule applies to commerce, so also does it apply to agriculture in developed and developing countries of the world.
Cassava (*Manihot esculenta*) is one of the most important crops in Nigeria, playing dominant role in rural economy especially in the southeastern agro-ecological zone and is increasingly gaining importance in other parts of Nigeria. Nigeria is currently the largest producer of cassava in the world with an annual output estimate of 45 million metric tonnes and global share of 19 percent (Philips, Taylor, Sanni & Akoroda, 2004). The crop supplies about 70 percent of the daily calorie intake of well over 50 million Nigerians (Ugwu, 1996). About 80 percent of Nigerians who reside in the rural areas eat cassava meal at least once a day; and when compared to rice and maize, cassava has carbohydrate content which is about 40 percent higher than rice and 25 percent more than maize (Nyerovwo, 2004; Muhammed-Lawal, Omotesho & Oyedemi, 2013). It also generates about 25 percent cash income of all food crops grown in the country (Eze & Nwibo, 2014 ; Nweke, 1994). The high demand for cassava today is largely due to the increasing industrial scale use of its products. In addition to providing food for the populace, its export is a major earner of foreign exchange for the country
The major problems facing these agricultural credit programmes irrespective of the institution channel are low credit recovery rates and patronage. For instance, between 1978 and 1990, the cumulative number and value of loans guaranteed by Agricultural Credit Guarantee Scheme Fund (ACGSF) stood at 122,246 valued at N765.4 million, while the total number and value of loans fully repaid by all categories of borrowers stood at 34,744 and valued at N179.68 million representing only 23.5% of the total loan value (Olagunji & Ajiboye, 2010). Osakwe and Ojo (1986) also reported that large rate of default has been the perennial problem of most government organized and supported agricultural credit schemes in Nigeria. Similarly, Olabode and Oladebe (2008) maintained that most of the defaults arose from poor management procedure, loan diversion and unwillingness to repay loans. However, many studies have focused on indispensability of credit in agricultural transformation. However, there is paucity of information on effects of socio-economic factors on repayment performance of these farmers in the study area using Tobit model. It is this gap this study sought to fill.

Study Objectives
The objectives of this study were to:

(i) examine their sources of loan; and

(ii) estimate effects and sizes of socio-economic factors on loan repayment performance of the recipients.

Study Hypothesis:
H$_O$: Socio-economic characteristics of cassava farmers do not significantly affect their loan repayment performance in the study area.

MATERIALS AND METHODS
The area of study is Imo State of Nigeria. Imo State lies between longitude 63°5'E and7°28'E and latitude 5°10'N and 5°57'N (Ministry of Lands Owerri, 1992). The state has land area of 5,289.49km^2 and estimated population of 3,934,899 (NPC, 2006). Imo State has an estimated farming family's population of 303,333 (Imo ADP, 2000). The state is bounded on the east by Abia State, on the south and south-west by River State, on the west and north-west by River Niger over which lies Delta State and on the north by Anambra State and Enugu State (Imo State of Nigeria Diary, 2010).

Multi-stage sampling technique was employed in the selection of respondents for the study. First, two local government areas were selected from each of the three agricultural zones in the state. The local government areas are Ihitte Uboma and Isiala Mbano, Ideato North and Orsu, Oguta and Ohaji/Egbema for Okigwe, Orlu and Owerri agricultural zones respectively. Second stage was the identification of the registered small scale cassava farmers in the six local government areas who take loans from Bank of Agriculture with the help of field officers of the bank which were 245 in number using simple random sampling while adopting Yemane (1967) fomular in the determination of sample size from the population. The fomular is given as:

$$n = \frac{N}{1 + N(\mathrm{e})^2}$$

Where: n= sample size
N= population size
e= tolerable error level (here 5%)

From the foregoing therefore you will obtain the following:

$$n = \frac{N}{1 + N(e)^2} = \frac{245}{1 + 245(.05)^2} = 152$$

Based on the above calculation the above total sample size was 152.

Data Analysis

Objective i and ii were analyzed using descriptive statistics while objective iii was analyzed with Tobit model. The Tobit (censored) regression model is a model whose dependent variable can be censored from left (below) or right (above). In this case all variables above the censored point are seen by the model as real values but below are seen as zero. The standard Tobit model is given as:

$$Y^* = x_i\beta + \varepsilon_i = 1\ldots, N$$

Where: y^* = unobserved latent dependent variable; y_i = observed dependent variable, β = the vector of coefficients, and ε_i = error term, assumed to be independently and normally distributed, i.e., $\varepsilon_i \sim N\ (\mathrm{O},\ \sigma^2)$ and x_i denotes the (K x1) vector of exogenous and fully observed regressors.

The model specification is as follows:

REP= f(AGE, GDR, EDL, EXP, HHS, OCP, NFY, FMS, INT) + μ

where:

REP= the percentage of loan repaid by the farmer within the period of study censored from below at 65% .

AGE= age of the respondent in years;
EDL= number of years spent in educational pursuit by the respondent;
GDR= gender of the respondent which takes 0 for male and 1 for female;
EXP= number of years the respondent has accessed loans;
HHS= number of persons in the respondent's household;
NFY= net farm income of the respondent;
FMS= area cultivated by the respondent during the period in ha;
AMT= amount of money collected by the farmer;
LSZ= amount of loan collected; and
INT= rate of interest on borrowed money in percentage.

RESULTS AND DISCUSSION

Sources of Funds for the cassava farmers

Study results (Table 1) shows that majority of the respondents (64%) obtained their loans from BOA while 22% obtained their loans from Union Bank and First Bank Plc respectively. also Bank of Industry supplies 20% of the loan funds. The implication of this finding is that cassava farmers obtain their fare share of loan funds from different sources. However, it is instructive that more of the funds should be made available to them in order to boost further production in order to make for possible improved repayment rate of the farmers.

Determinants of Loan Repayment Performance of Cassava Farmers

Table 2 shows that the Tobit model adopted in the analysis had a log likelihood ratio of -237.65 and a pseudo R^2 of 0.356 indicating that 36% of the changes in the dependent variable were brought about by changes in the explanatory variables. The Prob>Ch^2 was 0.000 which showed that the model was significant at 1%.

Significant variables were educational level, experience in loan use, household size, and net farm income. Educational level was significant at 1%, indicating that as more years are spent in educational attainment, repayment performance increased. This finding has been reported by Eze & Nwibo (2014) who worked on technical efficiency of cassava production in North East LGA of Delta State.

Experience in loan use was also significant at 1% indicating that having obtained loan for many years made borrowers repay highly than when they are new borrowers. This finding is also significant in the sense that those who know the importance of borrowing to their business usually avoided defaulting in loan repayment. This finding was also reported by Ibekwe, Chikezie, Obasi, Eze & Ukoha (2012).

Household size was also significant at 1% but negatively impacting on loan repayment rate. This means that the longer the number of persons in the farmers household, the more difficult the farmer to repay due to the weight of the bills of the household members. This is according to *a priori* expectation. The bills of the home in terms of food, health, education and other exigencies will make repayment low. This result has been reported by Fortong and Suriya (2011) and Wogna and Awunyo-Vitor (2013).

Net farm income was also significant at 5%. This indicates that as the farmer makes enough income in his business, repayment is higher. This indicates that more income in the farmers business will lead to better performance in loan repayment. This finding was also reported by Ohaka (2016).

CONCLUSION

The study concluded based on findings of the study that repayment performance is enhanced by socioeconomic characteristics such as educational attainment of cassava farmers, experience in loan use, household size and net farm income of cassava farmers. The study also recommends that lender should emphasize critically the above mentioned characteristics in lending in order to guarantee the repayment of loan given to cassava farmers.

ABSTRACT
Nigeria, the world largest producer of cassava is still struggling with commercialization of the crop despite efforts by government to create marketing outlets for it. This paper focuses on identifying the factors that determine commercialization on the welfare of cassava farmers' cooperative societies in Abia state. Forty five cooperatives were randomly selected from the three agricultural zones that make up the state. Relevant information from respondents was collected with a well-structured questionnaire. Both descriptive and inferential statistics were used to analyze data collected. Specifically, regression analysis was employed to estimate the determinants of commercialization of cassava in the study area. The result shows that level of education, household size, input cost, income and access to credit were the major factor that determines commercialization of cassava in the study area. Among the constraints to cassava commercialization identified in the study was: Insufficient capital, poor road network, high cost of living and pest and diseases infestation. It was therefore recommended that these factors identified to have influence on commercialization of cassava, be addressed by government and its agencies in partnership with the private sector, in order to trigger investments in cassava production.
Keywords: Cassava, commercialization, farmers, cooperatives,

INTRODUCTION
Cassava (*Manihot esculenta)* ranks first among the major food crops in Nigeria, in terms of calories; hardly will you find a family who doesn't consume cassava. It is a major source of food to producer in Nigeria and the most important root crops of the tropics. It is rich in energy and a source of raw material for the production of snacks such as bread, cake, chin-chin and also used as animal feed. It has other diverse uses in the pharmaceutical confectionery and livestock industries in Nigeria. Its production and processing provides employment and income for the poor masses especially women and children. Cassava has a lot of uses and by-products (Truman *et al.,* 2004).
Commercialization of this crop is one of the key strategies to promoting, accelerated modernization, substantive economic growth and development, hence eradicates poverty in the society (Manyong *et al.,* 2003). Commercialization of cassava products leads to greater market orientation of large production and a good source of economic growth. Commercialization is a rise in the share of market output or of purchased inputs per units of output. It is to increase in productivity of resource like land, capital and above all it helps to increase export potentials of agricultural products of Nigeria (Nkamileu, 2003). It leads to increase in income which in turn is a major determinant of welfare.
Welfare represents the people standard of living. It refers to economic wellbeing of an individual. Welfare is largely determined by agricultural productivity like (cassava) (Markus *et al.,* 2003). Much of the increase in Agricultural output in recent years has resulted from expansion of the area under cultivation, rather than from increased productivity (Akande, 2006). The challenge is to intensity agriculture commercialization of cassava in a suitable manner (Akande, 2006).
The main problem still remains the incidence of high rate of poverty among the people and its geometric increase by years. One of the causes remains narrow markets and commercialization for years has a negative influence on cassava, others factors highlighted includes inefficient marketing institution and inadequate rural infrastructure, lack of access to credit funds etc. couple with farm input like fertilizer poses a significant risk to commercialization of cassava production. Cassava production plays a major role in all issues concerning agriculture. There is need to harness the huge potentials of cassava in order to fight poverty through commercialization. This paper therefore seeks to identify the factors that determine commercialization on the welfare of cassava farmers' cooperative societies in Abia state.

METHODOLOGY
The study was conducted in Abia State, Nigeria. Agricultural cooperatives were identified through the Abia ADP and spread across the state. However, a list of the cooperatives separated by the three agricultural zones in the state (Umuahia, Aba and Ohafia) formed the sample frame. From this list, 15 Cooperatives were randomly selected from each agricultural zone, making a total of 45 agricultural cooperative used for the study. A structured questionnaire was used to collect relevant information from respondents. Data collected were analyzed with both

descriptive and inferential statistics. Specifically the regression analysis was used to know the determinants of commercialization of cassava in the study area. The regression model is implicitly stated as follows;

$$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8) + e_1$$

Where:

Y = commercialization index

$$\frac{\text{value of cassava sold}}{\text{total value of cassava produced}} \times \frac{100}{1}$$

X_1 = education (years)
X_2 = household size (number of people living under same roof)
X_3 = faming experience (years)
X_4 = farm size (hectares)
X_5 = input cost (Naira)
X_6 = access to credit (access to credit = 1, non to access = 0)
X_7 = income (Naira)
X_8 = farmers asset (Naira)
e_1 = error term

t-test was used to test if there is significant difference in the welfare of those fully and not fully commercialized. The T-test formula is shown below;
T cal = x

$$S\,x_1 - S\,x\,2 = \frac{x_1 - x_2}{\sqrt{\frac{S^2\,x_1}{n_1} - \frac{S\,^2x_2}{n_2}}}$$

Where;

X_1 = welfare value of those fully commercialized
X_2 = welfare value of those not fully commercialized

Double log regression analysis was chosen as the best fit model because it has the highest number of significant variables and highest R^2 values.

RESULTS AND DISCUSSION

The regression output of the four functional forms shown in Table 1 indicates that the double log function had the best fit and was used in the analysis. The Double Log was chosen as the lead equation based on the value of R^2 (Coefficient of multiple determination), F-ratio and the conformity of the sign of regression coefficients with *a priori* expectation. The value of R^2 is 0.690, meaning that 69% of total variations in the dependent variable is accounted for by the independent variables included in the model. Specifically level of education, household size, income and access to credit, were significant and positively related to commercialization while input cost was significant but negatively related to commercialization of cassava. This means that as such factors as level of education, household size, income and access to credit increases, commercialization of cassava also increases. Measures taken to increase these variables will also increase commercialization. Conversely, if the cost of production inputs increase in the study area, commercialization of cassava in the area will decrease. So stakeholders in the cassava industry should as much as possible reduce the cost inputs as to encourage commercialization of cassava in Abia State.

Table 2 shows the constraints associated with commercialization in the state. The result indicated that major commercialization constraints such as insufficient capital, poor road network, high cost of living, pest and disease were the major problems faced by farmers on commercialization.

CONCLUSION

Commercialization is an imperative if the farmer cooperative will benefit from their effort in cassava production. The study has identified the factors influencing commercialization of cassava. Such factors as level of education, household size, income, access to credit and input costs should be taken seriously in cassava production. Consequence of these, operators of cooperatives should embark on enlightenment campaign among farmers on the need to increase their marketable surplus and reduce waste through excessive consumption and gifts etc. by putting more resource on the education of their members. This will ensure more farmers getting fully commercialized consequently influencing their welfare positively. Cooperatives societies should collaborate with government and its relevant agencies on food security to access funds and farm inputs for her members (farmers). Cassava farmers should be empowered with credit and agricultural inputs. This will help achieve commercialization of cassava in the study area.

ABSTRACT
In this paper, we employed the Data Envelopment Analysis (DEA) to estimate technical efficiency of cassava-based farmers in Abia State. The findings of the study have implications for increased cassava production in the study area. Attainment of 85% efficiency means that farmers still have room to increase their efficiency to the optimum (100%).
Key words: Technical efficiency, Data envelopment analysis

INTRODUCTION
The question of efficiency in resource allocation in traditional agriculture is not trivial. It is widely held that efficiency is at the heart of agricultural production (Umoh, 2006). This is because the scope of agricultural production can be expanded and sustained by farmers through efficient use of resources (Udoh, 2000). For these reasons, efficiency has remained an important subject of empirical investigation particularly in developing economies where majority of the farmers are resource-poor. Also, efficiency measurement is important because it leads to a substantial resource savings (Bravo-Ureta and Rieger, 1991). However, three types of efficiency are identified in the literature. These are technical efficiency, allocative efficiency and overall or economic efficiency (Farrell, 1957; Olayide & Heady, 1982). Technical efficiency is the ability of a firm to produce a given level of output with minimum quantity of inputs under a given technology. Allocative efficiency is a measure of the degree of success in achieving the best combination of different inputs in producing a specific level of output considering the relative prices of these inputs. Economic efficiency is a product of technical and allocative efficiency (Olayide & Heady, 1982). According to Quan (2011), smallholder and family farming agriculture remain the key and leading sector in overall economic development of many developing countries in the world in addition to producing staple crops for domestic markets; smallholder farmers produce large shares of traditional exports in these countries. This shows how the economies of many developing countries still rely on smallholder-based agriculture.
Cassava production in Nigeria, the highest producer globally, was 156.8 per cent of that of Indonesia, the second top producer (FAO, 2013). According to Egesi *et al* (2006), Nigeria cassava transformation is the most advanced in Africa. It is strategically valued for its role in food security, poverty alleviation and as a source of raw materials for agro-allied industries in Nigeria. It has huge potential for the export market; and provides the livelihood for over 30 million farmers and countless processors and traders (Egesi *et al.,* 2007; CEDP, 2005).
According to Cooper *et al* (2011) Data Envelopment Analysis (DEA) is a relatively new "data oriented" approach for evaluating the performance of a set of peer entities called Decision Making Units (DMUs) which convert multiple inputs into multiple outputs. Meanwhile, there are two kinds of Data Envelopment Analysis models namely Charnes, Cooper and Rhodes (CCR) and Banker, Charnes and Cooper (BCC) models. The CCR model (Charnes *et al.*, 1978) is built on the assumption of constant returns to scale (CRS) of activities. Constant returns to scale (CRS) imply that a given increase in inputs would result in a proportionate increase in outputs and the feasible region of the envelopment problem becomes a conical hull (Pahlavan, 2012). Contrastingly, the BCC model (Banker *et al.*, 1984) is built on the assumption of variable returns to scale (VRS) of activities which is a restriction on intensity of the efficient DMUs in projecting inefficient DMUs onto the efficient frontier that leads to no condition on the allowable returns to scale. Thus, technical efficiency in this study was estimated using the input-orientated variable returns to scale (VRS) DEA model.

Banker *et al* (1984) recommended the use of variable return to scale (VRS). This decomposes technical efficiency to pure technical efficiency and scale efficiency. The model is specified as follows:

$$\begin{aligned} &\min \theta \\ &s.t.: \\ &y + Y\lambda \geq 0 \\ &\theta X_0 - X\lambda \geq 0 \\ &\lambda \geq 0 \\ &N_i\lambda = 1 \end{aligned} \qquad (1)$$

where

θ = the TE of DMU to be evaluated,
λ = the intensity of the efficient DMUs in projecting inefficient DMUs onto the efficient frontier, also called the convexity constraint. The optimal efficiency of a *DMU*, θ*, will be less than or equal to 1. *DMUs* with θ* < 1 are inefficient while *DMUs* with θ*= 1 form a set of boundary (frontier) points.
The question is: are cassava-based smallholder farmers efficient in the use of resources? This study is an attempt to answer this question with specific emphasis on the technical efficiency of smallholder farmers. The broad objective of this study was the technical efficiency of cassava-based smallholder farmers in Abia State, Nigeria. Specific objectives were to examine the socio-economics characteristics of cassava-based farmers and analyse the technical efficiency of resource use in cassava-based farming.

METHODOLOGY

The study was carried out in Abia State. Abia State is located within latitudes 40^0N – 47^0N of equator and longitude 70 – 80E of the Greenwich Meridian (NRCRI, 2010). The state has a total land area of about 5,410sq kilometers, with a human population of about 2,833,999 (NPC, 2006). The State is made up of 17 Local Government Areas (LGAs). The state is demarcated into three (Aba, Umuahia and Ohafia) agricultural zones. The people are predominantly farmers, producing such arable crops as cassava, yam, cocoyam, maize, vegetables, melon, banana/plantain and rice. Multi stage sampling technique was used. One hundred cassava-based farming households were sampled for the study. However, ninety four questionnaires were used for analysis. Data were collected in 2011. Data were collected on output of cassava (kg/ha), labour (mandays), fertilizer (N/Kg), herbicides (N/litre), and land (ha). Data were analyzed using descriptive statistics and Data Envelopment Analysis (DEAP version 2.1).

RESULTS AND DISCUSSION

Table 1 below shows the socio-economic characteristics of cassava-based farmers. The table revealed the mean age of the farmers to be about 59.4years. The implication of this is that the farmers are ageing. This may not be unconnected with the fact that agriculture is increasingly being rejected among the youths particularly because of preference for white collar jobs (Abdulazeez, *et al.*, 2014). In addition, the table shows that mean household size of the farmers is about six persons per household. This implies that the farmers can use members of the household as family labour thereby reducing the cost of labour in cassava production. Similarly, the table revealed the mean farm size of the farmers to be about 1 hectare. This shows that the farmers are smallholder farmers who perhaps depend more on low external inputs use.
Furthermore, table 2 below shows the efficiency measures and frequency distribution of return to scale for the sampled farmers. The table revealed that the mean technical efficiency (VRS) score of 0.85 suggests that input usage can be reduced by about 15 per cent while maintaining the same output level in cassava production. In addition, the table shows that 38 percent of the sampled farmers are operating under increasing return to scale (IRS) assumption. This implies that the output increases more than the inputs. Return to scale using Data Envelopment Analysis (DEA) shows the relationship of outputs to inputs. Return to scale can be constant, increasing or decreasing depending on whether the outputs increases in proportion to, more than or less than the inputs respectively. In other words return to scale indicates what would happen to output if all the inputs are increased simultaneously (Shehu *et al.*, 2010).

CONCLUSION

In this paper, we employed the Data Envelopment Analysis (DEA) to estimate technical efficiency of cassava-based farmers in Abia State. Overall, the farmers performed at an average technical efficiency of 85%, only about 40% of the farmers operated at increasing return to scale (IRS). The findings of the study have implications for increased cassava production in the study area. Attainment of 85% efficiency means that farmers still have room to increase their efficiency to the optimum (100%).

Table I. Socio-economic Characteristics of cassava-based farmers

Characteristics	Number of farmers	Percentage (%)

ABSTRACT
The study examined the effect of cooperative societies in the development of rural areas in Aba area of Abia State. A purposive sampling technique was used to select two local government areas Aba north and Ossisoma local out of the four local government area that make up the Aba area. Primary data was used for the study and a total of sixty cooperative societies were sampled. Data were analysed using descriptive statistic such as mean, percentage, frequency and standard deviation. Results shows that mainly (57.00%) of the cooperators were women while (43.00%) were men. The study revealed that majority of the cooperators (13.00%) were less than 31years old while 9.00%, 51.00% and 19.00% had age range of 31-40, 41-50 and 51-60 years respectively, most of the respondents were still young and active. Majority (60.00%) of the cooperators were part-time farmers while 40.00% were full-time farmers while 9.00%, 60.00%and 14.00% had cooperators experience range of 1-4, 5-8 and 9-12 respectively while 17.00% had more than 12 years of experience. From the results 23.00%, 54.00% and 12.00% of the cooperators had household size range of 1 - 3, 4 - 6 and 7-9 persons respectively while 11.00% had more than 9 persons. The mean responses of the outreach performances were all greater than 3.00 while the most important outreach performance was (7) (4.85) which ranked the highest, followed by (4) (4.66) and (5) (+4.43) which ranked second, third and fourth respectively. Others were (3) and (1) (4.40) each and (2) (3.49) which ranked fifth and seventh respectively.
Keywords: Cooperatives, rural societies, effect, Nigeria

INTRODUCTION

The problem of developing the rural area has received the attention of many experts and researchers as well as the government. This is because it constitutes a serious bottleneck to the socio-economic development of the country as well as the communities. It is in the light of this that I have decided to examine how rural areas would be developed with the help or assistance of co-operative societies in Abia State.

Rural development according to Diejomoah (2003) is "The process of not only increasing the level of per capital income in the rural area but also the standard of living of the rural population measured by food and nutrition level, health, education, housing, recreation and security. Also Rural development according to UNO (1960) is "The process by which the effort of the people themselves are United with effort of government authorities to improve the economic social and cultural conditions of the rural communities to integrate those community into life of the nation and to enable them contribute meaningful to national development.

Therefore, Rural Development is an integration activity involving the Implementation of programmes of agriculture, health, education, home management, provision of infrastructure and other community facilities under the supervision of the government, its agencies and the local people.

Co-operative society is one of the principal agents of rural development. It is not only an avenue for job opportunities, but also as a training ground for the rural dwellers and other society and economic benefits. Hence, it is a strong factor in the nation's economic development.

Helms (2005) on the other hand defines co-operative society as an association of persons who have voluntarily joined together to have a common end through the formation of a democratically controlled enterprise, making equitable contribution to the capital required and accepting a fair share of the risk and benefit of the undertaking in which the member activity participate. On the other hand it could be seen as a voluntarily association of persons having mutual ownership in providing themselves some needed service on non-profit basis usually organized as a legal entity to accomplish objectives through joint participation of its members.

As it is, the problem faced by the rural dwellers in Nigeria today is complex. It is those in the rural areas who have to produce not only enough for their families but also for industries and urban population. They also have to produce cash crops either for processing by local industries or for export. Still they lack the basic necessities of life.

Co-operative is a vital issue in every community in this world. This paper therefore, sought to examine rural development and discuss or diagnose strategies adopted by co-operative societies in developing rural areas and examine the problem areas of co-operative societies.

METHODOLOGY

The study was carried out in Abia State, Nigeria. The state is approximately within latitudes 4^0, $41^0$and 6^0, 14^0 north of the equator and longitudes 7^0, 10^0 and 8^0 east of the Greenwich meridian. It has seventeen (17) local government areas (LGAs) that are divided along three (3) agricultural zones namely: Ohafia, Umuahia and Aba. Abia State has seventeen (17) local government areas (LGAs) namely; Aba North, Aba South, Arochukwu, Bende, Ikwuano, Isialangwa South, Isiukwuato, Obingwa, Ohafia, Osisioma Ngwa, Ukwa East, Ukwa West, Umuahia North, Umuahia South, Umunneochi, and Isialangwa North(NPC, 2009). Majority of the inhabitants are Igbo's and their occupation are mainly agricultural-based which implies that most of the inhabitants are farmers. There are many Cooperative societies in Abia State, all of which support rural livelihood and creates roadmap for rural development.

The primary data which were used for the study were obtained through questionnaire. A purposive sampling technique was used to select 30 cooperatives from Aba North and 30 Cooperatives from Osisioma to make a sampling size of 60 respondents.Selected cooperatives include Amaelu (Aba North) MCS, Amos Memomorial (Osisioma),Akanwanna Abayi (Osisioma), Multipurpose Cooperative Society, Niger Delta Youth (Osisioma) MCS Ltd, Nwangozi (Aba North) MCS,Njionye (Aba) MCS Ltd, Nworgu (Aba North) MCS Ltd, Nagode(Osisioma) MCS Ltd,Ndienyioma (Aba) MCS Ltd. Nwabuike Amuke (FUG) Cassava Processing.

Data Analysis

Descriptive analytical tools were used access the profile of the selected co-operative societies and also to identify the outreach performances of the selected co-operative societies in Abia State.

5 Point Linkert Scale with the following: Excellent =5, Good =4, Fair =3, Poor =2 and Very Poor =1 were used to examine the roles of the selected co-operative societies in the development of rural societies in Abia state.

Model for 5 point Linkert Scale

$$\underline{X} = \frac{5+4+3+2+1}{5} = \frac{15}{5} = 3$$

Any mean of responses (X_R) higher than 3 will be regarded as being significant.

RESULTS AND DISCUSSION

The result in Table 1 showed that the mean responses of the outreach performances were all greater than 3.00 while the most important outreach performance was (7)(4.85) ranked the highest, followed by (4) (4.66) and (5) (+4.43) which ranked second, third and fourth respectively. Others were (3) and (1) (4.40) each and (2) (3.49) which ranked fifth and seventh respectively. The results show a mean performance rating of 1.54 which was lower than 2.00 indicating that the respondents were not satisfied with the performance of the cooperatives towards the development of the rural communities.

Table 2 shows a mean performance rating of 1.54 which was lower than 2.00 indicating that the respondents were not satisfied with the performance of the cooperatives towards the development of the rural communities. Table 3 shows that majority (92.00%) indicate that government and financial institutions were helpful in enhancing the role of cooperatives. Table 4 indicates that all the respondents (100.00%) indicated that government and financial institution help to enhance the role of cooperatives by equipment/materials and financial aids while 41.00% indicated loans.

Table 5 reflects the mean rating scale of 3.93 which higher than 3.00, indicating that the respondents were in agreement that cooperatives provide infrastructure towards the development of rural areas. Table 6 reveals that with a mean response rate of 3.25 which was higher than 3.00 indicate that the level of provision of infrastructure by cooperators was higher. Table 7 reflects a mean response rate of 4.71, implying that the respondents were in agreement that training of cooperative personnel was important towards enhancing their performance as instruments of development

Table 8 presents a mean response rate of 4.25 which was greater than 3.00 indicating that government policies and programmes affect the activities of the cooperative societies. Almost all the respondents (98.00%) indicate that such policy effect was in the positive direction.

CONCLUSION

The study analyzed the effect of selected cooperatives societies on the development of rural societies in Abia State. The results show that cooperative is indeed a strategy for rural development although the level of impact on rural development is low. Their activity can be improved through sound government policies and training that will ensure stability, sustainability and enhancement of rural development in the state.

Table1: Rating scale Analysis of Outreach performance of the selected Cooperative societies in the Development of Rural societies in Abia State

Performance	SA	A	U	D	SD	Obs	Total	Mean	Rank
Enhances socio-economic status of its members	40 (200)	60 (240)	-	-	-	100	440	4.40	5

SELLING ON-FARM OR OFF-FARM AMONG SMALL HOLDER YAM FARMERS IN OBINGWA LGA ABIA STATE, NIGERIA

A.C. Okoye and B.C. Okoye

National Root Crops Research Institute Umudike P.M.B. 7006 Umuahia Abia state, Nigeria
email:okoyeamalac@yahoo.com

ABSTRACT
The study analyzed the determinants of selling at the farmgate or market among small holder yam farmers in Obingwa LGA, Abia. A multi stage random sampling technique was used to select 90 yam farmers with the aid of structured questionnaire. The study described the socio economics characteristics of the respondents and determinants of choice of selling point for yam in the study area using descriptive statistics and Probit regression model respectively. The results show a mean age of 43.23 with a large household size of about 5 persons. The respondents were educated and have long years of marketing experience. The distance from the farm to the market was 5.45km and the farmers had a mean farm size of about 1.02 hectares. Majority (54.17% and 63.33%) of the yam sellers had access to credit and sell their yam at the market respectively. The Probit regression estimates of the determinants of choice of selling point for yam among the yam farmers in the study area show that the coefficient of membership of cooperatives was negative and significant at 5% level. This implies that farmers who belong to cooperative have increased probability of selling at the farm gate than their counterparts who are not members. The coefficients of credit access and communication facilities were positive and significant at 10% level each. This implies that farmers who had access to credit and communication facilities had increased probability of selling at the market than their counterpart whom does not have access. The coefficient of distance to market and transportation cost were negative and highly significant at 1% level each. This implies that any increase in these variables will lead to a corresponding decrease in probability of selling at the market. The result calls for institutional facilities like credit to reduce the transaction cost of participating in the market and infrastructural facilities like construction of good roads for easy evacuation of yam from the farm to the market for sale.
Keywords: Farmgate, Market and Yam Sales

INTRODUCTION
Yams (*Dioscorea spp*) are the most important staple food crops in west Africa (Ekpe *et al*, 2005) and also form an important staple food source in Africa, America, Caribbean, south pacific and Asia. In Nigeria, it is produced in large quantities, comprising 71% (37 million ton) of the world production (FAO, 2007). Common yam species are white yam (*Dioscorea rotundata*), water yam (*Dioscorea alata*), yellow yam (*Dioscorea cayanensis*), three leaf yam (*Dioscorea dumentonum*) and aerial yam (*Dioscorea bulbifera*). Among these cultivated species, white yam (*Dioscorea rotundata*) is common to be indigenous in West Africa (Degras, 1993). Consumer demand for yam is generally very high in Nigeria and yam production is very profitable despite its high production cost. Yams are perishable and bulky commodities and decision of place to market is invariably associated with farmers' choice, which if not contained may ultimately affect producers' competitiveness in the value chain or perhaps increase to a level where markets may be adjudged to be 'missing' (de Janvry *et al.*, 1991). This affects the choice of selling point, cost of production and consumption of yams across the country. As a result of poor market information coupled with bad infrastructure, the market women and buying agents usually worsen the situation by exploiting the farmers in offering a low farm gate price and ultimately low income. According to Kirsten *et al.* (2008), most often, markets are highly segmented and restricted, leading to farm gate sales, market failure and missing markets in some instances. De Janvry *et al*. (1991) define market failure as when the cost of transacting through market exchange creates disutility greater than the utility gain that it produces, with the result that the market is not used for transaction. Transaction costs also affect the choice of selling point (de Silva *et al.*, 2008).

For farmers, decision to sell in market or farm gate depends on distinctive characteristics, such as a variable responsiveness to price changes, low entry barriers, high transaction costs, and a lack of regulated contract schemes (Boughton *et al.*, 2007). Price-based interventions or imposed transaction costs are those associated with participation in the increasingly vertically coordinated markets. Such costs can be household specific, such as access to assets, or they can be the same for all farmers in a particular location, such as land quality, or producing a specific product, such as yams. Farmers will not enter markets when the value of participating is outweighed by the costs of undertaking the transaction (Sadoulet and de Janvry 1995). Therefore, this study analysed the determinants of choice of selling point among small holder yam farmers in Obingwa LGA of Abia State.

METHODOLOGY
The study was carried out in Obingwa Local Government Area of Abia State. A multi-stage random sampling technique was used to select 90 yam farmers in the LGA. At the first stage, 3 towns were randomly selected from

the LGA. In the second stage, 2 communities were randomly selected from each town given a total of 6 communities. And finally, 15 farmers were randomly selected from each community using the community list of farmers giving a total of 90 farmers for detailed study. The study made use of primary data (information on farmer's socio economics and transaction cost related) collected using the structured questionnaire. Descriptive statistics like means, percentages, and tables and Probit regression analysis were used for the study. The probit model was implicitly specified as:

$P_1 = P_r\{y_1 = 1) = P_r(^{u}{}_{1i} > {}^{u}{}_{oi}) = F_i(X_i\beta)$…………………………………………….. (1)

If Pi is the probability of participating in yam market which is unobservable and was only observed by the outcome Y=l if an individual sold at the markets and Y=0, if they sold at the farm gate.

Pr(Yi=l) =Pi………………………………... (2)

Pr (Yi=0) =l-Pi……………………………………………………………………………… (3)

Pr (Uli>U0i) implied that the probability of individuals that sold yam in the market or farmgate is dependent on the individual utility maximization which is subject to their socio-economic variables and beta estimates $X_i\beta$ (Normal cumulative function of error term Ui) of individual farmers.

X_i = matrix of the explanatory variables
X_1= Age in years
X_2 = Gender (dummy variable, 1 = male, 0 = female)
X_3 = Household size
X_4 = Membership of co-operative (dummy variable, 1 = member, 0 = non-member)
X_5 = Educational level in years
$X_{6=}$ Access to credit (dummy variable, 1= access, 0 = no access)
X_7 = Distance from farm to market
X_8= Transportation cost (1=yes, 0=no)
X_9=ownership of means of communication (1=yes, 0=no)
X_{10}=Road condition (1=good, 0=bad)
β = vector of parameters to be estimated
P_r = Probability function (1,0)
F $(X_1\ \beta)$ = Cumulative distribution function for random error term ($^{u}{}_{i}$) evaluated at X_1 β.

RESULTS AND DISCUSSION

The results in Table 1 show the socio economic characteristics of the respondents in the study area. The results show a mean age of 43.23 with a household size of about 5 persons. This indicates that the yam sellers were still strong and active and may sell more yam than their aged counterparts. Large households are more likely to provide labour that might be required to sell more yams to the markets. The results also show a mean value of 10.3 and 7.83 years of education and marketing experience. This shows that the respondents are educated and experienced. Education matters in terms of reducing the cost of searching for information. Moreover, the time taken to process and act on information decreases with education (Pingali *et al.*, 2005). Marketing experience is expected to reduce the transaction cost of participating in the yam market. The distance from the farm to the market was 5.45km and farm size of about 1.02 hectare. Increased farm size is expected to increase yam output and quantity sold. The results also show that many (53.33% and 51.67%) of the yam sellers were females and married. Less than half (48.33% and 40.00%) of the respondents were member of cooperative and owns means of transportation respectively. Well managed farmer groups have indeed proved reasonably successful in generating better terms of trade for producer members (Okoye, 2011). About 54.17% of the yam sellers had access to credit. Most (63.33%) of the yam seller sell their yam at the market. Mathye *et al.*, (2000) addresses the choice of marketing channel for small holder farmer and found that not all farmers sell their product. Those who sell tend to use different channel. Different factors affect the choice of the market channel which transaction cost is the key factor.

The results in Table 2 show the Probit regression estimates of the determinants of choice of selling point for yam among the yam farmers in the study area. The chi^2 value of 74.23 was highly significant at 1% indicating goodness of fit of the Probit regression line. The coefficient of membership of cooperatives was negative and significant at 5% level. This implies that farmers who belong to cooperatives have increased probability of selling at the farm gate than their counterparts who are not members. Fafchamps and Hill (2005) noted that if poor farmers receive a lower price because they sell in the farm gate, their welfare could be raised by offering institutional alternatives to farm gate sales, such as producers cooperatives. The coefficient of credit access was positive and significant at 10% level. This implies that farmers who had access to credit had increased probability of selling at the market than their counterparts whom do not have access. The coefficient of distance to market and transportation cost were negative and highly significant at 1% level each. This implies that any increase in these variables will lead to a corresponding decrease in probability of selling at the market. This may be because of the huge costs involved in moving the product from the farm to the market. Farmers may choose to sell at the farm gate as a result of this.

The coefficient of communication facilities was positive and significant at 10% level. This implies that farmers who have access to communication facilities sell at the market more than their counterparts who do not own one. With communication facilities, the farmers are expected to be more market efficient in term of source of market information and prices.

CONCLUSION

The study analyzed the effect of transaction cost of choice of selling point for yam among small holder farmers in Obingwa LGA of Abia state. The result show that majority of the yam farmers sell more yams in the market than at the farm gate. Importance factors influencing the choice of selling point includes; membership of cooperatives, credit access, distance to market, transportation costs and ownership of means of communication facilities. The study therefore calls for policies aimed at provision of communication facilities and construction of rural feeder roads to mitigate the effect of transaction costs and enhance market participation for yam by the farmers

ABSTRACT

The study assessed the determinants of raw materials demanded and finished goods supplied among bakery enterprises in Abia state, Nigeria. Data were collected by the use of a structured questionnaire, in all 50 respondents were selected for the study. Using multiple regression analysis, the coefficient of elasticity, frequencies, percentages and mean, data were analyzed. The number of costumers was a significant determinant of demand for raw materials in bakery enterprises. However, educational status, income level, the quantity of material and price of finished goods were all positive determinants of finished goods supplied to consumers hence an increase in these variables will result in an increase in the supply of finished goods. It was also revealed that elasticity of finished goods supply was significantly affected by raw materials, educational status, age, religion, labour size, means of supply, source of finance, income level and quantity of raw material implying that a change in any of the above factors will lead to a significant change in the finished goods supplied by bakery enterprises in Abia State. The result showed that in elasticity of raw material demand, age, labour size, years of experience, source of finance, income level, quantity of raw material, quantity of finished goods supplied, price of finished goods and finished goods available significantly affects the elasticity of raw materials demand which implies that a change in any of the above factors will lead to a significant change in raw materials demanded by bakery enterprises in Abia State. Having considered the study, it was revealed that age in years, educational status, labour size, means of supply, finance, income in naira, quantity of raw material (kg), type of raw material used are determinants of raw material demand and finished goods supply among bakery enterprise in Abia State, Nigeria.

Keywords: Bakery, Demand, Supply and Elasticity

INTRODUCTION

The bakery production which has been increasing steadily in the country is among the largest processed food industries in Abia. The two major bakery industries focus on bread and account for about 82% of the total bakery products. The bakery industries in Nigeria comprise organized and unorganized sectors. The organized sector consists of large, medium and small-scale manufacturers who produced majorly packaged bread. The unorganized sector consists of small bakery units, cottage, and household-type manufacturing goods and distributing their goods in the surrounding areas (World bank, 1995; BFW, 2005 and Warren 2002). Bakery products contain high nutritive value and are manufactured from combinations of wheat or other flours, sugar, baking powder, condensed milk, fat (ghee), salt, jelly, dry fruits, various essences, and flavoring. Different type of bakery products can be classified as dry bakery products and moist bakery products. Dry bakery products include soft biscuits, hard biscuits, cookies, crackers, fancy biscuits and cream wafer biscuits. Moist bakery products include sweet bread, milk bread, fruit bread, various types of buns, cakes, pastries etc. These products are available in various sizes, shapes, and forms (Beverage and Food World, 1998). The current demand for bread is likely to exceed 2.2 million tonnes considering their leading role as one of the major sources of energy, protein, iron, calcium, and several vitamins. Some commercial bread contains around 7.5% to7.8% protein respectively. In terms of cost, biscuits are amongst the lowest cost processed food in the country when compared to other salted snacks. Most of the bakery products are easy to use during travel or at home because of its availability in a variety of pack sizes. They are no longer viewed as a luxury tea-time snacks but essentially daily food component for an average Nigerian household. Considering the expanded product set of bakery enterprises, there is a need for advanced technology to optimize its category management processes to help meet business goals and deliver full value to its customers. Also with the population and purchasing power rising at a record breaking pace, there is a need for extended market share through immense investment. Effective production among bakeries in Nigeria has been hampered by poor innovations consequent upon poor performance. The majority of the bakeries which bumped into the market sometimes ago fizzled out of it due to business road bumps associated with the enterprise development. There have been the recurrent loss of market share and dropping of sales volume in the bakery enterprises operation in Abia. The identifiable road bumps to efficient bakery production in Abia included "a firm saddled with the burden of manual processes and cumbered with the inability to deliver in terms of efficiency"

(BFW, 2005). Bakery firms in Abia had the difficulty of inventory management contributing to thrift (waste in bakery business) and units (missed shipments to ultimate consumer). Financial uncertainties and capitalization inconsistencies have plagued and plundered bakery enterprise investment performances in Abia. In commercial bakery products venture, the acceptability of the product depends on the extent of capital invested into the firm to produce competitive products. In bakery firms, for instance, capital is needed to develop market acceptable packaging quality. The packaging of the bakery product is closely interlinked with the production, presentation, storage, transportation, marketing and other capital variables. The importance of the packaging can further be gauged from the fact that packaging constitutes a fair portion (10 to 25%) of the entire cost of production and the entire capital needs a functional bakery firm, (Cauvain and Young, 2005). The main objective of this study is to examine determinants of raw materials demand and finished goods supply among bakery enterprises in Abia State, Nigeria.

METHODOLOGY

The study location was Abia State of Nigeria. Abia State was carved out of the former Imo state on 27th August 1991 with its capital at Umuahia. The state is located in the southeastern region of Nigeria and has within the approximate latitude of 4º40 and 6o14 North and longitude 7º10 and 8º East (National Bureau of statistic, 2008) and its population is about 2,845,380 million (N.P.C. 2009a). The state is bounded by the North and Northeast by the states of Anambra, Enugu, and Ebonyi. To west it is Imo state, to the West and south-east are Cross River state and Akwa-Ibom state and to the South is River State. The Southern part of the state lies within the river line part of the country. It covers an area of about 5,24375 sq. km. The state is low lying with a heavy rainfall of about 2,400mm which is evenly distributed between months of April through October Agriculture is the major occupation of the people of Abia state. The data required for analysis of the study were culled from bakery enterprises records and account for the period 2007-2008. Questionnaire was also used to elicit other necessary information. Descriptive statistics, multiple regression analysis and elasticity of demand and supply function

For the demand elasticity function, it is stated thus:

ED/ (Raw material) = $\frac{\%Changeindemandofrawmaterial}{\%Changeinpriceofrawmaterial}$

For the supply elasticity function, it is stated thus:

ES/ (Finished goods) = $\frac{\%Changeinsupplyoffinished\ goods}{\%Changeinpriceoffinished\ goods}$

The multiple regression analysis is specified as follows

$\therefore Y_{a,b,c,d} = b_0 + b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4 + b_5x_5 \ldots\ldots + b_nx_n$+ei

Where

Y_a = Value of finished goods supplied in naira

Y_b = Value of raw materials demanded in naira

Y_c = Elasticity of finished good supplied

Yd=Elasticity of raw materials demanded

x_1 = Age in years

x_2 = Education in years

x_3= Religion (Christianity =1, others = 0)

x_4= Labour size (number of workers)

x_5= Years of experience

x_6= Means of finished raw material supply (farmer = 1, others = 0)

x_7= Finance = Naira

x_8= Income in Naira

x_9= Quantity of raw material (kg) (quantity of finished goods)

x_{10} = Type of raw material (wheat = 1, others = 0)

x_{11}= Price of finished goods/raw material

ei = Error term

$b_1 - b_n$ = Coefficient

b_0 = Constant

For elasticity models, the dependent variable $x_1 - x_{11}$ is the percentage change in the variables.

RESULTS AND DISCUSSION

Determinants of Raw Materials Demanded

This was achieved using multiple regression analysis. The outcome of the regression analysis is presented in Table 1. From the result of the regression analysis presented in table 1, the double-log model shows the line of best fit due to number of significant variables,R^2 value of 0.863 which is the coefficient of multiple determination implying that 86.35% of the total variation in the regression,were accounted for by the variables included in the model while the remaining 13.7% were due to variables not included in the model. The F-ratio 17.453 which was significant at 1% shows the overall significance of the regression model. From the result, educational status, religion, labour size, years of experience, the source of finance and income level were not significant determinants affecting the demand for raw materials in bakery enterprises. However, means of supply, the quantity of raw material available, the price of raw material, finished goods available, the price of finished goods and quantity of finished goods available were significant determinants affecting the demand for raw materials in bakery enterprises. An increase in all significant variables will result in an increase in the variability of raw materials demanded.

Determinants of Finished Goods Supply

From the result of the regression analysis presented in Table 2, the linear model shows the line of best fit due to number of significant variables, R^2 values of 0.943 which is the coefficient of multiple determination implying that 94.3% of the total variation in the regression were accounted for by the variables included in the model. While the remaining 5.7% were due to variables not included in the model. The F-ratio 45.984 which was significant at 1% shows the overall significant of the regression model. From the result, age, religion, labour size, years of experience, means of supply, the source of finance, raw materials and price of raw material are not significant, implying that they are not determinants affecting the supply of finished goods. However, educational status, income level, the quantity of raw material and price of finished goods were all positive determinants of finished goods supplied, hence an increase in these variables will result in an increase in the supply of finished goods.

Elasticity of Finished Goods Supply

The elasticity of finished goods supplied by bakery enterprise in Abia State was analyzed using multiple linear regression. The outcome of the regression analysis is presented in Table 3. From table 3, it was revealed that the F-test value of 45.984233 which was significant at 1% shows the overall significant of the model. It showed that raw materials, educational status, age, religion, labour size, years of experience, means of supply, source of finance, income level, quantity of raw material and price of raw material significantly affects the elasticity of finished goods supply, implying that a change in any of these factors will lead to a significant change in finished good supplied by bakery enterprises in Abia State.

From table 4, it was revealed that F-test value of 4.790557 which was significant at 1% shows the overall significance of the model. It showed that age, religion, labour size, years of experience, source of finance, income level, quantity of raw materials purchased price of raw materials purchased, price of material, quantity of finished goods supplied, price of finished goods and finished available significantly affected the elasticity of raw materials demand, implying that a change in any of these factors will lead to a significant change in raw materials demanded by bakery enterprises in Abia State.

CONCLUSION

This study assessed the determinants of raw materials demand and finished goods supply among bakery enterprises in Abia state, Nigeria with particular focus in analyzing their socio-economic characteristics, determinants of supply and demand in bakery enterprise and its effect. Findings from the study records that majority of the bakery enterprises were well educated and of experienced personnel, managed by middle aged with an appreciable income level and sizable labour were discovered to be instrumental to the performances of bakery enterprises Similarly, the price of finished goods and quantity of raw materials demanded were also found to determine the progress and smooth efficiency of bakery enterprise. However, religion was of no significance contribution to the determinants of supply and demand elasticity on the performances of bakery enterprises. It was observed that educational status, income level, the quantity of raw materials, and prices of finished goods were all determinants of finished goods supplied to the consumers and hence increase in these variables will result in an increase in the supply of finished goods and vice versa. Finally, the study also suggests that periodic training and capacity building programs be organized to enhance effective performances of bakery enterprise ,coupled with employing attractive incentives by the firms to increase their labour size, however quantity of raw materials and price of finished goods were all positive determinants of finished goods supplied and it's like which implies that there should be an effective communication between the consumers (customers) and the suppliers of raw materials to the bakery enterprise so as to minimize spoilage of finished goods and to determine the progress and smooth operation of bakery enterprise in Abia State. Nigeria.

ABSTRACT
This study analyzed the determinants of profitability and efficiency of livestock farmers In Abia State, Nigeria. The specific objectives are to determine the cost and returns associated with livestock production in the study area; identify the factors affecting the profit efficiency of livestock farmers in the study area and identify the constraints to profitable production of livestock in the study area. One hundred and twenty livestock farmer were selected via multi-stage random sampling method and questionnaires were used in the data collection. Descriptive statistics, farm budget technique, Cobb-Douglas function, and multiple regression analysis were used to analyze the data. The average PI for all farms was 0.64, the Rate of Returns on Investment was 181.1%, the Rate of Returns on Variable Cost (RRVC) was estimated to be about 386.76%, Operating Ratio (OR) was found to be 0.26 The Benefit-Cost Ratio (BCR) was estimated to be 2.81. The majority (83.3%) of the livestock farmers had attained a profit efficiency of above sixty (60) percent in their livestock farming. The government should make favorable policies on land acquisition procedures for livestock farmers who identified the cost of rent on land as a limiting factor to a profitable and efficient livestock business.
Keywords: Livestock, profit and efficiency

INTRODUCTION

Achieving profitability and efficiency is one of the major aims of livestock business in most rural and urban areas in Abia state. Livestock farming in the state is predominantly done in a semi-intensive management system and intensive in the rural areas and urban areas respectively mainly at a subsistent level. Livestock serves as an asset as well as a source of income for many Nigerians, creating jobs, the source of food and meat to meet the protein requirements, provides animal manure for crop production and provides power and transport options (Rahman and Yakubu, 2006). The value of livestock cannot be over-emphasized, considering the role they play in the society. Livestock makes use of left-over products, such as meat, milk, eggs, fibre etc. In addition to providing food, they provide income and other useful product to the people (Owolade *et al*, 2013). They contribute substantially to the livelihood of many rural households (Duru, 2006). However, livestock consumption is gaining wide prominence particularly in developing countries where 50% or more of their protein comes from livestock's Livestock production in Nigeria. This is because livestock products are more affordable, palatable and readily available than other sources of animal product (Mburu *et al.,* 2007). Otieno et.al (2009) estimated the total demand for livestock products in Nigeria stood at 2.1 million tonnes at 11.5kg per capita consumption whereas the domestic production is 352,460 metric tons. In Nigeria, a greater proportion of the livestock products is marketed fresh, while negligible quantity is preserved through Ice, smoking and sun-drying by main women at artisanal level. The preservation of livestock helps to increase utilization in the menu, reduced wastes of bulk catches and increased protein availability (Nganga, 2010). Income from livestock farming enhances productivity and standard of living by breaking the vicious cycle of poverty among rural farmers. There are indications that livestock farmers are limited by a lot of factors which limits their scale of operation and invariably affecting the level of pro accruing from the livestock business. In Nigeria, rigorous and inconsistent methods of production in addition to price fluctuations have an adverse effect on the level of profitability to farmers (Sani, 2000). Muburu et al., (2010) went further to buttress this problem faced in livestock production by stating that gender inequality in the ownership of assets, credit, services, markets and information on new technologies, consumer preferences and export trade requirements also affects the efficiency and profitability of livestock farmers. This reduces their chances of entering into contract farming agreements that could change their lives for good. Due to their lack of access to production resource effective livestock production activities are affected. In view of the unfolding reality coupled with the protracted debates, this study will attempt at examining the determinants of profitability and efficiency among livestock farmers in Abia state, Nigeria.

METHODOLOGY

The study location was Abia State of Nigeria. Abia State was carved out of the former Imo state on 27th August 1991 with its capital at Umuahia. The state is located in the southeastern region of Nigeria and has within the approximate latitude of 4°40 and 6o14 North and longitude 7°10 and 8° East (National Bureau of statistic, 2008) and its population is about 2,845,380 million (N.P.C. 2009a). The respondents were selected via multi-stage random sampling method. This technique was chosen based on the need to reduce the risk of bias and draw an inference from the sample about the population from which the sample is drawn with levels of confidence that can be statistically estimated (Alemandor, 2010). In the first stage, A Local Government Areas was randomly drawn from each of the three agricultural zones in the state. The agricultural zones are Umuahia agricultural zone, Aba agricultural zone, and Ohafia agricultural zones. In the second stage, two communities were randomly drawn from each of the three selected Local Government Areas from each of the three agricultural zones in the state. The third stage involved selecting two villages from each of the selected communities. The fourth stage involved the selection of 20 farmers into livestock production making a total of 120 respondents that was used for the study. Primary data were collected via the administration of a well-structured questionnaire. The study employed the stochastic profit frontier model to evaluate profit efficiency of the livestock farmers. The profit efficiency of the livestock farmers, efficiency equation model was used. The estimation was done using the Ordinary Least Squares method. The profit efficiency equation is fitted as:

$PE_i = a_o = a_iZ_1 + a_2Z_2 + a_3Z_3 + a_4Z_4 + a_5Z_5 + a_6Z_6 + a_7Z_7 + a_8Z_8 + a_9Z_9 + a_{10}Z_{10} + e_i$

Where,

PE_i = profit efficiency of the i^{th} livestock farmer

Z_1 = Age of the farmer (in years)

Z_2 = Household size

Z_3 = Farmer's level of education in years

Z_4 = Livestock rearing experience in years

Z_5 = Annual household non-farm income in naira

Z_6 = Amount of credit used (naira)

Z_7 = Membership of farmers' association or cooperative society (a dummy which takes the value of unity for members and zero if otherwise)

Z_8 = Distance to market commonly used (Km)

Z_9 = Foot and mouth disease zone (Yes = 1; No = 0)

Z_{10} = Information on livestock management access (Yes = 1; No = 0)

$a_0, a_1, a_2, \ldots a_{10}$ = regression parameters to be estimated

Four functional forms of linear, exponential, double-log and semi-log were fitted to the observed data. The choice of the lead equation was based on the magnitude of the coefficient of multiple determinations (R^2), the magnitude of the regression coefficient and conformity with a priority expectation of signs and the number and significance of the regression parameters.

RESULTS AND DISCUSSION

Cost and Returns in Livestock Production

The average cost and returns in livestock production among the farmers in the study area is presented in Table 1. Table 1 showed that the profitability ratios computed to establish profitability levels of the enterprise included profitability Index (PI), Rate of Returns on Investment (RRI), Rate of Returns on Variable Cost (RRVC) and Operating Ratio (OR). The average PI for all farms was 0.64, indicating that out of every naira earned; about 64 kobo accrue to the farmers as net income. The Rate of Returns on Investment was 181.1%, indicating that a farmer makes about ₦181 profit on every naira spent on livestock production. The Rate of Returns on Variable Cost (RRVC) was estimated to be about 386.76%, indicating that every ₦1 cost incurred on variable inputs generates about ₦386.76. This suggests that improvement in the profitability of livestock production in the study area was made possible through increased efficiency in the use of variable inputs. Moreover, the Operating Ratio (OR) of 0.26 indicates greater total revenue over total variable cost. The Benefit-Cost Ratio (BCR) was estimated to be 2.81, indicating that livestock production in the study area was viable as it returns ₦28 for every ₦1.00 spent. It can, therefore, be concluded that livestock production in the area is profitable. People should take up livestock productions as a means of livelihood.

Profit Efficiency of Livestock Farmers

The profit efficiency of livestock farmers was computed and the result is presented in Table 2. Table 2 shows that the majority of the respondents about eighty-three (83.3%) percent of livestock farmers had attained a profit efficiencies of above sixty (60) percent in their livestock farming. This result reflects the fairly high level of skills and expertise the farmers have acquired over time. This is hardly surprising considering the fact livestock farming is indigenous and integral part of most farmers in the study area and therefore most of the people grow up learning how to rear the livestock. The model technical efficiency was 0.61 -0.70 for the respondents.

Factors influencing the profit efficiency of Livestock farmers in the Study Area

The regression results on the factors that influenced the profit efficiency of livestock farmers in the study area are shown in Table 3. The exponential function was chosen as the lead equation based on the number and signs of the significant variables. The overall goodness of fit of the equation, as indicated by the coefficient of multiple determinations (R^2=0.883), showed that the independent variables included in model explained about 88.3% of the variations in waterleaf output (dependent variable) in the study area. The F-statistic was significant and confirms the significance of the entire model. Evidence from the result in Table 3 indicated that age, education, rearing experience, non-farm income, the amount of credit and disease were significant factors that influenced the profit efficiency of livestock farmers in the study area. Age was positively related to profit efficiency of livestock farming, an indication that profit efficiency of livestock farming increased as age increased. The level of profit made from livestock production depends on the age of the farmer because age determines the level of experience a livestock farmer would have gained over the years (Duru, 2006). According to Nwaru (2004) experience of a farmer increases with age. Experience creates confidence and could predispose a farmer to produce more. Profit efficiency of livestock farming is likely to increase as age increases. This relationship conforms to a priori expectation. Education (years) was positively related to Profit efficiency of livestock farming, an indication that profitability in livestock increased as the level of education increases. High level of education is an advantage to the livestock farmer, who would be privileged to have access to modern techniques of rearing livestock which will in turn translate into a profitable venture. Profit efficiency of Livestock farming is likely to increase the level of education increases.

Rearing experience was positively related to Profit efficiency of Livestock farming, an indication that Profit efficiency of Livestock farming increased as experience in livestock rearing increases. Farmers with relatively more experience can manage their farm operations better than those with less or no farming experience Nonfarm income of livestock farmers was positively related to Profit efficiency of Livestock farming, an indication that Profit efficiency of Livestock farming increased as non-farm income of livestock farmers increased. Nonfarm income is an incentive to the livestock farmers, income from farming activities are supplemented with non-farm income to increase the size of the livestock business and improve on the type of technology and techniques been adopted for the livestock farm. The amount of credit was positively related to Profit efficiency of Livestock farming, an indication that Profit efficiency increased as the amount of credit used by the Livestock farmers increased. The disease was statistically significant but negatively related to Profit efficiency of Livestock farming, an indication that Profit efficiency of Livestock farmers decreases as the incidence of disease increased. Disease incidence has a negative effect on profit efficiency because it reduces the output quantity and quality of the livestock farm.

CONCLUSION

The study revealed that livestock production in the area is profitable and the farmers had attained the fairly high level of profit efficiency from their livestock farming in the study area. Value of breeding stock, feed/fodder cost, family labour, capital employed, veterinary cost and cost of hired labour were the significant variables that influenced profitability of livestock farmers whereas age, education, rearing experience, non-farm income, amount of credit and disease were significant the factors that influenced the profit efficiency of livestock farmers in the study area. Based on the findings of the study the following recommendations are proffered; The government should make favorable policies on land acquisition procedures for livestock farmers who identified the cost of rent on land as a limiting factor to a profitable and efficient livestock business. The study revealed that most of the livestock farm operators in the study area were literate This, therefore, calls for the attention of the government to make protective policies that will encourage more literate people to be self-employed through starting up a livestock business. Such policies may include setting up a maximum price ceiling for livestock feeds and medication drugs, and regulating the prices of livestock in the market. Any effort to enhance the performance level of livestock enterprises in the study area should give serious consideration to those socio-economic factors that significantly influence the profitability level of the livestock farmers. Such efforts should be concentrated in reductively the high cost of inputs used in livestock production and scarcity of these inputs in the market. Any policies meant to increase production for should be geared towards improving the accessibility and affordability of producer to improved breeding stock.

Table 1: Average cost and returns farm of livestock production in the study area

ABSTRACT

Value addition has been the catalyst for increased income for agribusiness households. The study examines the value added cassava products in Ikwuoano local government area in Abia state; their profitability and determinants of value additions in the area. Data was elicited through a well-structured questionnaire administered to 60 cassava farmers in the area. Profitability analysis and regression analysis were the major tools of analyses. Garri was the most profitable value added cassava products in the study area with net returns of N82903; followed by Fufu with N71009 as net returns. Household size and education were significant and positively related to profit while experience, extension visits access to credit were significant and negatively related to profit of value added cassava products. Government and development agencies should organize sensitization programmes for cassava processors on the potentials that exist in the new emerging markets for value added cassava products.

Key words: value addition, cassava and profitability

INTRODUCTION

One of the major advantages cassava has over other tuber crops is its ability to be transformed into many products like garri, fufu, tapioca, starch, flour, chips, ethanol among others. Cassava is widely produced in Nigeria especially in the northern and eastern parts of the country because of its ability to withstand harsh weather conditions; it can be processed into different products, its appropriateness to the prevailing climatic conditions in the area and it's widely available and easy to plant and process. Nigeria is one of the leading producers of cassava. According to FAO (2015) statistics; Nigeria cassava production is by far the largest in the world; a third more than production in Brazil and almost double the production in Indonesia and Thailand. Ukpongson *et al* (2011) postulated that the concept cassava processing and value addition entails the special treatment of the cassava root before it is consumed to make it last longer. Traditionally, cassava is produced on small-scale family farms. The roots are produced and processed as a subsistence crop for home consumption and sometimes for sale in village and urban markets. The presence of high level of hydrogen cyanide (HCN) in roots of bitter cassava makes processing indispensable before cassava can be consumed by human being. Consequently, processing operation in cassava has essentially created an array of opportunities for enhancing the worth, quality and usefulness of primary products of cassava. Thus, the processes of enhancing cassavas worth, quality and usefulness is called value addition. Lawal and Jaiyeola, (2007) opined that value addition improves the shelf life of agricultural products and generates income for participants. Since most government interventions and policies are aimed at integrating the rural poor into the mainstream of the economy, one of the ways of achieving this is by adding value to their produce. Despite been the world biggest producers of cassava, Nigeria have not fully the tapped the potentials embedded in cassava production. Nigeria still imports starch from other countries and the local production is not sufficient for local production and thus the country has little to nothing left for export. The economic situation in Nigeria which is on a sprinting run to depression has made the cost of living very high. The price of food commodity is on a steady increase. This trend has pushed most farmers to add value to their products in the bid for the products to command a high price and compete favourably in the market. The tries to examine the value added products predominant in the study area; its cost and return and also determinants of value addition in the study area.

MATERIALS AND METHODS

STUDY AREA

The study was carried out in Ikwuano Local Government Area of Abia State, made up of four clans which comprise several villages/communities. These clans include: Ibere, Ariam, Oloko and Oboro. Each of these clans is made up of four autonomous communities.

Sample size and method of data analysis

Multi-stage random sampling technique was employed in the research. First, 4 of the autonomous communities were selected. A list of cassava value-added products consumers were compiled with the aid of the Abia. ADP Extension Agents in the area. Finally, 15 cassava value-added products marketers were chosen randomly from each of the clan giving a sample size of 60 respondents. Sampling was conducted without gender discrimination and replacement. A well-structured questionnaire was used to elicit information from the farmers.

Method of Data Analysis

Objective one was analyzed using descriptive analysis; objective two was analyzed with profitability analysis while multiple regression was used to analyzed the last objective. The multiple regression analysis is stated implicitly as follows;

$Y = F(X_n)$

$Y = F(x_1, x_2, x_3, x_4, x_5, x_6, e)$.

Where

Y = value added. (#)

X_1 = gender (male=1; female=0)

X_2= household size (number)

X_3 = education (years spent in school)

X_4 = labour (naira)

X_5 = extension (number of visits)

X_6 = experience (years)

X_7 = cooperative membership(yes=1; no=0)

X_8 = access to credit (amount recieved)

X_9 = cost of processing equipments

RESULTS AND DISCUSSION

Cassava value added products predominant in the study area

Table 1 show the value added products mainly produced in the area. Multiple responses on various value addition on cassava by farmers in the area. The result indicates that all the farmers 100% transform their cassava into garri in the area. This is no surprise as garri is a major household food which is consumed daily because it's readily availability and low cost. Fufu production followed with a proportion of 80%; 50% of the farmers produced abacha, 25% of the farmers engaged in cassava starch production and marketing, 16.7% added value to transform cassava into flour, while the least proportion of 5% were farmers who produced chips from cassava. This result shows that garri and fufu constitutes over 65% of the total products from cassava in Ikwuano L.G.A. Thereby paying a minimal attention to other possible value added products from cassava, such as cassava cakes, cassava salad creams, alcohol and pharmaceutics.

Costs and Returns analysis on value added cassava products

This section discusses the costs and returns to major products from cassava processing in the study area. The costs and returns to cassava processing are as presented in Table 2. Results from the Table shows that Garri production incurred the highest cost of production when compared with other valued added products at N262305 with cost of cassava accounting for 66.8% of the total cost of production. This is followed by cost of labour, fire wood purchased and transportation accounting for 19%, 7% and 5% respectively. The total revenue gotten from Garri production was N345208. Return on investment shows that 1 naira invested will yield 1.31 per naira invested. This shows the profitability of garri in the study area. For Fufu production, the total cost of production was 183780 which comprise cost of cassava at 70% of the production cost, labour at 14% and fire wood accounting for 7% of the cost of production. The total revenue from Fufu production was N254789. Value added cassava (Fufu) will yield 1.38 per naira invested in the study area. Abacha production in the study area had the least cost of production at N128647 with cost of cassava at 69% of the total cost of production, labour at 12%, transportation cost at 8% and cost of fire wood at 6% of the total cost of production. Abacha had the least return on investment when compared with other valued added products but it was still profitable with 1.16 returns for every naira invested. The results further show that, the cost of cassava is bulk of production cost for Garri, Fufu and Abacha respectively. This comes as no surprise as cassava is the raw material for production. Most of the respondents do not cultivate cassava but buy from the farmers who factor in their cost in the price and the cost of living in Nigeria is on a steady increase. From the table it was observed that Garri was the most profitable of the value added cassava products with net returns at N82903.Garri is an integral part of every household diet in the study and Nigeria at large because it is cheap, readily available and it is complementary to most dishes prepared in the study. This was in accordance with the findings of Muhammad-Lawal *et al* (2013) Achem *et al* (2013) who found garri to be more profitable when compared to other value added cassava products in Kwara state. The return on investement shows that all the three value added cassava products were profitable in the study area with abacha having the least return on investments.

Profitability determinants of cassava processing in the study area

The result of the regression shows that the semi-log functional form had the line the line of best fit among others. This is because it had the highest F- ratio of 2.785 which means the variables in the model have the line of best fit. Also, the semi-log was chosen because it had the highest coefficient of determination (R^2) at 0.635 which means that 63% of the variation on returns of fish farmers was explained by the independent variables in the model.

Household size was positively related to profit of value added cassava products at 10% level of significance. This implies the higher the higher the household size, the higher the profit. This comes as no surprise as high household size is a proxy for cheap labour as everybody contributes in the farm work and this reduces the amount spent on hired labourers. Education was significant and positively related to profit of value added cassava products at 5%. This positive relationship is as a result of the farmer's education which has broaden his horizon and increased their quest for new ideas, varieties and methods that will improve production and the need to add value to his product offering in other to make his products attractive and increase his returns. This result is in accordance with the findings of Ehinmowo *et al* (2015) who discovered that education increases the profitability of farmers in Ondo, Oyo and Ogun state. Number of extension visits was negatively related to profit at 5% level of significance. This means the lower the number of extension visits, the lower the profit. It suffices us to say that due to the fact that there is little or no extension visits from the extension agents, the farmers are not educated on ways to improve on their value addition technique, improved methods of production and this reduces the returns of the farmers. The result was in line with the findings of Onyemauwa (2012). Experience was negatively related to profit at 5% level of significance. This is against the apiori expectation of a positively relationship. This might as a result of most farmers holding tenaciously to old ways of production which might increase the cost of production and lead to low profit. Also, lack of extension contact in the study area might have an effect on the use of obsolete and orthodox production process to add value to products. Access to credit was significant at 10% and negatively related to profit. The high the cost of borrowed fun, the lower the profit. High Interest rate charged on the borrowed fund eats deep into the profit and as such reduces the profit. The high interest rate charged are caused by high defaults rate by the farmers, lack of collateral and the high volatility associated with agriculture.

CONCLUSION

This study was designed to examine the profitability analysis of value addition on cassava products in Ikwuano local government area of Abia state. The result showed that Garri was the most profitable when compared with the other value added cassava products in the study area with net returns of N82903; followed by Fufu with N71009 as net returns. Household size and education were significant and positively related to profit while experience, extension visits access to credit were significant and negatively related to profit of value added cassava products. The recommends that small scale entrepreneurs should seize the opportunities offered by cassava processing as a means of income diversification, more extension agents should be trained to help increase the extension network in the study area to teach farmers on new methods of value addition and usage of modern equipment and Government and development agencies should organize sensitization programmes for cassava processors on the potentials that exist in the new emerging markets for cassava products.

Table 1: Characterization of cassava value addition levels

	Frequency	Percentages (%)
Garri	60	100
Fufu	48	80
Starch	15	25
Abacha	30	50
Flour	10	16.7
Chips	3	5

PRACTICE THEORIES OF MOTIVATION AND EMPLOYEE PERFORMANCE: A REVIEW

E. Usim

Department of Agribusiness and Management, Michael Okpara University of Agriculture, Umudike, Abia State
usimekeke@gmail.com

ABSTRACT
The paper reviewed practice theories of motivation and employee performance with focus on examining to an in - depth extent the concept of motivation and its relationship with performance. It evaluated a number of motivation theories such as performance management theory by Taylor, reinforcement theory, expectancy theory, goal theory to mention but a few. Critique and descriptive approach were employed as method of analysis. The paper concludes by enumerating available motivational packages that will enhance performance both at employee and organizational levels.
Keywords: Motivation, theories, employee performance

INTRODUCTION
Motivation is a theoretical construct used to explain behavior. It represents reasons for people's action, desires and needs (Elliot et al, 2001). It is a goal directed behavior. This implies that motivation takes place when people expect that a given course of action is likely to lead to the attainment of a goal or a valued reward which satisfies their particular needs (Porter, Lawler, 1968). In other words, when a clearly and perceived valuable relationship exists between performance and outcome and the outcome is seen as a means of satisfying need, motivation takes place (Vroom, 1964). The level and extent of motivation has a direct effect on performance. This implies that a well-motivated workforce has a clearly defined goal and takes actions which they expect will achieve those goals (Erez and Zion, 1984). This understanding underscores the roll of human resource management function of performance management that aims at a targeted level of production or performance. By implication, the function of directing and controlling will not only aim at target production, but also on how or what will motivate employees to achieve set targets. Motivation is a critical factor in organizational performance given its essence of promoting commitment and initiative amongst employees. This can eventually translate into achieving a desired share of the market. However, to sustain a given level of performance, motivation should be geared towards inculcating organizational values, culture, tone and purpose to the employees. It is also a process of stimulating a voluntary and purposive action towards achieving the organizational goal(s). An employee can willingly undertake a designed course of action if his personal goal(s) is achievable with the same purposed action undertaken. This means achieving both organizational and personal goal within the same process (Zafron et al, 2009). Motivation packages must be defined, understood, and enticing to prospective recipient for him to strive to meet the expected target. However, what constitutes appropriate motivational packages or practice that can enhance employee performance or evokes differences of views among scholars, depending on which angle of man's need satisfaction or goal attainment he chooses to discuss. The question is which motivation practice or package can motivate employee to performance. Seeking to answer the arising questions, we shall review the opinion of some motivation practice theorists as to guide us to propose motivational practices or packages that can enhance employee performance.

Theoretical Review of Motivation
Fredrick Taylor (1856 – 1917) postulates performance management theory and it asserts that what will motivate a worker to higher performance includes provision of appropriate training and tools, financial reward and repetitive performance on the same or similar tasks. He emphasized on money as the most veritable motivator as workers are to be paid according to the level of their output. Taylor's theory is related to incentive, reward, and Hum's reinforcement theories. Herzberg (1957) described money as not a satisfier, though its presence is necessary. He further argued that though lack of money can cause dissatisfaction, but its provision does not result in lasting satisfaction either. He rather identified job enlargement, job enrichment and the empowerment of the employee as the real motivators of performance. Maslow (1954) considered money at the lowest level of his need hierarchy. He postulates that human needs are in a hierarchy and a satisfied need can no longer be a motivator. Each of the needs requires entirely a different motivator from another. For example a satisfier for food or safety cannot be a motivator of esteem or self-actualization. Interestingly, Goldthorpe et al (1968) research into the ''affluent worker'' tends to support Taylor's postulations by positing that, the dominant factor in the choice of employer and consideration of pay seem most powerful in binding people to their present job. Vroom (1964) expectancy theory linked performance to motivation as he posited in his three component expectancy theory that a person's belief that if his performance reaches expectation, he will receive a commensurate reward. Or the result of his effort will achieve him the adequate reward or goal attainment. Elton Mayo (1927) Heathron electricity

company experiment on motivation to performance proved that the factor that can influence productivity is relationship. He asserted that, if employees receive special attention and are encouraged to participate; they perceive their work has significance. They will therefore be motivated, provided, there is efficient communication feed-back system. Nevertheless, the other side of the argument is that some may misconceive their importance and constitute themselves into a log in the wheel of progress.

Edwin Locke proposed goal theory states that motivation and performance will be high if individuals are set specific goals which are challenging, but accepted. The goal setting theory of motivation (Locke and Ladham, 1968; 1990) explained that goal specification increases the desire to perform better. Challenging task when accepted results into higher performance than easy tasks. The main strands of goal theory are that, there must be optimal level of challenge, goal clarity, feed-back on activity or performance.

Intrinsic and Extrinsic Motivation

Behavioral theorists believe that understanding what stimulates desires, wants or curiosity can lead to determining what motivates employee performance. Motivation could be intrinsic, extrinsic or both. Pardee (1990) explained intrinsic motivator as the desire to seek out new things and new challenges, to experiment and gain knowledge. It is a drive by the enjoyment of a task that exists within an individual rather than relying on external pressure or desire for a reward. While extrinsic motivation refers to external drive to performance in order to attain a desired outcome (Ryan et al, 2000). Extrinsic desire is prompted by reward or what one wishes to gain or achieve; Mwita (2002) emphasized that extrinsic motivator can have a powerful effect but cannot last long. Unlike intrinsic, extrinsic desire is measured and driven by forces of what one thinks he can gain. The task or goal might not be enjoyable but the reward can attract one to undertake it. Employee who is intrinsically motivated is more likely to engage in the task willingly as well as work to improve his skills which will improve his capabilities (Wigfield et al 2004). Extrinsic motivation is used to attain outcomes which a person would not get from intrinsic motivation. This includes money, grades, promotion etc (Ryan, 2000). A manager's understanding of the role of intrinsic and extrinsic motivation in behaviorial pattern can effectively exploit both to select and apply appropriate motivational packages that can make task enjoyable, and at the same time afford reward or compensation for accomplished task(s).

Motivational Practice That Can Enhance Performance

Scholars of performance management agree that motivation can enhance performance but the challenge has always been choice and application of the appropriate motivational practice or package that can enhance performance. The administration of the appropriate motivational packages is a function of the type of organizations policy, strategy and managerial competencies. Policy is a blue print provided by the top management of an organization directing how the organization's activities and other related matters will be handled. It draws from the vision and mission of the organization to direct on the expected required tone, culture, process and span of control within the organization. The strategy defines the goals, objectives and the means of achieving them. Both policy and strategy need not be static but require periodic review in line with the unfolding economic and social developments within and outside the organization. Verhellam (1994) argued that motivation strategies should aim at creating a conducive working environment and develop policies and practices that will provide for higher level of productivity and thus performance from employees. Strategy must be all inclusive and employee friendly. This means creating an atmosphere of mutual trust amongst various groups, individuals and the organization. Encourage constant interaction between managers and subordinates with a view to locating individual and general needs of the employees. A progressive, easy to understand, transparent policy/ strategy will create the necessary atmosphere for performance; An environment where everyone knows what he requires to accomplish task before him and the reward for performance or what attracts sanctions. Company Strategy/ policy should create room for employees to express their initiative and innovative ideas. It strengthens commitment and desire to do more. The manager who implements the policies and strategies should be competent, impersonal and knowledgeable enough to know how best he can motivate his employees given the psychological and physiological status of the employee and the available incentives, rewards or personal goal attainment. He must have the will to equitably dispense compensation and justice According to Tarkenson (1986), the manager will be concerned with measuring motivation to provide an indication of areas where motivational practices need to be improved; ensuring as far as possible that employees feel, they are valued, improved leadership skill, job designs, compensation and reward management and the application of behavioral modification approaches.

DETERMINANTS OF INNOVATIVENESS: THE CASE OF SMALLHOLDER RICE FARMERS IN NORTH-EASTERN NIGERIA

J. F. Shehu[1], A.S. Gaya[2], S. I. Mshelia[1] & E.F. Adebayo[1]

ABSTRACT
This paper sought to identify the determinants of innovative behaviour among rice producers in North-Eastern Nigeria. Cross sectional data was collected from a sample of 270 rice farmers during the 2013/2014 cropping season using interview schedule. Descriptive statistics and logistic regression were used as analytical tools. The results revealed that adopters of modern rice production technologies obtained significantly higher yields than the non-adopters' counterpart. Also, significant differences existed in the two adoption status in terms of farmers' income and literacy level. However, no significant differences were found with respect to household size and farming experience between adopters and non-adopters. Furthermore, farm income, access to information, access to credit, literacy level of the decision maker, family size and membership of cooperative societies significantly influenced innovative behaviour of the farmers. It was concluded that knowledge of households' socio-economic and institutional attributes is invaluable when designing and targeting technologies for smallholder farmers. Policies that will ensure continued access to credit facilities and effective extension system should be vigorously pursued.
Keywords: Innovativeness, Rice Farmers and North-Eastern Nigeria

INTRODUCTION
Nigeria has made substantial investments in agricultural research and extension to increase agricultural production through new technologies. Despite considerable technological change however, agricultural production in this country continued to encounter substantial inefficiencies due to farmers' unfamiliarity with new technology, poor extension and education services, and infrastructure, among others (Shehu, *et al.*, 2007). The slowdown in agricultural productivity growth along with pressures to reform rural research and development (R&D) policy in Nigeria could be said to have escalated interest in finding ways to improve productivity, including through enhancing farmers' innovative capacity. Despite the seemingly simple link, the successful translation of R&D to improved farm productivity depends on many factors. In particular, much relies on farmers' capacity to adopt suitable innovations and successfully integrate them into existing farming systems. A broader understanding of innovative capacity and its contribution to farm innovation adoption and productivity growth can also aid in evaluating policies and investment decisions aimed at improving productivity growth. This study, therefore, was designed to examine innovative (adoption) behaviour among rice farmers in North-Eastern Nigeria. The specific objectives were to: compare the socioeconomic attributes of adopters and non-adopters of modern rice production technologies; identify factors that influence the farmers' innovative (adoption) behaviour towards modern rice production technologies in the region; and

METHODOLOGY
The study was carried out in North-Eastern Nigeria. Purposive and Multi-stage random sampling techniques were used to select respondents for this study. Cross sectional data was collected from a sample of 285 small scale paddy rice farmers on their household production activities during the 2013/2014 cropping season. However, only 270 were correctly filled and hence analysed.

Analytical Techniques
With the aim of achieving the objectives of the study descriptive statistics and binary logistic regression were used as analytical tools.

The empirical Logit Model
The Logit model was used to achieve objective 4 of the study. The empirical model is specified thus:

$(Y_i = 1/X_{ij};\ j = 1 \text{ to } 8) = F(Z_i) = 1/1+e^{-zi} = e^z/e^z + 1;\ i = 1 \text{ to } 270$ *1*

Where $Z_i = (\alpha, \beta_1 X_1, \beta_2 X_2, \ldots\ldots., \beta_8 X_8, \varepsilon)$

F(.) = Cumulative logistic function

Z_i is a theoretical or unobserved or an unobservable variable, that is, although X_i's was generated from the field, the β_i's are not observable. In order to obtain the values of Z_i, the likelihood of observing the sample needs to be formed by introducing a dichotomous response variable Y_i such that

$$Y_i = \begin{cases} 1 \text{ if the } i^{th} \text{ farmer is adopter of modern rice production technology *} \\ \end{cases}$$

0 if the i^{th} farmer is non-adopter of modern rice production technology
X_{ij} is the j^{th} socio-economic and institutional attributes of the i^{th} farmer as contained in Table 1
B_1 to β_8 are parameters to be estimated
α = constant term
ε = disturbance term assumed to have zero mean and constant variance.

Measuring innovative behaviour

The measure of innovative effort developed for each farm was based on the number and extent of innovations (production recommendations) that each farmer had adopted (during the 2013/2014 cropping season). Given that nearly all the farmers had adopted partially or fully at least one innovation (improved seed varieties, fertilizer, herbicide and/or insecticide), they were grouped into two categories of innovativeness: non-innovators (non-adopters) and innovators (adopters). If a farmer fully adopted three innovations, the farmer is regarded as an innovator (adopter) otherwise s/he is a non-innovator (non-adopter). Based on the foregoing, 100 farmers were classified adopters and 170 as non-adopters. This provides a useful basis for empirical analysis of the underlying factors that might contribute to a farmer's innovative capacity or willingness to innovate (adopt).

Determinants of Adoption (innovative) Behaviour

Several studies have indicated that the adoption of improved agricultural technologies are affected by many factors such as farm size, age, family size, education, availability of credit, access to information among others (Yishak, 2005; Taha, 2007). Researchers and institutions both within and outside Nigeria have conducted a number of empirical studies on the adoption behaviour of farmers. For ease of clarity the variables often identified as having relationship with adoption of agricultural technologies could be categorized as household personal and demographic variables (e.g., age, farming experience, household size, level of education, gender), economic factors (farm size, farm and non-farm income) and institutional factors (extension contact, access to credit, distance from market).

RESULTS AND DISCUSSION

Descriptive statistics of the socioeconomic and production factors

A summary of the some socioeconomic attributes of the sampled rice farmers is presented in Table 2. The results indicated that there were significant differences in farm income, education and extension contact between the two adoption status of rice producers at 5% level. Furthermore there were no significant differences between adopters and non-adopters in terms of age, household size and farming experience.

Determinants of innovativeness towards modern rice production technologies

Explanatory variables that were selected for econometric model were discussed based upon the model output. Accordingly, as indicated in Table 3, about 96 % of the total variation for the modern rice production technique is explained by logistic model. The $\chi 2$ result which is significant (P<0.001) shows that the model fits the data. The model correctly predicted sample size of 95 % and 96.5% for adopters and non-adopters, respectively. The odds ratio [Exp(B)] for this variable was 2.261 (Table 3), which suggest that farmers who had more contact with extension agents are more than two times likely to adopt modern rice technologies than those with no access to extension agents. Income derived from the farming activities indicates the level of profit of the farmers. The expectation is that farmers will have as much capital to plough back into the production process in order to increase profit. The results in Table 3 indicate that income was positive and significant (P<0.001). The implication of this finding is that farmers with good returns from their production activities are more likely to be able to afford and apply expensive inputs aimed at increasing productivity. The results in Table 3 revealed that access to information defined by number of visits by the extension agents to farmers significantly (P<0.001) affects adoption of modern rice production technologies. The positive and significant coefficient of access to information could be attributed mainly to the fact that knowledge gained from the contacts with extension agents by the farmers' influence them to adopt new technologies. This is in consonance with the findings of Tiamiyu *et al.* (2009) who reported a positive relationship between extension visits and technology adoption among growers of New Rice for Africa (NERICA) in savanna zone of Nigeria. The coefficient of access to credit had the hypothesized positive sign and significant (P<0.001). The significance of the variable stemmed from the fact that agricultural credit is a basic tool of production which provides farmers with additional source of investment in modern production technologies. The more access farmers have to credit facilities the higher the likelihood that they may adopt modern technologies recommended to them. The positive effect of the variable on adoption is a reflection of ability to purchase productive inputs for farming activities. This concurred with studies by Foti *et al.* (2008) who reported a positive relationship between farm size (taken as a surrogate for wealth and access to credit) and the adoption of selected soil fertility and water management technologies in semi-arid Zimbabwe. Literacy level had a positive coefficient and significant at 5% level. This conformed to *a priori* expectation. This is in consonance with the findings of Lawal *et al.* (2004) who reported positive and significant relationship between education and adoption of improved maize varieties among smallholder farmers in southwestern Nigeria. This shows that being literate farmers easily understand and analyze the situation better than illiterate farmers. Another explanation could be, the more years of formal schooling farmers had, the better enlightened they become and subsequently the easier it becomes for them to better understand and adopt production recommendations. As shown in Table 3, the coefficient of family size, which is defined by the number of people in a household had negative coefficient and statistically significant at 5% level. The negative coefficient of family size could be as a result of low adult ratio in the sampled households. The significance of the variable could be explained by the fact that labour is an important input in rice production. Membership of cooperative society had positive and significant ($p<0.05$) influence on adoption behaviour of the sampled farmers. The result is in agreement with that reported by Mihiretu (2008). Adoption of modern rice technologies could be motivated by belonging to a cooperative society. Cooperative membership popularizes innovation by making farmers exchange ideas, experiences; and makes it cheaper to source information, knowledge, and skills in order to enable them improve their livelihoods.

CONCLUSION

It was concluded that knowledge of households' socio-economic and institutional attributes is invaluable when designing and targeting technologies for smallholder farmers. Therefore, efforts geared towards ensuring that loans and other credit facilities are made available to the smallholder farmers at minimum interest rates. Also, there is need for the revitalization and priority funding of the extension delivery activities of the States' Agricultural Development programmes (ADPs). This is crucial for increased rice production in the country.

Table 1: Description of variables in the logit model

Variable	Variable code	Description and unit	*a priori* expectation
Income	INCOME (X_1)	Revenue from previous harvest farm (Naira)	+
Access to information	INFO (X_2)	Visit by extension worker (number of visit)	+

EFFECT OF CASSAVA-BASED TECHNOLOGIES ON THE WELFARE STATUS OF FARMERS IN IMO STATE, NIGERIA

E.O. Mbanaso & A.G. Ironkwe

Extension Services Programme, National Root Crops Research Institute, Umudike
eombanaso2013@yahoo.com

ABSTRACT

The study appraised the effect of cassava-based technologies on the socio-economic status of farmers in Imo State, Nigeria. Using the multistage sampling procedure, 144 farmers were randomly selected from two of the agricultural zones in the State, namely, Owerri and Okigwe. Data were collected using the structured interview schedule and analysed with the aid of descriptive statistics like percentages. Results show a high level of awareness for all the technologies except TMS 4(2) 1425. There was, generally, low level of adoption of the technologies. Only TMS 30572, NR 8082 and cassava/maize/melon intercrop had adoption levels of 60% and above. These technologies enabled the farmers feed their households, pay children's school fees, purchase clothes, acquire landed property and pay medical bills. There is, therefore, need to identify and address the factors constraining increased adoption of these technologies by farmers in Imo State.

Keywords: Cassava varieties, technologies and Imo State

INTRODUCTION

The main purpose of developing relevant agricultural technologies is to improve the livelihood of the end-users (Ironkwe, 2011). This necessitates the need to carry out impact studies some years after the technologies have been disseminated to assess the extent this purpose is being achieved. National Root Crops Research Institute (NRCRI), Umudike, has disseminated several technologies on root and tuber crops production. This action is geared towards increasing the productivity and income of the farmers to enhance their standard of living. This study was, therefore, conducted to ascertain the adoption level and assess the effect of the cassava-based technologies on the socio-economic status of the farmers in the South-east agro-ecological zone of Nigeria to whom the technologies were disseminated.

METHODOLOGY

The study was conducted in Imo State, Nigeria. Using the multistage sampling procedure, 144 farmers were randomly selected from two of the agricultural zones in the state, namely; Owerri and Okigwe. Data were collected using the structured interview schedule and analysed with the aid of descriptive statistics like percentages.

RESULTS AND DISCUSSION

Levels of awareness and adoption

As shown in Table 1, all the technologies except TMS 4(2)1425 (29.86%), had high levels of awareness. Cassava variety NR 8082 had the highest (98.61%) level of awareness. This was followed cassava/maize/melon intercrop (95.14%), cassava variety TMS 30572 (93.06%), cassava/maize/cocoyam intercrop (76.34%) and cassava/maize/melon/okro intercrop (73.56%). Others were odorless fufu (69.40%) and cassava flour (61.07%). With regard to adoption; the greatest (93.75%) proportion of the respondents adopted cassava variety NR 8082. Followed by cassava/maize/melon intercrop (79.18%), TMS 30572 (65.99%), TMS 4(2)1425 (65.00%), cassava/maize/cocoyam (53.50%), odorless fufu (53.50%) and cassava flour (50.73%). The least adopted was cassava/maize/melon/okro intercrop (44.48%). This means that high level of awareness does not necessarily entail high level of adoption. TMS 4(2)1425 which had the least (29.86%) level of awareness had adoption level of 65.00%, whereas cassava/maize/melon/okro intercrop with awareness level of 73.56% had the least (44.48%) level of adoption.

Socio-economic benefits

Table 2 revealed that the adoption of cassava-based technologies disseminated to the farmers helped to their socio-economic status in terms of provision of food, money and employment. Most of these technologies provided both food and money; none of them provided solely food or money. Subsequently, TMS 30572 provided food and money to all (100.00%) the respondents who adopted it. NR 8082 provided both food and money to 90.91% of the respondents and cassava/maize/melon intercrop to 73.56%. Similarly, TMS 30572 provided employment to 90.91% of the respondents, NR 8082 to 70.79% and cassava/maize/melon intercrop to 69.40%.

Tangible achievements through the cassava-based technologies

Table 3 showed tangible achievements made by the respondents through the adoption of the technologies. About 90% of the respondents had adequate food for their families through these technologies, 80.60% were able to take care of their children's education, 73.60% purchased clothes while 70.00% were able to acquire new property. The cassava-based technologies were able to help 69.40% of the respondents provide medicare to their families and 56.70% were able to purchase vehicles (cars and motorcycles) while 50.70% were able to purchase radios and televisions.

CONCLUSION

There was high level of awareness in almost all the technologies except in TMS 4(2)1425. However, this high level of awareness could not be translated into corresponding high adoption levels as most of the technologies recorded low rates of adoption. This result is in agreement with Ekwe *et al.* (2009) and Ironkwe *et al.* (2009). The adopted technologies had relatively significant effects on the socio-economic status of the farmers in the study area. It is recommended that increased efforts be made by the extension agency in the zone to enhance adoption of these technologies through intensive promotional campaigns. Other factors limiting adoption of the technologies should be identified and addressed to increase adoption.

Table 1: Distribution of respondents according to levels of awareness and adoption of improved cassava-based technologies

Technologies	Not aware	Aware	Not adopted	Adopted
TMS 30572	6.94	93.06	34.01	65.99
NR 8082	1.40	98.61	6.25	93.75

INFLUENCE OF APPRAISAL ON EMPLOYEE PERFORMANCE AMONG AGRIBUSINESS FIRMS IN ABIA STATE, NIGERIA

E. Usim

Department of Agribusiness Management and Entrepreneurship, Michael Okpara University of Agriculture, Umudike
usimekeke@gmail.com

ABSTRACT
This study analysis the influence of performance appraisal on employee performance among agribusiness firms in Abia State, Nigeria. Multistage sampling technique was employed in the selection of the locations (Abia, Ohafia, Umuahia Agricultural Zones) and a sample of 120 respondents. Correlation analysis was used to analyze and predict the relationship that exists between performance appraisal exercise and employees performance. The outcome posts a weak and inverse correlation relationship (-0.167) at 10% level of probability. It is an indication that the exercise makes an impact of approximately 17%, with both variables moving in opposite directions, suggesting that performance appraisal has negative effect on employee performance. This could be probably because the appraisal system in use was secret. It is recommended that management should replace secret appraisal system with open approach to show more transparency and also encourage team work through policy reengineering.
Keywords: Appraisal, Performance, Employees and Agribusiness Firms

INTRODUCTION
Organizations are very concerned about the development and orientation of their employees in a bid to enhance their productivity. This concern is hinged upon the realization of the fact that, organizations can only win a competitive advantage through people especially in the face of stifling competition for scarce resources (Obisi, 2011). The implication is that organizations can grow to the extent of quality of skill and knowledge of the people who work in them. In this regard, an organization is expected to encourage shared vision between itself and the employees by continuously reviewing and improving the knowledge and skills of the employees. In the same vein, they should recognize individual efforts and contributions through rewards, incentives and conducive working environment. A shared vision is such that convinces the employees that the success or failure of the organization is same as theirs. According to Zafron et al (2009), it may be possible to get all employees to reconcile personal goal with the organizational goal, thereby increase productivity. Employee performance appraisal is the act of evaluating performance during a given performance period to determine how well an employee has performed relative to agreed objectives or goals. It is a process that examines the record of outcomes of a specific job function or activity within a specified time frame (Bartol et al 1998), as to ascertain the degree at which they accomplished their work requirements (Milkovich and Broudereau, 1999). The essence is to identify employee requirements or needs with the objective to help him perform efficiently and effectively. Organizations may employ open, secret or open/secret appraisal methods. However, the present study showed that majority of the firms used secret evaluation method. Performance appraisal has become popular among organizations and employees of labour. It is considered as an important aspect of human resources management and a part of control process in administration (Kavassishal, 1999). Many organizations spend a lot of resources annually on this exercise with a view to achieve a high organizational culture standard of performance (Cumming, 1972). According to Mirsepassi (1998), the present appraisal system is window-dressing and may not lead to expected result. It wastes the managers' time as a mere formality. Many managers are incapable of managing the appraisal system resulting into even creating more problems in job assignment, promotion, transfers or dismissal, and inability of the appraiser to conduct free and fair appraisal exercise (Zarra zacheh, 1997). Among managers and employees, there is a mistrust of the system as some managers see it as a threat to their position, while many employees do not believe in it (Igwe, 2012). In 2006, Nigeria introduced performance appraisal system into the civil service with a view to enhance productivity of employees. A report on the implementation of staff appraisal in 2008 on the progress made and challenges faced upon introduction of the appraisal system into the state civil service was released. It highlighted the challenges the appraisal system is facing but fails to provide findings on the impact of the exercise on staff performance. Other reports and studies on performance appraisal system provide unclear indication on the impact of performance appraisal system on staff performance. From the forgoing, it is obvious that there is a controversy over the performance of the appraisal system. Available information on the performance of the system shows efforts made on introducing the system, the challenges and benefits of the system. However, little or nothing has been done to empirically verity the impact of performance appraisal system on employees performance. This study therefore investigates if any relationship exists between performance appraisal and employees performance.

METHODOLOGY

The study employed multistage sampling technique to obtain data from respondents within the 3 agricultural zones of Abia State (Aba, Ohafia, Umuahia). From a population of 210 agribusiness firms, 40 were randomly selected irrespective of their investment capacities. This gives a total of 120 respondents. The study employed Spearman's Rank correlation analytical tool for to analyze the stated hypothesis: Performance appraisal has no significant effect on employees performance, while descriptive statistics was used to analyze and determine the type of appraisal system that is in use.

$$r^2 = \frac{\sum 1-6ED^2}{N(n^2 - 1)}$$ where: r^2 = rank correlation efficient

$\sum$ = summation
D = Difference between ranks of corresponding pairs of X and Y
Xi = performance appraisal (confidential = 1, semi-secret = 2, open = 3)
Yi = employee performance proxied by remuneration ranked into low, medium and high incomes.
N = number of respondents.

RESULTS AND DISCUSSION

In addressing the objective on the effects of performance appraisal on employee performance, Spearman's correlation analysis was used and the result is as presented in the Table 1. The result showed a correlation coefficient of -0.167 and significant at 10% level of probability. The coefficient portrays a weak negative correlation; it implies that performance appraisal exacts a negative effect on employee performance. In other words, both variables tend to change together in the opposite directions. The use of confidential evaluation system by the majority of the agribusiness firms is not a healthy trend because it demoralizes the workforce and creates room for feeling of dissatisfaction. This might have contributed immensely to low output and productivity observed in the agribusiness sector. Field work data collating and interpretation shows that majority of the firms adopted the confidential (secret) appraisal system.

CONCLUSION

Open appraisal system is recommended. This gives employees opportunity to assess their performance with their supervisors. Or even comment on their scores for a senior manager to look into. Managers should be transparent, set and maintain a good cultural standard that will instill confidence in the system and create a learning organization within the firms. This is achievable through policy reengineering.

ABSTRACT
This study investigated the determinants of loan repayment performance among women farmers in Bende local government Area, Abia State, Nigeria. Primary data were collected from 100 women farmers who accessed loan in Institutional credit through purposive and random sampling techniques; tools used for the analysis were descriptive statistics such as mean, percentage, frequency, table and multiple regression analysis. The result of the socio-economic characteristics of women farmers' shows that 93.0% within the age range of 30-60years are energetic and active productive work force, 52.0% of women farmers are married, had a moderately mean household size of 6 persons per household. About 97.0% of the women had formal education and 76.0% had between 11-20years of farming experience. They had small farm sizes (87.0%), low monthly income (50.0%) and without collateral (68.0%). Regression results reveal that the coefficients of loan amount and distance were directly related to loan repayment at 1% level and education and farm income at 5% and 10% level respectively. the coefficient of age had an indirect relationship with loan repayment at 1% level. The study therefore recommends that Government should review policies that will improve the level of Education in the Rural Area thereby enhancing the level of awareness of loan repayment, also the income of farmers should be considered when the giving out credit in order to ensure repayment.
Keywords: Loan Repayment and women farmers

INTRODUCTION
The Nigerian economy is still predominantly agrarian and women are key players in the business of agriculture especially with rural women in agricultural production and processing. Traditionally, capital for investment in agriculture comes from two potential sources, namely personal savings of the farmers and farm credit borrowing. Henri-Ukoha *et al.,* (2011), noted that farmers are expected to pay the principal with the accompanying interest on their basis of their repayment performances. It is important that borrowed funds be invested for productive purpose and the additional income generated, be used to repay loans to have sustainable and viable production processes and credit institutions. However, failure by farmers to repay their loans on time or to repay the loan at all has been a serious problem faced by both agricultural credit institutions and small holders who have limited collateral capabilities. The problem of poor repayment of credit by rural women has been confirmed by various authors. Lawal *et al.,* (2009) noted that poor repayment of farm credit creates set back to productivity of rural women. Nto and Mbanasor (2008) observed that the ability of borrowers to repay amount of loans collected is crucial for the long term subsistence of the credit institutions. The renewed focus on agriculture as holding the key to national development in the face of an uncertain and vulnerable oil economy possess a compelling challenge to the rural farmer especially women farmer's access to institutional facilities and their full participation in sustainable agricultural development. Inadequate repayment capacities of farmers are believed to have significant negative consequences to aggregate technological adoption, agricultural productivity, food security, nutrition and health. Many studies have tried to examine loan repayment performance of many social-economic groups considering the socio-economic and environmental peculiarities across region. It is the therefore necessary to evaluate women loan repayment capacity as such this study seeks to investigate loan repayment performance among women farmers in Bende L.G.A, Abia State, Nigeria.

METHODOLOGY
The study was conducted in Bende Local Government Area of Abia State. The Local Government is purposely selected as a study Area because it is noted for high number of women participation in agriculture. The local Government lies between longitude 7°38'E and $7^0$63'E and latitude $5^0$34'N and$5^0$56'N. They produce food crops like cassava, yam, plantain, pepper, melon and vegetables, cash crop such as goat are reared for subsistence and commercial purposes. A purposive and random sampling technique was used in this work. The list of credit institutions registered and functional in the area include; Statesman microfinance Uzuakoli, Item microfinance Item, First Bank Amaokwe Item and United Bank for Africa (UBA) all in Bende LGA. First stage; The list of women farmers beneficiaries from the four banks in Bende L.G.A were assembled. Second stage; Random sampling of 25 women farmers beneficiaries were selected from each credit institution. Third stage; the 25 women farmer beneficiaries make up a total number of 100 respondents. The study was analyzed using descriptive statistics such as means percentage, frequency and table and multiple regression analysis.

Model **Specification for Repayment**

$Y=b_0+b_1Z_1+b_2Z_2$----b_9Z_9+e …………………………………………………………………..(1)

Where;

Y=Loan repayment (N); Z_1=Age (years); Z_2=Educational level (years); Z_3=Household size; Z_4=Farming experience; Z_5=Loan amount; Z_5=Interest rate; Z_7=Farm Association (dummy; 1=yes, 0=no); Z_8=Farm income (N); Z_9=Distance to loan source (km).

RESULTS AND DISCUSSION

This is an indication that the women in the study area were mostly middle aged farmers. The implication is that they are energetic and within the active productive work force, younger people are more energetic and more likely to combine farm and off-farm projects. The active mean age and years can influence adoption of improved production practices, which invariably requires credit. About 52.0% of the women farmers were married, while 38.0% of them were single. This implies that the married women were more involved in farming and thus credit access in the study. Married women are usually involved in this regards as they how best to utilize credit in farming activities and also because of the need to supplement family means of livelihood. The Table also shows the distribution of the women farmers according to household size. Many (50.0%) of the women farmers had household sizes of between 6-10 members. This result implies that these respondents have moderate family sizes. This has implications on labour supply to the farming business to augment family labour with hired labour. In the absence of well-functioning labor markets, smaller households face higher labor bottlenecks at critical points in their business. The Educational level of the women farmers in Bende Local Government Area of Abia State as shown in Table reveals that many (40.0%) women had secondary school education while 3% of them had no formal education. However, 97% of the women farmers in the study area were literate with diverse formal educational levels ranging from primary school education to tertiary education. Literacy (ability to read and write) would enable the women farmers to better utilize effectively and efficiently available resources in the area especially credit availed to them for farm businesses and curtail frivolous spending. As expected, higher education would enhance improved business ideas, skills, innovation and managerial ability for business sustainability. The table also shows that majority(76.0%) of the respondents had between 11-20 years of farming experience, while 10.0% of them had farming experience of between 21-30 years while only 1.0% of the respondents had farming experience of above 30 years. This could be explained by the fact that active mean age and years of experience can influence adoption of improved production practices, which invariably requires credit. The result also shows that the women farmers in the study area were small scale subsistence farmers as they were operating on 1-2 hectares of land. Nigerian agriculture involves small scale farmers scattered over wide expanse of land area, with small holdings ranging from 0.5-3.0 hectares, and characterized by rudimentary farming systems, low capitalization, and low yield per hectare.

Table 2 showed that Double log functional form was chosen as the lead equation for the analysis based on the conformity with a priori expectation of signs, magnitude of coefficients, overall significance of the functional form (F –ratio) as well as the explanatory power of the variables (Adjusted R^2) included in the model. The result revealed that 5 out of the 9 variables were significant. These were age, education, loan amount, farm income and distance of the respondents to credit institutions. The result also shows that education denoted by the number of years of schooling had a positive sign and is significant at 5.0% level. This implies that the higher the education, the higher the loan repayment. Educated women farmers know the implication of loan default. Loan amount had a positive coefficient and is significant at 1.0% significant level. This suggests that loan repayment increases as the size of the loan increases. This is attributable to the advantages associated with economics of scale which emanates from expansion of productions and purchase of farm inputs. The annual farm income of the women farmers had a positive coefficient and is significant at 10.0% level. This is as expected because as farmers' annual income increases, enough income would be available for prompt repayment of the loan. Coefficient for age was significant at 1.0% and negatively signed, implying that the age of farmers had an inverse relationship with loan repayment. The older one gets, the lesser the repayment of the loan considering the fact that older people don't consider the implications of loan default. This is consistent with the findings of Nto and Mbanasor, (2008).

Table 1.0 shows that 7.0% of the women farmers were within the ages of 21 – 30 years while 38.0%, 42.0 and 13.0% were within the age range of 31-40 years, 41-50 years; and above 50 years respectively.

CONCLUSION

Repayment performance among women farmers in Bende LGA is affected by education level of women, loanable amount, annual farm income, age and distance to credit source. Government policy direction should be geared mainly towards rural female farmer education and secondly an increased loanable funds to ensure good repayment performance by the women farmers.

ABSTRACT

The study assessed resource use efficiency of cassava farmers in Atiba Local Government Area of Oyo State. A two-stage sampling technique was employed to select 102 respondents as population of the study. Structured interview schedule was used to collect needed information from cassava farmers. Descriptive statistic was used to describe the socioeconomic characteristics of cassava farmers, budgetary analysis was used to determine the profit margin and Stochastic Production Frontier was used to ascertain the factors that influence technical efficiency of cassava farmers in Atiba Local Government Area of Oyo State. Budgetary result revealed that cassava production is profitable with Gross Margin of ₦34794.55/ha and labour cost constituted 81 percent of the total variable cost of production. Stochastic Production Function result revealed that hired labour and cost of fertilizer have positive significant influence on cassava output at 1 percent and 5 percent significant level respectively. The study recommended provision of machineries and tractors at a reduce hiring rate so as to serve as labour saving techniques in order to reduce the cost of production and improved cassava farmers' profitability.

Keywords: Efficiency, Resource Use and Cassava Farmers

INTRODUCTION

The world largest producer of cassava is said to be Nigeria with other top producers being Indonesia, Thailand, Democratic Republic of Congo and Angola (FAOSTAT, 2012). The large harvest of cassava in Nigeria is attributed to rapid population growth, internal market demand, availability of high yielding improved varieties of cassava tuber, and increase hectare of farm land allocated to cassava in the country. Broadly speaking, cassava growing belts falls within three agro-ecological zones in Nigeria which includes: southwest, southeast, and the north-central regions. Cassava is regarded as famine reserve crop which requires relatively low amounts of inputs (FAOSTAT, 2012).The crop can withstand stress such as drought as it can stay in the ground for several months (Adeyemo et al, 2010). Cassava is available all year round, thus providing household food security (Ogundari, 2007). Although cassava is cheap to cultivate, it can generate good income for peasant farmers (Amos, 2013). It is widely acknowledged that the scope for agricultural production can be expanded and sustained by peasant farmers within the limits of existing resource base and available technology if farm productivity is raised by efficient use of resources (Udoh, 2005). This exposition therefore, forms the fundamental point why the concept of farm efficiency has remained important economic study especially in developing agricultural economies like Nigeria, where resources are meager and opportunities for developing and adopting better technologies are dwindling. Efficiency analysis in agricultural production is generally associated with the possibility of farms producing a certain level of output from a given bundle of resources or certain level of output at least cost (Girei et al., 2014). Also technical efficiency implies the ability of a firm to obtain maximum output from the given inputs. It is the ratio of output to input and the greater the ratio, the more the magnitude of technical efficiency (Ogundari, 2007). However, Resources are said to be efficiently allocated when the value of marginal product of each resource equals its price (Udoh, 2005). Allocative efficiency of resource use is critical to enhanced productivity and incomes (Amos, 2013**)**. The major goal of any production system is the attainment of an optimally high level of output with a given amount of effort or input. Thus, efficient utilization of resources is also instructive in achieving broad-based economic and agricultural growth. Moreover, the term smallholder usually has embedded in it the connotation of limited land availability (Ogundari, 2007). Others sketch a broader view of 'resource poor' farmers, such as those with limited capital (including animals), fragmented holdings, and limited access to inputs. Govereh (2012) identifies eight major types of risks faced by smallholders including production risks, credit risks, income risks, labour and health risks, nutritional risks, price risks, vulnerability to unethical trading practices, and employment risks. In general, land holding is perhaps the most direct and easily introduced indicator of who smallholders' farmers are. FAO (2007) maintains that agriculture is predominantly on a smallholder basis in Nigeria, and about 90% of farm holdings are less than two hectares in size.

Thus, to assess the resource productivity of cassava farmers in Atiba Local Government of Oyo State is one of the prerequisites for increasing agricultural productivity in the study area. The main objective of the study is to investigate the resource efficiency of cassava farmers in Atiba Local Government Area of Oyo State.

METHODOLOGY

The study was conducted in Atiba local government area of Oyo state, Nigeria. It's headquarter is in town of Ofa-meta, it has an area of 1,757km² with an estimated population of 168,246 (2006 NPC). The study area comprises of ten (10) political and six (6) wards were selected randomly for the course of study. Eighteen (18) farming household were randomly selected from each ward to give a total of 102 respondents as sampling population. Primary data were collected with the aid of interview schedule from rural farming household in the study area. Data collected were summarized using mean, frequency count percentage and stochastic production function

RESULTS AND DISCUSSION

Table 1 show the budgetary result for farming system of cassava farmers in the study area. The total variable cost per hectare (TVC/ha) was estimated at ₦217568.8/ha with labour constituting the larger proportion (81 percent) of Total Variable Cost of production. Furthermore, the Total Revenue (TR), Gross Margin (GM) was estimated at 252563.30/ha and 34794.55/ha respectively in the study area. This implies that cassava farmers perform better in terms of Margin between total revenue and total variable cost. Table 2 revealed the parameter estimates of the production function of cassava farmers. The table showed that hired labour and cost of fertilizer have positive and significant influence on cassava output at 1 percent and 5 percent respectively. This was in line with Oladeebo and Oyetunde (2003) which reported that low levels of production in cassava production is associated with capital, labour, fertilizers usage, farm size, and cost of input. The variance parameter for sigma-square for cassava farmers was estimated at 0.322. The sigma-square attests to the goodness of fit and correctness of the distributional form of the model while the gamma revealed the systematic influences that are unexplained by the production function and the dominant sources of random error. This implies that about 32 percent of the variance in output of cassava farmers in Atiba L.G.A is due to the differences in their technical inefficiency.

CONCLUSION

The Stochastic Production Functions shows that about 32 percent of the variation in output of cassava farmers is due to the differences in their technical inefficiency. The study therefore recommends that government should provide agricultural inputs such as fertilizers, agrochemicals, tractors and labour at a subsidized level as this will equally enhances their production.

ABSTRACT
The study was on the effect of socio-economic characteristics on technical efficiency among fish farmers in Adamawa State, Nigeria. The objectives of the study were to: describe the socio-economic characteristics of fish farmers and determine the disparity of technical efficiency among fish farming in Adamawa State. Data were collected using structured questionnaire administered to 150 fish farmers who were sampled using snowball sampling techniques. Data were analysed using descriptive statistics and stochastic frontier production function. The socio-economic result shows that majority of the respondents are married, male civil servants who used their personal savings and were 40 years of age and above, are educated, has less than ten members in their household, provided most of the labour force on their farms and with extension contact more than twice per production circle. The stochastic frontier analysis revealed that the mean technical efficiency is 0.80. The study recommends that; youth and women should be engaged in fish farming, inputs should be supplied at subsidized rate and credits facilities should be provided to fish farmers.
Keywords: Socio-economic, Technical efficiency and Fish farming

INTRODUCTION
Fish farming development at the global level has been viewed as a measure of improving food security and as a means of supplementing income for low income earners. In many countries, particularly in Sub-Sahara Africa, fish farming is almost entirely for subsistence, with little surplus production being sold at farm gate. In Africa; economic analysis in aquaculture is a relatively recent practice and not much work has been reported on its technical, social and economic impacts (FAO, 1996). Meanwhile, various studies as cited by Filli, (2011) confirmed the relative technical efficiency of aquaculture in Nigeria even in the present economic settings. Government investment with demonstration farms has been inconsistent and evidence of inadequate planning and lack of adequate commitment abound in every fish farming business embarked on. It is now left for private sectors and individual farmers to determine the efficiency and potentials of the business (Igun, 1997). Aquaculture is also considered to be a contributor to rural development and poverty reduction as it forms an important component within agriculture and farming systems development through employment, income provision, protein supply, poverty alleviation, food security etc (Asche and Khatun, 2006). Making cultured fish more readily available for Nigerian consumers will give them faster and fresher access to one of the healthiest sources of animal protein. Meanwhile, supplying high-grade fish with strong nutritional content is a challenge for many farmers today. Quality fish requires quality fish feed, which is expensive for farmers to purchase; processing fish to meet diverse market demands depends on farmers having the correct technical and economic knowledge in addition to investment capabilities. Fish culture will not only helps generate jobs and revenue, but also help to meet requirements for food security and improved nutrition; especially for adult population (USAID, 2013). Studies on production efficiency of economic agents have long been of interest to agricultural economist. Much empirical work has centered on imperfect partial measures of productivity, such as yield per hectare or output per unit of labour (Coelli and Battese, 1995). The Parametric Stochastic Frontier Production Function Approach (Meeusen and Van dan Broek, 1977 and Aigner *et al.*, 1997) and the non-parametric mathematical programming approach commonly referred to as Data Envelopment Analysis (DEA). The parametric approach relies on a parametric specification of the production function while the non -parametric approach imposed non-a priori parametric restriction to the underlining technology (Adewuyi and Okunmadewa, 2001). Therefore, the need for research of this nature to verify the profitability of fish farming in relation to efficiency of input-output and to forecast the output scale of fish farming in future.

METHODOLOGY
The study was conducted in Adamawa State, Nigeria. Adamawa State lies between Latitude 7^0 and 11^0 North of the Equator and between Longitude 11^0 and 14^0 E of the GMT. The state has two major seasons (wet and dry) wet season commences in April and ends in late October, while the dry season starts in November and ends in April. The mean annual rainfall of the area is about 1000mm (Adebayo, 1999). The study area falls within the Northern Guinea Savannah Zone of Nigeria with 21 administrative local government areas, land mass of 2,310.05km^2 and a population of 3,178,950 which is projected to be 4,111,704 in the year 2016 at 2.9% yearly growth rate (NPC, 2006). The area is bounded by Taraba State to the south, Gombe State to the west, Borno State to the north and Cameroun Republic to the east respectively. There are a lot of fishing activities in the study area as one of the

major rivers in Nigeria (Benue) links with some major water reserves (Kiri, Njuwa, Chuchill, Yinagu, Chachelek and Gerio) located within the study area, also two large commercial farm (Gessedaddo and Sebore) are located in the state, where fish are harvested on relatively large scale. The peak period of fish harvest from the natural water bodies is in August-October, while in April-May it drops to its minimum harvest in which the dams (restricted fishing areas) occasionally open at such time for its fish capture. Common natural fish species around are Catfish and Tilapia. The wild fish are mostly harvested using fishing gears (nets and hooks). Most homestead fish-farmer harness period of low fish output from the natural (capture) source for their harvest. Data for this study was derived mainly from primary source which was collected with the use of structured questionnaire. Snowball sampling technique, was used to contact150 respondents for this study. The data was collected from across the state, majority collected from the urban and peri-urban areas of Mubi, Michika, Yola, Mayo-Belwa, Numan, Ganye and Guyuk. The analytical tools that were used in this study were Descriptive Statistics and stochastic frontier model.

RESULTS AND DISCUSSION

Socio-Economic Characteristics of the Respondents

The variation in the age classifies the active age group that can be easily engaged in the tasking agricultural activities. Table 1 shows the distribution of respondents based on their age. Majority (92.7%) of the respondents were under 60 years of age, while only 7.3% were 60 years and above. This is an indication that fish farming is dominated by working class individuals. The result in Table 1 showed that about 69% of fish farmers in the study area are male, while 31% are female. This implies that fish farming in the study area is usually undertaken by both men and women. This was attributed generally to gender biasness which set women behind men with access to agricultural assets, inputs and services as well as rural employment opportunities in developing countries. About 55% of the respondents are married, 22% single, 15% widows and 8% divorced. This shows that those that are married men are more in fish farming in Adamawa state than those with other marital status. This may be as a result of greater family responsibilities placed on household heads, such as feeding, clothing, healthcare, educating the younger dependents among others, which may not be the same for the non married category. About 75% of the respondents had six members or more in their household, while only 25% of them had less than six members in their household. The implication is that, respondents with large household size were more in fish farming in the study area to earn money to meet up with the regular demands of their household dependants. Table 1 pointed out the educational level of the respondents. It indicates that about 11% of the farmers had no formal education, 15% had primary education, 15% had secondary education and about 59% of the respondents had post-secondary education The, higher the educational level of a fish farmer the more technically efficient the farmer will be. This revealed that fish farming in the study area is mostly practiced by educated people, as almost all (89%) of the respondents had one form of formal education or the other. This also correlates with positive effect of education on fish farmers' technical efficiency. It therefore showed that fish farming requires some basic education to enable them acquire basic skills and training required for fish cultivation.

Experience exposes man's mistakes and suggests correction which increases efficiency and improve productivity and high yield. The more experience the farmer acquires, the more efficient and effective the farmers' activities. Table 1 shows the distribution of respondents based on fish farming experience. The study revealed that few of them (26%) had two years or less of experience in fish farming, while majority (74%) had experience of more than two years. This indicated that despite the fact that fish farming is a relatively new venture in the study area; most of the farmers had more experience. They were becoming conversant with fish farming practice at the time of this research. Their practice and management indicated relatively high efficiency. Occupation explains the time someone has for specific activity as it affects the productivity of every business. Fish farming is expected to compliment the main occupation of the fish farmers where the fish farming is not the primary occupation of the respondent. Table 1 outlined the main occupation of the respondents. It indicated that 54% of the respondents were civil servants, while businessmen were 12%, farmers were 14%, house wives were 11% and students were 9%. These may be due to the fact that most fish farmers in the study area were engaged in one occupation or the other to earn extra-income to aid them augments their salaries which is insufficient to carter for their dependants needs. In addition, the civil servants correlate with those that had higher education level indicating positive relationship between education and civil service. Meanwhile fish farming was not time demanding like other agricultural activities that civil servants can easily engage in. There is economic advantage and disadvantage of having one animal or more in terms of inputs utilization and maintaining output (protein supply). Some farm animals have some common inputs with fish. Table 1 shows the farm animals reared by the respondents, it revealed that majority (81%) of the fish farmers reared one animal or the other or jointly; poultry and livestock in addition to fish. Only 19% of them had no other animals. These suggested the comparative advantage of rearing more than one animal as they share some common resources (inputs) such as water, land, power, fuel etc and also, it sustain consistent in protein supply in the market.

Labour is employed based on quantity in terms of number and quality in terms of skills required for high efficiency and optimum output. Labour could be sourced from family, hired or both; this depends on the family size, as well as the quantity and quality of labour required. Table 1 shows the type of labour employed by the respondents. It shows that majority (67%) of the respondents used family labour, while 29% of them used hired labour for their fish farming. Only four percent (4%) used mixed labour. This is because labour requirement in fish farming was not tasking as compared to other agricultural practices. The most important thing in fish farming was management skills, constant attention and supervision, which most times, the household members were ready to do small scale production. Access to new innovations/technology, skills and modern inputs are linked mostly to extension services and training. The extension service could be through individual contact, group contact, focal persons or workshop. Other sources are through mass media; radio, television, news papers, internet services etc. Table 1 shows how respondents had contact with extension services. About 82% of the respondents had contacts with extension workers more than twice; only about 18% had once or twice contact with extension workers in a production cycle. This indicates that majority of the farmers had chances of adopting new innovations of fish farming skills through proper and formal extension service on fish farming practices as indicated in the result of technical efficiency; that extension services positively improve fish farmers performance. Access to funds gives the financial strength of every business which provides effective implementation of business plan and enhances productivity. Table 1 depicts the sources of capital used in fish farming, 46% of the respondents borrowed money for fish farming, while majority (54%) who are likely civil servants as reflected on the major occupation of fish farmers used personal savings for fish farming business.. However, the civil servant can plan to save a little from their monthly income for investment like this.

Technical Efficiency

In every production, each individual has his/her respective performance depending on personal technical efficiency of an individual which could be attributed to variation in social and economic characteristics. It also provides the mean and mode of the average efficiency in the study area. Table 2 shows the frequency distribution of Adamawa State fish farmers' technical efficiency (TE). It revealed that, 21% of the fish farmers had TE of 0.70 and below, 37% of them were on TE range of 0.71-0.80. The same percentage of fish farmers (37%) were on 0.81-0.90 and only about 5% had their TE 0.91 and above. This showed that majority (74%) of the fish farmers in Adamawa State were operating on 0.71- 0.90 TE. The mean technical efficiency of fish farmers was 0.80 (80%). This implies that the fish farmers were not fully efficient as their observed output was 20% less than the maximum output on average. Their efficiency can be increased by 20% through improved resource allocation and proper management with no additional cost. The arithmetic mode of the technical efficiency was 0.80 (80%) meaning that majority of the farmers had technical efficiency of 80%. The statistical range between the most efficient and the least efficient fish farmer was also large, 0.41 (41%), showing that the least efficient farmer will need 41% improvement to meet up with the most efficient fish farmer in Adamawa State. From these views, the study indicated that most of the fish farmers were 20% below the maximum output as a result of technical inefficiency. Meanwhile, the farmer with 0.98 (98%) efficiency is identified as '*model farmer'* operating at almost the frontier of the production in this study has seven years experience, attained tertiary education, he is fifty years of age, he had six contact with extension worker, he insured his farm and having eight people in his household,. Meanwhile, the farmers had an option of improving on their technical efficiency through experience, education, age, farm insurance and contact with extension worker in Adamawa State as it agreed with the work of Adeogun *et al.,* (2007); Kudi *et al.,* (2008) and Apata, (2012).

CONCLUSION

The study revealed that socio-economic characteristics such as education, age, experience, extension contact affects farmers technical efficiency and farmers had the potential of raising their production efficiency by 20% by improvement in resource allocation. Based on the findings of the study, the following recommendations were made. Farmers should improve on their socio-economic characteristics such as education, age, experience, extension contact so as to improve their technical efficiency. Training on new technology and awareness through cooperative groups on fish farming practice should be geared up, so as to encourage the practice.

ABSTRACT
This study analyzed the economics of irrigated spinach production in Langtang North Local Government Area of Plateau State, Nigeria. The study estimated cost and returns and input and output relationship of spinach farmers in the study area. Spinach farmers were randomly selected and 81 questionnaires were distributed. Results were analyzed using cost and return and production function model. Result on cost and return analysis revealed that gross revenue/ha was (₦93,818/ha) with a total cost/ha of (₦67,246/ha) while a gross margin/ha was (₦26,572/ha). The result from production function revealed that seed and labour had positive coefficient and significant at 1% level of probability while herbicides have negative coefficient and significant at 1% level of probability. The results call for policies aimed at provision of improved seeds to farmers at subsidized rates and efficient utilization of herbicides for increased production.
Keywords: Irrigation, Spinach and Economics

INTRODUCTION

Irrigation has a positive effect on the sustainable agricultural development because it can reduce the amount of land to produce a given amount of food (Ingawa (2005). This is because it leads to rapid agricultural land expansion in the face of scarcity of farm lands with the associated damage of natural soil and wastage of water resources (Ibekwe and Adesope (2010). For Nigeria to increase its staple and export food crops, it has to increase its irrigated area. Nigeria needs to utilize its agricultural and water resources fully to meet domestic food demand while expanding production of export crops. The accomplishments of this means, more irrigation areas and irrigation schemes have to be developed. Vegetable (in this context spinach) are the most important and extensively cultivated food and income generating crops in many part of Africa (Adebisi et al., 2011). According to (Mohammed, 2002), it can give high yield per unit area of land and hence generate high income for the farmers. Growing vegetables is particularly suited for small-scale farmers and their families because of their limited resources (Sabo and Dia, 2009). Spinach (Amaranthus spp) is one of the leading green leafy vegetables in Nigeria. Spinach takes an important place in the population diet because of its affordability and the nutrient it provide. It is often grown and consumed in rural, urban and peri-urban areas in Nigeria. Therefore, the broad objective of this study is to examine the economics of irrigated (Spinach) production in Langatang North Local Government Area.

METHODOLOGY

The study was carried out in Langtang North Local Government Area of Plateau State. It is located at Latitude 9^0 and 8′N, and Longitude 9^0 and 7′E. The area has an annual rainfall of 23mm with average monthly temperature range of 15 - 32°C. The cold, dry and harmattan make the month of December to January averagely cold while the month of March and April record high temperature. The people are predominantly peasant farmers growing various crops such as guinea corn, vegetables, millet, rice, maize etc. A multistage sampling technique was conducted in three (3) districts out of four districts that have highest population of vegetable spinach production in the area .One village was chosen from each of the three (3) districts selected. This is based on the number of population of the farmers cultivating vegetable spinach; the villages include Zamko, Kuffi, and Dadur. Based on the population of the villages 15% of the population was used to determine the number of respondent in order not to be bias. This gave a total of (81) questionnaire which was used in the study area. The primary data used in the study were obtained from 81 spinach producers based on the population within the villages with the use of structured questionnaire. This structured questionnaire was used to collect data from the farmers during 2014/2015 season. Data were analyzed using net farm income and production functions model.

Model specification

Net Farm Income

The farm budget techniques were used in this study, the tool the Net farm income is expressed as follow.
NFI = GF1-TC
Where:
NFI = Net Farm Income, GFI =Gross Farm Income, TC= Total Cost
The variable used include,
Seed (W/kg), Labour (Man per day) ,Fertilizer (₦/kg),Land Rent (₦/ha),Herbicide (₦/Litre)
Fixed Cost

Depreciation on Implement (₦), Pumping machine (₦)

Production Function

This tool was used to know the nature of production of spinach in the study. In implicit form, the model is presented as follows:

$Y = f(Y_1, Y_2, Y_3, Y_4, Y_5) + e$

Explicit form of the mode can be expressed as :

Double log Function:

$Log = b_0 + b_1 \log X_1 + b_2 \log X_2 + b_3 \log X_3 + b_4 \log X_4 + \log_5 \log X_{5+} e$

Model Specification:

X_1=Seed (kg),X_2 =Labour (Man/day),X_3=Fertilizer (₦/kg),X_4=Herbicide(₦/Lt),X_5=Capital(₦),e=error term or disturbance term

Where:

Y=output, a=Constant, b= regression coefficient, e=error term

RESULTS AND DISCUSSION

Cost and Return analyses for Spinach Production

The total costs of production include the fixed and the variable costs. The total variable costs consist of the labour seed, fertilizer, pesticides, fuel and weeding. While total fixed costs consist of land used value and depreciation non water pumps used. The variable cost stood at (₦ 25746) respectively (₦748) of the total cost while the remaining (₦ 42,248) constituted the fixed cost as in the table. The fertilizer cost constituted the highest fraction of (12.47%) followed by labour cost which stood at (9.09%) while chemical hand the lowest percentage of (2.2%) under dry (irrigation) season production of less weed intensity. The total fixed cost stood at about (₦41, 500).Gross revenue was (₦93, 818), total cost of production was (₦67, 246) and Net farm income was (₦26572) while return per naira invested was (1.39). This implies that production of spinach (irrigated) is profitable in the study area.

Production Function for Spinach

The production function analysis gives the physical or technical relationship between inputs and output in any production scheme or process (Olukosi and Erhabor, 1999). This tool is used to examine the nature of production function in production of spinach in the study area. Double log production function was the lead equation out of the four fitted and was estimate the Coefficient of the inputs utilized by spinach formers. The result in Table 2 shows the coefficient of multiple determination of 0.650 implying that 65% of the variation in spinach output was accounted for by the inputs included in the model. Out of the variables only three variables were significant which includes seeds, family labour and Herbicides. **Seeds:** This variable had positive coefficient (1.539) and significant at 1% level of probability. The implication of this finding is that a unit increase in this input implies a unit increase in output. This agrees with (Goni et al., 2013). **Labour:** This variable has a positive coefficient (32.388) and significant at 1%level of probability. This implies that a unit increase in labour results to an increase in the production output.

Herbicides: This variable has a negative coefficient (- 0.951) and significant at 1% level of probability. This negative sign suggest an inverse relationship with output production. This may be due to the fact that the farmer used a wrong application of input.

CONCLUSION

The results call for policies aimed at provision of improved seeds to farmers at subsidized rates and efficient utilization of herbicides for increased production.

Table 1: Cost and Return Analysis on Spinach Production

Items of Cost/Return	Amount (₦/ha)	Percentage (%)
Variable Cost		
Fertilizer	8,390	13
Labour	6,115	9
Chemical	1,480	2
Seeds	7,013	10
Fuel	2,000	3
Land rent	748	1
Total Variable Cost	**25,746**	
Fixed Cost		
Implement	3,500	5
Pumping Machine	38,000	57
Total Fixed Cost	25746 + 41500	
TC = TVC + TFC	= 67, 246	
Total Return	= 93,818	
NFI (TR - TC)	= 26,572	
Rate of Return ($^{TR}/_{TC}$)	= 1.39

ABSTRACT
The study was carried out in Riyom Local Government Area of Plateau State, Nigeria, on the benefit-cost analysis of Sammaz 15 maize variety. Data was obtained from 70 maize farmers through the use of structured questionnaires. The data collected were analyzed using benefit-cost model. The result of the study shows that benefit – cost ratio is greater than one (1). The major constraints faced by respondents are; inadequate capital, inaccessibility to credit, high cost of inputs, inadequate extension contact, and high cost of labour. It is recommended that cost of inputs should be subsidized and efforts should be made to make credit accessible to farmers. Furthermore, number of extension agents should be increased to introduce Sammaz 15 variety to farmers, and an effective input supply system which would sustain the expansion of maize output by farmers in the study area should be put in place.
Keywords: Benefit-cost, Sammaz 15, Maize production and Plateau state

INTRODUCTION

About 70% of Nigeria's estimated population of 140 million lives in the rural areas. Although Nigeria is Africa's second largest economy (after South Africa) with a GDP of about US $40.0 billion, yet, about two-third of the population live below the national poverty line (FGN 2008). It is an irony indeed that Nigeria, a vast agricultural country "endowed with substantial natural resources" which include: 68 million hectares of arable land; fresh water resources covering about 12 million hectares, 960 kilometers of coastline and an ecological diversity which enables the country to produce a wide variety of crops and livestock, forestry and fisheries products (Shaib, *et. al*., 1997) should find itself in the group of low-income food-deficit countries (LIFDCS) in Africa. It is clear therefore that the country has not been able to harness its vast natural resources for sustainable agricultural development. This has been aptly captured in the National Food Security Program document, which is the most recent and authoritative policy statement by the Federal Government on the state of the nation's agriculture. According to the Government (FGN,2008), although "agriculture remains a key component of the country's economy, currently contributing about 40% of the GDP and employing about 70% of the active population, the sector has significantly underperformed its potential". This has been clearly manifested in the very high food prices nationwide, food insecurity both at the household and national level and malnutrition especially in children. Thus the agricultural production and food situation in the country today is anything but impressive. In spite of the potentials and prospects of producing food for home consumptions and export, achieving a balance between food and population growth is a serious problem in Nigeria today. This problem of production deficit and consequent decrease in per capital availability of food has resulted from the declining ability to produce enough food in the face of increasing consumption capacity. This situation has shown that Nigeria still manifest the typical symptom of a peasant agriculture where the farms are dominated by small scale farmers who are responsible for about 95 percent of total production (Shaib, *et. al.*, 1997).

Increasing agricultural productivity is considered as one of the major solutions to effectively addressing the current Nigeria food crisis. Maize is the most important cereal in Sub-Saharan Africa (SSA) and an important staple food for more than 1.2 billion people in SSA and Latin America. All part of the crop can be used for food and non-food products. In industrialized countries, maize is largely used as livestock feed and a raw material for industrial products. Maize accounts for 30-50% of low income household expenditure in Eastern and Southern Africa. However, heavy reliance on maize in the diet can lead to malnutrition and vitamin deficiency diseases such as night blindness and kwashiorkor (IITA,2013). Maize is also important source of income for smallholder farmers as well as enhancing the food security and reduction in the number of those suffering from hunger, hence the achievement of the MDG's, Maize also plays a key role in ensuring the environmental sustainability of bio-fuel production (NFIC,2013). Maize is one of the major staples in Nigeria. Report of a food consumption survey shows that maize was the most often consumed staples, with 20 per cent of the population eating it at least once a week (IITA, 2013). Current production is about 8 million tonnes and average yield is 1.5 tonnes /Ha. The average yield is low when compared to the world average of 4.3 tonnes /Ha; it is even low when compared to average yield from other African countries like South Africa, Mauritius and Egypt with average of 2.5 tonnes /Ha, 5.8 tonnes /Ha and 7.1 tonnes/Ha respectively (FAO, 2009). Thus, there has been a growing gap between the demand for maize and it supply. Despite the effort by the Nigeria government, to increase production, maize production still remains below demand (Remission, 2005). Also, the performance of maize in Nigeria and other African countries can be attributed to the fact that, bulk of the country's farm, over 90% is dependent on subsistence agriculture (small holder farmers) with rudimentary farming system, low capital and low yield per hectare (Olayemi, 1994 in Ogundari *et al.*, 2006). In Nigeria, like other developing country, food production is closely related to peasant or subsistence nature of agriculture which farmers have practiced for century and which has been handed over to several generations. The old fashioned agricultural system leads to low productivity and food shortage.

METHODOLOGY

The study was conducted in Ryom LGA of Plateau State, Nigeria. The LGA has a total land area of about 807km2 and a population of 131,778(NPC., 2006). Riyom LGA consist of three (3) districts namely Riyom, Bachit and Ganawuri, with two major ethnic groups (Berom and Aten). The LGA has boundaries with Kaduna and Nasarawa. Riyom lies on the Northern Guinea Savannah at longitude 9038'N and Latitude 8046'E. Multistage sampling procedure was used to draw sample for the study area. In the first stage, three (3) districts who are the major sammaz 15 maize producers were purposively selected: Riyom, Bachit and Ganawuri districts. In second stage, two villages were randomly selected from Riyom, and Bachit districts while two villages were randomly selected from Ganawuri district in Riyom LGA, based on the level of maize production. In the second stage, four (4) villages were purposively selected, namely; Atakar, Tse, Dong and Ganawuri these are the major maize producing villages in the study area. The third stage involved random selection of proportionate number of respondents from each of the selected villages in the study area. For all the four (4) villages, a set of seventy (70) questionnaires were administered on respondents.

Gross margin (GM)

i. Gross Margin (GM) Gross margin is the difference between the gross farm income and the total variable cost (Olukosi and Erhabor, 2008).

Therefore; GM = GFI – TVC

Where GM = Gross margin

GFI = Gross farm income

TVC = Total variable cost

Profitability Ratios

Profitability ratio is a class of financial metrics that helps investors assess a business's ability to generate earning compared with its expenses and other relevant costs incurred during a specific period. When these ratios are higher than a competitor's ratio or than the company's ratio from a previous period, this is a sign that the company is doing well (Okwu and Acheneje, 2011). Some examples of profitability ratios are listed and explained below:

ii. Benefit Cost Ratio BCR)

Benefit cost ratio or analysis is the term that either refers to helping to appraise, or assess the case for a project programme or policy proposal and an approach to making economy decision of any kind. From definition, the process involves whether explicitly or implicitly weighing the total expected costs against the total expected benefits of one or more actions in order to choose the best or most profitable option.

Therefore; BCR = TR/TVC

Where TR = Total Revenue

TC = Total cost

Therefore; BCR = TR/TVC

Where

TR = Total Revenue

TVC= Total Variable cost

RESULTS AND DISCUSSION

Table 1 is a summary of the costs, returns and gross margin of sammaz 15 maize productions in the study area. The total cost incurred on fertilizer/Ha is ₦4,760 representing 17% of the total cost of production, the cost of agrochemicals is ₦6, 419/Ha representing 23%, cost of labour is ₦ 13,343/Ha representing 48%, cost of seed is ₦ 2,244/Ha representing 8% and cost packaging and transportation is ₦ 1,123/Ha representing 4%, cost of water is ₦ 4.61/bird representing 0.51%, transportation. The summation of these costs gave a total variable cost of ₦27, 889/Ha. This result shows that sammaz 15 maize farmers were efficient in production in the study area. The gross income obtained from maize production per hectare ₦84, 558/Ha. The gross margin per hectare is ₦ 56,669/Ha representing 67% of the gross income. The implication of this is that farmers involved in sammaz 15 production will survive in the short-run because the resources engaged in its production were efficiently utilized. This findings is consistent with Mukhtar, 2012) findings on the profitability of layer poultry production in Bauchi Local Government area of Bauchi State. The size and the positive value of the gross margin shows that the respondents were able to cover their operating costs with the level of gross margin obtained and had a sizeable proportion as return to management less the depreciation cost. The implication of this is that increasing the scale of sammaz 15 productions in the study area may lead to increased income and the profitability of this enterprise. However, it is important to stress here that income can still be improved upon with appropriate pricing, adoption of proper cultural practices and accessing low cost inputs through bulk purchasing by farmers' cooperatives. The Benefit – Cost ratio is one of the concepts of discount method of project evaluation. As a rule of thumb, any business with benefit cost ratio greater than one, equal to one or less than one indicate profit, break-even or loss respectively (Olagunju *et al*., 2007). The analysis of ratios in table 4 reveals that the Benefit cost ratio (BCR) was greater than one (3.03). It is also in agreement with the work of Emokaro and Ekunwe (2009) who examined the efficiency of resource-use among catfish farmers to be viable. Since the ratio (BCR = 2.90) it implies that sammaz 15 maize variety is profitable in the study area. It is therefore much possible to have higher value of BCR with increase in capitals and skilled labour.

CONCLUSION

From the findings of this study, it is concluded that sammaz 15 variety production in Riyom local government is profitable as indicated by the B-C ratio which is greater than one (1). However, performance of sammaz 15 maize variety can still be improved upon with appropriate pricing, adoption of proper cultural practices and accessing low cost inputs through bulk purchasing by farmers' cooperatives.

Table 2: Benefit-cost analysis of Sammaz 15 maize farmers

Cost	₦/Ha	%
Fertilizer	4,760	17.10
Agrochemicals	6,419	23.02
Labour	13,343	48.00
Seed	2,244	8.05
Packaging and transportation	1,123	4.03
Total Variable Cost(TVC)	**27,889**	
Gross Income	84,558	
Gross Margin (GI-TVC)	56,669	
Benefit Cost Ratio	3.03

ABSTRACT
The research was carried out in Nkanu West Local Government Area of Enugu State and it was designed to examine the constraints militating against yam production in the area. A multistage randomised sampling technique was used to select 90 respondents in the study area. Structured questionnaire was used to collect the data on, socio-economic characteristics of the farmers, and constraints to increased yam production in the area. The data was analyzed using descriptive statistics such as averages, percentages, frequency distribution table. It was generally observed that farmers in the study area were constrained by lack of essential infrastructures/amenities, lack of capital, absence of extension agent, use of improved varieties and incidence of pest on their farms. It was recommended that Farmers should be encouraged to form cooperatives, government should ensure that farm inputs such as improved yam varieties, fertilizers, tractors and agro-chemicals are made available to farmers at a highly subsidized rate and extension agents should assist yam to ensure that they use improved varieties
Keywords: Yam, Production, Constraints and Farmers

INTRODUCTION
Yams (Discorea species) are annually root tuber bearing plant with more than 600 species out of which six are socially and economically important in terms of food, cash and medicine (IITA, 2009). Some of its species are water yam (*Dioscorea alata)*, white yam (*Dioscorea rotundata*) and yellow yam (*Dioscorea cayanensis)* (FAO, 1998; Ike and Inoni, 2006; Zaknayiba and Tanko, 2013). Yam as a staple food crop is grown in tropical regions (Thouvenel and Fauquet, 1979) and mostly produced in the savannah region of West Africa, where rainfalls are divided into wet and dry seasons (Etejere and Bhat, 1986; FAO, 1998). Yams are the fifth most harvested crops in Nigeria, following after cassava, maize, guinea corn, and beans/cowpeas. More so, after cassava, yams are the most commonly harvested tuber crops in the country (NBS, 2012). Nigeria is the largest producer of the crop, producing about 38.92 million metric tonnes annually (FAO, 2008). Yam production in Nigeria has more than tripled over the past 45 years from 6.7 million tonnes 1961 to 39.3 million in 2006 (FAO, 2007). This increase in output is attributed more to the large area planted with yam than increase in productivity (Nwosu and Okoli, 2010). However, there has been a general decline in yam production in Nigeria over years. Madukwe *et al.* (2000), Agwu and Alu (2005) and International Institute of Tropical Agricultural [2009] reported that both area under yam cultivation and total yam output were declining. The decline in average yield per hectare has been more drastic, as it dropped from 14.9% in 1986-1990 to 2.5% in 1996-1999 (CBN, 2002, Agbaje *et al*, 2005 and FAO, 2007).In Nigeria, some of the constraints to yam production are unavailability of planting materials, soil degradation, poor handling and storability, pest and disease and other environmental factors (Ibitoye and Attah, 2012). Seed yam for cultivation has continued to be a problem for the farmers. The cost of producing yam is also observed to be higher compared with other tubers in the country. This is largely due to the high cost of seed yam. On the average, about 25% of the annual yam harvest is used as seed yam (Kushwaha and Polycarp, 2001). This situation has caused yam cultivation to suffer a severe setback due to high cost of production. Despite the importance of yams to people and as a source of food security, the attention to yam production is still questionable, as many rural dwellers are still living in hunger in Nigeria. The objective of this study includes to: describe the socio-economic characteristics of yam production in the study area, determine the effect of the socio-economic characteristics on farmers, estimate cost and return in yam production in the study area and to identify the constraints affecting yam farmers in the study area.

METHODOLOGY
The study area was conducted in Nkanu West Local Government Area of Enugu State. Nkanu West is one of the seventeen (17) local government areas that make up Enugu State. Nkanu west is made up of 37 Communities namely Akpugo, Amuri, Agbani, Akegbe, Amodu, Obuofia, Ozall at Obe. It's headquarter is at the town of Agbani. Nkanu West Local Government in Enugu is located in $6^0 18^1$ North, $7^0 33^1$ east greenish meridians; it has an area of 364km^2 (141.5%). It has a population of 146,695 according to the NPC (2006 census. Nkanu West share boundary with Udi LGA. A multistage random sampling procedure was used to select communities, villages and the respondent. In the first stage six communities were randomly selected out of the 37 communities namely

Akpugo, Amuri, Agbani, Akegbe, Ozalla, Obe, In the second stage, three villages were randomly selected from the six communities to make a total of 18 villages., In the final stage, five questionnaires were administered across each of the eighteen Villages to give a total of ninety respondents. Data collected were using descriptive statistics

RESULTS AND DISCUSSION

Socioeconomics Characteristics of Respondents

Table 1.0 show that 54.4 % of the respondents were female while 45.6% were male. This implies that women are very much involved in the yam production than their men counterpart. This is in agreement with Adesimi (1991) who stated that root crops in developing countries are essentially promoted by women.

Table 1.0: Frequency Distribution of Respondents according to Gender

Gender	Frequency	Percentage
Male	41	45.6
Female	49	54.4
Total	90	100

Source: field survey, 2015

Table 1.1 shows that 27.8% of the respondents were between the age of 50-59 years and 8.9 % were aged farmers while 20 and 30% of the respondents were youths in the study area. This shows that yam production enterprises are owned and managed by middle aged and young farmers. This is in agreement with O.E Okelola, (2011).

Table 1.1: Frequency Distribution of Respondents According to Age

Age	Frequency	Percentage
20	10	11.1
20-29	20	22.2
30-49	27	30
50-59	25	27.8
60-70	8	8.9
Total	90	100

Source: Field survey, 2015

Table 1.2 shows 50 % of the respondents have farm size of 1.00-1.99ha; this implies that half of the total respondents have less than 2.00ha of farm. This also implies that majority of the farmers in the study area are small scale farmers due to problem such as land ownership, capital, and absence of extension agents. This tend to affect the yield output on the farm..

.

Table 1.2: Frequency Distribution of Respondents According to farm size

Size	Frequency	Percentage
Less than1.00ha	34	37.8
1.00-1.99ha	45	50.0
2.00-2.99ha	8	8.9
3.00-3.99ha	3	3.3
Total	90	100

Source: Field survey, 2015

Table 1.3 shows that 35.6% of the respondents indicated capital/incentives as their major problems, followed by lack of land ownership (13.3%), lack of essential infrastructures (18.9%) This is expected since most of the farmers are poor and lack funds for farming activities. Other constraints are Lack of Use of improved varieties, Land ownership, Incidence of Pests and Absence of extension agents which had 15.6%, 13.3%, 8.9% and 7.8% respectively,

Table 1.3: Frequency Distribution of Respondents According to major constraints

Constraint	Frequency	Percentage (%)
Lack of Use of improved varieties	14	15.6
Lack of essential infrastructure	17	18.9
Lack of capital /incentive	32	35.6
Land ownership	12	13.3
Incidence of Pests	8	8.9
Absence of extension agents	7	7.8
Total	90	100

Source: Field Survey, 2015

CONCLUSION

The result shows that yam production is carried out by women in the study area.. Yam farmers experience series of problems such as land ownership, lack of capital, absence of extension agent, use of improved varieties and incidence of pest on their farms. There is therefore a collaborative need to fight against these problems and make yam farming a more profitable venture in the study area. Based on the Research Findings, the Following Recommendations were drawn:

1. Government should ensure that farm inputs such as improved yam varieties, fertilizers, tractors and agro-chemicals are made available to farmers at a highly subsidized rate.
2. Farmers should be encouraged to form cooperatives. This is to enable them pool their resources together and have advantage of large economics of scale in their production.
3. Agricultural Extension agents should assist yam farmers with relevant documentations necessary to ensure financial assistance from banks or any other credit institution. Agricultural engineers should be encouraged by government to fabricate machines that are efficient, cost effective, available and affordable to farmers..
4. Access road should be provided by the government and through community effort in the rural areas. This would reduce transportation cost and improve buyer-seller relationship. Thereby enabling farmers to make regular sales.
5. Extensions Agents and farmers should visit yam fields regularly so that pests and disease can be controlled before they reach economic threshold.

ABSTRACT
The study was carried out in Ibadan North-East Local Govt. of Oyo-State in 2010. The objective of the study was to determine consumers' preference for frozen fish. Structured questionnaire was used to elicit the information from the respondents. Systematic sampling technique was used to select a total of 123 household respondents. Data were analyzed using descriptive statistics. The result of the study showed that most (79.0%) of the household were male and 21.0% were female. 62.7% of the household are within the middle age of 25., 85.5% of the respondents have post-secondary education. The result also shows that 22.6% of household consume Titus Fish while 75.8% consume other varieties of frozen fish. The results further revealed that 38.7% of the household consume Titus Fish twice in a week while 34.9% consume it daily. This indicates that majority of household prefer Titus fish to other Species. It was also shown that 53.3% of the household consume below 3kg of Titus Fish, 40.3% consume 3 – 6 kg and 6.4% consume more than 7 kg weekly respectively. About 75% of the sampled household size earned above ₦25,000 income from fish business monthly while 3.3% earned below ₦7500.The results of the study revealed that the respondents have small household size, they are low income earners and they consume an average of 3-6kg of fish weekly. Policy towards improving mass education of nutritional importance of fish and adequate support should be given to fish traders to enhance its production and availability
Keywords: Consumers, Preference, Consumption and Frozen Fish

INTRODUCTION
Nigerian aquaculture industries ranked second in Africa though, yet to reach the country's full production potential in terms of available natural, environmental and socio-economic factors (Ojo *et al*., 2006a). The contribution of aquaculture to total fisheries production rose between 7.38% in 1997 to about 10.11% in 2003 (Ojo et al., 2006b). Although the demand for fish has been rising rapidly as a result of increase in population, per capita income, and high prices of alternative sources of animal protein, Nigerians have to shift to the consumptions of fish which is mostly in fresh and frozen form. It is expected that with increasing aquaculture production and negative acceptability trend of frozen fish, perhaps consumer preference might shift towards the consumption of cultured fish (Ojo and Fagbenro 2004).Fish products are highly diversified in the sense that there are many species of edible fish and each species differs significantly from each other in terms of taste, price, production volume and location. Pieniak *et al*.(2008) reported that fish consumption is mostly affected by tradition and habit and the level of consumption is also enhanced by nutritional awareness. An increase in consumers' taste and preferences for a particular product tends to increase the quantity demanded for that product. Consumer's tastes and preferences affect demand for a given product and in measuring taste and preferences, only the qualitative impact on demand can be evaluated not the quantitative impact. There is a widening gap between production and demand due to inadequate demand information which is capable of hindering optimization of production and marketing in the fish production sub-sector (Ajana, 1999). This study therefore examines consumers' preferences for consumption of frozen fish with a view to developing a guide in the area of fish processing policy in Nigeria.

METHODOLOGY
The study covered the whole of Ibadan North-East Local Government. A total of 123 household respondents was selected using systematic sampling technique. The data for this study was obtained from primary sources. Questionnaire was the main instrument for data collection. It was however complimented with interview schedule. The analytical method for the research work is simply the use of descriptive statistic such as frequency count, percentage, mode and mean in measuring the socio-economic characteristics of the respondents and other variables.

RESULTS AND DISCUSSION
The result in table 1 shows that most (79.0%) of the household are male and 21.0% were female. 62.7% of the household are within the middle age of 25 and 50 years and household above the age of 50 are 28.0%. About 8.8% of the household population in the studied area is less than 25 years. It also shows that 75% of the sampled household size earned above ₦25,000 while 3.3% earned below ₦7500. 85.5% have post-secondary education ed This agrees with Ojo (2004) who stated demand for fish has been rising rapidly as a result of increase in awareness

due to educational background. The result in table 2 shows that 22.6% of household consume Titus Fish while 75.8% consume other varieties of frozen fish which include; stock, Herrings, Horse Mackerel (Kote) etc. The result in table 3 shows that 38.7% of the household consume Titus Fish twice in a week while 34.9% consume it daily. This indicates that majority of household prefer Titus fish to other Species. The result in table 4 shows that 53.3% of the household consume below 3kg of Titus Fish, 40.3% consume 3 – 6 kg and 6.4% consume more than 7 kg weekly respectively .This result is in consonance with Pieniak *et al*. (2008) and Abdullahi *et al*. (2011) who reported that fish consumption is mostly affected income and household size. The results of the study revealed that the respondents preferred to consume Titus species of fish more than other species; this could be attributed to availability of the fish in the area of study

CONCLUSION

The study examined consumers' preference of frozen fish. The results of the study revealed that the respondents have small house hold size, they are average income earners and they consume an average of 3-6kg of fish weekly. Policy towards mass education of nutritional importance of fish is here by advocated.

EFFECT OF FINANCIAL MOTIVATION ON ORGANIZATIONAL PERFORMANCE IN SELECTED FIRMS IN ABIA STATE, NIGERIA

D.C. Anoliefo & I.N. Nwachukwu

Department of Agribusiness and Management, Michael Okpara University of Agriculture, Umudike, Abia State
chididoris@gmail.com

ABSTRACT
The study analyzed the need to examine the relative Effect of financial motivation on organizational performance in selected firms in Abia State. It specifically assessed the socio-economic profile of the workers, analyzes the factors that influence worker performance and ascertain the relationship between financial motivation and worker productivity. This profit can only be achieved when the organization produces at the lowest minimum cost. The data for the study were collected from primary and secondary sources. The primary data were obtained through the use of questionnaire, which was designed to collect data on the socio-economic characteristics of the employees of selected firms, their productivity and other relevant data and information while the secondary information sources includes texts, journals and other research publications. In the course of data analysis, descriptive statistics, correlation and multiple regressions were employed.
Keywords: Financial, Motivation and Performance

INTRODUCTION
In contemporary system, industrial harmony is generally taken to be an important element of organizational success. Effective employee performance depends on the level of motivation. This is manifested in workers job satisfaction and improved morale. The fulfillment of workers satisfaction is very important, it does not only help to keep the cost of production low, but also helps to retain skilled manpower in such organization. The goal of the worker is to satisfy his personal needs. Needs which provide the motivating force for work, while the goal of the employer is to maximize profit through high productivity and to remain in business. This profit can only be achieved when the organization produces at the lowest minimum cost. Workers are a vital key to the success of an organization and a productive workplace. The proper communication between managers and employees is the first and best way to keep productivity and satisfaction high and boast a low turnover rate. Research concerning communication between managers and employees has shown how to create a workplace where the employees are productive. Many researchers believe that when management participates and communicates with the employees, positive outcomes are considerable and job satisfaction and productivity are greatly increased (Jackson, 2008; Hoerr, 2009; Peterson and Hillkirk, 2009; Bluestone and Bluestone, 2009; Bernstein, 2009; Sims, 2007).The objective of the study was to determine the effect of financial motivation on organizational performance in selected firms in Abia state, Nigeria.

METHODOLOGY
Abia State is one of the 36 states in Nigeria. The state lies between longitude 04^0 45^1 and 06^0, 07^1 North and latitude 07^000^1 and 08^010^1 East. It is situated in the South-East of Nigeria and is bounded by Imo state at the Western border, Ebonyi/Enugu state at the North, Cross River/Akwa Ibom states at the East and Rivers State at the South. Abia State has a relatively high population density of 580 persons per square kilometer given its population of about 2.883million (NPC, 2006). About seventy percent of the people in Abia state are involved in agribusiness concerns and that accounts for the plethora of such firms in parts of the state. The data for this study were collected from mainly primary sources. The primary data were obtained through the use of questionnaire, which was designed to collect data on the socio-economic characteristics of the employees of selected firms, their productivity and other relevant data and information while the secondary information sources include texts, journals, and other research publications. The study used descriptive statistics, correlation and multiple regression in the analysis of data. Descriptive statistics such as tables, percentages, frequencies were used to assess the socio-economic profile of the worker. However, the correlation analysis was performed to ascertain the relationship between financial motivation and worker productivity while multiple regression was used to analyze the socio-economic factors that influence workers performance

RESULTS AND DISCUSSION
The Relationship between Financial motivation and Productivity
The correlation analysis was used to ascertain the relationship between motivation and productivity. Using the formula, the following result was realized. From Table 1, it could be observed that the rank coefficient for assessing financial motivation/productivity relationship among the workers was 0.711. This implies that there is a positive relationship between them. Thus, the productivity of the workers increases as they are motivated.

Factors Influencing Worker Productivity

To determine factors that influence worker productivity, multiple regression analysis was performed. The four functional forms were tried and the lead equation was selected on the basis of statistical and econometric criteria. The criteria employed include number and magnitude of significant variables, magnitude of R^2 and F-ratio and their conformity with a priori expectation. The R^2 (coefficient of multiple determination) which is 0.700 shows that the model is 70.0% variation in productivity are accounted for by the independent variables included in the model and it indicates goodness of fit. About 30% can be attributable to error and omitted variables in the model. Experience was significant at 1% probability level and positively related to productivity, indicating that as experience increased, productivity increased. Skill level was significant at 1% risk level had a positive coefficient indicating that skill level increased as financial productivity increased. It further implies that any 0.001% increase in skill level would increase productivity at work.. Marital status of the respondents was significant at 1% probability level and had a positive coefficient, implying that male employees outperform their female counterparts. By the implication of the significance of the work environment, it implies that conducive environment enhances worker productivity. In line with a priori, age was negative and thus, indicates that increasing age brings about declining productivity.

CONCLUSION

The complaints of managers, in recent times, about low performance, reduced output and dwindling productivity have been traced to little or no financial motivation of their workers. Lack of financial motivation occurs when the workers perceive non-challance on the part of management in his personal issues which dampens hard work, commitment and to the detriment of the organization. The need to address the issue has necessitated the study. Having found that financial motivation has a positive relationship with worker productivity and factors such as experience, skill level, marital status, work environment and age influence productivity significantly, opportunities exist for improvement. Appropriate mix of the determining variables will bring productivity enhancement.

ABSTRACT
This study examined the agricultural project (poultry egg production project) and employment generation in Kaduna state, Nigeria. The farm proposes to start with about 1100 chicks and with possible expansion to about 2, 000 layers within five years. The objectives are to produce more animal protein and maximize profit. The location of project area is Sabo Gaya, Chikun local government area of Kaduna state, Nigeria. Inputs for poultry egg production have been found to be numerous in the area. Deep litter system will be employed. The fixed inputs involved are land, poultry house, borehole, pick-up van and farm equipment while the variable inputs involved are day old chicks, feeds, vaccination, labour, etc. The proposed total fixed cost in raising about 1,000 layers was ₦5, 496, 650 while the variable will be ₦5, 825, 038. Loan of ₦5, 000, 000 will be collected and to be repaid in four equal instalments. The business was projected for five production cycles in order to determine whether is viable or not. The viability indicators such Net Present Value (NPV), Benefit/Cost Ratio and Internal Rate of Return (IRR) were used to determine the viability, profitable and worthwhile of the project. The calculations, from NPV, B/C ratio at 8% were ₦4, 068, 178 and 1.10 respectively. This showed that the project is profitable, viable and worthwhile; therefore, project should be undertaken at 8% discount factor. The result also revealed that NPV was negative (-₦196, 404) and B/C ratio was also less than 1 (0.9) at 100% discount factor. It means the project should be rejected at 100% discount factor. The result also, indicted that IRR was 62%, which means that investor will be better off, if he collects loan at interest rate less than 62%. Therefore, from the calculations and estimations carried out, the project is viable, profitable and worthwhile. Based on these, the project should be accepted.
Key words: Poultry egg production, project, profitable and viability

INTRODUCTION
A project is any activity on which we will allocate scare resources in expectation of returns and which logically seems to learn itself to planning, financing and implementation as a unit. The various types of agricultural projects include water resources development project, agricultural credit project, agricultural development programmes, agricultural industrial and commercial development. Also, agricultural project are usually classified by types of enterprise such as tree crop projects, arable crop project, macro and micro livestock (poultry, cattle, sheep, goats, rabbit, piggery, snail, grass cutter etc) , fishery project, mixed farming projects etc. Poultry egg enterprise plays a very significant role in providing Nigerians with cheap animal protein. In spite of the great nutritional contribution of eggs, some degrees of discrepancies between its production and consumption persist (World Bank, 1998 and Saliu, 2013). Based on the financial contribution of the poultry industry to local producers, many people are interested in taking to poultry farming as a business or a supportive economic activity. Ali (2002) observed that Nigeria's poultry production is expanding but not keeping pace with rapidly increasing domestic consumption requirements. The domestic supply shortfall is estimated at 25, 000 metric ton per annum. This Scenario implies that egg production have to be increased to a sustainable level. Like many agricultural production economics, the project has the following objectives which includes to produce more animal protein to fill in (partly) the existing gap in protein consumed by households and maximize returns or optimize profits through minimization of costs while goals of the project are to ensure the food security of household and to increase commercial egg production in Kaduna state, Nigeria.

METHODOLOGY
Study Area
The study area is Sabo Gaya, Chikun Local Government Area of Kaduna State. Two hectare of land have been acquired and cleared for the purpose. The piece of land is near a small stream which dries off during the dry season. The farm site is 15km from Kaduna City. Inputs such as labour, water, market have been found to be numerous apart from the availability of concentrate feed ingredient (soybean) which the researcher is carrying research on in order to reduce the overall cost of production. The fixed cost considered include land acquisition and clearing, construction of poultry house, pick-up van, borehole and farm equipment while the variable cost include day old chicks, feed vaccination, drug/medicine, labour, consumable/utilities, maintenance, contingencies and depreciation

As target consumers are mostly retail provision shops, egg rolls makers and five star hotels.

In addition to this, advert to create awareness for consumer of egg and spent hens was sold as at when due.

i. Current price of a crate of egg = ₦ 650
ii. Current price of a spent layer = ₦ 800
iii. Current price of manure = ₦ 300/100Kg bag
iv. Current price of a empty bag ₦ 20

Financial Analysis

It is good to determine the returns expected in the future in order to know whether the project is worthwhile and acceptable. The major viability indicators normally used in determine these are net present value (NPV), benefit/cost ratio (B/C ratio) and internal rate of return (IRR). The calculations and interpretations are as follow.

- Net present value of a project is the value of today of the surplus that the firm makes over and above what it could make by investing as its marginal rate. Mathematically, this is given by this formula.

$$NPV = \sum_{t=1}^{n} \frac{B_t - C_t}{(1+r)^t} \quad \text{.............................. (1)}$$

Where
B_t = benefits in each project year.
C_t = costs in each project year.
n = number of years
r = interest (discount) rate.
The project should be undertaken if NPV is positive.

- The Benefit/Cost Ratio is the ratio of discounted costs to discounted revenue and given by the formula:

$$B/C \text{ ratio} = \frac{\sum_{t=1}^{n} \frac{Bt}{(1+r)^t}}{\sum_{t=1}^{n} \frac{C_t}{(1+r)^t}} \quad \text{.............................. (2)}$$

Where;

$\sum_{t=1}^{n} \frac{Bt}{(1+r)^t}$ = Discounted Benefit

$\sum_{t=1}^{n} \frac{C_t}{(1+r)^t}$ = Discounted Cost

The project should be undertaken if benefit/cost ratio is greater than 1. If the benefit/cost ratio is exactly 1, it means that the project just breaks even. That is, it is making neither profit nor loss.

- The Internal Rate of Return (IRR) is the rate of return that is being earned on capital tied up while it is tied up, after allowing for recoupment of the initial capital it is also called the yield of an investment. Mathematically it is given by: $IRR = L + \frac{\mathrm{NPVL(H-L)}}{NPVL+NPVH}$ .... (3)

Where;
IRR = Internal Rate of Return;
L = Lower discounted factor;
H = Higher discounted factor;
NPV_L = Net Present Value at Lower discounted factor;
NPV_H = Net Present Value at Higher discounted factor;

RESULTS AND DISCUSSION

Calculations of NPV and B/C Ratio at 8% for the project:

From Table 1, Net Present Value (NPV) at 8% equal to N4, 062, 174 which is positive. This means that the project is profitable and worthwhile; therefore, the project should be carried out. Also, Benefit/cost ratio at 8% = $\frac{Discounted\ Benefit}{Discounted\ Cost} = \frac{45{,}468{,}842}{41{,}406{,}665}$ = 1.10. The benefit/cost ratio for the project is greater than 1. This means that the production is in stage II which indicated that the producer is making profit; therefore, the project should be accepted.

Calculations of NPV and B/C Ratio at 100% for the project: It could be deduced from the Table 2, the Net Present Value (NPV) at 100% equal to -₦196, 404 which is negative. This implies that the project should not be undertaken at the discount factor of 100 per cent. It further shows that Benefit/cost ratio at 100% = $\frac{Discounted\ Benefit}{Discounted\ Cost} = \frac{9,338,809}{9,846,634}$ = 0.9 which is less than one. It means that the production is at stage III and it implies the project should not be implemented at the discounted factor of 100 per cent.

Estimated cash flow analysis of the project (Internal rate of Return): The analysis of the data from the Table 3 shows that Net Present Value (NPV) at 60% is equal N40, 370 which is positive and small profit still made, project should be undertaken. Also, at 65 per cent Net Present Value (NPV) at 65% = -N72, 931 which is negative, the project should be rejected at 65 per cent. Furthermore, IRR $= L + \frac{\text{NPVL(H−L)}}{NPVL+NPVH} = 60 + \frac{40{,}370(65-60)}{40{,}370+72{,}931}$ = 60+1.78 = 61.78%, therefore IRR = 62%. It means that for every ₦1 that is invested, the investor will receive ₦1:62K. After paying 7kobo on the naira to the lender, he will be better off by 55kobo.

CONCLUSION

The findings and the above estimates, all things being equal, the project is viable, worthwhile and profitable. It is highly recommended for its expected contribution to the development of the community.

ABSTRACT
The study assessed access of family farmers to microfinance facilities in Ibarapa Central Local Government area, Oyo state. Two-stage sampling technique was used to select 141 family farmers as sample size for the study. Data collected through interview schedule were analyzed using frequency counts, percentages, weighted means score (WMS), rank and mean while Pearson Product Moment Correlation was used to test the relationships that existed between selected socio-economic characteristics and family farmers' access to microfinance facilities. Results revealed the mean age of respondents was 47years and 36.9% of respondents had no formal education. Of all the microfinance facilities accessible to family farmers, thrift and credit collectors ranked 1st; rotational group savings ajo ranked 2nd. Incomplete contributions by some members in the group savings scheme ajo ranked 1st among constraints in accessing microfinance facilities. Results of Pearson Product Moment Correlation analysis showed that age (r = 0.301, p<0.05) and educational status (r = 0.304 p<0.05) have significant relationship with family farmers' access to microfinance facilities. It is hereby recommended that family farmers should organize adult literacy class and, also, improve the structures of their group savings scheme to meet microfinance needs of members.
Keywords: **Family Farmers, Microfinance Facilities, thrift and credit**

INTRODUCTION
Family farming was described by Adewale (2014) as consisting of agricultural forestry, fisheries, pastoral and aquaculture production being managed and operated by a family and relies primarily on labour from the family. It is any agricultural activity involving fishing, poultry, rearing and cultivation of crops owned by group of people who are related by blood or marriage. Family farming could be for subsistence or commercial, or for both. In developing countries, family farmers are usually small-scale farmers or food producers who are at the forefront of eradicating hunger. Incidentally, they are usually resource-poor farmers who hardly have access to fund or wherewithal to carry out their farming activities. Financing family farming activities depend mostly on microfinance sources. Wikipedia viewed microfinance as a source of financial services for entrepreneurs and small businesses lacking access to real banking and related formal services www.enwikipedia.org/wiki/microfinance.Jaffari, *et al. (*2011) defined microfinance as the provision of financial services to the poor who are traditionally not served by the conventional banks. The distinguishing features of microfinance are the smallness of loans advanced and savings collected, near absence of assets-based collateral as well as simplicity of operation (Iorchir, 2011). This kind of financial services give family farmers the opportunity to access finance and this affords the opportunity to sustain their family enterprises more efficiently and effectively, thereby providing investment opportunities for better economic returns (Amao and Kolawole, 2015). In Nigeria, microfinance institutions were established by successive governments in order to make credits available to non-formal sector, especially people in the rural areas, where family farming dominates. Such institutions include rural banking scheme, Peoples Bank, Family Economic Advancement Programme, Nigerian Agricultural Cooperative and Rural Development Bank, Community Bank, and currently Microfinance Banks (Acha, 2012). While microfinance operates by providing credit and other financial services to economically active but low income households and businesses (Acha, 2012) including family farmers and their farms, studies have shown that family farmers have constrained access to microfinance facilities and this continue to reduce their production potentials. Arising from this problem, this study assessed access of family farmers to microfinance facilities in Ibarapa Central Local Government Area of Oyo State. The specific objectives of the study were to:

1. identify socio-economic characteristics of family farmers in the study area
2. determine family farmers' means of accessing microfinance facilities in the study area
3. identify constraints being faced by family farmers in accessing microfinance facilities. The study also tested the hypothesis that – there is no significant relationship between selected socioeconomic characteristics of family farmers and their access to microfinance facilities.

METHODOLOGY
The study was conducted in Ibarapa Central Local Government area of Oyo state. The population of the study comprised all family farmers in the study area. Snowball technique was used to select 141 farmers as sample

frame and all the family farmers were sampled purposively. Data were collected through a well-structured interview schedule. Data were analyzed with descriptive statistics and correlation model

RESULTS AND DISCUSSION

Respondents' socioeconomic characteristics

The results in Table 1 showed that majority 31.3% of the respondents fell between 41-50 years, while the mean age was 46 years. This implies that most family farmers in the study area were adults and have agility to pursue farming activities. It is also revealed that majority of the respondents (48.2%) had family size of range 6 – 10 while the mean household size was 7 members. This implies that family farmers in the study area have large family size who are likely to be involved in family farming activities. Table 1 also revealed that many respondents (36.9%) had no formal education. This implies that literacy level is relatively poor among family farmers in the study area and this may limit them from accessing microfinance facilities as being illiterate may hinder them from filling cumbersome documents required to access loan.

Facilities through which family farmers' access microfinance in the study area

Data from Table 2 showed that thrift and credit collectors ranked 1st as the most common microfinance facility accessible to respondents. This implies that thrift and credit collector offers the greatest opportunity for family farmers to access microfinance facility because the finance does not usually interest-free. Since thrift and credit collection arose from farmers' savings, it means that personal savings is the commonest and most assured means of accessing finance for family farming. Microfinance banks that was least accessed may be due to the fact that farmers who could not meet the banks' stringent conditions or are not literate enough to interact with banking bureaucracy could not access fund through microfinance banks.

Constraints faced by family farmers in accessing microfinance facilities in the study area.

Table 3 revealed that incomplete contribution of money by some group savings *ajo* members especially those who have benefitted from the contributions (1st), is the commonest constraint that the respondents faced in accessing microfinance facilities, little amount of money is the 2nd, partiality in issuing loan 3rd and condition for obtaining loan is cumbersome also ranked 3rd, delay/postponement of loan payment to applicants ranked 4th. This implies that accessing loan from microfinance facilities is always bedeviled by constraints which hamper family farmers from accessing loan

Test of hypotheses

Ho1- There is no significant relationship between selected socioeconomic characteristics of family farmers and their accessibility to microfinance facilities in the study area.

Pearson Product Moment Correlation (PPMC) results in Table 4 revealed that there is significant relationship between age ($r = 0.301$, $p< 0.05$), educational status ($r = 0.304$, $p < 0.05$) and family farmers' access to microfinance facilities. This implies that the older the farmer, the more such farmer has access to microfinance facility. This is because age is perceived to command integrity and loan-worthiness. Also, the more literate a farmer is, the more he or she has access to microfinance facility.

CONCLUSION

Based on the findings of the study, it concluded that the bulk of microfinance facilities accessible to family farmers revolves round their personal savings. It is hereby recommended that family farmers should form or improve the structures of their group savings scheme *ajo* to meet microfinance needs of members. Also, family farmers should organise adult literacy class designed to create awareness on available microfinance opportunities.

ABSTRACT
The study was conducted in the three zones of Abia State. Multi-stage random sampling technique was employed in selecting the blocks, circles and respondents in the study area. Structured questionnaire was used to elicit information from 120 respondents on socio-economic characteristics, level and factors influencing the use of credit and constraints to Bank of Agriculture (BOA) credit. Data collected were analyzed using descriptive statistics (percentage and frequency,) and inferential statistics (Probit Model analysis). The result of the study revealed that majority (35%) of farmers fell within the ages of 51 – 60 years, mostly (78.3%) males, highly educated (44.2%), greatly married (93.1%) with moderately (37.5%) household size of 4 – 6 persons, mainly (67.5%) part-time, and 80 percent belonged to cooperative society. However, farmer's gender, household size, awareness of credit, cooperative society and access to loan were significant at 1.0% and 10.0% levels of probability while farm size was negatively significant. Based on the above, Abia ADP should create awareness of the importance of BOA credit by encouraging and assisting farmers in the formation of cooperative society for easy access and use of credit. Also Federal government should reduce the lending interest rate and intervene on the late payment of BOA credit for timely accessibility.
Key words: Credit, Bank of Agriculture, Farmers, Interest, Accessibility and Institution

INTRODUCTION

Agricultural production engages about 80 percent of the Nigerian population, majority are rural small-scale farmers producing food with traditional technologies because of lack of financial accessibility to acquire the necessary tools and materials (Onunka, 2011). Accordingly, most farmers in the developing countries such as Nigeria, purchase farm inputs and pay for production services with self-sourced capital (personal savings) without accessibility to credit .Most rural Nigerian farmers earn little income and save less since much of their earnings are used to fund consumable goods. Hence, their marginal propensity to save and invest on productive ventures such as agricultural production tends to zero (Afolabi, 2010). Savings and investment are dependable on level of income of individual earners. Some Nigerians falls under low income category, they try to save in unorthodox ways. For instance cases abound where savers save idle funds under their pillows, or in ditches, with such funds being stolen or destroyed by termites. The problem of accessibility to credit for agricultural production has triggered to a greater extent that their decisions to demand for credit to finance agricultural investment are high. This has resulted also to low productivity, low income, low savings and mass poverty. The increasing need for credit in agricultural production becomes more obvious as the society responds to adoption of improved technologies of farming so as to produce enough food for the teeming growing population. Credit is a vital component of agricultural support service to be generated from the agro-service system. Credit also plays a crucial role in agricultural production and rural development as it enables farmers reap economics of scale, venture into new fields of production, employ new technologies and empower them to provide utilities for a widening market. The increasing need for credit in agricultural production becomes more obvious as the society responds to the campaign for monogamy, birth control, mass literacy and use of improved methods of agricultural production so as produce more food for the teeming growing population. As a matter of necessity, Nigerian government in sponsoring credit institution for agricultural production created specialized credit institution called Bank of Agriculture (BOA), to carter for the credit needs in the agricultural sector, thereby alleviating poverty of the small-scale farmers in the country (Oladebo and Oladebo, 2008). BOA was formally called Nigerian Agricultural Bank (NAB) in 1973 and 1978, which was changed to Nigerian Agricultural and Cooperative Bank (NACB) in 1990s and subsequently known as Nigerian Agricultural Cooperative and Rural Development Bank (NACRDB) in 2000. In an attempt to reposition the nation's financial institution in meeting the credit needs of the average farmer, and effectively sustain the national agriculture, led to the establishment of Bank of Agriculture (BOA) in 2010. BOA has its branches in all the states of the country including Abuja with its credit functions of direct lending, on-lending, collaboration and monitory of credits to agriculture and non-agricultural small businesses.

In addition, government policies and objectives towards this direction are to enhance the farmers' opportunity of becoming self-sufficient, increase yields/productivity, increase income and better their living standard by improving their farm operations and technologies in the form of credit with little or no interest rate. However, this can be achieved through creating awareness, access and availability of the small-scale or average farmers to have full information about the latest or existence of the new development so as to take decision on the use.Considering the importance of credit as production power in agricultural business, it is therefore, expedient to examine the use of credit from Bank of Agriculture (BOA) by farmers in the study area.

METHODOLOGY

The study was conducted in Abia State which is one of the state in the south East region of Nigeria. It lies within approximately latitude 4^o. 49^1 N and $6^o.47^1$N and longitudes 7^oE and 8^oE of the Greenwich meridian with its capital at Umuahia. Multi-stage sampling technique was employed to select the respondents according to the zone, block and circle. Six (6) blocks were selected from the 3 zones and 2 circles from the each block, making it 12 circles randomly selected. Ten (10) farmers (respondents) were selected and interviewed using structured questionnaires from each circle, making it a total of 120 farmers as sample size. Data collected was analysed using descriptive statistics (tables, percentages, frequencies) and inferential statistics (probit model estimate).
Probit model estimate is specified explicit in the form below:

Pi [Y1] = [Fzi] … (1)

Where

$Zi = \beta0 + \beta1X1 + e$

$Yi = \beta1 + \beta2X2i + \ldots\ldots.. + \beta kXki + e$ … (3)

Yi* is unobserved but Yi = 0 if Yi* < 0,1 if Yi* >0

P (Yi = 1) = P (Yi* >0)

P (μ i ≥ -β1 + β2X2i ………………. -βk X kL …(5)

Where i = 1,2 ……………120

Where Yi = Accessibility (Accessible = 1, Not accessible = 0)

β=A factor of unknown coefficients.

[βo] = Intercept

[β1] = Regression Coefficients

ei = Error term

X_1 = Gender (Male = 1, Female = 0)

X_2 = Age of respondents (years)

X_3 = Marital status (married = 1, non-married = 0)

X_4 = Educational status (years)

X_5 = Household size (in number)

X_6 = Type of farmer (full-time = 1, part-time = 0)

X_7 = Farming experience (years)

X_8 = Awareness Credit(Yes = 1 No = 0)

X_9 = Access to Bank of Agriculture(Yes = 1, No = 0)

X_{10} = Extension contact (Yes = 1, No = 0)

X_{11} = Utilization of Agric loan (Yes = 1, No = 0)

X_{12} = Farm size (ha) X_{14} = Farmers' income (₦)

RESULTS AND DISCUSSION

The socio-economic characteristics of the respondents are presented in Table 1. It shows that majority (35%) of farmers fall within the ages of 51 – 60 years which might explain that credit/loan requires responsible and matured minds. Most of the respondents (78.3%) are males, probably because of collateral involved, well read (44.2%) and married (93.1%). The average household size is 4 – 6 persons (37.5%), mainly part-time (67.5%) farmers and majority (80%) belong to cooperative society. Table 2 show the Tobit analysis on the factors influencing adoption of credit from BOA. It reveals that five (5) independent variables (gender, household size, awareness, cooperative society and access to loan) are significant at 1% and 10% levels, in explaining the important of use of credit from BOA in the study area while farm size is negatively significant. The x^2 value (131.33*) is significant at 10% level of probability. Gender has a strong positive significant relationship (1% level) with the farmers in the use of BOA credit. The result is in agreement with the outcome of Onunka (2005) that gender mediates access, and control of resources and decisions to adopt new techniques. Also, household size increases the use of credit because increased household leads to increased farm lands, awareness and utilization of credit. Membership of cooperative society indicates positive relationship, implying the more the farmers join cooperative groups, the more they use credit from BOA. This might be that Banks easily gives credit to cooperatives more than individual farmers for the fear of defaulting. Access to loan is positively significant with the use of credit, indicating the importance of collateral in financial institutions, while farm size is of no significant and relationship to the use of credit from BOA in the study area. Table 3 shows the major constraints to BOA credit use by farmers such as lack of collateral (1st), high interest rate (2nd) and late approvals/payment (3rd), in the study area. This result is in agreement with *aprio ri* expectation observation that small-scale farmers have difficulties in their transactions with the institutions due to the inaccessibility of the funds as a result of high interest rate and the bureaucratic procedures.

CONCLUSION

The results of the study have brought to bear the determinants of use of credit from BOA in the study area. It is obvious that socio-economic characteristics of respondents shows that the majority (35%) fall within the ages of 51 – 60 years, mostly males which are highly educated, married with moderately household size, mainly part-time farmers and members of cooperative society. Independent variables such as gender, household size, awareness, cooperative society and access to loan are significant at 1% and 10% levels and farm size is negatively significant. The respondents have major constraints – lack of collateral, high interest rate and late payment of credit from BOA in the study area. Considering the need for credit to small-scale farmers, the Abia ADP should create awareness of the importance of BOA, assist and encourage the farmers in forming cooperative society for credit accessibility. Further, federal government should reduce the lending interest rate and emphasis on the early payment of BOA credit to farmers for more investment.

ABSTRACT

The study was carried out to assess the cost and return of yam production in Ikwuano Local Government Area of Abia State. Structured questionnaire was used to elicit information from the farmers. Multi-stage Random Sampling method was used in the study. Two clans were randomly selected out of four clans in Ikwuano, they are Oboro and Ibere. Two communities from each of the selected clans were randomly selected, making it four communities and they are Umuariaga Oboro, Ndioru Oboro, Amuro Ibere and Itunta Ibere. 30 farmers from each of the four Communities were randomly selected for the study. In all 120 respondents were used as the sample size. List of farmers collected from the community head served as the sample frame. Data were analyzed using descriptive statistics. Results showed that majority of the farmers (46.7%) are between 41-50 years and 27.5% (31-40) years. This showed that yam production requires able bodied men for its cultivation and production. The result also revealed that yam farming is profitable with the net income of ₦352,906.85 realized within a production season. This result establishes the fact that yam production is profitable in Ikwuano LGA of Abia State. The result also revealed that about 64.2% of the respondents have no extension agents' contact within the period under review. There is therefore, the need for the government to reactivate extension system by giving them necessary support as to enable them disseminate proper information to yam farmers in Ikwuano for food security and improved livelihood. Also, farmers' in Ikwuano area should get involved in yam production for food security and improved livelihood since it is a lucrative enterprise.
Keywords: Cost, returns, yam production and economics

INTRODUCTION

Yam (*Dioscorea* species) is an annual tuber-bearing plants with more than 600 species out of which six are socially and economically important in terms of food, cash and medicine (IITA, 2009). Some of its species are water yam (*Dioscorea alata)*, white yam (*Dioscorea rotundata*) and yellow yam (*Dioscorea cayanensis)* (FAO, 1998). In Nigeria, yams contribute significantly to the national economy and income by providing employment to many rural dwellers (Asumugha *et al*., 2010) and cheap carbohydrate staple food for over 80 percent of the populace (Nwachukwu, 2008). It plays significant roles in the social-cultural and economic wellbeing of thousands of people in Nigeria. The yam peel may also have economic values; it can be recycled and used as feedstuffs for livestock, since it is highly rich in carbohydrate (Oladeebo and Okanlawon, 2010). Yam production in Nigeria has more than tripled over the past 40 years from 6.7 million tonnes per annum in 1961 to 27 million tonnes per annum in 2001 (FAO, 1999). This increase is however attributed to larger hectares of land planted to yam than to increased productivity as a food crop, the place of yam in the diet of the people in Nigeria cannot be overemphasized. It contribute more than 200 dietary calorie per capital daily for more than 150 million people in west Africa while serving as an important source of income to the people (Babaleye, 2003). Yam production is regarded as a source food security and employer of labour in many areas where it is cultivated. Despite the importance of yam in food availability, income and employment generation, its production has not been given the utmost attention in Ikwuano Local Government area. The objective of the work is to describe the socio-economic characteristics of the farmers and assess costs and returns of yam production in the study area.

METHODOLOGY

The study was carried out in Ikwuano North LGA of Abia State. Structured questionnaire was used to elicit information from the respondents (farmers). Multi- stage Random Sampling method was used to select two clans out of four clans in Ikwuano Local Government Area, they are Oboro and Ibere. Two communities from each of the selected clans were randomly selected, making it four communities and they are Umuariaga Oboro, Ndioru Oboro, Amuro Ibere and Itunta Ibere. 30 farmers from each of four Communities were randomly selected for the study. In all 120 respondents were used as the sample size. Data were analyzed using descriptive statistics. To determine the cost and return of yam production in Ikwuano Local Government Area, it was analyzed using the formula below.
The cost and return of yam production was analyzed thus:
TR = P*Q ------------------------------------ (i)

TC = TVC +TFC ------------------------------ (ii)
GM = TR – TVC ----------------------------- (iii)
NI = GM- TFC -------------------------------- (iv)
Where TC = Total Cost
TVC = Total Variable Cost
TFC = Total Fixed Cost
TR = Total Revenue

Q = Quantity of yam produced
GM = Gross Margin
NI = Net Income

RESULTS AND DISCUSSION

Results in Table 1 shows that majority of the farmers (46.7 %) falls between 41-50 and 27.5% of the farmers falls between 31-40 years. This showed that yam production requires able bodied men for its cultivation and production. The results also showed that majority of the farmers constituting 96.7% possess formal education. Education makes farmers receptive to new ideas and techniques (Anyaegbunam *et al*., 2006). The result in table 1 also revealed that most of the farmers (72.5%) are male while about (27.5) % are female. Traditionally, it is believed that women in Igbo land are not meant to cultivate yam and it requires a lot of energy for its production. According to Ironkwe and Ewuziem (2010), traditionally yam is regarded as ''Man's crop''. Results in table 1 also show that 60.0% of the respondents were married, while the remaining 22.5% were single. According to the married people, farming is a necessary condition for them to lift their households out of poverty and ensure hunger free situation in their homes. For these reasons, they are more engaged in agriculture than unmarried people in the area. The results also indicate that the majority (50.0%) of the respondents have between 5 and 9 household members. This implies that the birth rate in the area is still high. Traditionally, yam production is a labour intensive enterprise, family size was a necessity for the size of the farm and increase production of yam in the area. It was also revealed in the table 1 that 90% of the farmers got labour source from both their families and hired labour while only 10% of the farmers do their farm work by themselves. This implies that yam production is labour intensive.

Costs and Returns

Table 2 shows the result of the analysis of costs and returns accrued to yam farmers in the study area in the year 2016. The result indicates that the farmers invested about ₦4,858,964.15 in the production of yam, these includes cost of labour, seed yams, implements, agro-chemicals and other necessities. Cost of seed yam acquisition (97.20%) ranked first in the list of items for yam production. This implies that cost of planting material (seed yams) is the major cost item associated with yam production. Cost of labour ranked second, accounting for 1.86% of total cost. This showed that yam production requires much labour while Agro-chemicals and Transportation ranked third and fourth accounting for 0.20% and 0.05% of total cost of yam production respectively. Cost on depreciation constituted 0.39% while land charges as rent had 0.32%. The total variable cost items showed ₦4,824,375.4 while the fixed cost had ₦34,588.75. The table further revealed that the total revenue of ₦5,211,871 was earned by the farmers during the period and that the farmers made net income of ₦352,906.85 in the production season. The result obtained here agrees with Oladeebo and Okanlawon (2010).

CONCLUSION

The result revealed that the farmers made net income of ₦352,906.85 in the production season. This establishes the fact that yam production is profitable in Ikwuano LGA of Abia State. It was revealed that about 64.2% of the respondents have no extension agents' contact in their farming season Therefore, government should reactivate extension system and give them necessary support to enable them disseminate proper information to yam farmers in Ikwuano for increased yam production and more profit. Also, farmers' in Ikwuano area should get involved in yam production for food security and improved livelihood since it is a lucrative enterprise.

ABSTRACT

The study analyzed the cassava value chain in South Eastern Nigeria Specifically, it sought to identify the actors, roles and interrelationship across the chain, map the value chain, ascertain the benefit cost ratio of cassava processing, identify factors affecting growth and competitiveness of various channels, and then potential business solutions that will address constraints. The study was purposively carried out in Anambra and Imo States based on the intensity of cassava production, two local government areas (LGAs), and 30 respondents were selected from each of the LGAs, making it a total of 120 respondents comprising of producers, processors and marketers. Information was elicited from the respondents by means of focused Group Discussion (FGD), interview schedule and structured questionnaire. Data were analyzed with descriptive statistics. The results also show that the most important constraint militating against growth and competitiveness of the channels was unavailability of credit (85.00%) which ranked highest, followed by high cost of transformation (76.67%) high labour cost (69.17%) and high cost of processing (62.25%) which ranked second, third and fourth respectively. Potential business solution that will address constraints identified were access to credit (87.5%) which ranked first; this was followed by construction and rehabilitation of rural and feeder roads (81.67%), provision of storage facilities (76.67%) which ranked second and third respectively among other factors.It is advocated that policies regarding these identified potential solutions should be put in place and the resultant effect will be development and maintenance of a well-functioning market for Nigerian cassava and its products that will be able to compete favourably with products from other countries. Cassava value chains can also be enhanced through farmers cooperatives organized under a public private partnership strategy.

Keywords: value chain, cassava, growth and Nigeria

INTRODUCTION

Nigeria is the largest producer of cassava in the world with an estimated annual production of about 54 million metric tones (FAOSTAT, 2013). About 90% of this is however consumed as food in form of gari, abacha and fufu and also 70% of cassava produced in Nigeria is processed into gari (Onabalu, 1997).Across the country, cassava production has witnessed a tremendous increase for different reasons mainly due to introduction of high-yielding and disease-resistant varieties among other factors This increase in production between 2004 and 2006 came about as a result of the interventions of the Nigerian Government and some developmental agencies. The Nigerian Government facilitated the development of new disease-resistant cassava varieties by the joint efforts of International Institute of Tropical Agriculture (IITA), National Root Crops Research Institute (NRCRI), Root and Tuber Expansion Program (RTEP), and the Federal Ministry of Agriculture, in conjunction with State Agricultural Development Programs and cassava farmers. (Sanni *et al*, 2009) The Presidential Initiative on Cassava, launched in Nigeria in 2003, brought cassava and its potential to the national limelight (Sanogo and Adetunji 2008). The Initiative had as its goal the promotion of cassava as a viable foreign exchange earner and also the development of the production system to sustain the national demand. The Presidential Initiative focused its intervention on the development of production, processing, and marketing of the processed products.The cassava market in Nigeria can be classified into two broad categories based on the nature of demand namely: the traditional food-oriented market and the industrial market. The former refers to the demand for food consumption by individuals and households while the latter is the demand for cassava for industrial purposes (Knipscheer, et al, 2007).There is increasing demand for cassava product due to rapid population increase, high rate of urbanization and increased use of cassava products in the livestock, confectionery and starch industries.A value chain process involves all the activities that are undertaken in transforming raw materials into a product that is sold and consumed (Vermeuleu *et al.*, 2008).More so Value chain analysis (VCA) can be defined as a method of accounting and presenting the value that is created in a product or service as it is transformed from raw inputs to a final product consumed by end users Value chain activities include direct functions of primary production, collection, processing, wholesaling and retailing as well as the support functions. In value chain system, value is added at each point in the chain.Ananmbra and Imo states produce cassava in large quantity. In -depth value chain study in the states is scanty; the study investigated factors affecting growth and competitiveness of the various channels and the potential business solution that will address constraints and tap the opportunities.

METHODOLOGY

A purposive multistage sampling technique was used in selecting states and respondents. Two states, Anambra and Imo states were chosen from the five states in south eastern Nigeria based on intensity of cassava production. Two Local Government Areas were selected from each state, Awka North and Oyi for Anambra state, Ohaji Egbema and Owerri North for Imo State respectively.30 respondents were selected from each LGA making a total of 120 respondents comprising producers, processors and marketers. Information was elicited from the respondents by means of focused group discussion, interview schedule and structured questionnaire. Information gathered bordered on cassava production, processing and marketing. Data were analyzed using descriptive statistics

RESULTS AND DISCUSSION

Constraints militating against growth and competitiveness of the various channels

The results in Table 1 show the frequency distribution of respondents according to constraints militating against growth and competitiveness of the various channels . The results show that the most important constraint militating against growth and competitiveness of the channels was unavailability of credit (85.00%) which ranked highest, followed by high cost of transformation (76.67%) high labour cost (69.17%) and high cost of processing (62.25%) which ranked second, third and fourth respectively.

Others were; inadequate storage facilities (60.00%), unstable prices (53.33%), seasonality of product (47.50%) and use of crude facilities in processing (40.83%) which ranked fifth, sixth, seventh and eight respectively. Among the least constraints were; poor demand (34.17%), inadequate market information (30.00%), high market charges (23.33%) and unstable government policies (18.33%) which ranked ninth, tenth, eleventh and twelfth respectively.

Potential business solutions that will address constraints

The results in Table 2 show the frequency distribution of respondents according to potential business solutions that will address constraints. The results reveal that the most important potential business solution that will address constraints militating against growth was access to credit (87.5%) which ranked first; this was followed by construction and rehabilitative of rural and feeding roads (81.67%), provision of storage facilities (76.67%) which ranked second and third respectively. Others include; prices (68.33%), traditional wholesale and retail outlets (59.17%), National trade policies (51.67%), specialized wholesalers (50.33%) which ranked fourth, fifth, sixth and seventh respectively. Among the least solutions were, preferred suppliers (48.33%), information technology (45.33%), penetration into lower economic market segments (44.16%), centralized procurement (39.117%), domestic regulations (33.33%), market concentration (29.17%) and competition among retailers which ranked eighth, ninth, tenth, eleventh, twelfth, thirteenth and fourteenth respectively.

CONCLUSION

The study revealed that a lot of constraints militate against the growth and competitiveness of the value chain process; these include unavailability of credit, high cost of transportation, high labour costs, high cost of processing, inadequate storage facilities and unstable prices among others. Potential business solutions that will address the constraints identified were access to credit, construction and rehabilitation of rural feeder roads, provision of storage facilities, stable prices, traditional wholesale and retail outlets and specialized wholesalers among others. It is advocated that policies regarding these solutions and adequate strategies should be put in place and the resultant effect will be development and maintenance of a well-functioning market for Nigerian cassava and its products that will be able to compete favourably with products from other countries.

ABSTRACT
This research work focuses the economic analysis of Gari processing in Ibarapa Central Local Government Area of Oyo State. It described the socio-economic characteristics of Gari processors, identified the processing methods available in the study area, identified the constraint encountered by the processors and determined its profitability among local producers. Farmers' use of indigenous knowledge in the processing of cassava into Gari for immediate economic returns and continuous revenue generation calls for critical evaluation. A multistage sampling technique was employed with a sample size of 120 processors. Descriptive and budgetary analysis were used and major findings revealed that only female were involved in cassava processing into gari with mean age being 40 years. Total fixed cost accounted 19.4% of total cost incurred in cassava processing. Therefore, the business can easily be set-up. Benefit Cost Ratio (BCR) is 1.90 which implies that every ₦1.00 invested in cassava processing into Gari, will yield ₦1.90. This shows that cassava processing into gari is profitable and sustainable with little capital. Lack of capital and market price fluctuation were the major constraints facing cassava processing into gari in the area.
Keywords: Gari, processing, economic analysis and Nigeria

INTRODUCTION
Cassava (*Manihot esculenta*) is an important staple food and cash crop in several tropical Africa country especially Nigeria where it play a principal role in the food economy. Nigeria is the largest cassava producing country in the world with an annual estimate of 49 million metric ton (Odedina and Adebayo, 2012). Among the starchy staples, cassava provides high carbohydrate production which is about 40.0 percent higher than rice and 25.0 percent more than maize. According to (Nweke *et al.*, 2002; Nweke, 2004), 80.0 percent of Nigeria in the rural areas eat cassava meal at least once a day, hence it plays a major role in the country food security. According to (Odedina and Adeboye, 2012), no Continent depends as much as on root and tuber crop in feeding the population as does Africa. In humid and sub-humid areas of tropical Africa, it is either a primary staple food or secondary co-staple. In 2002, cassava gained prominence in Nigeria following the pronouncement initiative on the crop. Cassava roots are used for human food and animal feed in a large number of different products. Various processing methods are used to produce different food products, depending on locally available processing resources, local customs and preferences. Cassava processing improves palatability, increases shelf-life, facilitates transport and, most importantly, detoxifies cassava roots by removing cyanogens (Westby, 2002).
A combined process of grating (shredding) and fermentation of cassava roots is important in the processing of roots for many West African products, including roasted granules (*Garri*), steamed granules (*Iattieke*) from Côte d'Ivoire and some of the fermented pastes (*Agbelina* and *placali* from Ghana and Côte d'Ivoire respectively) (Westby, 2002; Obilie *et al*., 2004). Furthermore, cassava generates income for its producers, processors, transporters and marketers and it serves as raw material in industries such as bakery, textile, paper, plywood and confectioneries (Anaekwe, 2012; FAO, 2003). In view of the benefits of cassava processing into Gari highlighted as aforementioned, efforts are being intensified towards increasing cassava processing into Gari in the country to the level of self sufficiency. One of such commitments was the pronouncement and investment of the Obasanjo administration to increase cassava processing into Gari to a level that it serves as the nucleus of much industrial production in Nigeria (Fakayode, 2008). However, farmers' use of indigenous knowledge in the processing of cassava into Gari for immediate economic returns and continuous revenue generation calls for critical evaluation. Hence, the focus of this study is to analyse the economics of cassava processing into Gari by describing the socio-economic characteristics of Gari processors, identifying the processing methods available in the study area, identifying the constraint encountered by the processors and determining its profitability among local producers, in Ibarapa central local government of Oyo State, it is generally observed that there is low level of investment in small scale cassava processing into Gari. This is evident in the preponderance of women most of whom are resource poor in cassava processing into Gari enterprises. Inadequate empirical data on value addition to cassava processing into Gari might be the bane of the inability of the enterprise to attract the necessary attention of private entrepreneurs in the sector. This therefore portends negative consequences for the food security and employment generation situations in Ibarapa central local government area in particular and Nigeria in general. Considering the intensified effort of research so far to maximize the use of various method of processing Gari, hence, this study becomes essential to bring in productivity into Gari processing and great income for Gari processors and cassava planting farmers thereby making them to be food secured.

MATERIALS AND METHODS

Oyo State is divided into administrative or agricultural zones: these are the Ibadan-Ibarapa, Oyo- Iseyin, Saki and Ogbomosho. Ibarapa zone is composed of three local governments which are Ibarapa North, Ibarapa East and Ibarapa Central. The study was carried out in Ibarapa central Local Government Area of Oyo State. Primary data were obtained through the administration of well-structured questionnaires which were used to obtain information from 120 Gari processors with the use of a multistage random sampling technique. Information such as age, sex, marital status, education, household size, religion, cost and return quantity and expenditure, revenue among others were obtained. Descriptive statistic (such as frequency count, percentage, mean), gross margin and regression analysis were used for the analysis. Gross margin was used to determine the cost and returns while regression analysis was used to determine the effect of socio-economic characteristic on the profitability level of the processor. Analysis of variance was used to test the hypothesis. The gross margin is specified as;

GM = TR – TVC

Where;

GM = Gross margin, TR = Total revenue, TVC = Total variable cos, TFC= Total fixed cost

GM – TFC = profit

In line with the use of ordinary least square multiple regression (OLSR) analysis; four functional forms were fitted into the data. The equation that gave the best fit was then selected as the lead equation based on conformity with a priori expectations (expected signs of the estimators, the magnitude of the coefficient of multitude determination (R^2) and the statistical significance of the parameter estimate). The explicit forms of the function are given as;

Y = b0 + b1X1 + b2X2 + b3X3 + b4X4 + b5X5 + b6X6 + b7X7 + b8X8 + b9X9 + e

Exponential = lnY = b0 + b1X1 + b2X2 + b3X3 + b4X4 +b5X5 + b6X6 + b7X7 + b8X8 + b9X9+ e

Semi log = Y= b0 + b1lnX1 +b2lnX2 +b3lnX3 + b4lnX4 + b5lnX5 + b6lnX6+ b7lnX7 + b8lnX8 + b9lnX9+e

Double log= lnY = b0 +b1lnX1+b2lnX2 +b3lnX3 + b4lnX4+ b5lnX5+ b6lnX6+ b7lnX7+ b8lnX8 +b9lnX9+e

Where;

Y= profit (N), X_1 = Quantity of cassava tuber, X_2 = Amount spend on transport of product, X_3 = Equipment cost, X_4 = Amount spend on labour, X_5 = Amount spend on firewood, X_6 = Amount spend on basket, X_7 = Amount spend on broom, X_8 = Grating cost, X_9 = Market charges, e = error term.

RESULTS AND DISCUSSION

Socio-Economic Characteristics of the Respondents

Table 1 shows that all the respondents were women which implies that only women were involved in Gari processing while men believed that Gari processing is women's job and therefore preferred involving in production rather than processing. A good number of the processors were in their active age with 39.68 years as the mean age with 7 years as average year of experience. Majority of the gari processors had no formal education which implies that gari processing in the study area cannot accept new innovation and modern technology easily since most of them were not educated. Majority of them were not members of Gari processing association/society, they believed that joining association/society required an entry cost which they were not ready to part with. Almost all of them had farming as primary occupation with mean household size of 4 persons per household. Above average of them used both hired and family labour for production. This implies that they have available family labour, though not enough with 4 persons per household size of household. It was also revealed that all of the processors adopted manual gari processing method with the opinion that the cost of modern processing machines are high and could not afford them. Almost all of them do not have more than one processing unit.

Major Constraints: Lack of capital and market price fluctuation were reported to be the most serious constraints facing gari processing in the area.

Costs and Returns

Table 2 shows that total fixed cost accounted 19.4% of total cost incurred in gari processing. Therefore, the business can easily be set-up. Benefit Cost Ratio (BCR) was 1.90. The BCR value shows that cassava processing into gari is profitable in the study area. The value means that for every (₦1.00) invested in cassava processing into Gari will yield ₦1.90k.

Regression Analysis

Regression result of which linear functional form was chosen as the lead equation shows F-value to be 65.638*** and R^2 to be 84.3% which implies that 84.3% factors that determine the revenue of cassava processors in the study area were explained by explanatory variables while the remaining 15.7% has been captured by the stochastic Error term. Note, independent variable with *, **, and *** is significant at 10%, 5% and 1% respectively.

$$\mathbf{Y = 4000.491 + 1.403 InX_1 + 10.964X_2 + 0.398X_3 + 1.338X_4 + 0.916X_5 + 3.623X_6 - 1.250X_7 + 5.729X_8 + 2.322X_9}$$

(4557.902)	(0.081)***	(3.455)	(0.422)	(5.241)	(0.257)***	(2.048)*	(-6.861)	(6.861)	(0.841)***

The above regression equation implies that if the ages of the respondents (X_1) are increased by three (3) units, then the output on quantity of cassava tuber monthly would be increased by 1.403 units. If the level of education (X_5) of the respondents is increased by three (3) units, then the amount spend on fire wood would be increased by 0.916 units. If the household size (X_6) of the respondents is increased by one (1) units, then the amount spend on basket would be increased by 3.623 units. Also, if the cost spent on transporting cassava is increased by three (3) units, then the market charges would be increased by 2.322 units. There would be an increase as a result of positive correlation between these variables X_1, X_5, X_6, X_9 and the output of cassava processing.

CONCLUSION

Although, cassava processing in the study area did not achieved absolute efficiency in the use of variable inputs, however, the study concluded that cassava processing into gari is profitable and sustainable with little capital. Based on the major findings, the study recommend that gari processors should use modern processing machines to improve their output, gari processors should be encouraged to join cooperatives societies so that the respondents will be able to increase their income and also there is need for adequate market with good stable prices for the respondents' products.

ABSTRACT

Marketing of fluted pumpkin in Ekpoma Esan West local Government Area of Edo State, Nigeria was studied using eighty marketers (forty retailers and forty wholesalers) drawn from two markets using simple random sampling technique. Data for the study were captured from primary and secondary sources. Percentage response, marketing margin and marketing efficiency were used to address the objectives. The results of the study showed that the marketers were inefficient in their marketing margin as their values were less than 1, while both were efficient in their marketing efficiency. The major constraints to fluted pumpkin marketing were commission agent, poor access to credit facilities and poor storage facilities. Provision of improved storage facilities, reconstruction of rural roads, improved marketers' access to credit and stabilization of price were recommended.

Keywords: Marketing, fluted pumpkin, Wholesalers and Retailers

INTRODUCTION

Fluted pumpkin belongs to the family cucurbitaceae and supplies essential micronutrients in human nutrition, source of income and offer employment opportunities to the populace, especially women who formed the substantial producers in Southern Nigeria (Adaigbo, 2010).The leaf extracted from fluted pumpkin is used as blood tonic, the fruit case and pulp can be used for livestock feedstock, the pectin content of the pulp is used in the production of marmalade and the protein extracted from the leaf of fluted pumpkin can be used to feed farm poultry in form of protein concentrates (Obasi and Kalu, 2010). Marketing occupies a significant position in an exchange economy especially in areas where there is increasing commercial activities and high rate at urbanization exist (Iheme, 2008). It aids in addition of place, form and time utilities to a commodity as it moves from production to point of consumption (Nwaru, 2004). Marketing of fluted pumpkin products cover the services involved in moving fluted pumpkin product from the farm to the final consumer (Iheke, 2009). In developing countries such as Nigeria, marketing of cropsis faced with lots of problem which include seasonal price variations, transportation of harvest produce, storage and processing, grading, communication and credit facilities. These problems have negative influence on the efficiency of the marketing system of most agricultural commodities such as fluted pumpkin (Irene, 2002). Despite all the marketing problems of the vegetable which affect its supply and price, the demand of fluted pumpkin in the study area continue to be high. This necessitates the need for the study of marketing of fluted pumpkin so as to make appropriate recommendations on the efficient marketing of the vegetable in order to improve on the people's food security status as well to enhance the marketing employment potential of the crop especially to women that formed the substantial marketers. Specifically, the objectives are to determine the socio-economic characteristics of the marketers, assess the marketing margin of the marketers, appraise the marketing efficiency of the marketers and identify the problems encountered by the marketers (retailer and wholesalers).

MATERIALS AND METHODS

This study was carried out in Esan west of Edo State. Edo Esan West lies between longitude 060 04'E and 060 43'E and latitude 050 44'N. The markets in Esan west are Ekee by Ekee, idefas and new market. Questionnaire was used to collect the relevant data for the study. Eighty marketers (forty retailers and forty wholesalers) were selected using multi stage random sampling technique. The objectives of the study were analysed using percentage, marketing margin and marketing efficiency.

Wholesaler marketing margin = Selling price - purchase price

$$\text{Retailer marketing margin} = \text{Selling price} - \frac{\text{purchase price}}{\text{Selling price}}$$

The objective (iii) was captured using marketing efficiency.

$$\text{Wholesaler marketing efficiency} = \frac{\text{Marketing benefit X 100}}{\text{Marketing cost}}$$

$$\text{Retailer marketing efficiency} = \frac{\text{Marketing benefit X 100}}{\text{Marketing cost}}$$

RESULTS AND DISCUSSION

Table 1 show that female marketers dominated fluted pumpkin marketing for both wholesalers (70%) and retailers (75%) in the study area females are better hagglers of price than male counterpart. Large proportion (55%) of the wholesalers and retailers (50%) fell within age range of 21-41 years respectively, while the least 5% of wholesalers and 17.5% retailers' fells with age range of 42-62 years respectively. Youth marketers have the tendency of withstanding stress associated with marketing than aged ones (Obasi and Kalu, 2010). Forty percent (40%) of the wholesalers and forty two doth five percent (40.5%) of retailers were married, while 57.5% and 50% of wholesalers and retailers were single respectively. Also, 2.5% and 7.5% of the wholesalers and retailers respectively were widowed. Married people are likely to be assisted in the business by their household members. The Table 2 showed that wholesalers had selling price of ₦93, 600 and the retailer had ₦78, 400. The purchasing price of the wholesalers and retailers were ₦69, 900 and ₦58, 900 respectively. The wholesalers and retailers had marketing margin of 0.25 each. This implies that both wholesalers and retailers were inefficient since the values were less than one (Iheme, 2008).

Marketing efficiency is marketing benefit divided by the marketing cost multiple by 100. The marketing benefit is selling price, minus purchasing price which is equal to ₦23, 700 and ₦19, 500 for wholesalers and retailers respectively. Marketing cost items are specified in the Table 3. Table 3 showed that the total marketing costs were ₦71, 490 for wholesalers and ₦13, 880 for retailers. The cost items considered among the wholesalers; transportation (43.57%) was the highest. This finding is in line with (Iwena, 2009) who reported that high transportation cost could be associated with poor road network in most rural areas. However, marketing efficiency of 331.5% for wholesalers and 109.66% for retailers were indicated in table 4. This implies that both wholesalers and retailers of fluted pumpkin marketing were efficient in the marketing of fluted pumpkin in the study area.

Table 4 showed that 80% and 70% of wholesalers and retailers respectively reported on poor access to credit, Credit is needed to offset marketing cost and pays laborers involves in the business (Ume *et al*., 2009). More so, 60% of the wholesalers and 45% of the retailers encounter the problem of high cost of transportation .Transport, help for easy evacuation of the goods from points of production to final consumers at reduce cost, unfortunately, most rural roads are not accessible especially during rainy season (Arene, 2002). The other problems were poor storage facilities (60% of the wholesalers and 37.5% of the retailers), high perishability of commodity (77.5% and 75% of the wholesaler and retailers respectively), and problem of commission (60% of the wholesalers and 50% of the retailers).

CONCLUSION

The marketers were inefficient in their marketing margin, while efficient in their marketing efficiency of fluted pumpkin. Poor access to credit, poor/high cost of transportation and lack of storage facilities were the major constraints to fluted pumpkin marketing. The study recommended the need to rehabilitate rural roads, improves marketer's access to credit and improved storage facilities to reduce rate of spoilage of the vegetable.

ABSTRACT
The study was carried out to examine the maize grain market structure in Saminaka town which is noted for marketing of maize grain. Single stage sampling was adopted for the purpose of this study. A total of fifty maize grain marketers (twenty wholesalers and thirty retailers were randomly selected at the central market) were chosen as respondents. Data were collected by the help of structured questionnaire and interview schedule. Analyses of data were done using descriptive statistics and Gini Coefficient. Product differentiation existed and there were little barriers to entry into the maize grain market. The Gini Coefficient values of 0.1987 (wholesalers) and 0.09275 (retailers) were recorded, indicating an existence of some degree of sellers' concentration in the wholesalers side. Government policies should be directed towards reducing transportation costs, rent charges by the local government authority and provision of micro-credit for the traders to expand their purchases.
Key Words: Assessment, maize grain, market structure and Gini coefficient

INTRODUCTION
Marketing is the sum total of all business activities performed in the movement of commodities from the point of initial production until the commodities are in the hands of the ultimate consumer (Adekanye, 1998). Market structure refers to the number and size distribution of buyers and sellers, product differentiation and presence or absence of barriers to entry into the market (Anuebunwa, 2002; Okereke *et al.,* 1988). The origin of maize is not yet fully known but many Authors claimed that maize is native of tropical America where it is cultivated for thousands of years ago. It was said to be introduced to America few years after the discovery of America in 1492. The source of introduction to Africa was not quite certain. The plant might have been introduced through the first European contact with the West Africa Coast (Adegbola *et al.*, 1976). Maize is scientifically called *Zea Mays*. It is a cereal crop. With the rapid expansion of livestock industries in the country and the higher food demand by the ever-increasing population, the need to increase and improve on maize production is imperative. Given the critical roles of adequate food and nutrition in the development process and in supporting world peace and stability, greater attention has been paid to food and nutrition issues at the levels of national government especially in the less developed countries as well as by the international community (World Bank, 1986). Maize production is an appropriate system to supply the fast growing human population with dietary deficiencies among households. It also has the capacity to produce additional income to the generally resource-poor families especially women which in the long run contributes significantly to food security and poverty alleviation (Gue'ye, 2002). The high risks and uncertainties, price fluctuations, transportation cost, inadequate market information and facilities had been identified as responsible for the high marketing cost in food marketing (Anuebunwa, 2007; Anuhihe and Eze, 2002). This study therefore was designed to assess the market structure of maize grain in Saminaka town of Kaduna state, Nigeria which is known to produce large quantity of maize in the state and the country at large.

METHODOLOGY
The study was purposively carried out in Saminaka town which is noted for production and marketing of maize grain. Single stage sampling was adopted for the purpose of this study. The Saminaka central market is selected which is noted for its marketing of maize grain. A total of fifty marketers (twenty wholesalers and thirty retailers were randomly selected in the market) were chosen as respondents. Data were collected by the help of structured questionnaire and interview schedule. Analyses of data were done using descriptive statistics such as percentages, frequencies, means and tables and Gini Coefficient. The Gini Coefficient (G) was used to determine the structure of the maize grain market.
The model is stated in line with Anuebunwa (2008) as:

$$G = 1 - \sum_{I=1}^{K} X_i Y_i$$

Where,

X_i = percentage of maize grain traders in the ith class of traders
Y_i = cumulative percentage of maize grain traders in the ith class of traders

k = number of class

The Gini coefficient varies from 0 to 1, where 0 implies perfect equality in the distribution (perfect market) and 1 implies perfect inequality (imperfect market, high level of seller concentration) (Okereke and Anthonio, 1988).

RESULTS AND DISCUSSION

Socio-economic characteristics of the Respondents

Table 1 shows the socio-economic characteristics of the marketers in the study area. The table shows that gender wise, male poultry chicken marketers constituted 68% while females are 32 percent. This implies that there are more male maize grain marketers than females in the study area. The table further revealed that majority (56%) of the marketers fall within the age range of 31-50 years while 34% of the marketers are above 50 years. This implies that the marketers are still in their productive age. It is expected that respondents in these age brackets can take risks and initiatives which are expected factors marketing activities as they have the strength to move from one location to another. Moreover, majority (94%) of the marketers are married and most (94%) of the marketers have one form of education or the other. The table shows that 28% of the marketers have less than 10 years of experience in local maize grain marketing while majority (68%) have 11- 30 years marketing experience. A similar study by Okereke and Anthonio (1988) established a significant relationship between marketing experience and volume of sales in the wholesale and retail trades. The table also revealed that 72% belong to the local maize grain traders association, while 28% do not. This implies that prices for the crop most times are determined by the association. According to Anuebunwa (2008), membership in traders association offers opportunity for the creation of implicit barriers to entry and exit into the trade. This influenced the nature of the market. Table 2 shows the distribution of maize grain wholesalers by monetary value of monthly sales. The table reveals that the wholesaler's average monthly sales were ₦2,401,700. Majority of the wholesalers (80%) sold maize grain worth of ₦47,500,000 representing 98.9% of the total value of monthly sales whereas 15% of the wholesalers sold maize worth of ₦259,000 monthly. The distribution gave a Gini coefficient of 0.6294. A Gini coefficient of 0.1987 implies inequality in the distribution showing the market to be an imperfect market. The result is in consonance with previous works by Anyaegbunam (2012); Okereke and Anthonio (1988) and Anuebunwa (2002; 2007) respectively who reported an imperfect competitive markets for staple food items. Similarly, at the retailers' level. Table 3 shows the distribution of maize grain retailers by monetary value of monthly sales. The table reveals that the retailer's average monthly sales were ₦263,050. Thirty percent (30%) of the retailers sold maize valued ₦4,500,000 representing 57.1% of the total value of monthly sales whereas 6.7% of the retailers sold maize worth ₦1,790,000 representing 22.7% of the total value of monthly sales. The distribution gave a Gini coefficient of 0.09275 which implies inequality in the distribution showing the market to be an imperfect. Many varieties of maize grain were displayed for sale but they differ in terms of size, colour and weight. There are little barriers to entry into the maize grain marketing business. At the wholesalers' level, prospective marketers have to register with the cooperatives for quicker sales of their products while most of the retailers do not necessarily need to register with marketers association. Results of the study indicated that there existed some degree of market concentration in the wholesalers' side. The gini coefficient of 0.2 (wholesalers) and 0.1 (retailers) confirmed the finding.

CONCLUSION

The study examined the maize grain market structure in Saminaka town of Kaduna state. The Gini coefficient analysis showed that maize grain marketing system is an imperfect competitive market as shown by the results of the Gini coefficient. Government policies should be directed towards reducing transportation costs, rent charges by the local government authority and provision of micro-credit for the traders to expand their purchases.

ABSTRACT
The study evaluated the factors affecting productivity of arable crop farmers in Imo State. Convenience sampling technique was used in selecting the three agricultural zones in Imo State. Simple random sampling techniques were used in selecting 3 L.G.As in each zone. Mbaitolu, Ngor-Okpala and Mbaise L.G.As were chosen from Owerri agricultural zone whereas Obowo, Okiqwe and Ehime-Mbano L.G.As were from Okiqwe agricultural zone and Orsu, Ideato-south and Nwangele L.G.As were from Orlu agricultural zone. One community was randomly selected from each L.G.A., from which 10 farmers were randomly selected, thus bringing sample size to 90. Data were analyzed using frequencies, means and the Ordinary Least Squares method of multiple regression analysis. The result shows that the most common cropping system practiced by arable farmers in the study area is mixed cropping and cassava is the most common crop planted by all the farmers interviewed., 92.22% of the crop combinations which was highest had cassava, yam, maize, okra, melon, vegetables and cocoyam. The co-efficient of extension contact (X_6) and Planting material (X_7) were highly significant and positively related to the gross value of output which suggests that if extension services to farmers and improved planting material are increased this will lead to increase productivity. However, basic amenities, finance, high cost of labour resources and others are the problems militating against increased productivity of farmers. It is recommended that soft loan and subsidized improved varieties of crops should be provided by government including tractors to substitute declining labour resource.

INTRODUCTION

Food remains the most essential need of man (Okon *et al.,* 2005). Agriculture provides over 80% of the food needs, contributes more than 30% of the total gross domestic product, employs about 70% of the non – oil export of Nigeria (Adegboye, 2004). In recent times, low production and productivity have characterized this sector and in effect cannot effectively perform these roles. This has mostly manifested as food insecurity (Eze *et al*., 2012). Food insecurity indicated according to FAO (2012) include reduction in both capacity and attitude to work, poverty, corruption, low life expectancy, infant mortality and malnutrition among others. Small holder farmers produce on subsistence level and are not involved in commercial agriculture (Oladeebo, 2004). To ensure food availability, accessibility and affordability (food security), agricultural production needs to be increased by 2.3% annually over the next decade in order to meet the population growth of 2.1% (Onyenweaku *et al.,* 2010). The apparent disparity between the rates of food production and food demand led to massive food importation and high food prices in the country (Eze *et al.,* 2012). Food shortage is attributed to inefficiency in production and small scale operation by farmers (Ibeawuchi *et al.,* 2007). The crucial issue in the Nigeria agriculture is that of low productivity (Bamidele *et al.,* 2006). Despite all human and material resources devoted to agriculture, the productive efficiency for most crops still fall below 60% (FACU, 1992; FDA, 1993; FDA, 1995). The inefficiency problem is attributed to factors such as use of low input technologies, lack of knowledge of available high input techniques or inadequate management (due to lack of skills, motivation etc), use of poor crop varieties, cropping pattern practiced, lack of poor extension services, unavailability and affordability of input such as fertilizer, improved seeds and seedlings. This aims at evaluating the cropping system produced by arable crop farmers. A study of this nature is expected to serve as a useful guide to policy makers, extension agents and farmers on possible measures that could facilitate increased arable crop production in the study area.

MATERIALS AND METHODS

The study was carried out in Imo State of Nigeria. Imo State is located in the south-eastern part of Nigeria with a total land mass of 7480 square kilometers and a population of 3,932,899 million people (NPC, 2006). The State lies between latitude 40 41S and 6041E. The State is divided into three agricultural zones namely Okigwe, Owerri and Orlu agricultural zones. The study evaluated the factors affecting productivity of arable crop farmers in Imo State. Convenience sampling technique was used in selecting the three agricultural zones in Imo State. Then simple random sampling techniques were used in selecting 3 L.G.As in each zone. Mbaitolu, Ngor-Okpala and Mbaise L.G.As were selected from Owerri agricultural zone while Obowo, Okiqwe and Ehime-Mbano L.G.As were selected from Okiqwe agricultural zone and Orsu, Ideato-south and Nwangele L.G.As were selected from Orlu agricultural zone. One community was randomly selected from each L.G.A. From each community, 10 farmers were randomly selected thus bringing the sample size to 90. The farmers were classified according to types of farm enterprises they are practicing. The sampling frame comprised the list of all registered arable crop farmers obtained from the Imo State Agricultural Development Programme (ADP). The primary data used for the study were collected from the field using well structured questionnaire. Data collected were analyzed using descriptive statistics and the ordinary least square method of multiple regression analysis. In line with the use of ordinary least square multiple regression (OLSR) analysis; four functional forms were fitted into the data. The equation that gave the best fit was then selected as the lead equation based on conformity with a priori expectations (expected signs of the estimators, the magnitude of the coefficient of multitude determination (R^2) and the statistical significance of the parameter estimate). The explicit forms of the function are given as;

Linear function= $Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + e$

Exponential = $\ln Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + e$

Semi log = $Y = b_0 + b_1\ln X_1 + b_2\ln X_2 + b_3\ln X_3 + b_4\ln X_4 + b_5\ln X_5 + b_6\ln X_6 + e$

Double log = $\ln Y = b_0 + b_1\ln X_1 + b_2\ln X_2 + b_3\ln X_3 + b_4\ln X_4 + b_5\ln X_5 + b_6\ln X_6 + e$

Where;

Y = gross value of output (Naira), X_1 = age of farmers (years), X_2 = educational level (years), X_3 = farm size (hectares), X_4 = farming experience (years), X_5 = household size (number of persons), X_6 = extension contact (number of visits by extension agents), X_7 = Expenditure on planting material (Naira), X_8 = labour input (man-days) and e = error term.

RESULTS AND DISCUSSION

Socio-Economic Characteristic of Arable Farmers

Results of socio-economic characteristic of arable farmers' shows that those between 41-50 years of age constituted the highest (37.78%) followed by those between 51- 60 years of age constituting 26.67%. This implies that there were more aged farmers than younger ones and this would affect the productivity of farmers as farming activities requires strength and bending work like planting, weeding, heaping and carrying objects. Educational level shows that those who spent between 7-12 years in school constituted 37.78% as highest followed by those who spent between 0 - 6 years in school constituting 26.67%. Caswell *et al.*, (2001) remarked that education is thought to create a favorable mental attitude for the acceptance of new practices especially information on improved crop varieties and better management methods. The number of years spent in farming shows that those who have spent 6-11 years in farming constituted 58.33% as highest while those who had farming experience of more than 12 years and above followed with 36.67%. This gives an indication of practical knowledge acquired on how the farmer can overcome certain inherent problems associated with that farming business (Nwaru, 2006). Those with farm size of 0.10 to 1.9 hectares constituted highest with 44.44% followed by those having 0.0 to 0.10 hectares constituting 30.00%. Farm size has negative impact on productivity if the farmer does not use mechanized methods in the light of large farm size. Majority of the farmer's household size have 5 - 8 persons constituting 48.89%, followed by farmers having more than 9 persons constituting 34.44%. Large household size if properly used could reduce cost for the farmer and increase productivity of the farm. This is necessary as households count more on household members for labour than hired labour in their farms. This finding is synonymous with Iheke, (2010). About 86.67% of the farmers are married while 13.33% are single which shows that farming is a serious business. Based on gender, women represent 56.67% of the farmers while 43.33% are men which agree with Okoye and Onyenweaku, (2007) who reported that women dominated in farming activities. Result further shows that 53.33% of the farmers have farming as their main occupation as engagement in other non-farm activities causes them to have divided attention.

Cropping System

Table 1 shows the frequency of farmers according to crop mixture. It showed that the most common cropping system practiced by arable farmers in the study area is mixed cropping and cassava is the most common crop planted by all the farmers interviewed., 92.22% of the crop combinations being highest had cassava, yam, maize, okra, melon, vegetables and cocoyam. According to Ibeawuchi *et al.*, (2007), these crops dominate most crop combinations because of the position they occupy in the daily life of people of the state. This could be attributed to the relative importance of the crops involved. Cassava is a major source of cheap calories and can be processed and consumed in various forms. Its usage as a source of ethanol for fuel, energy in animal feeds and starch for industry is increasing. Vegetable is a good source of minerals and vitamins. Melon which is used to prepare delicious soup is a good source of vegetable oil and contains some levels of protein. Maize is a source of carbohydrate and protein. It also serves as feed for animals. Yam is a good source of carbohydrate while 13.33% as the least had cassava, vegetables, melon, and maize and okra. Which is similar to the one above?

Table 2 shows the result of the ordinary least square multiple regression estimate on the determinant of value of output of arable farmers. Four functional forms (linear, double-log, semi-log, exponential) were fitted to the data and based on the magnitude of the co-efficient of multiple determinations (R^2), the model with the highest number of significant explanatory variables in conformity with the priori expectation and the model with best fit were chosen. Semi-log was chosen as the lead equation based on the values of the multiple determinations (R^2) and it is the model with the highest number of significant explanatory variables in conformity with the priori expectation and also the model with best fit. The coefficient of multiple determinations (R^2) of 0.62 implies that 62% of the variation in the value of value of gross margin can be explained by the joint action of the included explanatory variables. The table shows that the co-efficient of extension contact (X_6) and Planting material (X_7) were highly significant and positively related to the gross value of output. This suggests that total factor productivity will increase significantly if extension services to farmers and improved planting material are increased above their present levels of use. It is expected that productivity will increase if more experienced and educated farmers cultivate hectares of farm land while Age (X_1) is inversely related to productivity. This suggests that if these factors are increased above their present levels, productivity will decrease significantly. This is expected if aged and weak farmers are involved in agricultural production, it decline productivity as they would be too old and weak to farm.

Farming Constraints

Under this circumstance of farming constraints, majority of the respondents lacked basic amenities as represented by 92.22% of the respondents. This can be attributed to lack of good roads, storage facilities, markets for goods produced and lack of power faced by the farmers. It was followed by finance which was represented by 82.22% of the respondents. This could be attributed to high interest rate from financial institutions, making access to finance impossible for farmers and there is no financial help from government such as soft loan or subsidized farm inputs for farmers to increase their productivity. Another major problem revealed by the respondents was declining labour resource which indicated 48.89%. Scarcity of labour force could be attributed to urbanization where youths are looking for much gainful employment or white collar jobs in the urban centers.

CONCLUSION

Based on the result of the study which showed that the resource inputs were not efficiently utilized, allocated and managed by the arable farmers and in order to attain optimality in the use of farm resource inputs factors such extension agents should encouraged and increase in number to educate farmers on innovation in agriculture increase their productivity and to make available better improved planting materials needed by farmers to increase production. Based on the findings and discoveries from the study, it is recommended that basic amenities required by farmers to cultivate and transport their produce should be provided by government, soft loan and improved subsidized new varieties of crops, tractors to substitute declining labour resource, extension departments in ministries, good road network to and from farmers farm and government agencies like ADP, Fadama should be empowered to enlighten and empower farmers to increase their production level. Modern facilities should be provided to attract and encourage younger farmers and men.

Table 1: Frequency Distribution of Farmers According to Crop Mixture

Crop mixture	Frequency	Percentage	Crop mixture	frequency	percentage

ABSTRACT
This study examined the productivity enhancing farm practices' effect on farmers' income in the Nigerian savanna belt of Northern Guinea Savanna and Sahel Savanna. By the use of structured questionnaires, data for the study were obtained from 170 farmers. Descriptive statistics and multiple regression analysis were used to analyze data obtained. The result presented average age of farmers to be 42 years as the household size mean value was found to be 13.4 ranging between 3-29 people. About 41.8% of the farmers are not learned in English language while also, about 56% have between weekly to monthly contact with extension services. The productivity enhancing farm practices like usage of chemicals, fertilizers, improved seeds, credit facilities, animal traction, tractor facilities, crop rotation practice, technical labor, storage practice and crop processing were assessed. The influence of these improved farm practices was found to be positive and significantly related to the farmers' income. Recommendations were made for farmers to adopt these farm practices and for improvement in extension linkages to sensitize small-scale farmers on the need for the adoption of improved farm practices.
Keywords: Productivity enhancing farm practices, farmers income, Savanna region and Nigeria

INTRODUCTION

The Northern and Southern Guinea Savannas, (Sub humid zone) and the Sudan Savanna, (higher rainfall part of the semi-arid zone) have the highest potential for crop–livestock farming in the whole of West Africa (Winrock 1992). The Savannah region of Nigeria is a region where the people mostly are dependent on agriculture and stock raising for their livelihood, and as a rough estimate, it is propounded that 3 out of 4 people in this zone are engaged in these activities (FAO, 1974). The agricultural production of the staple crops in Nigeria is however largely from this region. The national estimated cereals production for the year 2010 shows that the savannah region alone produced between 94-100% total cereal productions for the year. Kano and Kaduna states alone produced 21.2%, 16.3%, 15.8% and 13.38% of the estimated total national output of sorghum, maize, rice and millet respectively (NAERLS & NPAFS, 2010). Cowpea, which is another household staple in the country, the Savanna alone produced over 98% of the total national production, while Kano and Kaduna states altogether produced 6.81% of the sum. The national agricultural production data for vegetable crops are similar in this regard (NAERLS & NPAFS, 2010). Gallup and Sachs (2000) have however estimated that wet tropical countries have 27% and dry tropics 42% lower productivity than temperate regions. The Nigerian Savannah of course falls within the 42% lower productivity in comparison to the temperate region. In Nigeria, agriculture is predominated by small-holder farming. Up to 90% of total agricultural production is directly linked to small-holder farmers, which cultivate about 2 hectares of land on average (Government of the FRN, 2006). These farmers are illiterates and their mode of cultivation is rudimentary. Traditional agriculture is widely practiced, with the use of hoes and low usage of productivity enhancing farm inputs like the improved seeds, credit facilities, fertilizers and chemicals, are widespread. Agriculture in the country is therefore plagued with low productivity per hectare and consequently, farmers are poor. These problems have led the government to embark on policies which are capable of developing the agricultural sector. In this regard, a series of agricultural development programmes have been instituted while a number of research institutes and universities founded in other to enhance growth in agricultural sector through the generation of adaptive research and extension linkages for farmers to adopt improved agricultural farm practices in the country. These research institutes and universities are established to develop new technologies and improve on the existing ones through basic and applied researches and disseminating their findings to farmers all over the country to help improve the food producing sector of the country's economy. Noteworthy, however is the fact that literatures on the usage of productivity enhancing farm practices, so introduced to farmers over the years from these adaptive researches, are few, and the influence of the adoption of improved practices on the farmers income, as a measure of farmers livelihood, are not well researched. This study is aimed at bridging the research gap, as the results will indicate the influence of usage of these farm practices as the anticipated findings will be useful to the extension outfits, local and international research institutes, and undoubtedly, the farmers who will begin to see the potential possibilities of intensifying production, increase their farm output and returns to agricultural production.

MATERIALS AND METHODS

This study was carried out in Kaduna and Kano states in the northern part of Nigeria, covering two agro ecological zones—the Northern Guinea and the Sudan Savannah regions of the country. These zones lie between latitude 8^0 and 13.5^0N, and longitude 3^0 and 15^0E. Agriculture is the main occupation of the largely Hausa-Fulani tribes-men of the region. The regions are marked with dissimilar and remarkable differences in farming practices as shown in Figure 1. For example, the Northern Guinea Savanna is the moist-semi-arid zone and the largely cultivated food crop is Maize and with movement further drier north, Sorghum becomes the more essentially cultivated food crop towards the dry semi-arid; Sorghum and Millet are the two major cereals cultivated in mixed cropping. In the Sahel Savanna however, Millet takes higher importance with increasing aridity (FAO, 1980). A three level multistage random sampling method was use for this study. At the first stage, a random sample of 11 and 6 local governments areas in Kano and Kaduna states, which are made uo of 44 and 23 local government areas were respectively, representing a 25% sample frame, was done. At the second stage, a random selection of two villages within the local governments where done. At the last state, 5 farmers were further sampled per village, meaning that in each local government area, ten farmers were administered questionnaires. Altogether, 170 farmers were sampled. The tool of analysis for this study included descriptive statistics, used mainly to express the socio-economic characteristics of the farmers and identify the adopted improved farm practices of the farmers. Furthermore, regression analysis was used to determine the effect of adopted productivity enhancing farm practices on farmers' income.

The model is implicitly specified thus:

$$\mathrm{Yi} = \alpha \mathrm{Xi} + \mathrm{Ui}$$

Y_i = Farmer's total revenue in naira
X_1= Total land area in hectares
X_2= Total cost of labour in naira
X_3 = Total cost of improved seed in naira
X_4= Total cost of fertilizer in naira
X_5= Total cost of chemicals in naira
X_6= Total cost of traction in naira
X_7 = Adopted improved farm practices, scored
α = Coefficients of variables specified
U = Error term

RESULTS AND DISCUSSION

Table 1 shows the result of the findings made from the observation of the socio-economic characteristics of the farmers; that 63.3% of the respondents are observed to be in the age range of 31-50 years which is noted to be the virile age range where farmers can do a lot of farm work. The average age of the farmers was found to be 42 years. The farming population is essentially a young one. Furthermore, it was revealed that 82.4% of the farmers have been farming with the experience of more than 10 years. This represents a sizeable percentage of farmers in the sampled area. It is to be expected that with growing numbers of years of farming, farmers tend to gain better understanding in the art of farming to the advantage of acquiring experience and increasing productivity. This also helps to identify farmers who have perhaps lived all or most of their lives farming (Ojeleye, *et al.*, 2014). The mean figure for farming experience in years was found to be 22.7 years. Table 1 also shows that 51.8% of the farmers have household sizes between the ranges of 11-20 people per household, while 3.5% of the sampled farmers have household sizes greater than 20 people. The mean household size was however found to be 13.4. Our study also shows that about 6.5% of the farmers had no formal education. 35.3% of the respondents had Quranic education while 9.4% have had adult education. For primary, secondary and post-secondary educations, about 32.9%, 11.7% and 4.1% of the respondents, respectively have acquired these forms of education. Education allows for better judgment of farmers, aiding them to adopt new innovations, and improved farm practices that are vital for increased productivity. The frequency of extension contact is also captured in Table 1, as about 56% of the sampled respondents had between weekly to monthly contact with extension services. Only 12.4% of the respondents have no contact at all with extension services, while 8.8% had between once to twice in a year contact. Regular and frequent contact with extension agents, extension services and platforms, are expected to facilitate the adoption of improved farm practices.

Usage of Productivity Enhancing Farm Practices

Farmers' use of productivity enhancing farm practices is shown in Table 2. The use of chemicals in the form of pesticides and herbicides is widespread, 78.2% of the farmers, showed a high level of awareness and usage. This will undoubtedly bring about increased productivity, particularly, if the usage of these chemicals follows recommended practices. Fertilizer use among the farmers was of 92.9% of the sampled farmers. The widespread and high frequency of observation of the use of these chemicals is a good indicator for higher productivity. The response of farmers to the use of improved seeds was also captures by this study. Animal traction usage received a wide coverage among the sampled respondents. It was observed that 75.3% and 81.2% of the respondents are aware and use improved seeds and seedlings, and animal traction respectively, for their farm operations. The access to and usage of farm credit was only about 10% of the respondents. It simply means that 90% did not gain any form of access or usage of farm credit. Tractor use and access to heavy machineries like crushers, seed drill, threshers, which are modern farm machineries mostly tractor mounted, in effect substitute human drudgery on the farm, thereby permitting increased cultivation, production and productivity. The presentation in Table 2 shows that only 24.7% of the sampled respondents patronize tractor facilities. The access to technical labour, that has to do with skill labour required for modern and sophisticated machineries, which the farmers can not readily operate, is connected to this. It is shown in Table 2 that 60.6% of respondents responded to the access of technical know-how personnel, only 50.5% of these respondents patronized these skilled, technical men. In other words, 49.5% of those that responded to knowing about technical labour do not patronize them (Table 2). Farming system adapted for traditional agriculture in the country included crop rotation. It is made to order for the management of soil fertility, the control of erosion, pests and weeds. Only about 69% of the respondents are in the know of the usefulness of this practice, and equally responded to regularly put to use, this farm practice for their farm operations. Use of cottage storage facilities for farm products and processing of produce, that is, adding value to raw agricultural commodities were also captured in our study. These influence production and productivity and consequently on the livelihood of farmers. Storing farm products is the holding of goods from the time of production until when they are needed while processing entails conversion of a commodity from its raw state to a form more acceptable to the buyers (consumers) or to the next stage in the distribution chain (Ojeleye, *et al.*, 2014). Ojeleye *et al.* (2014) further state that storage and processing can be traditional, intermediate or of improved or advance technology, but essentially, they enhance farmers' productivity and income. It was however observed that 62.9% of respondents sampled responded to using one form of storage facilities or the other as indicated in Table 2. Also, just 28.2% of the respondents undertake the processing of their products. This is not unconnected with the fact that processing generally involves the use of expensive and sometimes sophisticated machines. Markets provide both opportunities and pressures for farmers. Engagement in them may lead to higher living standards or more diverse consumption, but at the same time, it exposes them to the possibility of ruin either from adverse price trends or from the exercise of unequal market power. In other words, good market accessibility and participation can mar or enhance farmers' production intensification and efficiency. About 82% of the sampled farmers do have access to some certain markets.

Effect of Productivity Enhancing Farm Practices on Farmers' Income

A linear regression model was chosen to determine the effect and relationship of selected independent variables and the score from adaptation of improved farm practices used (Yi) as related to their influence on total revenue from the farmers output. Table 3, shows that total money value, that is, the cost of improved seeds and seedlings, and fertilizer were significant at 1%, while total land cultivated and the cost of chemicals (herbicide and pesticides) were significant at 5% level of significance. It was also noted that the score of adopted improved farm practices, X, which was included to show the influence of usage, was significant at 1% level to the total revenue of the respondents (Table 3). This implies is that, if the farmers will adopt the use of these farm practices identified, it will improve their standard of living, because of the significant, positive relationship this has on their income. The coefficient of cost of labour was negatively related to the total revenue function and this might explained the effect that hired labour has on the farmers' income. It may be noted, that some farmers who undertake farming as a secondary occupation, for instance, do not have or make for adequate time for farm operations and so employ the services of hired labour with little or no supervision, and thereby hindering optimum use of resources. This resulted in lower productivity of resources. The estimated, R square from the multiple regression model was 51%, meaning that the independent variable included in the equation considerably explained the dependent variables. A very high F-value, significant at 1% was also noted. Five (5) of the seven (7) variables were noted to be significant and their signs fit *a priori* expectations.

CONCLUSION

An inference is therefore drawn from this study particularly on the relationship of the adoption of improved farm practices with the income of farmers. It has been found that increasing income of farmers which essentially means increasing standard of living relates directly and positively to increasing adoption of recommended farm practices. Transformation of traditional farming system for increased food production calls for adoption of these improved farm practices. In the light of this, it is recommended that farmers adopt these practices in order to improve their standard of living by the increase of their level of income. The study also recommends improved extension linkages to sensitize small-scale farmers on the need to adopt these improved farm practices.

SOCIO-ECONOMIC DETERMINANTS OF AGRICULTURAL OUTPUT, AMONG COOPERATIVE FARMERS IN ABIA STATE, NIGERIA

E. I. Offor & N. G. Nnamani

Department of Agricultural Economics, Michael Okpara University of Agriculture Umudike, Nigeria
glad_nnamani@yahoo.co.uk

ABSTRACT
The study the socio-economic determinants of agricultural output, among cooperative farmers in Abia State were carried out to examine the socio-economic determinants of agricultural output, among cooperative farmers in Abia State. Structured questionnaire was used to collect data from the members of farmers' cooperative. Ninety (90) agricultural cooperative members were randomly selected from fifteen (15) registered agricultural cooperatives in the three agricultural zones to fill-in the questionnaire. The data collected were analyzed, using descriptive statistical tools, such as frequencies, means and percentages. The socio-economic determinants of agricultural output were analyzed using multiple regression analysis. The result from the descriptive statistics indicated that majority of the cooperative farmers were relatively young people, with mean age of 39.7 years, and dominated by males represented by 67.8 percent. About 70 percent of the respondents were married with mean household size of 4 persons. Also, majority of the respondents were literate, and 50 percent had farming experience of between 11 – 20 years. The regression result identified the significant socio-economic determinants of agricultural output to include age, level of education, years of farming experience, income, farm size, and bank credit. The study recommendations that the younger farmers, should be adequately sensitize on the benefits of cooperatives to join farmers' cooperative. Extension services should be made available and accessible to the farmers and also Farmers' cooperatives access to credit should be made easier and at a reduced cost.
Keywords: Cooperatives, farmers, agricultural output and socio-economics

INTRODUCTION
Nigeria does not produce enough food for its large and growing population. The rise of the oil sector to a position of economic preeminence in the early 1970s resulted in the neglect of the agricultural sector. Consequently, Nigeria began to experience a shortfall in domestic production that transformed the country from food sufficient net exporter of food products, to a net importer of many different agricultural products including palm oil, rice, wheat and maize (Ogen, 2007). The primary objective of forming group farming cooperative is to increase agricultural outputs, according to Zarafshani et al., (2010). Agricultural cooperative acquire some incentives from the government to enhance the effectiveness of their production and marketing of the items, with the hope of increasing agricultural output and benefit to members economically. Some of these incentives received by the cooperatives were outlined by Ogieva, (2003) included: access to loans, farm inputs such as fertilizers, agricultural extension services, farm equipment, mobilization of savings, management of credit and attraction of government's supports. International Cooperative Alliance, ICA (2015), defined cooperative as an autonomous association of persons unified voluntarily to meet their common economic, social and cultural needs through a jointly owned and democratically controlled enterprise. It is a business voluntarily owned and controlled by its member patrons and operates for them and by them, on a non- profit basis. There is no uniform classification of agricultural cooperative. Enikanselu *et al*., (2005) gave the following classifications of agricultural cooperatives as farmers' multipurpose cooperatives, produce marketing cooperatives, food crop production and marketing cooperatives, livestock cooperatives, fisheries cooperatives, agro-industrial cooperatives. Many authors including Alexandratos, (2005); Enikanselu *et al*., (2005); Erebor, (2003) and Ogieva. (2003) had variously stated the benefits of farmers' cooperatives that influences their agricultural output though from different perspectives were summarized to include; promotion of farm labour efficiency, promotion of environmental friendly farm practices through Sustainable Agricultural and Rural Development (SARD); applying environmental friendly technologies such as Integrated Pest Management (IPM). Furthermore, dissemination to the members of the agricultural cooperatives on appropriate technology through extension services to increase their agricultural sustainability, development of the rural economies, provision of social services such as education, transportation, provision of rural infrastructure through government machinery for rural poverty alleviation and development. Despite the incentives to agricultural cooperatives to increase agricultural output in Nigeria, food production has not been able to keep pace with the increasing population. According to Ibe, (2002), it was reported that at the introduction of formal cooperatives in Nigeria, over seven years ago, cooperatives was used as a plat form for improving agricultural production and farmers' income. Following the current trend in food insecurity in the country, the study therefore examines the socio-economic determinants of agricultural output among cooperative farmers, in Abia State, Nigeria.

METHODOLOGY

The study area was Abia State. Abia State is located in the South Eastern Nigeria. The state has three agricultural zones namely: Aba, Umuahia and Ohafia, and seventeen (17) Local Government Areas. Abia state has a total population of about 2,845, 380 (NPC, 2006). Majority of the population in the state engage in agricultural production at different scales as their predominant occupation. There are also various agricultural cooperatives societies in the study area. Primary data were used for the study. Structured questionnaire were used to collect data from the respondents with the assistance of extension agents from ADP, Umuahia. Multi-stage, stratified sampling technique was used in sample selection. In the first stage the three agricultural zones namely: Aba, Umuahia and Ohafia were selected with the assistance of Agricultural Development Programme (ADP) in the State, using lists of the registered and functional farmers' cooperatives. In the second stage, five (5) agricultural cooperatives were randomly selected from each of the three zones which giving a total of fifteen (15) farmers' cooperatives. And in the third stage, from each of the 15 farmers' cooperative, six (6) respondents were also randomly selected for the giving a total of ninety (90) respondents for the study. Data collected were analyzed using descriptive statistical tools such as frequencies, means and percentages. Furthermore, the socio-economic determinants of agricultural output among cooperative farmers were analyzed using multiple regression model. The implicit form of the regression model was specified as;

$Y = f(X_1,X_2,X_3,X_4,X_5,X_6,X_7,X_8,X_9,e_i)$

Where;

Y = Agricultural output (Naira)
X_1 = Age (years)
X_2 = Gender (male = 1, female = 0)
X_3 = Marital status (married = 1, single = 0)
X_4 = Household size (number of persons)
X_5 = Level of education (years)
X_6 = Farming experience (years)
X_7 = Farm income (naira)
X_8 = Farm size (hectare)
X_9 = Bank credit (naira)
e_i = error term

Four functional forms of the regression model namely: the linear, semi log, cobb-douglas and exponential forms were used to analyze the data. The equation that formed the best fit was chosen as the lead equation based on the basis of the multiple determination (R^2) and the number of significant variables and its conformity to a priori expectations.

RESULTS AND DISCUSSION

Socio-economic characteristics of the respondents

The socio-economic characteristics of the respondents was summarized and presented in Table 1. It shows that the cooperative farmers had mean age of 39.7 years, this indicates that the majority of the cooperative farmers were relatively young people. Farmers' cooperative in the study area was dominated by males as 67.8 percent were represented by males. The marital status of the respondents revealed that 70 percent of them were married with mean household size of 4 persons. Majority of the respondents were literate since 80 percent represented those that attained either secondary or tertiary education respectively. Half of the respondents (50 %), had farming experience of between 11 – 20 years. Table 1 shows that the cooperative farmers had mean age of 39.7 years, this indicates that the majority of the cooperative farmers were relatively young people. Farmers' cooperative in the study area was dominated by males as 67.8 percent were represented by males. The marital status of the respondents revealed that 70 percent of them were married with mean household size of 4 persons. Majority of the respondents were literate since 80 percent represented those that attained either secondary or tertiary education respectively. Half of the respondents (50 %), had farming experience of between 11 – 20 years.

Socio- economic determinants of agricultural output among cooperative farmers

The socio – economic variables that have significant influence on agricultural output is shown in Table 2. The table contains the result obtained with semi – log functional form of the regression analysis which gave the best fit. The R^2 value was 0.89 which implied that 89 % of the total variations in the dependent variable were accounted for by the independent variables. F- Statistic was significant at 1%, indicating the fitness of the model. The result shows that six variables namely age, level of education, years of farming experience, income, farm size and bank credit significantly affect the agricultural output among cooperative farmers. Age was negatively related to output and significant in determining output among the farmers. The inverse relationship implies that as the age of the farmers increase, their output decreases. The result is in agreement with a related study by Olagunju and Ajiboye, (2010) that most or nearly all agricultural activities are believed to be tedious, energy draining and farmers are expected to be physically active to ensure higher output from farm. Level of education attained by the farmer was significant at 1% level and positively related to output. The implication is that the higher the level of education attained by the farmer the higher the expected output. This is in conformity with a prior expectation that the level of education of the farmers enhances productivity. Years of farming experience was positively related to output and significant at 5 % level. The result implies that the longer in the number of years a farmer is in the farming business, the higher the output. This result is consistence with that of Nwaobiala and Onumadu (2010), that farming experience has shown to enhance the participation and adoption of improved techniques by farmers thereby increasing agricultural output. The effect of income in determining agricultural output was significant at 1 % level and positively related to output. This implies increase in the farmers' income leads to a corresponding increase in their farm output. This may be attributed to the fact that an increase in income enables the farmer expand the farm business and also purchase farm input as required. Farm size was significant at 10% and positively related to output. This implies that a unit increase in farm size resulted in proportionate increase in output. Access to credit was positively related to agricultural output at 10%. Access to credit has been positively linked to agricultural productivity in several studies in Nigeria (Abu, *et al.*, 2010 and Ugbaja, 211).

CONCLUSION

Regression result identified the significant socio-economic determinants of agricultural output to include age, level of education, years of farming experience, income, and farm size and bank credit. Recommendations were that the younger farmers through adequate sensitization on the benefits of farmers' cooperative should be encouraged to join the cooperative in order to attain higher output. Extension agents should avail their services to the farmers to enable them acquire the necessary improved agricultural technologies that increases farm output. Farmers' cooperatives access to credit should be made easier and at a reduced cost, this can encourage farmers to expand size of farm operations, have adequate cash to meet up farm capital needs to attain higher output and income.

ABSTRACT

This study is focused on assessing the implications of land reforms system on agricultural production in Nigeria. The study set three major objectives which include to; provide an overview of land reforms, examine the problems of land reforms and finally, consider the implication of land reforms on agricultural production in Nigeria. Land reform is usually linked with agricultural and rural development. This is so because the bulk of the population especially those involved in primary production depend on the availability of land in whatever form it may be required. Land must be available to persons and/or groups of people who are ready to put it to productive use. It is the farmers' most important asset and it plays an essential role in sustaining agricultural production. However, ownership of land often interferes with its use as an agricultural asset. The employment of land use reform is therefore needed to ensure equitable allocation, availability and distribution of land to ready users both in rural and urban areas of the country. The Nigeria Land Use Act need be revisited to make room for easy and efficient land access to individuals, corporate institution and their likes that would be ready to use land for productive purposes.

Keywords: Agriculture, agricultural production, land reform, land tenure and land use act

INTRODUCTION

In Nigeria, land is considered to underpin all social, economic and political development of a person or a household. Therefore, access to land also defines one's inclusion (or exclusion) in social, economic and political processes. There has been a plethora of literature on the nexus between land ownership and access to opportunities in social, political and economic spheres. Lack of access to land is linked to social exclusion (Chikaire, et. al., 2014). In the agrarian economy, land is central to income and livelihood. Lack of income and livelihood opportunities and continuous work on low wages have made landless people not able to take part in the social and political processes within the community or at larger levels. Access to land is also essential to enable rural poor to have equal opportunities created by market. Their access to land will make them able to take some of these opportunities created by the market. Land and the institutions that govern its ownership and use greatly affect economic growth. Lack of access to land and inefficient or corrupt systems of land administration have a negative impact on agriculture especially in a developing country like Nigeria. Access to even small plots of land to grow crops can also greatly improve food security and quality. Policies that foster lease markets for land can also contribute to the emergence of a vibrant non-farm economy (Chikaire, et. al. 2014). Improving land administration may also contribute to broader public service reform and provide a basis for wider reforms. Tenure rights to resources play a fundamental role in governing the patterns of natural resource management, as well as in the welfare of individuals and communities dependent on those resources (Chikaire, et. al., 2014). In the words of the World Bank, land reform is "concerned with changing the institutional structure governing man's relationship with the land, involving intervention in the prevailing pattern of land ownership, control and usage in order to change the structure of holdings, improve land productivity and broaden the distribution of benefits" (World Bank, 1996). Parsons (1996) defines land reform as the aggregate of ideas and courses of action designed to resolve tenure problems. His viewpoint is generally in line with the one expressed by the World Bank. It may consist of government initiated or government backed approach to property redistribution of land or as in the case of Nigeria, an outright transfer of ownership of land from the citizens to the state. The common characteristic of land reform is usually the modification or replacement of existing institutional arrangement governing possession, use and title. Thus, while land reform may be radical in nature such as large scale confiscation and transfers of land from one party to another or to the state, it can also be less drastic and conciliatory in nature such as regulatory reforms aimed at improving land administration (Dale, 2007). The land use pattern in Nigeria estimated arable land to be about 33% of the total land area, permanent pastures cover 44%, permanent crops cover 3%, forests and woodlands 12% and others 8%. Thus land is still the main asset of rural Nigerians where over 80% are peasant farmers; however this asset has not been fully utilized for agricultural production (Atilola, 2010). Public investments in agriculture have been extremely low (less than 2% of total federal expenditure between 2001 and 2005), and corruption has been identified in areas where the federal and state governments have played a role (e.g., fertilizer distribution). The general objective of this study is to assess the implication of land reform system on agricultural production in Nigeria. The specific objectives are to provide an overview on land reforms in

Nigeria; examine the problems of land reforms in Nigeria and consider the implications of land reforms on agricultural production in the country.

The Nigeria land use act

The current law guiding land administration in Nigeria is the Land Use Act, Cap L5, 2004, originally promulgated in 1978 (Chikaire et. al., 2014). It has however generated a lot of clamour for its review to make it more relevant to the needs of the present day. Until the introduction of the Land Use Act in 1978, the Crown Lands Law was adopted for the management and administration of land in the then Western, Mid-Western and Eastern Regions (when the country had Regional Governments). The provisions of the variants of the Crown Lands Act were substantially similar though it did not cover the administration of freeholds lands in those regions. They however differed significantly from the law governing the management of lands comprised in the then Northern Region, where the Colonial Administration nationalized land, divesting the Emirs who held the land in trust for the citizens (Chikaire et. al., 2014). The nationalization was consolidated by the Land and Native Rights Proclamation of 1914, which was later replaced with the land Tenure Law of 1962 (Chikaire et al., 2014). Thus, while the State Land Law of the Southern regions applied only to State lands, the Land Tenure Law of 1962 applied to all lands in the Northern region. The major difference between the laws in the South and North was the fact that freehold was possible in the South while only leasehold applied in the North. However, the land registration law applied equally to the Regions. The unfortunate implication was that different laws governed tenurial system to Nigeria while a single law governed land registration. Furthermore, the laws, especially with regards to the North, were not quite in accord with the original culture and tradition of the people. Like experienced by other African countries in the hands of their colonial masters, they created new land rights over the existing rights of the indigenous population. The Land Use Act was an effort at solving the multiple land tenure system that existed in the country. The expectation was that it would make land acquisition easier so that a larger number of citizens would have access to land. The Act which essentially adopted the Land Tenure Law of Northern Nigeria to nationalize all land in Nigeria vested all lands comprised within the territory of a state in the Governor of that state (except lands vested in the Federal Government). By transferring the radical title of non-state land to the Governor, the Act sought to introduce a uniform land tenure system throughout the country. The controversy that has trailed the Act explains how poorly it has addressed the land administration problems in Nigeria. There is a persistent clamour for its review and indeed it has not been reviewed for the nearly forty years that it has operated. One major factor hindering its review is the fact that it is entrenched in the 1999 constitution of the country making it difficult to isolate for review (Ukaejiofo, 2008). The Land Use Act has never been fully implemented. Most citizens, especially most rural citizens, are unaware of the Act and few have applied for certificates of occupancy. In many areas, the Land Allocation Advisory Committees are reportedly not functioning, and the rural populations continue to look to their chiefs and emirs on matters relating to land. The chieftaincy or emirate (in northern Islamic states) is responsible for managing the community land, making allotments to individuals and households, establishing the areas of communal land (e.g., washing areas, grazing land, market sites), setting rules regarding communal land and its resources (and in some circumstances, the use of land allotted to individuals), and adjudicating land disputes (Blench, et al., 2006). Even in urban areas, where the majority of the population lives in informal settlements, customary and Sharia' law govern rights and obligations relating to land (Olayiwola and Adeleye, 2006).

Problems of the land use act

Although the decree has made it easy for governments to acquire land for public purposes, drastically minimised the burden of land compensation and considerably reduced court litigations over land, it has since its inception created a new genre of serious problems for land management in the country (Mabogunje, 2002). Most of the problems with the Land Use Act border more on the implementation procedure rather than the provisions themselves; however the following problems with the provisions are pertinent. The lack of prerequisite maps for determining who owns what land; the non-explicit demarcation of urban and rural areas, and the assumption that the prerequisite national cadastre and geospatial data infrastructure, which are very essential for any land tenure reform, were available (Atilola, 2010). The exclusion by the decree of the rights of families or individuals to develop private lay-outs has led to the emergence of a disjointed, uncoordinated and incoherent system of physical planning in Nigerian cities and a declining rate of housing provision and even agricultural production in the country. Each succeeding Federal Government since the promulgation of the Act had exhibited lack of political will to implement various provisions of the Act to make it succeed. The Act made allowance for transitional provisions for the orderly assimilation of the land tenure systems it hoped to replace, but 30 years, after these other land tenure systems are still being operated (Atilola, 2010). Many state governments failed to establish the Land Use and Allocation committee in their states for many years. This has hampered the steady and continuous delivery of land for building purposes.

The operation of the land Use Act by its "trustees" – the State Governors and local government Chairmen had been characterized by its use as political weapon, lack of transparency, arbitrary and selective administration of its provisions (Atilola, 2010). The power of governors and local government chairmen to revoke any right of occupancy over land 'for overriding public interest' has been used arbitrarily in the past and helps to underscore the fragility of the rights conferred by the certificate. In consequence, there is increasing reluctance by both the courts and the banks to accept the Statutory Certificate of Occupancy neither as a conclusive evidence of the title of the holder to the land nor as adequate security in an application for loan. Equally serious is the fact that some governors use the provision requiring their consent for assignments or mortgaging as a means of raising revenue for their states through imposition of heavy charges for granting such consent. Thereby making the process of obtaining title to land is expensive and tedious. It is antithesis to a dynamic market land economy. Also many governors do not give the urgent attention needed to their responsibility of granting consent for land assignments thereby impeding the development of an efficient land market and housing. The inconveniences and delays in securing Statutory certificates of occupancy have induced many land transactions among Nigerians to move to the informal market or be falsely dated as having been concluded before March 28, 1978; the operative date for the Land Use Decree. Consequently, 30 years after its operation less than 3% of land in the country, mainly in the urban areas, is covered by title deeds (Olayiwola and Adeleye, 2006; Dada 2010; Butler 2009, Atilola, 2010). The Act has not succeeded in removing the uncertainties in title to land; instead, it seems to accentuate it. It does not protect small scale peasant farmers who continually lose their farm lands through acquisition for urban expansion and large-scale acquisition of land for commercial agriculture, most of which are speculative, without paying adequate compensation (Atilola, 2010). As of 2006, roughly 2 million people had lost their homes and land to compulsory land acquisitions (USAID, n.d.). The government's use of its acquisition power is subject to increasing challenge – both by residents resisting eviction and by organizations questioning the ―public purpose in taking land from one set of private parties to give to another set (Nuhu, 2007). The philosophy of the Act, that all land belongs to the state; all undeveloped land has no value and hence has no market value; and that there is no freehold of land deterred the development of market land economy in Nigeria. The decree as it stands represents an abrogation of the right of ownership of land hitherto enjoyed by Nigerians, at least in the southern half of the country, and its nationalization by the government is inconsistent with democratic practices and the operations of a free market economic system. The Act abolished the existing freehold title to land and limits the title that can be granted under it to leasehold interests not exceeding 99 years (Atilola, 2010). Thus under the act all allottees of state land and owners of properties covered by a Certificate of Occupancy became tenants of the State.

Need for land reform in Nigeria

The inadequacies of the current land tenure system as embodied in the Land Use Act, informed the agitation for its review by many stakeholders. Apart from the need to overhaul the land tenure system, government was made to realise that there could be no true development without the economic empowerment of the rural dwellers through the conversion of their natural asset, land, to capital by granting them titles to their land holding and creating an open land market economy (Atilola, 2010). According to Mabogunje (2007), the importance of the State taking a firm hand with respect to land reform can thus not be underestimated. Defined land ownership whether of a leasehold or freehold type is crucial for promoting the capabilities of rural producers, enhancing their access to credit, enabling them to invest in farm infrastructure and improved input, and generally improving their productivity. Without it all talks of poverty eradication and hunger alleviation especially at the rural end is at best no more than fighting the symptoms rather than causes of poverty (Mabogunje, 2007). Thus land is a natural asset of the common man which government should help in converting to capital and means of empowerment. At present this natural asset of majority of rural Nigerians is locked up as "dead capital" as various interests in them does not possess titles to raise capital. Only about 3% of the land in Nigeria is covered by title deeds (Chikaire, et. al., 2014). It is this low level of land titling that accounts for the high level of poverty in the land as it is not possible to harness the potentials in land without title deeds. The philosophy of the Land Use Act that all land belongs to the state and should be held in trust by the governor for the people., and that undeveloped land has no value, constitute a great obstacle to the development of a dynamic market land economy. Therefore, needs a surgical review for the current initiatives of unlocking the commercial potentials of land in Nigeria to be realised. It is the current dysfunctional nature of land administration dynamics in Nigeria, and concerns arising from its unproductive nature, that informed the need to provide a better strategy that will make Land Administration work and also provide benefits to all citizens of Nigeria. The other problems are operational and bureaucratic issues, including lack of institutional, administrative, infrastructural and professional expertise for the operations, which negatively affect the effectiveness of the law.

Furthermore, a minimum limit could also be fixed and farmers encouraged and assisted to cultivate enough land to meet the subsistence and non-farm needs of their families and provide a sellable surplus to meet the needs of urban population. To makes this possible, it may be important to undertake a cadastral survey and to explore the possibilities of colonizing unused arable land for the benefit of needy farmers. Experiences in other parts of the world demonstrate that you cannot guarantee equality of opportunity or prevent invidious class differentiation on in the farm sector, if you do not sufficiently restricts the size of individual holdings. Another fundamental problem with the Land Use Act lies in the fact that it has not taken the farm structure and landholding patterns and their implications for productivity and economic security into serious consideration. Its emphasis is on formal tenure, i.e. on the definition of the types of rights individuals and groups have relative to the state. It failed to address the problem of 'Lilliputian and fragmented holdings' which is prevalent in our farming system and the question of measures that can be taken to assist farmers to increase their resources base improve their productivity and incomes (Chikaire, et. al., 2014). This is a key problem because the question of what use is made of the land is as significant as that of ownership. You cannot guarantee ownership of the land by the poor by merely preventing absolute individual ownership. For any land reform to become an important instrument for equalizing access to land, it must contain policies that can raise productivity and income of farmers (Chikaire, et. al., 2014). For example, a fragmented and marginal holding which cannot provide adequate income or full time employment for farmers exposes them to the possibility of being forced to become landless and jobless. The existence of a free market in land and differentiation on the basis of wealth and social and economic power clearly indicates there is a strong possibility for greater disparity in landholding, welfare and performance and points to the enormity of the real and potential insecurity for the poor farmers. This will happen as farmers land get increasingly fragmented; if they continue to lack ability to produce enough from their land, and as they are exposed to increasing population pressure and greater commercialization of interests in land made possible largely by urban capital.

The results of this development could be very devastating as there seems to be a growing investment in agriculture on the part of those who get substantial income from the non-farm sector, more so as the majority of our farmers are caught in a cycle of poverty arising mostly from technical deficiencies, shortage of working capital and lack of access to improved technology that could make their effort profitable. Thus, by ignoring to plan simultaneously to tackle the problem of land use, the Act has indirectly exposed marginal farmers to the possibility of losing their only means for economic survival (Chikaire, et. al., 2014). This is most likely because of a dismal shortage and mal-distribution of the supportive services that could make farming more profitable and secure. According to USAID (n.d.), differing views as to the most effective methods of land tenure reform have been expressed. While some believe smallholder farmers should be allowed to expand in adjacent plots and otherwise consolidate their holdings to encourage mechanization and economies of scale, others solicit for the preservation of smallholdings and provision of smallholder farmers with appropriate technologies. Some have also expressed the need for tax landholdings to obligate farmers to increase their efficient utilization and bring large tracts of underutilized land into production or that lands that have been acquired in dubious fashion should be redistributed. Still others maintain that markets should replace the administrative allocation processes enshrined in the Land Use Act. In 2007, Nigeria's past administration introduced a 7-Point Agenda, which included land reforms that optimized economic growth through the release of state land for commercialized farming and other large-scale businesses operated by the private sector, (USAID, n.d.). In any case, in it was stated that National Assembly rejected bill to establish a National Land Reform Commission for the restructuring of land matters across the country (USAID, n.d.) by the then government in 2010. Following this development, a Presidential Technical Committee on Land Reform was formed to advise the government on the creation of a national cadastre, a plan for registration of landholdings, and the development of mechanisms for land valuation and conflict resolution. The land reform committee in Nigeria is aimed towards enabling the state to be effective managers of land. It is aimed to provide a systematic cadastral survey of land in the entire federation the term of reference makes it an essential body to assist both states and local government to carry out cadastre survey and codify the possessory right of the majority of the people access to land and landowners. The term of reference necessitate the body to collaborate and provide technical assistance to the states and local governments in undertaking cadastral survey and to ensure the demarcation of land boundaries and title holdings in such a way that communities, hamlets, villages and towns are recognized it was also saddled with the responsibility of encouraging state and local governments to establish adjudication mechanism for land ownership, conflict resolution and to make recommendation for mechanism for valuation in both rural and urban areas.

CONCLUSION

Land is the farmers' most important asset and it plays an essential role in agricultural production. Ownership of land however, often interferes with its use as an agricultural asset. The employment of land reform is therefore needed to ensure equitable allocation, availability and distribution. The Land Use Act was promulgated in 1978 with the objective of making land accessible to all Nigerians. However, it can be said that this objective has not been realised probably as a result of the numerous problems associated with the Act. For any land reform to be effective, it must contain policies that can raise the productivity and income of farmers. The inadequacies of the current land reform system as embodied in the Land Use Act have called for its review by stakeholders. Land is important to the life of man. Land is wealth, prestige and power. It is important for poverty reduction and food security. Its availability ensures economic development and growth. For agriculture to develop; land must be readily available – reform is one vehicle that ensures availability and access to land. Land tenure reform measures taken by the state empowers its citizens to realize their potentials in the development process. After careful observation of the current situation of the country's land reform system, this study recommends that; the masses should be educated about the reform objectives, laws and procedures and the relationship between the state and local governments and the farmers should be further strengthened to increase the access to land for agricultural purposes. The possibilities of colonizing unused arable land for the benefit of needy farmers should be explored.

ABSTRACT
The idea of this research work focused on the fund security status of piggery operators in Akwa Ibom state, Nigeria. The major aim of the microfinance movement is to provide funds for investment in micro businesses, thus lifting people out of poverty and promoting economic growth. Multistage sampling technique was adopted in selecting 90 (ninety) piggery operators. Simple descriptive statistics such as means, frequencies, percentages as well as Tobit model were used for the analysis. The results of this study showed that piggery operators' fund security was positively related to years of education, farming experience and stock size and negatively related to the age of operators, household size, total annual expenditure, value of inputs and interest rate. By this, government is encouraged to provide credits to the operators at low interest rates so as to give a quantum leap to the crawling productivity level previously experienced by these operators. Piggery operators can also form viable cooperative societies to provide mutual assistance to her members so as to assess bank loans with minimal restrictions in terms of collateral.
Keywords: Fund security, small-holder and pig operation

INTRODUCTION
The swine industry in Nigeria has not gotten developed like the ruminants and poultry because pigs are not generally used for meat purposes by majority of the population (Adebosin and Malion, 1986 in Banta *et al.*, 2012). This is based on the culture and religion which makes it a taboo for pigs to be eaten by some people. In Nigeria, pigs account for 4.5% of the total meat supply of the country (Adebambo, 1982 in Banta *et al.*, 2012). Pork is a source of meat which has high nutritional value particularly in the supply of fat that is rich in energy. The piggery industry also provides employment opportunities for the populace, thereby serving as a source of income to the Nigerian people because of the high profile nature of pigs. One of the advantages of the piggery industry is that feed materials are often industrial wastes which are easily obtained at low cost. The industry faced challenges ranging from religion to poor financing. Further, Onwumere (2008) identified some of the constraints to piggery operators output to include operators' education level, total cost of production and access to research and extension services. Efforts to deliver formal credit and financial services to the rural poor in developing countries have failed over the years (Adams, 2009). Commercial banks generally do not serve the needs of the rural poor because of the perceived high risk and the high transaction costs associated with small loans and savings deposits. To fill the void, many governments have tried to deliver formal credit to rural areas by setting up special agricultural banks or directing commercial banks to loan to rural borrowers. However, these programs have almost failed because of the political difficulty for governments to enforce loan repayment and because the relatively wealthy and powerful, rather than the poor, received most of the loans (Adams *et al.*, 1984, Adams and Vogel, 1986). In Nigeria, credit has been recognized as an essential tool for promoting Small and Micro Enterprises (SMEs) (Morduch, 1999; Olaitan, 2001). About 70 percent of the population is engaged in the informal sector or in agricultural production, piggery inclusive. The federal and state governments in Nigeria have recognized that for sustainable growth and development to occur the financial empowerment of the rural areas is vital, being the repository of the predominantly poor in the society and in particular the SMEs (CBN, 2005; Akinbogun, 2008; Atanda and Adeyemi, 2011). If this growth strategy is adopted and the latent entrepreneurial capabilities of this large segment of the people is sufficiently stimulated and sustained, then positive multiplier effects will be felt in the economy. To give effect to these aspirations, various policies have been instituted over time by the Federal Government to improve agricultural production capabilities, positively channel the potential of SMEs to enhance people standard of living and to put the sector in the front burner of Government's development strategy (Olaitan, 2001; Akinbogun, 2008; Ayanda and Adeyemi, 2011). Serious quantitative studies showing the actual fund security status of livestock operators especially piggery operators have not been done reasonably, thus this study seeks to ascertain the various determinants of microfinance assessed among piggery operators as well as their fund security position in a bid to improve their productivity.

METHODOLOGY
The study area of this research is Akwa Ibom state. The multistage sampling technique was adopted in this study. The survey sample includes 90 (ninety) respondents. 30 (thirty) small-scale piggery operators were selected from each of the three local government areas purposely selected from three agricultural zones (Essien Udin, Abak and

Ikot-ekpene) selected out of the six agricultural zones in the study area based on their relatively high livestock activities. The data for this study was from primary sources which involved administering well-structured questionnaires to the piggery operators. Simple descriptive statistics such as means, frequencies, percentages as well as the tobit model were used for the analysis.The tobit model is stated below:

Following McDonald and Moffit (1980) as adopted by Adesina and Baidu-Forson (1995), Akanni (2007) and Idowu *et al.* (2011), the Tobit regression model is explicitly specified as:

Mfi = Bi Xi + e_i

Where:

Mfi = Probability of adequate micro-financing or volume of financing (Fund Security Index), for Gi ^ Z; Mfi is continuous if Mfi > Mfo; Mfi = 0 if Mfi < Mfo; Mfo = The non-observable threshold level. Xi = Vector of explanatory variables; p_i = Vector of respective parameters; e_i = independently distributed error term.

MF = Volume of financing/funding (Naira)

Z = Fund insecurity line

Gi = Intensity of micro-financing which is defined as: (Wi - Yi) / Wi and

Wi = Optimum funding level (Naira)

Yi = Mean Piggery farm per capital expenditure (₦)

The set of explanatory variables which describe the effect of the use of micro-finance on the output of piggery operators are;

X_1 = Operator's age (years)

X_2 = Educational Status (years)

X_3 = Piggery Farming Experience (years)

X_4 = Household Size (number of dependents)

X_5 = Number of Pigs (stock size)

X_6 = Total Annual Expenditure (₦)

X_7 = Gender of Piggery Operators (1 for male and 0 if otherwise)

X_8 = Value of Inputs (₦)

X_9 = Interest rate (%)

RESULTS AND DISCUSSION

Socio-Economic Characteristics of Respondents

Majority of the piggery operators were between ages 30 and 39 accounted by 39% of the sample size. The implication of this finding is that youths participated actively in piggery operation in the study area. The result showed that males accounted for 58% against the 42% occupied by the females. 61% of the respondents were married, 28% were single while only 10% were widowed or divorced. However, it is known that married operators are more efficient since family members may assist in the farm operations. Further, 43%, 32%, 15% and 10% of the piggery operators possessed maximum of secondary, tertiary, primary and no form of education respectively. Operators whose household sizes were between 4 and 6 were in the majority given by 70%. Operators with 7-9 household sizes had 18% while the least was among household sizes of 1 to 3 and 10 to 12 with only 6%. Personal savings showed the highest at 57%. 48% of the operators had experience of 1 to 3 years. This represented majority of the respondents.

Fund Security Status of the Piggery Operators

The result of the fund security status of the piggery operators indicates that less than half of the operators were fund secure given by only 43%. The implication of this high fund insecurity status among the piggery operators is that they would not be able to procure the necessary inputs needed to expand output. Other challenges like inadequate and irregular services of skilled labor would abound. These will compound to reduce effectiveness as well as reduce the operators' profitability.

Determinants of Fund Security of Piggery Operators

Age, household size, total annual expenditure, value of inputs and interest rate reduced the probability of the operators to be fund secure at 5%, 1%, 1%, 5% and 1% respectively while years of education, years of experience and stock size reduced the probability to be fund secure at 5%, 10% and 1% respectively.

CONCLUSION

The results of this study showed that piggery operators' fund security was positively related to years of education, farming experience and stock size and negatively to age of operators, household size, total annual expenditure, value of inputs and interest rate. By this, government is encouraged to provide credits to operators at low interest rates so as to give a quantum leap to the crawling productivity level previously experienced by these operators. This can be done through the Central Bank of Nigeria instructing commercial banks to keep a certain percentage of their total reserve for small-scale agricultural purposes. Operators can also form viable cooperative societies to provide mutual assistance to her members so as to assess bank loans with minimal restrictions in terms of collateral, purchasing inputs in bulk to enjoy scale economies.

ABSTRACT
Economic of garri processing in Ivo Local Government Area of Ebonyi was studied using 100 garri processors selected using multi-stage random sampling technique. Structured questionnaire were used to collect data bothering on the objectives of the study. The results showed that garri processing is profitable in the study area with average profit value of ₦23,914. Furthermore, among the constraints to garri processing were inadequate raw materials, high labour cost and poor access to credit. Policies that will enhance processors' access to credits and raw materials should be formulated.
Keywords: Economics, Garri and Processing

INTRODUCTION
Cassava is a major root crop grown for food, cash and raw materials for agro allied firms in form of starch, alcohol and among others. It is the second most important staple crop after maize in terms of calories consumed (Nweke, 2004). Nigeria is the highest producer of cassava in the world with annual production of 38.179 million metric tons (IITA, 2005; Onwumere, 2010). Post-harvest deterioration is a major problem with the crop and tackling this problem will open the crop potentials in fighting poverty. FAO (2004) reported that amongst the ways to overcome the aforesaid problem is through processing. Processing has the capability of reducing the bulkiness of the crop, reduction in transportation costs, extends shelf life as well as adding value to the products (Anyaegbulam, 2010). In Nigeria among the major staples, cassava can be processed into, garri is the most popular and indispensable staple food (Mensa, 2002). The reasons include it is ready to eat, storable and easily processed to conform to the organoleptic preference of the consumers (FAO, 2004). Statistics on garri consumption according to Anyaegbulam (2010) reported that approximately 28.41 million people and 31% of Nigerian community consume garri once, twice and thrice daily respectively. Cassava is processed into garri at village levels by variety of small scale methods using graters, millers and pressers. Nevertheless, these processors are beset with problems bothering on climatic factors, inadequate raw materials, high cost of labour, firewood problems, especially during rainy season, high energy costs. Others are poor access to credit, high cost of machine spare parts and competition among processors (Ezedinma and Otti, 2001; FAO, 2004). The study tends to examine the profitability of the enterprise and the constraints confronting garri processors.

MATERIALS AND METHODS
The study was conducted in Ivo Local Government Area of Ebonyi State. It is located between Latitude 6´17 and 5º27´E of Equator and Longitude 12´34 and 7´42N of Greenwich Meridian. A total of 100 garri processors were randomly selected from 13 communities in Ivo Local Government Area for detailed study. Structured questionnaire was used to collect baseline information in processors' socioeconomic characteristics and inputs and outputs of cassava tuber processing into garri. Percentage response was used to address the processors' socioeconomic characteristics and the constraints to garri processing. Budgeting technique was used to address the profitability of garri processing.

$$\pi = TR - TC$$

Where π = profit; TR = total reverence; TC = Total Cost

RESULTS AND DISCUSSION
Table I revealed that most (70%) of the processors were woman and fell below 40 years of age. Most of the respondents (80%) were married with 60% being full time processors. Most (70%) of the respondents used hired labour and used cassava roots from their farms (70%). Table 2 shows estimated costs and return in garri processing. The results revealed that 250kg of garri was obtained from 1000kg of cassava roots. The total variable costs incurred was ₦32,560 and gross margin of ₦29,940 was realized. The total fixed cost incurred was ₦6, 000 with net profit of ₦23,914 realized. The benefit cost ratio of 1:1:6 was realized, implying that in every 1.00 spent, ₦1.6 is realized. Table 3 revealed constraints facing garri processors in the study area include shortage of raw material (80%). This problem is more particular during dry season when the soil is hard, that harvesting becomes

difficult. The other problems were high labourer cost (70%), high energy cost (60%) and lack of access to credit (50%).

CONCLUSION

Garri processing is profitable in the study area. The constraints to the processors were high cost and scarcity of raw material, high labour cost and poor access to credit. The study recommended that processors should form cooperative groups to pull their resources together to overcome financial problem. Policies that will enhance availability of labour of affordable price should be encouraged.

ABSTRACT
The objective of this study was to determine the factors that influence the amount of credit received by Cassava-Based Crop Farmers under the National Special Program for Food Security (NSPFS) in Abia State, Nigeria. Data analysis involved the use of descriptive statistics such as means, percentages and ordinary least squares regression technique. The results show that there were more female beneficiaries than male beneficiaries on the credit scheme. Age, farm size and value of assets owned were positive and significant determinants of the amount of credit received by the farmers at 1% educational status positively and significantly influenced the amount of credit the farmers received at 5% while sex negatively but significantly influenced the amount of credit the farmers received at 1%. Small (inadequate) size of credit was disbursed to the farmers. Farmers should be provided with adequate credit in order to assist them to achieve their potential for increasing output and consequently income on a sustainable basis.
Key Words: Determinants, Influence, Credit, Cassava-Based, Farmers

INTRODUCTION:

The inadequate use of improved inputs consequent upon the low resource endowment of the peasant farmers has made Nigerian Agriculture to remain at the rudimentary and traditional level. Onyebinama *(2004)*, observed that despite the huge investment in science and technology, agricultural production in Nigeria has remained at a subsistence level. A fundamental requirement for correcting this problem is the injection of investible funds into peasant Agriculture.

The recognition of credit as a powerful instrument for the reduction of low income in the developing countries has led to a multitude of programs on agricultural credit, cooperative and integrated rural development (Onyenucheya & Ukoha, *2007)*, Credit for the smallholder, especially in agriculture is assuming increasing importance in many parts of the world as a deliberate response to the needs of numerous entrepreneurs (farmers) with limited capital base (IFAD, 2001). In Nigeria, the transformation of smallholder agriculture from subsistence orientation to market orientation is emphasized by government *(*oboh & bush waha*, 2009)* and this requires the availability of adequate capital. Traditionally, capital for investment in agriculture comes from two sources, namely; personal savings of the farmer and farm credit *(*Oboh & kushwaha, *2009).* However, because of low yield and price uncertainty associated with farming in developing economies, farmers are often entangled in the viscous cycle of low output, low income, low savings and low investment, which again result in low output – a concept often referred to as the vicious cycle of poverty *(*Nwagbo *et al, 1989).* Therefore, credit either from the formal or informal sources remains the major means of improving farm capital investment.

Specifically, the study examined the Determinants of Factors that Influence Amount of Credit Received by Cassava-Based Farmers under the National Special Program for Food Security in Abia State, Nigeria.

METHODOLOGY:

This study was carried out in Abia State, Nigeria. The State is located within the forest belt of Nigeria and lies between latitudes $04^{o}45^{1}$ and $06^{o}17^{1}$ North and longitudes $07^{o}00^{1}$ and $08^{o}00^{1}$ East *(Abia ADP, 2005)*. It has a land mass of 5,833.77km^2 *(ASPC. 2005)*. There are two seasons, the rainy season (April-October) and the dry season (mid-October-March). The temperature ranges between 20^{o}c and 36^{o}c (Abia ADP, 2005). The population of Abia is 2,833,999 (NPC, 2006).

Three communities were purposively selected for the study-Ihim in Ikwuano LGA representing Umuahia zone; Umuobasiukwu in Bende LGA representing Ohafia zone and Obi-ozaa in Ukwa West LGA representing Aba zone. There is an NSPFS project in each of these communities. A random sample of 25 loan beneficiaries from each pilot community was taken. This gave a sample size of 75 respondents. Data were collected using a well structured questionnaire and oral interview of the farmers. Data analysis involved the use of descriptive statistics and z-test to examine the socio-economic characteristics of the program beneficiaries. Ordinary least squares regression technique was used to identify the factors that determine the amount of credit received by the farmers. The model was specified implicitly as follows:

$Y_1 = f(x_1, x_2, x_3, x_4, x_5) + e$

Where y = amount of credit received (₦), x_1= age of respondents (years), x_2 = educational status of respondents (years), x_3 = sex of respondents (male=I, female=O), x_4 = farm size (hectare), x_5= value of assets owned (₦), e = error term

RESULTS AND DISCUSSION:

Table 1 above shows the socio-economic characteristics of the loan beneficiaries. The table reveals that majority (71%) of the beneficiaries were between 40-59 years old with the mean age as 53 years. Onyebinama and Onyejelem (2010) reported mean ages of 50 years and 55 years for farming households in Kwara State, Nigeria and for cassava farmers in the rural areas of Abia State, Nigeria respectively. Also, majority (51%) of the beneficiaries were females showing that more women benefited from the credit scheme than men. Empowering women will likely enable them to embark on income generating activities. Increased income generation by the women will enhance their capacity to assist in providing food for the household, thus ensuring stability at home *(*Mafimisebi, *2008).*

Above 96% of the farmers have at least 0.1ha of land showing that majority of the beneficiaries are small holder farmers. Credit provision will probably enhance the acquisition of more farmland holding per farmer which in turn is expected to lead to increased output and income *(*Nwosu *et al, 2010).*The proportion of the farmers that are literate is about 85%. Literacy of the farmers is likely to influence the amount of credit they receive by enhancing their ability to access information which puts them in a better position to cope with the intricacies of new factor and product markets that the adoption of new technologies and credit introduces them to *(*Onyebinama & Onyejelem, *2010).*

Most (about 93%) of the beneficiaries received loans below N100,000.00 (One Hundred Thousand Naira). This is a common phenomenon in Nigeria that farmers demand for credit is far higher than the supply for credit due to several criteria used to screen successful applicants. Shortage of funds tends to give rise to credit rationing among successful loan applicants *(*Oboh & Kush Waha, *2009).*

Determinants of farmers that influence amount of credit received by program beneficiaries: The lead equation is exponential. The regression results show that age, educational status, farm size and value of assets owned were significant and positively related to amount of credit received. While sex of beneficiaries was significant but negatively related to amount of credit received.

Previous experience of the farmers in farm business activities over the years, as their age increases, enables them to set realistic cost and time targets and utilize credit efficiently *(*Onyebinama, *2004).* As a result, credit allocation to the farm business will increase with the age of the farmer *(*Oboh & Ekpebu, *2011).* The better educated the farmers were, the more favorably disposed they would be to receiving larger amount of credit from formal financial institutions, though the loan sizes may be administratively determined. Education will enable farmers to allocate and utilize credit optimally and identify production risks easily *(*Ebukiba, *2010).*

The result shows that as farm size increases, amount of credit received increases, therefore, farmers with larger farm sizes had increased amount of credit received than farmers with small farm sizes other things remaining constant *(*Okoh & Kushwaha, *2009).* The value of assets owned by the farmers indicates that the larger the value of the assets they owned, the more the amount of credit they received. The reason for this may be a significant number of the farmers had assets of significant value relative to the amount of credit they received. This is consistent with the findings of Mohammed and Temu *(2010),* who reported that the less poor farm households were better advantaged at increasing the amount of formal credit they received than the poor and more poor farm households.

Female beneficiaries had lower amount of credit received than their male counterparts. This is consistent with a priori expectation. The reason may be that female farmers are not considered to be major decision makers and title holders to farmland over and above the male farmers in Africa *(Oboh & KushWaha, 2009),* therefore the female beneficiaries received a total amount of credit that is altogether less than the total amount of credit disbursed to the male beneficiaries although the female beneficiaries were more in number. The null hypothesis that states that, 'farm size, educational status, value of assets owned and sex do not significantly influence the amount of credit received by program beneficiaries is rejected.

CONCLUSION

The result of this study indicates that age, educational status, farm size and value of the assets owned by the farmers increased the amount of credit they received. Male beneficiaries received a total amount of credit that was altogether more than their female counterparts.

Juziem2000@yahoo.com

ABSTRACT
This paper focused on the imperatives of processing and marketing of ginger to meet the global quality requirement as a potential economic diversification strategy in Nigeria. It relied on information from secondary sources such as food and agriculture organization, commodity trade statistics and field experiences of the authors. The study showed that Nigeria has comparative advantage in ginger quality and production. If these attributes are exploited, Nigeria is capable of leading the world ginger market and provides a platform for wooing the private investors into ginger processing and marketing. It was however observed that the processing methods of Nigerian ginger is still to a large extent, haphazard and not yet standardized, leading to low pricing in the international market. Economic diversification measures, targeting ginger as a major export crop should consider a number of imperatives for a successful policy shift in this direction. Such imperatives include the urgent need for mechanizing the entire manual system of processing ginger in Nigeria, Integrating ginger processing operations through inter-firm agreements, Getting the farmer to recognize the need to maintain higher standards of hygiene during production and processing through seminars, workshops and method demonstrations, encouragement of the private sector involvement, substantial improvements in product quality, market development and access to market information among others.
Keywords: Processing, Marketing, Ginger, Imperatives

INTRODUCTION

Economic diversification is a process of broadening the range of economic activities both in the production and distribution of goods and services (Anyaehie and Areji 2015). It does not necessarily entail increase in output but it enhances stabilization of economies by diversifying their economic base. To diversify the economy demands active participation in wide range of sectors, and firmly integrated into different regions, are better able to generate robust growth and great potential to increase Nigeria's resilience and contribute to achieving and sustaining long economic growth and development in the country. The discovery of crude oil has contributed and assisted Nigeria's economic prosperity and growth. Nevertheless, the current dwindling in oil price since June 2014, after five years of oil windfall, has immensely affected the economy of major oil exporters like Nigeria.

In this present predicament of Nigeria, diversification presents the most competitive and strategic option for the country in light of her developmental challenges and given her background. Diversification has a lot of benefits for Nigeria to maximally utilize her abundant resource – base to rebuild the economy and enjoy the benefits of all the linkages, synergy, economies of scale, grow national technology and foreign investment profile, build human capital, exploit new opportunities, lessen averagely operational costs, increase national competitiveness and grow the standard of living and confidence of the citizens for national renaissance (Seberu *et al* 2015). Diversification according to Ayeni, (1987) and Iniodu, (1995) implies "movement into new fields and stimulation and expansion of existing traditional products." Diversification does not discourage specialization, but requires that resources be channeled into the best alternative uses.

Before the discovery of oil in 1956 in Nigeria, Nigeria was famous in her agrarian economy through which cash crops like palm produce, cocoa, rubber, timber, ground nuts, were exported, thus making Nigeria a major exporter in that respect (Uzonwanne 2015). The high economic gains of the oil industry made the nation to abandon agriculture and depend solely on oil industry. The situation has led to non development of the agricultural sector of the economy. Thus, over the years, agriculture has suffered from years of mismanagement, inconsistent and poorly conceived government policies, neglect and the lack of basic infrastructure. This has exposed the nation to economic instability occasioned by the vagaries of international oil markets, gross unemployment and poverty in the face of plenty.

Nigeria, having experienced disappointment from the oil sector, is attempting to bring back agriculture. This was expressed by the introduction of the value chain approach to agricultural development. Onwualu (2012) maintains that the value chain approach to agriculture has the potentials to open up the economy and generate various activities, which are capable of creating jobs and enhancing industrialization and thus makes the non-oil sub-sector to hold the aces for future Nigeria's sustainable economic growth.

Ginger is a tropical herb extensively grown for its pungently aromatic underground stem or rhizome which is an important export crop valued for its powder, oil and oleoresin (NEPC 1999). It has been used as spices in most countries of the world. Ginger is an important cash crop in Nigeria, which is one of the major world producers and exporters of the crop (Ojiako *et al* 2007). Nigeria currently has the world's largest area under ginger cultivation and is one of the largest producers and exporters of the crop; especially the split-dried form. Large scale production of ginger started in 1927 (Arene *et al* 1986) in Southern Kaduna. Between 1927 and 1982, the production for export fluctuated and ultimately declined due to poor prices in the export markets and because of the economic boom of mineral oil during the 1970's. This situation, led to the neglect of crops that have great potentials to attract foreign currency to Nigeria. One of such neglected crops is ginger. The effect of this is that the area under ginger cultivation declined between 1999 and 2003, after which it recorded a steady increase, though marginally. However the production of ginger has been on the increase except in 1999 when there was a drop from 1998 figures. Available records shows that Nigeria is a very active participant in the world ginger trade. Now that the leadership in Nigeria appears keen to take agriculture seriously, a critical look at ginger could proffer solution to the country's economic woes. Considering the strength of having one of the best quality ginger in the world, their exist ample opportunity to increase production and improve processing methods as a veritable strategy for economic recovery.

Ginger processing and marketing imperatives

The ginger rhizome processing is defined as series of activities that take place from harvesting period (sorting and washing of the rhizomes) to the stage of bringing the rhizomes into various shapes and sizes that will add value to it and aid in shortening the period of drying time. It also entails splitting, peeling, slicing, blacking, rough scraping and grinding, drying for quality product, preservation (Fresh green ginger leaves), extraction of oleoresin and oil products from dried product, stability, packaging for exports and end users (Nwokadi and Ewuziem 2016). Regrettably, despite the popularity of ginger, coupled with its daily usage all over the world; its industrial processing techniques are still under developed, particularly in Nigeria and some major producing countries. Nigerian ginger attracts low prices in the international market. This was attributed to the its quality as reported by Yiljep *et al* (2005) that the processing of Nigerian ginger was not standardized with the result that microbiological, organoleptic and chemical properties of the product often fall short of importers' specifications. This was supported by Okwuowulu (2005) who reiterated that Nigerian ginger was valued as mere raw material for distillation and extraction, hence attracts drastically low price.

Ebewelle and Jimoh (1981) traced the low quality of Nigerian ginger at that time to the traditional drying methods used by farmers to dry ginger, which according to them are varied, haphazard and risky, resulting to mould growth, loss of some volatile oil by evaporation and destruction of some heat sensitive pungent properties. Unfortunately, this situation still prevails today in Nigeria after over one decade of identifying this challenge.

Efforts to mechanize ginger processing started in 1992 when Federal government of Nigeria through the sponsorship of priority Research Project (PRP) that provided funds to National Root Crops Research Institute (NRCRI) Umudike to solve the problem of designing a prototype processing machine for ginger rhizomes. The machine was sent to ginger farmers in Northern Zaria of Kaduna state for field trials and evaluation. The trials were encouraging and more of the type machines were fabricated and sent to Port Harcourt, Owerri, Okigwe and other areas for the same purpose. This machine was reported to have problems in its efficiency of splitting. A new version of this machine has been developed by NRCRI Umudike. It has been tested on farm and sent to kwoi in Kaduna state, Nwaoriebi in Imo state.

Nigeria is among the top ten ginger exporting countries in the world. The aggregate export of the Nigerian increased sharply, rising by more than 50%, by the early 1970s, but also declined rapidly by more than that proportion, with no export at all in 1978, 1980 and in 1981. This rapid decline is believed to be connected with poor producer prices, poor market organization and lack of coordination and regulation of trade practices and quality control standards. However, the world Ginger market grew at a speed of 10% annually from 2008-2012 in terms of quantity (UN COMTRADE 2015: www.gointernational.org.np). The price of Ginger also grew at 12% per annum during that period. At that time, the unit price for Nigeria ginger was $2,463 per ton when the world average was $727 per ton. In the trade Indicator of ITC 2013, Nigeria has been listed on 6th position for ginger export. It is on record that the world is paying prime price for Germany's ($3758), UK's ($3450) and Nigerian Ginger ($2468). Despite the relative advantages of Nigeria in ginger market, the country exported ginger worth only $2.83 Million in 2012 as against $48.42 Million in 2010 and $40.03 Million in 2011.

Processing and marketing Imperatives for economic diversification

The new federal Agricultural Promotion Policy (APP) specified that government will prioritize for export markets the production of such crops as ginger and work with a network of investors, farmers, processors and other stakeholders to deepen the supporting infrastructure to ensure that quality standards are defined and maintained across the value chain. That will involve adding more testing laboratories, improving traceability of crops, disseminating intelligence on export markets and consumer preferences, etc. (FMARD 2016). Whether Nigeria will be able to compete with other countries and remain relevant in the world ginger trade, will therefore depend upon the extent to which we can achieve substantial improvements in processing and marketing techniques. This is clearly seen from the fact that the price of ginger in the world market is closely associated with the origin and quality of ginger. Consequently, policy measures for establishing a viable ginger industry in Nigeria must include processing and marketing issues. Consumer demand for more stringent quality control in the spice industry is ever increasing. Each of the major importing countries has set its own quality standards for dried ginger and its derivatives. These standards are indication of the increasing sophistication of consumers even in the ginger producing countries. In the light of above observations, techniques for processing ginger products should be tailored towards meeting the legislative controls regarding quality standards for different products that favoured markets in destination countries may require.

Integrating ginger processing operations through inter-firm agreement whereby the processor will be in a position to determine the type of ginger varieties planted and the time of planting and harvesting them in return for provision of technical advice, production inputs or credit advance to the producers. This ensures that the right types of varieties for different applications are available in sufficient amount for processing. This is also crucially important to avoid running the processing plants at less than full capacity. Getting the farmer to recognize the need to maintain higher standards of hygiene during production and processing through seminars, workshops and method demonstrations is imperative for improvement of the quality of Nigerian ginger. Also, the development of mechanized processing culture will help. The pressing and urgent need for mechanizing the entire manual system of processing ginger in Nigeria is paramount. Consequently, the direction for the future is to mechanize the processing operations.

Mechanized techniques for processing ginger have been developed at NRCRI, in collaboration with the Product Development Agency (PRODA), Enugu and the National Centre for Agricultural Mechanization (NCAM), Ilorin. The only missing link is the private sector, as a result of negative attitude about investing in agriculture, probably because of the relatively long gestation period of such investments. Government and non-governmental organizations (NGOs) therefore have a crucial role to play in this direction. On its part, government should provide adequate incentives such as tax holidays and other tariff waivers in order to encourage investment in industrial processing. It should also provide affordable credit incentives to farmer cooperatives groups to enable them acquire available processing machines.

Prior to Nigeria's independence, the responsibility for the marketing of export crops, including ginger, was invested on the Nigerian export marketing board. In 1986, the commodity Boards were abolished for reasons connected mainly with the relatively low producer price paid to producers. Currently, the quality and marketing for ginger is both uncontrolled and unregulated. Present marketing system for the export of ginger is essentially the same as that for the domestic trade in ginger. Rural assemblers, speculative middlemen and commissioned agents buy and assemble ginger from producers in the hinter land and sell the ginger to wholesalers. The wholesalers take up the bulk-breaking function of exporting the ginger to the various overseas markets. This implies that substantial improvements in product quality are imperative in order to enhance the competitiveness of the Nigerian ginger in the world trade.

CONCLUSION

Oil has disappointed Nigeria, despite the huge revenues from the sector. Bulk of the oil revenue was not adequately utilized to develop the agricultural sector which used to be the bedrock of Nigeria's economy before the advent of oil. Now there is a call for the revamping of the agricultural sector as a viable means of economic diversification. One of the crops that Nigeria enjoys comparative advantage in its quality and production is ginger. Nigerian ginger is expected to attract high value in the international market, but its processing quality is an impediment to its demand. To this end therefore, Processing and marketing of ginger should be taken seriously in Nigeria, since the crop is cultivated in large quantities, because of its economic values. Despites it's various uses in the country and elsewhere, the utilization is low due to the fact that processing and packaging practices are not mechanized while the marketing systems are not developed. The crop processing methods entails different unique operations such as splitting, peeling, slicing, grinding and scrapping that require different machine operations separately or combined machine functions that will aids the production industries to complete favorably in terms of quantitative and qualitative product in international market. To realize the policy trust of the new federal agricultural promotion policy requires that the private sector will be attracted to the processing and marketing of ginger by setting processing and marketing standards that will the specifications of importing countries. By so doing, huge amount of foreign exchange will accrue to Nigeria and this will go a long way towards achieving the much desired economic recovery in Nigeria.

Table 1: Properties of ginger by major source of supply

Attribute	Jamaican ginger	Indian ginger	Nigerian ginger
Size	6.25-8.75 cm long	Irregular	Irregular
Shape	Irregular, branched and palmate	Irregular	Irregular
Colour	Very light buff	Pale brown	Dark or grey-brown
Appearance	Clean, hard and somewhat fibrous, and free from cork	Fibrous, with cork not entirely removed	Wrinkled
Aroma	Agreeable, aromatic, and somewhat pungent odour	Pronounced lemon-like aroma	Coarse aroma and flavor
Taste	Aromatic, pungent, biting taste	Similar in taste to Jamaican ginger	Very pungent taste
Volatile oil content (%)	1-1.3	1.9-2.2	2-2.5
Non-volatile ether extract (%)	Ca. 4.4	Ca. 4.3	Ca. 6.5-7.0

ABSTRACT
This is a positional paper that reviewed the business opportunities available for investors in various aspects of ginger production in Nigeria. The paper gave the botany, cultivation and distribution of ginger in Nigeria. It later X-rayed the business opportunities available in ginger production such as seed ginger production and ware ginger production. The reviewed agreed that unavailability of high quality seed is a major constraint to large scale ginger production. Also the business opportunities in ginger storage were reviewed. It was the popular opinion that buying fresh ginger rhizomes at the glut period and selling them during scarcity will be a profitable agribusiness. Ginger splitting although is said to experiences high level of drudgery but if exploited, it can offer a trade boom. Process of ginger into powder, oil and juice is proposed as an opportunity to industrialists while array of business opportunities are available in ginger marketing and export.
Key Words: Ginger, Business, Opportunities, Marketing

INTRODUCTION
Ginger (*Zingiberofficinale*) is an important spice both locally and globally. Its main active ingredients oleoresin and ginger oil are used for a wide range of culinary, confectionary, and pharmaceutical purposes (Sidi-Aliyu, 2006; Whitney, 2012; Amadi et al, 2013). It is traded globally in various forms such as fresh, preserved, dried, and powdered ginger. Ginger also enters the global market as processed products like ginger oil, ginger oleoresin, ginger candy, ginger soft drinks, ginger shreds, ginger prickles, ginger chutney etc (FAO, 2002). Nigeria has nearly a century experience in ginger production and has established herself as an important producer, consumer and exporter of ginger. Ginger is now the main cash crop supporting the livelihood and improving the economic level of many ginger growers in the main producing areas.
Two commercial varieties are commonly cultivated in Nigeria. The yellow ginger variety (UG 1) locally called "TafinGiwa" with a bold yellow rhizome flesh is stout with short internodes. The black ginger variety (UG 2) locally called "YatsunBiri" with a dull-grey colour rhizome. The yellow variety is more popular than the black variety apparently due to its high yielding capacity and pungency (Kure, 2007, Nmadu and Markus, 2011, Amadi et al., 2012). Trends in harvested land area, yield and total production from 2003 to 2013 is presented in table 1.
Nigerian ginger are amongst the cheapest in the world market due to its poor post-harvest handling processing which results in low quality (Ekundayo*et. al*., 1988; Okwuowulu, 2005). Consequently, the need to improve the quality of Nigeria ginger has been stresses (Okafor and Okafor, 2007). Despite this setback, the innate hotness and aroma of Nigerian ginger is appreciated worldwide ensuring that it commands a high demand both locally and internationally to support viable investment in various sectors of its value chain. Ewuziem et al., (2015) reports that the world is paying prime price for Nigerian ($2,463) ginger and that it contributed a total of $115.564m on the basis of value to the world ginger value of $2401.756m representing a share of 4.81%between 2008-2012. Cumulatively, a total of 51,483 tons of ginger was contributed by Nigeria to the world ginger market which is 1.35% of the world total (3,800,098 tons) during the same period. This paper relied on secondary data to highlights opportunities in ginger value chain in Nigeria that can support viable investments as we seek to diversify our economy to non-oil sources

Business opportunities in ginger value chain

Seed ginger production
High quality seed is a major constraint to large scale ware ginger production (Islam et al., 2012) Ewuziem et al, 2012, reported that high cost of planting material exerted serious pressure on total variable cost of ginger production and recommended a seed ginger multiplication programme as a panacea. At present farmers depend on self-saved seeds or those they get from other farmers. Investment in seed ginger production is therefore a viable venture because of expected patronage from ware ginger producers. In addition, technical backups for such enterprise can be obtained from National Root Crops Research Institute (NRCRI) Umudike which has the national mandate for ginger.

Ware ginger production
Ware ginger production has reported to be profitableboth in Nigeria and many other countries (Islam et al, 2012, Ewiziem et al, 2012, Nmadu and Marcus,2011). Many farmers and their households depend on it especially in major ginger producing areas of Southern Kaduna. An investment of ₦1 in ginger production has been reported to guarantee a return of ₦2.94 (Ewuziem et al, 2012) in the southern guinea savanna of Nigeria based on the yield of 16.5tons per hectare and the following assumptions: labour cost ₦400; mulch is harvested within the farm area hence labour cost of cutting the mulch is used as a proxy for the cost of mulch; and land used is not leased and

therefore did not attract any charges for rent. These assumptions are not sacrosanct and seem highly unlikely in the prevailing circumstances in Nigeria at least for large scale production. Nmadu and Marcus, 2011 showed by the data presented in table 2 that in Southern Kaduna area (The major Ginger growing area in Nigeria), ginger production is profitable agribusiness.

Ginger Storage

Buying fresh ginger rhizomes at the glut period (ie at peak harvest time) when the prices are low and selling them during scarcity when prices are high can be a profitable agribusiness. This of course depends on whether price deferential between the glut and lean times compensates for cost of storage and postharvest losses during storage.

Ginger splitting

A significant proportion of Nigerian ginger is marketed in the split dried form. Splitting of ginger involves a lot of drudgery hence the use of machines to split ginger helps to eliminate this drudgery and save time which can be applied to other useful endeavours. Just like in Cassava where grating has been turned into a viable business and people take their roots to graters for grating, ginger splitting can be developed as an enterprise that will be patronized by farmers, end-users and other stakeholders in ginger. Ginger splitting machines are available on demand from the Engineering Unit of NRCRI Umudike. The Institute also provides repair services for her machines.

Ginger Powder

Ginger powder is one of the popular forms in which ginger is stored and utilized.Split dried rhizomes are ground and sieved to produce the flour or powder. Ginger powder packaged in various forms is available in many markets and shops all over Nigeria. Ginger powder production is a profitable agribusiness enterprise that can accommodate more investors.

Ginger oil

The varieties produced in Nigeria UGI and UGII are high in monoterpene and oil, giving a more pungent aroma and pungency therefore making them ideal for the production of oils and oleoresins (KADP, 2000; Chukwu & Emehute, 2003). Ginger oil has a lot of industrial uses. There are two companies producing oleoresin at present in Nigeria. There is a lot of space for more investors. However investors should note international standards for ginger oil presented in tables 3 & 4 and ensure their products meets these specifications to ensure international acceptance. The Food Chemical Codex standards for ginger oil are the following:

Ginger Juice

The ginger juice, as a convenience food ingredient, may find its widespread use in the industry. The catering industry is itself made up of a variety of outlets such as hotels, restaurants, canteens, hospitals, nursing homes, school meals and prisons. Higher incomes and more active life styles in recent years have resulted in consumers seeking high quality, convenient food items in the markets. The ginger juice, for its anticipated widespread use, may help fill the needs of consumers for a convenient food ingredient. Ahammed et al., (2014) found ginger juice to be stable up to 6 months after evaluation with acceptable sensory and organoleptic properties. This should allow enough time for the marketing of the product.

Ginger Marketing

Ginger is consumed and marketed all over the country. However major ginger markets are located in the major producing areas of Kachia, Kardako and Kwoi. These primary markets feed other secondary and tertiary markets all the country. Marketing ginger both at farmgate, wholesale and retail levels is a thriving business that has sustained many households. In the market, ginger is available in various forms; fresh ginger rhizome, powder ginger and dry ginger rhizome. Out of this, 10% is locally consumed as fresh ginger while 90% is dried primarily for the export markets.

Ginger Export

Ginger as a produce is in very high demand internationally hence ginger export business in Nigeria can accommodate new investors. Nigerian ginger is reputed worldwide for its intrinsic quality. Thus Nigerian ginger is in high demand globally. Though prices are highly variable, local price of ginger is about $2400 per ton while international price is $4000 per ton. However exporters of ginger must note that certain standards are required of ginger meant for export. This minimum international (Asta, 1999) standard is presented in table 5.

CONCLUSION

The hotness and aroma of Nigerian ginger is appreciated worldwide. There is therefore a high demand for quality ginger both locally and internationally to support new investments in most sectors of ginger value chain. This is more so in a depressed economy like we have in Nigeria now that is in dire need of diversification from oil to non-oil sources. Investing in ginger therefore provides an alternative roadmap to our economic emancipation

Table 1: Trends in land area, yield and production of ginger in Nigeria (2003-2013)

Year	Area	Production	Yield (t/ha)
2003	167000	110000	0.66

FACTORS AFFECTING FOOD SECURITY AMONG COCOA FARMING HOUSEHOLDS IN NIGERIA

K.A, Oluyole, T.M. Orisasona, E.E.O.Agbebaku & O.A Dada

Cocoa Research Institute of Nigeria, PMB 5244, Ibadan, Nigeria
kayodeoluyole@yahoo.com

ABSTRACT
There is little or no information on the factors affecting food security among cocoa farming households in Nigeria. Therefore, this study investigated the factors affecting food security among cocoa farming households in Nigeria. Multistage sampling technique was used to select 200 cocoa farming households in the study area and structured questionnaire was used to collect information from the respondents. The data obtained from the information were analysed using descriptive statistics as well as logit model. Findings show that the mean age of the respondents was 52 years while about 58% of the respondents had their age above the mean age. The mean household size in the study area was about five. Result of the logit analysis shows that enhanced farming experience of household heads, increased output of roots and tubers, increased output of cereals and increased output of cocoa drive food security positively among respondents while increase in household size and increase in age of household head retard food security status of respondents in the study area. Arising from the foregoing, this study recommends birth control campaign as well as production of food and cocoa crops in right mix to enhance food security status of respondents.
Keywords: **food, cocoa, farmers, factors, logit model**

INTRODUCTION
Food security exists when all people at all times have access to safe nutritious food to maintain a healthy and active life (FAO, 1996). The main goal of food security is for individuals to be able to obtain adequate food needed at all times, and to be able to utilize the food to meet the body needs. According to (World Bank, 2001), food security is of three folds, these are food availability, food accessibility and food utilization. Food availability for farming households means ensuring sufficient food is available to the households through production. However, it should be noted that simply making food available is not enough; one must also be able to purchase it, especially the low income households (Sen, 1981). Hence, food security connotes physical and economic access to adequate food for all household members, without undue risk of losing the access.

However, while food security for individuals is often the main focus of attention, there are also household, national and international dimensions of food security (Olayemi, 1998). For individual food security, household food security is a necessity. Also important at the individual food security level are non-food factors such as health conditions, social and cultural practices which can affect individual nutrition. At the household level, food security implies adequate access to food at all time. There is adequate access when there is adequate food available to the household and, at the same time, the household has adequate capacity for effective demand for available food. At the national level, food security connotes adequate availability of food from all sources to meet the per capita food requirement of the population over time

In Nigeria, the production of food has not increased at the rate that can meet up with the food demand of the increasing population (Ojo, 2003). While food production increases annually at the rate of 2.5 percent, food demand increases annually at a rate of more than 3.5 percent due to high rate of annual population growth of 2.83 percent (NBS, 1996). The apparent disparity between the rate of food production and demand for food in Nigeria has led to a food demand-supply gap, leading to a widening gap between the food available and the total food requirement and hence posing a threat to national food security. In order to combat the food problems, the federal government of Nigeria over the last 10 years (1998-2007) embarked on different policies and strategies deemed appropriate to solve the problems. Some of these are geared towards empowering the people (through job creation, provision of credit facilities, promoting peace and security) and boosting production by promoting private enterprise. Nonetheless, providing food at affordable prices still remains a mirage.

Arising from the foregoing discussions on food security and production in the cocoa growing area, this study strives to provide answers to the following questions: what is the food consumption pattern of cocoa farming households and what are the factors affecting the farming households' food security status in the study area?

METHODOLOGY
The study was carried out in Ondo state of Nigeria. The state has eighteen Local Government Areas (LGAs) out of which fifteen of them produce cocoa. The study employed multistage random sampling technique for the selection of its respondents. The first stage involved a purposive selection of four notable cocoa producing LGAs. The selected LGAs included two high cocoa producing LGAs (Idanre and Ondo East) and two low cocoa producing LGAs (Akoko South East and Akoko North West). The second stage involves the random selection of

two communities from each of the selected LGAs while the third stage involves the random selection of respondent households from the selected communities. However, from the eight communities, a total of two hundred respondent households were randomly selected. The number of samples taken from each community depends on the entire population of the farming households in the communities. Hence, the sampling was carried out proportionate to size. Descriptive statistics as well as logit model was employed as analytical tool in this paper. Logit model was used to analyse the determinants of food security status in the study area. Logit model is usually applicable where the dependent variable is dichotomous and not continuous. Logit model is a probability function and can be represented by taking Y (dependent variable) as a probability. The logistic (logit) probability function is represented as

$P_i = 1/1+e^{-zi} = f(Z_i)$……………………………………………………...(i)

$\log (P/1\text{-}P) = f(Z_i)$…………………………………………………………..(ii)

But $Z_i = \beta X_i$ ……………………………………………………………..(iii)

Therefore, $\log (P/1\text{-}P) = f(\beta X_i, u)$…………………………………...……...…..(iv)

$\log (P/1\text{-}P) = 1$ if $C_i \geq Z_i$, while $\log (P/1\text{-}P) = 0$, if $C_i < Z_i$. (Hence, any household whose C_i is equal to or greater than Z_i is said to be food secure while any household whose C_i is less than Z_i is said to food insecure).

Where:

Z_i = Recommended daily per capita requirements (2450Kcal.); C_i = Per capita calorie consumption of household$_i$; log(P/1-P) = Food security status of households (1, for food secure households; 0, for food insecure households); X_i = Vector of explanatory variables; β = Estimate of the explanatory variables; u = Independent distributed error term.

The explanatory variables included in the model are:

X_1 = Household size (number); X_2 = Age of household head (years); X_3 = Farming experience (years). X_4 = Output of roots and tubers (Kg); X_5 = Output of cereals (Kg); X_6 = Output of cocoa (Kg); X_7 = Off farm income (₦); X_8 = Level of education (formal education = 1; otherwise = 0); X_9 = Association membership (1, if belongs to an association, 0, if otherwise).

RESULTS AND DISCUSSION

The mean age for cocoa farming households' head is 52.2 years (Table 1). About 42% of the total respondent households' head had their age below the mean age, while about 58% of the respondents had their age above the mean age of 52.2 years. Hence, there were more older households' head than their younger counterparts in the study area. This may have negative impact on the farm size since young people are stronger and are expected to cultivate larger-size farm than older respondents (Oni *et al*, 1999). Also, Table 1 shows that 83.5% of the respondent households were headed by males showing that majority of the households in the study area were headed by males. As regards to the educational status of the respondent household heads, 65.5% of the respondent household heads had formal education. Hence, most of the household heads in the study area had formal education. Education is a form of human capital; hence it could impact positively on household ability to take good and well informed production and nutritional decisions. It could also be observed in Table 1 that 93.5% of the respondents were married. This shows that majority of the household heads in the study area are married implying that there is likelihood that there could be more family labour, available to farming households. The mean household size in the study area is about five members per household (Table 1). The household size could have great implications for labour supply for farm work and also food security. A large household is expected to provide more labour for the cultivation of large farm size.

Table 2 shows the result of the logit model. The value of Chi-square shows that the overall model is significant at 1% level. This indicates that the model has a good fit to the data. Out of the nine independent variables used in the model, six variables were found to be significant in determining the food security status of the farming households. The variables are household size ($p<0.01$), age of household head ($p<0.1$), farming experience of household head ($p<0.05$), output of roots and tubers ($p<0.01$), output of cereals ($p<0.1$) and output of cocoa ($p<0.01$).

Household size was a significant factor in determining household food security status in the study area. A unit increase in household size will reduce the probability of household to be food secure by 0.23. Hence, increase in household size would lead to decrease in the food security status of the household. This result is expected because increase in the member of household means more people are eating from the same resources, hence, the household members may not be able to have access to enough food when compared to a situation with smaller household size. The result is in line with the findings of (Agbola, 2004). Findings also showed that age is a significant determinant of the probability of a household to be food secure or food insecure. A unit increase in the age of household head will reduce the probability of household to be food secure by 0.000074. This could be attributed to the fact that the productivity of old household head will decline as they get old thereby impacting on their food security status. This result is in consonance with (Agbola, 2004) who claimed that increase in age decreases food security. As for farming experience of household head, a unit increase in farming experience of household head increases the probability of household to be food secure by 0.0090. This result is expected because a more experienced farmer is likely to have higher level of productivity and hence be able to provide more food for his household members. With respect to the output of roots and tubers, a unit increase in output of roots and tubers increases the probability of household to be food secure by 0.00022. This finding is in line with (Olayemi, 1998). The finding could be attributed to the fact that increases in output for roots and tubers is likely to be synonymous to the availability of more food. Findings further revealed that output of cereals was a significant determinant of the probability of a household to be food secure or food insecure. A unit increase in output for cereals increases the probability of household to be food secure by 0.000094. Increase in output for cereals would make more food (cereals) available to the household and hence would make the household to be more food secure. In terms of the impact that output of cocoa had on food security status of households, findings showed that a unit increase in output of cocoa increases the probability of household to be food secure by 0.00051. Cocoa being a cash crop will enable household to generate more income. This will make money more available for use for households to buy food anytime they wish and hence would make the households more food secure.

CONCLUSION AND RECOMMENDATIONS

Based on the empirical evidence emanating from this paper, it concludes that household size, age of household head, farming experience of household head, output of roots and tubers, output of cereals and output of cocoa significantly impact on the food security status of respondents in the study area. The findings also made this study conclude that experience and age of farming household heads as well as right mix in production of food items as well as cocoa will improve the food security status of respondents in the study area.

The study therefore recommends that there should be an enlightenment programme in the study area on the need for birth control since the study reveals that food security decreases with increasing household size.

ABSTRACT
This study was carried out to evaluate the profitability of goat farming and identify the constraints associated with the enterprise in Bassa local government area of Plateau state. Multistage sampling procedure was employed in selecting the respondents in the study area. Well-structured questionnaires were used for primary data collection.. The data collected were analyzed using budgetary techniques (profitability analysis) and descriptive statistics. Budgetary analysis revealed that the gross margin (GM) and net farm income (NFI) were ₦171,200/small-holder goat farm and ₦139,700/small-holder goat farm respectively. Also the results of the efficiency ratios estimated includes; returns per naira invested (0.81), operating expense ratio (0.45), and benefit cost ratio (1.81); indicating that goat farming was a profitable enterprise. The major problems identified were financial constraints (94%), poor foundation stock (75%), and poor remunerative income/poor pricing (69%). Based on the findings from the study there is need to improve small scale goat farmer's access to agricultural credit through microfinance institutions and commercial banks sources. Also, livestock research institutes should be encouraged to produce more superior quality breeding stocks. More agricultural service centers should also be established. These constraints, if addressed, would improve productivity and profitability of goat production in Bassa Local Government Area (LGA).
Keywords: Goat farming, profitability analysis, constraints

INTRODUCTION
Goats were among the first farm animals to be domesticated. Goats disseminated all over the world because of their great adaptability to varying environmental conditions and the different nutritional regimes under which they were evolved and subsequently maintained (Peacock, 2005). They proved useful to man throughout the ages due to their productivity, small size, and non- competiveness with him for food. In Nigeria, goats make a very valuable contribution, especially to the poor in the rural areas (Aliyu, 1999). Goat undeniably plays a vital role in the rural economy of many developing countries in Africa. Goats are very important in the protein diets of the people, as well as a good, stable source of livelihood especially for the poor in the rural areas. Goat production is mostly carried out by smallholder farming households where the animals are kept in small flocks at an average of 5-10 head/family. It requires low initial capital and guarantees a high return on investment in as fast as two years; hence, it is an attractive undertaking among rural households. Goats are hardy and well-adapted to harsh climates. Due to their grazing habits and physiological characteristics, they are able to browse on plants that would normally not be eaten by other livestock species (Ojoye, 2006). Goats provide their owners with a broad range of products and socio-economic services; hence they can be used as gifts, in traditional and religious rituals and rites (Ojoye, 2006). Goats can play a vital role in ensuring the food security of a household, often being the only asset possessed by most rural farming households (Peacock, 2005; Birthal *et al.*, 2005). Goats play an important socio-economic role in rural areas. They are prolific and require low inputs for a moderate level of production, reach maturity early and are profitable to keep (Dolberg. 2001). Farmers and pastoralists are increasingly relying on goats as means of survival and a way of boosting their income (Peacock, 2005). Goats can withstand heat stress and can endure prolonged periods of water deprivation. They have additionally great adaptability to adverse climatic and geophysical conditions, where cattle and sheep cannot survive. They can efficiently utilize poor quality forage. Goat meat is widely consumed in the developing countries. According to FAOSTAT, (2008), total meat inventory is about 280 million MT. Goat meat represents only 2% of this total. The total amount of goat meat produced in 2008 was 4.9 million MT. The developing countries produced approximately 97% of this amount, reflecting the great importance of goat meat to feed millions of people in these countries. Although there are now considerable amount of published research on small ruminants in tropical areas of Africa, there is limited information available on small-holder goat production in Nigeria (FAOSTAT, 2008). The contributions of goats to the people and economies of Nigeria is well underestimated, basically because their production is considered as small in scale, and goat products seldom enter a formal marketing system. For these reasons, goats are accorded a low status and given a low priority in national development in most African countries. Much of the work published has the disadvantage of having been carried out under controlled conditions at research stations and the results may not reflect the actual situation of small scale production systems prevailing in rural areas (FAOSTAT, 2008). Thus it is necessary to study the performance and limitations of goat farming in order to recommend strategies for their improvement. Therefore, the general objective of the study is to estimate the profitability and constraints associated with goat farming in the study area, while the specific objectives are to; (i) determine the profitability

of goat farming (ii) identify the constraints associated with goat farming in the study area. Knowledge of this is necessary to assist the current or prospective goat farmers and agricultural policy makers in taking decisions and making recommendations that will improve production and profitability of goat enterprise.

MATERIALS AND METHODS

The study was conducted in Bassa Local Government area of Plateau State, Nigeria. Multi stage sampling procedure was employed in selecting the respondents for the study. The first stage, involved the purposive selection of Bassa Local Government Area (LGAs) which is noted for rearing of goats out of the 17 other LGAs in Plateau state. Second stage involved the purposive selection of three (3) districts out of nine in Bassa LGA at constant proportion of 0.334. The districts include Jere, miango, and mista ali. The final stage involved random selection of the respondents from a list of four hundred (400) goat farmers in the selected districts, compiled by the local extension agent at a constant proportion of 0.20. A total of eighty (80) respondents were interviewed. Primary data was collected using questionnaires. Data generated was analyzed using profitability analysis and descriptive statistics. To further substantiate the profitability of this enterprise, efficiency ratios such as: percentage profit margin, return per Naira invested, operating expense ratio (expressed as a percentage) and benefit cost ratio were analyzed.

RESULTS AND DISCUSSION

The estimated gross margin and net farm income were ₦171,200/small-holder goat farm and ₦139,700/small-holder goat farm, respectively (Table 1). Cost of foundation stock accounted for half (50.8%) of the total cost while revenue from weaned kids had the highest share (61.4%) of total revenue. The total revenue on the average was ₦312,000. The profit margin percentage was 45% while return per Naira invested was 0.81, implying that every ₦1 expended returned ₦0.81 to the enterprise and the operating expense ratio of 0.45 indicates that 45% of gross revenue was used to cover operating expenses, which accounted for about 81.7% of the total costs. The benefit cost ratio was 1.81These ratios are indicative of the profitability of goat enterprise in the study area.

Constraints associated with goat farming

The major constraints associated with goat farming in the study area are financial constraints (94%); accessibility of institutional credit for goat farming projects was relatively cumbersome, poor foundation stock (75%). Difficulty in getting good quality breeding stock (buck) was also a major constraint. The absence of organized efforts for breed improvement of goats has further compounded this problem. Another major (69%) constraint was poor remunerative income and low pricing of the surplus live goats. The trade of live goats is unorganized and their pricing in most cases does not favour the goat farmers. The live goats were sold not on the basis of their body weight in the livestock markets; this resulted in under-estimation of the value of live animals, hence low profit (Kumar, 2007).

CONCLUSION AND RECOMMENDATIONS

Based on the major findings from the study provisions should be made by private, public and other stakeholders in the agricultural sector to improve the livestock marketing structure as well as provide small scale goat farmers access to institutional credit through microfinance institutions and commercial banks sources. This could enable farmers to embark on large scale goat farming projects, obtain good quality breeding stock to increase production and profitability. Also, livestock research institutes should be encouraged to become the centers of production of superior quality breeding stocks. These will reduce the problem of poor foundation stock. In addition, more agricultural service centers, e.g., ADPs, etc., should be established to provide technical knowledge, recommended inputs and market information this will help to improve the quality of output, thereby solving the problem of poor remunerative income/poor pricing.

ABSTRACT
*The study examined the socio-economics of three leafed yam (Dioscorea dumetotum) to rural households in Emuoha Local Government Area of Rivers State. Structured interview schedule was the instrument used to get information from 100 bitter yam farmers from ten communities using the simple random sampling technique. Data collected were analysed using the descriptive statistics and cost benefit ratio. The result reveals that majority of the respondents are females (52%), married (60%), between the ages of 41-50 years (42%), had First School Leaving Certificate (FSLC) and have been farming bitter yam for over 12 years (42%). The cost benefit ratio is 1.79, indicating a profit of ₦0.79 for every ₦100 invested in bitter yam production. The constraints to bitter yam production include lack of capital (x = 3.15), infection of bitter yam by beetle (x= 3.00), spoilage/rottenness of bitter yam (X=2.73) and flooding of farms (x=2.63). The study therefore, recommended that technologies on how to prevent beetle from attacking bitter yam and how to prevent spoilage of bitter yam should be disseminated to farmers and rural households should be encourage to go into bitter yam farming as a source of livel*ihood since it is a profitable venture.

Keywords: Bitter yam, Economics, Household, Food

INTRODUCTION
Bitter yam (*Dioscorea dumetorun*) is among the yam family that belongs to the genus *Dioscorea* and family *Diocoreacae* (Bai and Ekanaayake, 1998). There are other names for bitter yam which include trifoliate (three leafed) yam and cluster yam. Bitter yam is called 'ji una or ji ona by Ojoto and some Igbo speaking communities or areas or towns in the south-eastern staes in Nigeria while in Emohua Local Government Area of Rivers State, it is called ele-he-lu (White bitter yam), nkpu-ta-nkpu (Pupple bitter colour) and ngwa Benin (Yellow bitter yam). They are generally called ele-he-elu in Ikwerre speaking language. It is usually eaten as as a food mainly for adult. In the study area, bitter yam also serves as food for the diabetic patients and as herb for the treatment of various ailments such as elipsy. In the south-western Nigeria, bitter yam is used in the treatment of malaria (Dike *et al*, 2012) which indicates that bitter yam has ethno-medicinal benefits to the rural people. Bitter yam is rich in phyto-nutrients, including proteins (Medoua *et al*, 2005, Alozie *et al* 2009), yet it is among one of the most uncultivated tropical tuber (Enujiugha and Ayodele-oni, 2003). In spite of the numerous potentials found in using bitter yam in bakery, homes and pharmaceutical industries (Musieba *et al*, 2013). The state and nation are faced with the problem of inadequate food supply because of government over reliance on oil, land degradation as a result of oil activities and the attendant malnutrition problem in the rural areas necessitated the study with the aim of finding how food supply could increased and be available for people to utilize them.
The white colour does not stay long after harvesting but the rest can stay longer. The most preferred one is the white coloured bitter yam. However it could not be kept overnight. It has to be harvested and eaten under 24 hours. But the yellow and purple specie bitter yam could stay as long as the farmer wants. It can be harvested and kept in the house for one to two weeks. However, they are not preferred by rural households. Another limitation of the use of bitter yam is the unpalatable bitter taste and high post-harvest hardening nature of the tubers (Medoua *et al*, 2005). High post-harvest hardening of tubers could be prevented by drying and milling bitter yam into flour. In this regard, it is necessary to survey bitter yam production among rural farmers in Rivers State and investigate simply methods of how to improve on the traditional method of drying and milling.

METHODOLOGY
The major occupation of the people of Emohua is farming such as yam, cassava, three leaf yam, vegetable, pepper, okro, and cocoyam. Emohua is made up of 21 communities. Ten communities were purposively selected from the LGA. This was based on the highest number of farmers who produce bitter yam. The selected communities were: Egbeda, Omudioga, Ubinin, Ibaa, Rumuji, Ndele, Ovogo, Npremini, Ogbakiri and Itue. From each of the selected communities, a proportionate number of 10 bitter yam farmers were randomly selected, giving a total number of 100 bitter yam farmers. A well-constructed structured interview schedule was used for relevant data collection. Data collected were analyzed through the use of mean statistics, percentages and cost benefit ratio.

RESULTS AND DISCUSSION

Table 1 reveals that a higher percentage (42.0%) of the respondents was in the age bracket of 41-50 years, was females (52%) and married (60%). The mean year of 42.2 years indicates that the respondents were still young and active and in their productive stage, females are more in bitter yam production and they are responsible men and women. Also, majority (57%) of the respondents had First School Leaving Certificate (FSLC) and have been farming bitter yam for over 12 years (42%) indicating low literacy level in the study area however, they have enough experience in bitter yam farming. The mean year of farming is 12 years.

The above result shows that a total cost of ₦19500 was required to produce 10 kilogrammes to 50 kilogrammes of bitter yam. This gave ₦35000 when a heap of 50kg is sold for ₦3500. The total revenue is ₦35000. This gave a profit of ₦16000 indicating that bitter yam production is a profitable venture. Also, the net return for bitter yam production is ₦35000 in Emohua LGA of Rivers State. Furthermore, the cost benefit ratio shows that for every ₦100 invested in bitter yam production, a profit of ₦0.79 is returned. This shows that the business is profitable.

Perceived socio benefits of Bitter Yam production

Table 2 shows that a little above half (51%) of the respondents perceived that the socio benefits of bitter yam production to the rural dwellers is that it is very cheap to buy followed by 40% of the respondents who say it is a source of livelihood and 12% said it is very good for diabetic patients.

Constraints to Bitter Yam Production

The constraint to bitter yam production is shown in Table 3. From Table 3, using a mean score of 2.50 as the decision rule, out of the seven variables given for respondent to react, only four of the variables were accepted as constraints to three leaf yam or bitter yam production. They lack of capital (x = 3.15), infection of bitter yam by beetle (x= 3.00), spoilage/rottenness of the yam (X=2.73) and flooding of farms (x=2.63). This implies that lack of capital; insect's infection and flooding were the major constraints to bitter yam. This agrees with Albert and Ekine (2012) who observed that lack of funds was a major constraint to the development of rural business in the state.

CONCLUSION

Bitter yam is popularly grown as a food crop in Nigeria. Although there are some cultural bias against it but it is grown by farmers of different social class. This often is attributed to its cost which is very minimal compared to other varieties of yam. Since insufficient fund is the main constraint to the production of bitter yam, it is recommended that the farmers should be formed into cooperative groups for easy access to farm credits.

Cost Benefir Ratio for Bitter Yam Production
Cost of Production
Fixed cost
Land Inherited/leased for one
Variable Cost
Cost of labour ---------------------------Family Labour
Cost for clearing land ---------------------- ₦4500
Cost of bitter yam seedlings -------- ₦1500 for 10 tonnes x 8 plots of land(1 hactare) = ₦12000
Total Cost of Production -------------------- ₦16500
Revenue
One heap(10tonnes) of 50 sold for -------------------- ₦3500 x 10 = ₦35000
Gross Margin Profit = Total Revenue – Total Cost
= ₦35000 - ₦9500 = ₦16000

$$\text{Cost Benefit Ratio} = \frac{\text{Total Revenue (TR) TR} = ₦35000}{\text{Total Cost (TC)} \quad \text{TC} = ₦19500} = \frac{₦35000}{₦19500} = 1.79$$

Table 2: Percentage Distribution of Types of bitter yam cultivated

Benefits	Frequency	Percentage
Good for diabetes (medicinal)	12	12.0
Very cheap to buy	51	51.0
Very easy to plant and harvest	4	4.0
Is a source of business	40	40.0

ABSTRACT
The study was carried out in Ebonyi State, Nigeria, to determine the socio-economic characteristics of the farmers; the technical efficiency of the farmers; and the constraints to production of trifoliate yam by smallholder farmers. The study involved a multistage sampling technique and a random sample of 60 smallholder farmers. Random field data for the study were collected from the respondents using well structured questionnaire and oral interview. Data collected from the study were analyzed using simple descriptive statistics and Cobb-Douglas stochastic frontier production model. The results of the study showed that among the trifoliate yam farmers in the study area, the mean farm size is 0.19ha, and the mean farm output is 2117.17kgha^{-1} annually. Farm size and fertilizer input are significantly positively related to trifoliate yam production, while the use of stakes is significantly negatively related to trifoliate yam production. Sex and farming experience are significantly positively related to the technical efficiency of the farmers. The technical efficiency of the farmers ranges from 44.0 to 90.0 percent, with a mean of 57.0 percent. The mean technical efficiency of 57.0 percent implies that the output of trifoliate yam farmers in the study area can be increased by about 43.0 percent with the existing level of resources. This can be achieved by adequate access to credit for production through farmers' cooperative societies and micro-finance institutions among others.
Keywords: Technical efficiency, production, trifoliate, yam

INTRODUCTION
Trifoliate yam (*Dioscorea dumentorum*) is an important food security crop among smallholder farmers in Nigeria. It readily intercrops with maize, vegetables, okra and cowpeas, and occupies a prominent position in the diet and farming systems of southeastern agricultural ecological zone of Nigeria (Onyekwere *et al.*, 2010). Nutritionally, it is superior to commonly consumed yams, having higher protein and mineral content (Baquar and Oke, 1976). It contains dry matter (28.62%), crude protein (11.07%), ash (2.20%), fibre (2.06%), fat (1.73%), total carotenoid (217.73 µg/100g) and carbohydrate (69.71%). The high fibre content makes it an important diet for people with high cholesterol level in the blood. Trifoliate yam is not a good source of carbohydrate as other yam varieties, hence it can be recommended for the diabetics (Ezeocha *et al.*, 2009). In spite of the economic values of trifoliate yam in Nigeria, there is a dearth of information on the technical efficiency of trifoliate yam smallholder farmers, and this study attempts to provide the information. Technical efficiency refers to the ability to produce the highest level of output with a given bundle of resources (Onyenweaku and Nwaru, 2005). Farrel (1957) provided the impetus for developing the literature on empirical estimation of technical, allocative, economic and profit efficiency of the farmer. Efficient use of farm resources is an important part of agricultural sustainability which enables increase in farm production by improving efficiency within the input of existing resource base and technology (Ajibefun, 2004). Among the approaches used in measuring efficiency, stochastic frontier approach has been used extensively in measuring the level of efficiency and inefficiency. Aigner *et al.*, (1977) and Meeusen and Broeck (1977) independently proposed the stochastic frontier model. The stochastic frontier approach is preferred for accessing efficiency in agriculture because of the inherent stochastic involved (Kirkley *et al.*, 1995; Coelli *et al.*, 1998). In the light of the foregoing, the specific objectives were to determine the technical efficiency of the farmers and the constraints to production of trifoliate yam by smallholder farmers in the study area.

MATERIALS AND METHOD
Multistage sampling technique was used for the study. Two (2) Agricultural Zones were randomly chosen from the three (3) agricultural zones in the study area. Four (4) Local Government Areas (LGAs) were purposively selected for the study. These comprised 2 LGAs known for trifoliate yam production from each of the 2 agricultural zones selected for the study. Twelve (12) randomly selected communities comprising 3 communities from each of the 4 purposively selected LGAs were used for the study. A random sample of 60 smallholder farmers comprising 15 respondents from each purposively selected LGA were used for the study. Random field data for the study were collected from the respondents using well structured questionnaire and oral interview. Data were collected on the socio-economic characteristics of the farmers including their age, sex, educational level, farm size, household size, farming experience, farm output and farm income. Also data were collected on the farmers'

farm specific factors including rent on land, planting material, staking material, fertilizer, labour and depreciation of farm assets, and farmers' production constraints.

Data Analysis

Data collected from the study were analyzed using descriptive statistics and econometric model. The socio-economic characteristics of the farmers were described using simple means and percentage values. The technical efficiency of the farmers in the use of farm specific factors in production was determined using the explicit functional form of the Cobb-Douglas stochastic frontier production model which is specified as:

$InY_i = \beta_0 + \beta_1 I_n X_1 + \beta_2 I_n X_2 + \ldots + \beta_7 I_n X_7 + V_i U_i \ldots (1)$

where:

In = natural logarithm; Y_i = trifoliate yam output (kgha^{-1}) of the *i-th* farmer; X_1 = rent on land (₦ ha^{-1}); X_2 = planting material (kgha^{-1}); X_3 = staking material (₦ ha^{-1}); X_4 = fertilizer (kgha^{-1}); X_5 = labour (MDha^{-1}); X_6 = depreciation of farm assets (₦ ha^{-1}); β_0= constant intercept; $\beta_1 - \beta_5$ = estimated coefficients; V_i = random error term; U_i = technical efficiency which has half-normal distribution and is independent of V_i

The socio-economic factors that influence the technical efficiency of the farmers in the study area were estimated as:

$TE_I = b_0 + b_1Z_1 + b_2Z_2 + \ldots + b_7Z_7 + e$ ………… (2)

where: TE = technical efficiency of the *i-th* farmer; Z_1 =age of farmer (years); Z_2 = sex of farmer (Dummy variable: 1=male; 0 = female); Z_3 = household size; Z_4 = Educational level; Z_5 = Farming experience; Z_6 =Extension contact; b_0= Constant intercept; b_1 - b_1= Coefficient to be estimated

Equations 1 and 2 were jointly estimated using the Cobb Douglas stochastic frontier production model in a single stage maximum likelihood estimation procedure using computer software frontier version 4.1. Constraints to production of trifoliate yam in the study area were identified during the study, and these formed the basis to improve the productivity of the farmers based on recommendation from the findings of the study.

RESULTS AND DISCUSSION

Table 1 shows the maximum likelihood estimates of the Cobb Douglas stochastic frontier production function for trifoliate yam farmers in Ebonyi State, Nigeria. Table 1 indicates that the total variance (sigma square) (0.0263) is statistically significant at 10 percent probability level, and this implies the goodness of fit and the correctness of the specified assumptions of the error terms distribution.

The estimated production factors (Table 1) used by the farmers indicate that the coefficients of farm size (0.0186) and fertilizer input (0.0030) are significantly positively related to trifoliate yam production according to *a priori* expectations, implying that the more the farm size and the quantity of fertilizer used by the farmers, the more the output of trifoliate yam produced in the study area. The coefficient of stakes (-0.3109) is significantly negatively related to trifoliate yam production, implying that as the farm size increases the farmers resort to staking methods that lead to reduction in their cost of production.

The estimated efficiency (socio-economic) factors (Table 1) influencing the technical efficiency of trifoliate yam production indicate that the sex and farming experience are significantly positively related to the technical efficiency of the farmers at 10.0 percent probability level. While more female farmers (Table 1) participate in the production of trifoliate yam in the study area, farmers with more years of farming experience are more likely to be technically efficient in the production of trifoliate yam, in agreement with Onyenweaku and Nwaru (2005).

Table 2 shows the frequency distribution of technical efficiency of trifoliate yam farmers in the study area. The technical efficiency of the farmers ranges from 44.0 to 90.0 percent, with a mean of 57.0 percent. This implies that the most technically efficient farmer will require 10.0 percent cost saving to become the best practice or frontier farmer, while the least technically efficient farmer will require 56.0 percent cost saving to become the best practice or frontier farmer. These figures compare favourably with the technical efficiency of between 31 and 95 percent observed by Onyenweaku and Nwaru (2005) in a study of food production in Imo State, Nigeria, and the technical efficiency of between 21 and 88 percent observed by Dung *et al*. (2010) in a study of Hausa potato production in Kaduna State, Nigeria. The mean technical efficiency of 57.0 percent implies that the output of trifoliate yam in the study area can be increased by about 43.0 percent with the existing level of resources.

Table 3 shows the production constraints of trifoliate yam farmers in Ebonyi State, Nigeria, which include inadequate capital (75%), high cost of seed yam (66.67%), low yield (35%) and poor storage facilities (58.33%).

CONCLUSION

The results of the study show that among the trifoliate yam farmers in the study area, the mean farm size is 0.19ha, and the mean farm output is 2117.17kgha^{-1} annually. Farm size and fertilizer input are significantly positively related to trifoliate yam production, while the use of stakes is significantly negatively related to trifoliate yam production. Sex and farming experience are significantly positively related to the technical efficiency of the farmers. The technical efficiency of the farmers ranges from 44.0 to 90.0 percent, with a mean of 57.0 percent. The mean technical efficiency of 57.0 percent implies that the output of trifoliate yam farmers in the study area can be increased by about 43.0 percent with the existing level of resources. This can be achieved by adequate access to credit for production through farmers' cooperative societies and micro-finance institutions, while information on solutions to low yield and poor storage facilities can be obtained through increased farmers' contact with the extension service.

A REVIEW OF MARKETING STRATEGY CONCEPTS, CLASSIFICATION AND APPLICATION: IMPLICATION FOR AGRICULTURAL TRANSFORMATION

E.N. Ohajimadu

Department of Agribusiness and Management
Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
Email:edithohajimadu@gmail.com

ABSTRACT
The paper attempted to re-examine marketing strategies and their implication for agricultural transformation. It employed descriptive approach in the methodological analysis of the concepts and derived useful implication of the marketing strategies for the agricultural sector. On the basis of the marketing strategies analyzed, the paper recommended concerted focus on the downstream subsector of Nigerian agriculture with the application of the marketing strategies to ensure that what was produced gets to the final consumer. This recommendation is coming on the heels of our current economic state where the country is experiencing recession and in dire need of economic diversification.
Keywords: marketing strategies, agriculture, transformation

INTRODUCTION
Strategy is the first level of planning for an organization, making the big decisions that shape the lower-level detail. It takes account of resources available and makes broad decisions about how these are to be allocated. Medium-term strategy takes account of the longer-term strategic intent of the firm, including its vision, mission and values. Strategic planning is the process of identifying and formalizing strategy, including writing the strategic plan. Strategic planning usually looks at least a year ahead and possibly up to ten years or more. How far you can practically plan for depends on the rate and depth of change. An organization's strategy that combines all of its marketing goals into one comprehensive plan. A good marketing strategy should be drawn from market research and focus on the right product mix in order to achieve the maximum profit potential and sustain the business. The marketing strategy is the foundation of a marketing plan. Marketing strategy both influences and is influenced by overall organizational strategies. It has a primary customer focus in selecting who should be customers and then guiding what and how to sell to them. The marketing strategic plan is best written in parallel with the business strategic plan so each influences the other. Sometimes the reality is that the marketing plan follows the business plan (though this can cause many problems). There are no shortcuts to achieving the ultimate goals of your business through a proper marketing strategy. You should be ready to invest a lot of time, effort, patience, and finances in this goal. When you pay attention to the key elements of a good marketing strategy, it will be easier for you to develop a logical, effective plan that will lead your business to success.

Components of Marketing Strategy
There is hardly a small business owner who is not obsessed with this term: marketing strategy. That's the main aspect that makes the difference between successful entrepreneurs and those that fail. It's strange how everyone cares about discovering the perfect marketing techniques for their business, but we don't bother realizing what *marketing strategy* really means. Let's start from the fundamentals. Marketing strategy is a collection of techniques that enable a particular organization to direct its resources towards the best opportunities in terms of increasing sales and achieving sustainable advantage over the competition. A company's marketing strategy consists of long-term activities that contribute towards developing strong brand awareness. Now that we have a clear definition of the term, it's time to get into the details: when can you be sure that you have a good marketing strategy? Pay attention to the following components, and you'll get there:

Target Audience
Who are you trying to reach through your marketing efforts? Who falls into the category defined as *the perfect customer*? This is the first step in every marketing strategy: identify your target audience. This doesn't mean you'll ignore potential buyers who don't fit into the criteria you set at this stage. Everyone interested in your products and services will still be able to get them, but you should definitely narrow your marketing efforts to the category of people you are most likely to attract. When you identify the interests of your target customer, you'll adjust the overall style of your marketing strategy in a way that suits this category of users. You'll create the perfect TV ads, you'll write blog posts in a language they understand, and you'll easily connect with them via social media.

Awareness
The ultimate goal of any business is to gain more trust with current clients and achieve better brand awareness among the target audience. Some of the classic ways to boost the awareness for your brand include advertising

(TV, newspapers, magazines, and online) and word of mouth. These tactics are not outdated as many contemporary marketers think. You should still consider them as part of your content marketing strategy.
In the current market conditions, the concept of building brand awareness is mostly determined through online marketing techniques. This means that your business needs a website, as well as a blog where you will post high-quality articles related to your niches. Videos, podcasts, info graphics, images, and presentations are also important. Visual and audio content creates lasting impressions.

Unique Advantages

Your brand has to offer a unique advantage if you want your target audience to choose it over competitors' offers. What are the main things that distinguish your product/service from the similar offer on the market? If you cannot identify such advantages, you better think of them as soon as possible. Then, you'll focus your marketing strategy on promoting them.
If for example, you are promoting new photo editing software, you'll face huge competition and you'll have to attract the audience with unique features. The customer wants effectiveness, speed, great choice of filters and editing options, and unique flare that will make the photos different from the mainstream trends. If the description of your offer gets the attention of your target audience, you'll be one step closer to achieving the goals of your marketing campaign.

Communication with Your Clients

It's important to know when and how to communicate with your audience. You cannot simply create social media profiles and use them whenever you have time for them. The connection you develop with your customers is a key aspect for the success of your marketing strategy. Social media is certainly important, but you have to use it strategically. Consider paid advertising on Face book, Twitter, and other platforms. These ads will be featured in front of a huge audience, so you'll easily attract a base of followers with this method.
When you obtain a decent number of followers, you'll need to maintain successful communication with them. Don't make it all about your business. You'll certainly promote your products and services as the best choice on the market, but you should focus your attention on the needs and wants of your followers. Identify the problems they have and show how your business is a proper solution. Monitor the activity of your audience and make sure to publish updates during traffic peak times!

Elements of Marketing Strategy

There are many elements of marketing and, if a marketing-led view of the firm is taken, they touch all aspects of the company. Although these elements are discussed separately below, they are all interlinked and can have bi-directional influence on one another.

Segments

The first big decision is who should be our customers and who should not. In other words, what customer segments will be addressed? This is based first on the overall strategic intent of the firm, for example to be a high-end exclusive and low-volume provider, or to compete in mass markets where price is critical .The decision is also based on research that indicates the profitability of different customers groups and how well the company is able to compete in each segment.

Brand

The brand is the overall intended message of the company, its products and services. It describes what customers and others should think and feel whenever they encounter the company or its products and services. Brand is influenced by and influences the strategic intent of the firm and helps focus all other communications, products and interactions. Brand is fragile in that it is what customers think and feel rather than what the company communicates. This makes shaping decisions about brand critical.

Competition

An important marketing decision is the nature of competition, for example whether to compete on quality, price, service, etc. Decisions here will be affected by brand and will shape further activity such as the approach towards promotion, the use of advertising, the response to competitive action, and so on.

Products

Having understood and selected customers, marketing strategy should have a significant influence on the products created. This not only includes the overall functionality but also the focus on quality, features, price points and so on, in order to produce products that align with the brand and complete effectively in the marketplace.

Price

While the exact price may not decided in strategic planning, the price ranges should be understood particularly in terms of what the target customers are willing and able to pay, and also what price breaks are important to be able to compete in the markets being addressed.

Promotion

Promotional strategy includes decisions about what approaches to promotion will be used, for example TV advertising, direct marketing and so on. Promotion can be extremely expensive, so a key part of the strategic decision here is in the amount of budget that is being allocated.

Communication
Related to brand and promotion, the way that communications with customers and other stakeholders (such as the media) need to be decided should be considered. This includes broadcast information about products, one-to-one and things in between. It also includes how service conversations will be conducted, for example using web interfaces or directs phone conversation.

Outsourcing
A big decision that can be applied within any of the above is the 'make or buy' choice of whether to do things in-house, bring in external experts or pass on the work to third party suppliers. Two key factors in the outsourcing decisions are first the ability of the company to do the work in comparison with suppliers, and secondly the costs of doing this. The impact on brand should be a key consideration also. Many companies who outsource such as service calls have suffered huge brand damage from suppliers who do not deliver brand values.

Types of Marketing Strategies
Marketing is a strategy used by companies to communicate with the consumer and make him knowledgeable about the various features of their products and services. It is an essential part of attracting the target buyers to a particular product, and companies use various innovative or tried-and-tested techniques to stay ahead of their competitors and make their place in the market. Some of the strategies include affinity marketing, alliance marketing, ambush marketing, call to action marketing, close range marketing, cloud marketing, community marketing, content marketing, cross – media marketing, database marketing, digital marketing, guerilla marketing, evangelism marketing, freebie marketing etc.

CONCLUSION
The multiplicity of marketing strategies examined by the study indicates that agricultural transformation in Nigeria can enjoy a boost if the marketers of agricultural produce are acquainted with them. The problem of agriculture in the country has gone beyond production; much focus is now on the downstream subsector which encompasses processing, value addition etc. These developmental efforts are not likely to make serious economic sense if these products do not get to the final consumer. It is therefore important that stakeholders in the agricultural sector should begin to integrate marketing of agricultural produce and byproducts into the development plan of the sector as a means of ensuring that the capacity of the sector to contribute to economy is enhanced. This is an important issue to be considered especially now diversification of the economy is imperative and the need is imminent.

ABSTRACT
There has been much emphasis on the fight against corruption by different administrations in Nigeria. Simultaneously, Transparency International (TI) has continued to rank nations on its corruption index over these years. Between 1996 and 2015, Nigeria's position on this scale has been fluctuating, bringing with it varying implications for the agribusiness sector. Against this backdrop, it has become necessary to empirically ascertain the nation's overall performance in her fight against corruption. Data obtained from Transparency International over the period covering 1996 to 2015, were subjected to descriptive and inferential analysis using trend function. The results showed that Nigeria's corruption index for the period was 19.725(1.34) on a scale of 0-100. At the beginning of the period (1996), Nigeria was ranked the most corrupt country in the world with an index of 6.90. The pre-democracy period (1996-1998) recorded mean index of 14.50(6.62). The three different civilian dispensations of 1999-2007, 2008-2010, and 2011-2015 recorded indices of 16.33(4.12), 25.33(1.53), and 25.60(0.89), indicating improvements in reducing corruption. The trend analysis returned a time coefficient of 0.857 which was significant at 1% alpha level, and an r^2 value of 0.714; these are indications that improvements in corruption reduction in Nigeria were as a result of interplay between varied factors over time. It is recommended that government institutions be strengthened to intensify their efforts at reducing corruption in the nation's public life.
Keywords: Corruption, corruption index, transparency, trend analysis

INTRODUCTION

Nigeria has over time been cruelly identified with the unfortunate characteristic of one of the most corrupt countries in the world. Corruption is a complex social, political and economic phenomenon that is prevalent in all countries in varying degrees. There is no international consensus on the meaning of corruption. In the literature, corruption is commonly defined as the misuse of public power for private benefit (Lambsdorff, 2007). Although this definition has been widely adopted, several critics have observed that such a definition is culturally biased and excessively narrow (UNDP 2008).

The trend of corruption observed over time indicates that Nigeria's fortunes may be dwindling. The international community has finally appreciated and come to terms with the reality of the "cancer of corruption" and its ubiquitous nature; hence, corruption being a persistent feature of human existence worldwide, its solution lies in the collective action of key global institutions with organized international joint efforts against corruption. These efforts have produced a lot of anti-corruption measures including bi-lateral and multilateral agreements, enactment of national anti-corruption laws such as the Nigeria's Economic and Financial Crimes Commission Act, 2004, the designing of international framework and strategies for the prevention of corruption and the making of an all-important United Nations Convention Against Corruption which has now become the reference point for anti-corruption fight all over the world.

The need to study corruption and anti-corruption has continued to generate passionate commentaries and academic interests. While it is obvious that this interest has made the subject matter better understood to an extent, the hundreds of information being incorporated into its study, research data and the diversity of some of the findings have sometimes established some levels of complications too. Apart from the fact that some have attempted to mischaracterize corruption as a tool for development under such labels as "grease the wheels" arguments or the "efficiency grease", the question still persists, for instance, on how corruption should be situated, whether within the context of the "moralists", "developmentalists" or "functionalists" definitions. More directly, should the definition be public-office centered, market-centered or public-interest centered? Whatever opinion that finally prevails, the fact that the country has been submerged in a deep ocean of corruption over time is undisputed. This situation spells doom for the agribusiness sector, which is built on legal frameworks, corporate identities and business drives. To sustain the tempo in resuscitating the agribusiness sector, with the view to create more jobs, and diversify Nigeria's economy away from oil, it has become necessary to empirically ascertain the nation's experience in corruption over certain time periods. Thus, the focus of this is to estimate the trend of corruption in Nigeria, using data obtained from Transparency International between 1996 and 2015.

The definition of corruption becomes more complicated when viewed in terms of such classification as supportive corruption, transactional corruption, extortive corruption, defensive corruption, investive corruption, personal and institutional corruption, traditional and modern corruption, local, national or international corruption, or representational corruption, grand and petty corruption. Or simply put, should corruption be viewed as corruption and nothing more? Many questions continue to arise in our experience and engagement of corruption and corrupt practices.

Corruption has been defined as the dishonest or fraudulent conduct by those in power, typically involving bribery. It is the illegitimate use of power to benefit a private interest (Morris 1991). Corruption is the giving of a bribe to an official so that the truth will not be told. It involves the embezzlement of public fund for personal use and any act which is considered to be criminal act according to the law of a particular society. Andvig *et al.* (2000) identified four main forms of corruption namely bribery, embezzlement, fraud and extortion. While bribery is understood as the payment (in money or kind) that is given or taken in a corrupt relationship. Equivalent terms to bribery include, for example, kickbacks, commercial arrangements or pay-offs. These are all notions of corruption in terms of the money or favours paid to employees in private enterprises, public officials and politicians. They are payments or returns needed or demanded to make things pass more swiftly, smoothly or more favourably through state or government bureaucracies. They identified embezzlement as theft of resources by people who are responsible for administering them, e.g., when disloyal employees steal from their employers. It is not considered corruption from a strictly legal point of view, but is included in a broader definition.

METHODOLOGY

This study focused on the Nigerian experience of corruption over different government administrations in the country. It adopted time series approach using data obtained from the database of Transparency International. Specific data used was the corruption index (CI) computed for most countries of the world. The data covered a period of 20 years, from 1996 to 2015 (Table 1). Data were subjected to trend analysis through OLS procedure. The data were segmented according to different political dispensations in the country, and examined; while a regression model was fitted to examine the trend of corruption in Nigeria for the period under investigation. The model was explicitly specified as follows:

$$CI = a + bt$$

Where,

CI = Corruption index of Nigeria (Proxy for incidence of corruption)

t = Time (in years)

a = Intercept of the function

b = Slope coefficient estimated.

RESULTS AND DISCUSSION

Nigeria's Corruption Profile between 1996 and 2015

The trend analysis conducted indicated that despite all the policies of the different administrations examined in the preceding sections, Nigeria's lot among nations with respect to maintaining a clean image was on the decline, as suggested by the results presented in the preceding sections according to different administrations, spanning the period under study. A general observation of the summary statistics of Nigeria's corruption indices as presented in Table 2 shows rather an unpleasant situation for the country.

As shown in Table 2, Nigeria's corruption profile for the period under investigation was not bright. The corruption index which is measured on a scale of hundred, adjudges the country with the highest score (100) as clean, while the country with the least score (0) is regarded as most corrupt. Nigeria's mean score for the twenty years under review was 19.73; with 6.90 recorded in 1996 as the least, and 27.00 recorded in a number of later years as the highest.

Incidences of Corruption in Nigeria under Different Administrations

Pre-Democracy Nigeria (only for 1996-1998)

Nigeria's military governance experience spanned for 38 years of the nation's sovereignty. Within this period, abundant cases of corruption were experienced and reported by different people in the country. However, data for quantitatively measuring these cases were absent, until 1996 when Transparency International (TI) began computing the now widely-accepted corruption index for countries. Thus, the pre-democracy era which this study captures was only a three-year period of between 1996 and 1999. The pre-democracy era was the darkest of all in Nigeria's corruption history. Mean corruption index in this period was 14.50%, and Nigeria was ranked the second most corrupt country in the world within this period of Gen Sani Abacha's dictatorship. Also, during this period (1996), Nigeria recorded her worst corruption profile with an index of meager 6.9%. Of course, little was done to curb corruption by the government of the day, except to gag perceived and real political and social activists.

Democracy Dispensations

Administration of Olusegun Obasanjo

On assumption of office in 1999, the president made verbal commitment to sanitizing the Nigerian public life. The extent to which he was able to realize this can be measured by the corruption indices recorded for the country under his watch. This regime brought Nigeria up from her previous profile by a 1.83 points on the scale to mean index of 16.33 between 1999 when it came to power to 2007 when it exited. Strong fluctuations can be observed in the data before 2005 when a steady improvement was recorded. However, given the perceived intensity of the fight against corruption within this period, one can safely opine that the achievement was minimal. It can be recalled that it was within this period that the ICPC and EFCC, two institutional bodies that were constitutionally empowered to fight corruption, were created. As such, it would have been expected that greater results be obtained.

Umaru Yar'Adua's Administration

Although short-lived, indices indicate that his administration's fight against corruption probably using the EFCC and ICPC and humane and gentle approach yielded greater results. After one year in office, Yar'Adua lifted Nigeria's index by 5 points on the scale to 27% in 2008 (the highest the country has ever attained till date), and ranked the country 141 in the world, after the 2007, 148 ranking. By 2010 when he died, Yar'Adua had brought Nigeria's ranking to 134. The change in Nigeria's corruption index between the two administrations (Obasanjo and Yar'Adua) was a leap of 9 points of the index (25.33 – 16.33), and a climb of 14 (from 148 in 2007 to 134 in 2010) points in position. This was the best single jump the country ever got.

Goodluck Jonathan's Administration

After taking over power as required, he (Jonathan) continued in the fight against corruption still using ICPC and EFCC. Although he continued the fight he met, Jonathan failed to improve upon the achievements of his predecessor. Although there was only a 1% increase in 2011 from the index of 2010, Jonathan sadly plummeted Nigeria to a position of 143 in 2011, a complete reversal of the 2010 ranking left by Yar'Adua. However, by the end of his administration, the country had moved up to the 136th position with an index of 26%. It can be seen from the data that this administration only maintained the results it inherited on the average, remaining at a mean index of 25.60% (previous administration's index was 25.33%). The standard deviation of 0.89 shows that the indices obtained for the different years under the regime varied little, giving the impression that the fight against corruption within this period lost the tempo it met on ground from its predecessor.

Trend of Corruption in Nigeria

The results of the trend analysis in Table 3 shows a negative intercept of the function to the value of -1698.82, which is an indication that Nigeria's fortune in this regards is still below the acceptable benchmark. The negative intercept is an indication that the country needs a lot of improvement to shift from the region of more corrupt countries to cleaner lots. An r^2 value of 0.714 indicates that over time, Nigeria's corruption index varied by about 71%. The implication is that the variations observed in the corruption indices recorded for the country was greatly influenced by time differences.

The coefficient of time which is 0.857 that is significant at 1% alpha level is an indication that the corruption index was positively influenced by time; increasing by the value of the coefficient on yearly basis. This scenario reflects poor improvement, since between 1996 and 2015 the country could only add 20.10 points (the range) on her index, despite the highly publicized fight against corruption especially by civilian administrations in the country. This is equivalent to 1% increase per year. The time coefficient of 0.857 which was significant at 1% alpha level, and an r^2 value of 0.714; these are indications that improvements in corruption reduction in Nigeria were as a result of interplay between varied factors over time.

CONCLUSION

This study has used available data on countries' corruption profile compiled by an independent body to assess Nigeria's fortunes on international standards over a period of twenty years. The analysis which was streamlined along government dispensations within the period under study, has shown that the country's corruption profile improved over time, with very visible fluctuations within and between different administrations. The result equally suggests that there is a lot of room for improvement on the corruption index. It is glaring that if this trend is not nipped in the bud, the difficulty of Nigerians in feeding themselves will deepen. In fact, the entire agribusiness industry which is primary in the development of the country will worsen. It is the opinion of this study that the institutions vested with powers to curb the rate of corruption in the nation wake up to their constitutional duties, and ensure that when this present administration expires, Nigeria would have jumped astronomically to higher ranks and scores when measured against any anti-corruption scales used by anyone.

Table 1: Nigeria's corruption index from 1996 to 2015

Year	Corruption Index (%)
1996	06.90

COMPARATIVE ANALYSIS OF ECONOMIC AND TECHNICAL EFFICIENCY IN CRAYFISH PRODUCTION IN OIL AND NON-OIL PRODUCING COMMUNITIES OF AKWA IBOM STATE, NIGERIA

E.E. Nyong, O. Ubokundom & F.N. Namso

Dept. of Agricultural Economics and Extension, Akwa Ibom State University , Ikot Akpaden, Mkpat Enin, P.M.B.1167,Uyo,Akwa Ibom State , Nigeria
e-mail:**eenyong16@gmail**

ABSTRACT
The paper examined the comparative economic and technical efficiency of resource utilization in cray fish production in oil and non-oil producing communities of Akwa Ibom, Nigeria, using a production function approach. Data for the study were obtained from a cross section of 40 respondents each from both oil and non-oil producing areas using a multi-stage sampling procedure. Regression results indicated that capital, fixed costs and fuel were not significant (P < 0.05) determinants of output in oil producing communities. The index of resource-use efficiency revealed that respondents from oil producing communities were not only inefficient in the allocation of productive resources, but grossly over-utilized, capital, fuel, labour and fixed costs with an allocative efficiency index of 0.0761, 0.00043, 0.00770, and 0.005324, respectively. However, respondents from non-oil producing communities were inefficient in the allocative of productive resources, and also under-utilized fixed costs, fuel and labour with and allocative efficiency index of 2.3010, 4.562, and 3.315, respectively. Given the over-utilization of fixed costs, labour, and fuel strategies and policies aimed at controlling and monitoring the activities oil companies oil exploration and exploitation in oil producing communities will thus significantly improve efficiency of utilization of resources; but, given the under-utilization of resources in non-oil producing areas, strategies aimed at sensitization of crayfish farmers on efficient utilization of resources become imperative.Generally, access to insurance scheme, effective extension service delivery programme, access to loan at one digit rate will raise output and net returns in crayfish production.

Keywords: Economic and Technical efficiency, crayfish, oil and non – oil.

INTRODUCTION
Fisheries occupy a unique position in the agricultural sector of the Nigerian economy. In terms of Gross Domestic Product (GDP), the fishery sub-sector has recorded the fastest growth rate in agriculture to the GDP. The contribution of the fishery sub-sector to GDP at 2001current factor cost rose from ₦ 76.76 billion to ₦ 162.61 billion in 2005 (CBN Report, 2005). Fish is an important source of protein to large teaming population of Nigeria. Fish provides 40% of the dietary intake of animal protein of the average Nigerian (FDF, 1997).
Crayfish as a common source of animal protein have been very expensive and out of reach of the common man. This is as a result of low production by excessive dredging, oil spills and toxic waste disposal into rivers. However, the use of crayfish is wide and extensive, including ecological sustainability, economic and socio-cultural uses, biotechnological and recreational values. World Bank (1995) observed that Nigeria is confronted with numerous environmental problems estimated to cost $3 billion annually if unchecked. Other problems are desertification and loss of bio-diversity.
The efficiency or inefficiency of utilization of available resources for crayfish farming has remained an unanswered question in the quest for increased crayfish production in Akwa Ibom State in particular, and Nigeria in general. An efficient method of production is that which utilises the least quantity of resources in order to produce a given quantity of output. A production process that uses more physical resources than an alternative method in producing a unit of output is thus said to be technically inefficient. However, since economic efficiency embodies both technical and allocative efficiencies, once the issues of technical inefficiency have been removed the question of choosing between the set of technically efficient alternative methods of production, allocative efficiency, comes to fore .According to Oh and Kim (1980), allocative efficiency is the ratio between total costs of producing a unit of output using actual factor proportions in a technically efficient manner, and total costs of producing a unit of output using optimal factor proportions in a technically efficient manner. However, a farmer using a technically efficient input combination may not be producing optimally depending on the prevailing factor prices .Thus, the allocatively efficient level of production is where the farmer operates at the least-cost combination of inputs. According to Yotopoulos and Lau (1973), a firm is allocatively efficient if it was able to equate the value of marginal product (MVP) of each resource employed to the unit cost of that resource; in other words, if it maximises profit. Therefore allocative efficiency measure, quantifies how near an enterprise is to using the optimal combination of production inputs when the goal is maximum profit (Richetti and Reis, 2003).Although a number of studies have been carried out

on efficiency in livestock and crops production in Nigeria ,most of such studies dwelled on technical efficiency with only a few dealing with the critical issue of allocative efficiency (Okoruwa *et al*., 2001; Agbamu and Fabusoro, 2001; Ajibefun *et al*., 2002; Ojo, 2003;Ogunyinka and Ajibefun, 2004).

METHODOLOGY

Study Area: The study was conducted in the oil block zones and non-oil block zones of some Local Government Areas in Akwa Ibom State. Akwa Ibom State is the nation's third largest petroleum producer (NNPC, 2007). The state has a population of 3.9 million people, as of 2006 with a density of 35 persons per square meter, (NPC, 2006). Akwa Ibom State is situated between latitudes $4^0 32^1$ N and $5^0 3^1$N and longitude $7^0 25^1$ E and $8^0 25^1$ E and situated between Cross River, Rivers and Abia State on the South Eastern Nigeria sandy deltaic coastal plain. It has a total area of 8412km^2, a shoreline of 129km long and encompasses the Qua Iboe River Basin, the eastern part of the lower Cross River Basin and the eastern half of the Imo River estuary (NES, 2000). The Qua Iboe River, Cross River, Imo River and their tributaries control the drainage, and deposition of sands and clays. Qua Iboe River is the major hydrographic feature, which drains a greater part of the state and enters the sea at Ibeno, which is the major operational base of Mobil Producing Unlimited in Akwa Ibom State. Multi – stage sampling technique was used in the selection of 77 respondents drawn from different locations in the study area while structured questionnaire sets were employed in generating information and data from them.

Model Specification and Estimation

The production response function model was implicit according to Oladumi (1998) and Mbanasor and Obioha (2003).

$Y = F (b_{1,} b_2, b_3, b_4, b_5,)$---1

WhereY = value of output in naira; $b_{1,}$ = fixed cost invested (₦); b_2, = value of variable cost (₦); b_3, = labour (man days); b_4, = Fuel (₦); b_5 = fire wood (₦); b_6 = value others outputs; e = error term

Elasticity of Production

The elasticity of production shows the change in output relative to a unit change in input (Mbanasor and Obioha, 2003). The marginal value product (MPP) was used to determine the productivity of the marginal factors cost (MFC), which was used to determine efficiency use. MFC was either the purchased unit price of the input or the opportunity cost. Six percent interest rate was used to obtain the opportunity cost of fixed assets and other production inputs Ie for every one naria spent in fish production (fish hunting) was therefore ₦1.06. Labour and fishing materials were valued at their current market price. However, MPP is taken as the MVP since

$\text{Log } Y = \log b_0 + b_1 \log x_1 + b_2 \log x_2 + b_3 \log x_2 + b_3 \log x_3 + b_4 \log_4 + b_5 \log x_5 + b_6 \log x_6 + ei$----------------2

The objective was realized by calculating and comparing the allocative efficiencies of fish production in oil and non-oil producing communities. However, a rigorous comparison of allocative efficiency of any two groups of farms requires that they are characterized by constant nature of scale and the same configuration of input and output prices (Onyenwaka, 1994). Examining the allocation efficiencies of the two groups of farmers, the following implicit production function was estimated for each group: Four functional forms of the equation, namely, linear, exponential, double-log and semi-log were tried for each data set and the best fit was taken for the lead equation. Allocative efficiency was determined by equality of the Marginal Value Product (MVP) of the ith input to its price or Marginal Factor Cost (MFC); that is,

$MVP_{Xi} = P_{Xi}$ or Py fi = PXi---3

Where: MVPXi = 1, 2, 3…………..e the Marginal Value Product of the ith input, and

fi = dy/dxi = Marginal Physical Product (MPP) of the ith input, and

py = Unit Output Price

For all the resources measured in physical units, the allocative efficiency index, wij, for each farmer type was given as:

$$\frac{MVPXi}{PXi} = \frac{pyfi}{Pxi} = Wij \text{ ------------------------------------ } 4$$

Where i is a particular resources, j is the farmer type and all other variables are as defined.

The equation above is translated to: MVPXi = pyfi = wij for resources measured in monetary terms.

The maximum or absolute allocative efficiency for a particular group of farmers is confirmed with respect to a given resource if Wij = 1. The resources is over-utilized if Wij <1 and under-utilized if Wij >1. The groups of farmers would have equal allocative efficiency if Wij = Wi_2. This explained hypothesis (iii). Furthermore, to ascertain the level of which a particular resource should be increased or decreased from the current level of use in order to achieve maximum allocative efficiency, the following formula was used:

Kij = (1 - Wij)

Where Kij is the percentage by which the level of use of a particular resource should be increased or decreased to achieve the objective of maximum allocative efficiency.

Allocative efficiency estimates

The results of the estimates of allocative efficiency in crayfish production in oil and non-oil producing communities are shown in Table 2 and 3. However, the estimation of resource-use efficiency required the determination of parameters such as marginal physical product (MPP), marginal factor cost (MFC), and marginal value product (MVP). The marginal factor cost of each input was determined as the average farm cost of an input per unit output, according to Chukwuji et al. (2006). Estimates of allocative efficiency of production resources employed crayfish production were 0.00761, 0.0043, 0.00771, – 0.005392, and 0.0003510 respectively for labour, fuel resource, boat, fixed costs and oil. The indices indicate that apart from fire boat that was under-utilized, all other resources were over-utilized implying sub-optimal resource allocation in crayfish production in oil producing communities, while in non-oil producing communities estimation of allocative efficiency were 2.3010, 4.562, 3.315, and 1302 for labour, fuel, fixed costs, and boat, respectively. Problems of oil spillage and gas flaring associated with activities oil exploration exploitation may be responsible for the over-utilization of fixed costs, labour, and fuel in oil producing areas in the production process. The gross inefficiency and over-utilization of labour found in both areas of the study may be attributed to free education, massive migration of people from fishing ports to urban, lack of social amenities. Comparable results of the over-utilisation of labour in small-scale agricultural production and processing in Nigeria, have been reported by Olarinde and Kuponiyi (2004), Akanni and Adeokun (2004), Nyong and Nweze (2012).

CONCLUSION AND COMMENDATIONS

The findings reveal t hat oil exploitation has some negative impact on the socioeconomic status of crayfish farmers' productivity, crayfish farmers' income, resource utilization and allocation. The study shows that continuous pollution of oil communities and impact of better job opportunities have resulted in over-utilization of resources of fish production in oil producing communities. The result of the crayfish farmers in both areas implies that they could increase their productivity by effectively and efficiently utilizing allocative resources. Based on the findings, adequate compensation both in cash in kind should be given to crayfish farmers affected by oil pollution while the government through its agency such as Niger Delta Development Commission (NDDC) should be directed to fund agricultural programmes by giving special grant to crayfish farmers affected by oil spillage.

ABSTRACT
Access to adequate capital for their operations has been identified as one of the factors limiting agricultural cooperatives in achieving their production potentials, as well as developing market opportunities to sustain production. Identifying the factors which played significant roles in capital accumulation by cooperatives posed research challenges. This study which was carried out in Abia State Nigeria, described some of the characteristics of the cooperatives, identified their sources and types of capital, and volume of capital, and determined the factors that influenced this volume of capital. Thirty (30) agricultural cooperatives were randomly selected from three LGAs from the three (3) agricultural zones of the state which were Aba, Umuahia and Ohafia zones. Data were collected with structured questionnaire which was administered to the representatives of the selected cooperatives; and analysed with descriptive and inferential statistics. Four independent variables were fitted to a multiple regression model to determine the effect of these factors on the volume of capital used by the cooperatives. The results showed that membership size, retained income, and access to credit were found to have significant effects on the volume of capital available to the cooperatives, with coefficients of 5077.66($\alpha_{.=0.05}$), 0.288($\alpha_{.=0.1}$), and 54706.23($\alpha_{.=0.01}$), respectively. It was recommended among others, that farmers should be encouraged to form cooperative societies; while the government is enjoined to free up the bottlenecks that hinder credit administration in the country to enable farmers tap into the immense benefits intended to accrue from access to agricultural credit.
Keywords: Cooperatives, capital accumulation, credit access, Nigeria.

INTRODUCTION

The general roles of finance apply to all types of businesses. Like any other, agricultural cooperatives must maintain sufficient level of capital to ensure financial stability for their operations. Once a cooperative is up and running, it is expected that it will be able to accumulate sufficient capital through successive successful business operations to cover continued functioning costs, finance growth, and build up the net-worth of the cooperative (Rathbone, 1995; Von. Pischke, 1995; Harris, 1998; Von. Pischke *et al*, 2004).

Cooperatives offer their members distinct advantages in addressing a variety of production, product marketing and distribution situations and issues. Producers, through cooperative actions have the opportunity to own and control businesses related to their production operations, and are thus allowed to address common problems or develop market opportunities which they could not otherwise achieve alone (Rathbone and Davidson, 1995; Harris, 1998). In Nigeria, the role of cooperative societies in enhancing the living standards of the rural farmers (and the entire populace) cannot be over-emphasized. Farmers form cooperative societies with the cardinal aim of improving their productivity through collective supply of materials and inputs, consolidating product prices through harmonized bargaining opportunities and consistent stabilized marketing outlets. Furthermore, members of cooperative have the highly important advantage of owning and controlling their business through democratic processes and procedures. All these benefits raised above notwithstanding, the impacts of cooperatives in the country are not perceived, as it ought to be due to many problems which face them.

With the above benefits of cooperatives in mind, the Department of Cooperatives of the Abia State Ministry of Agriculture and Rural Development has continued to register, under relevant acts, hundreds of cooperative societies whose businesses are diversified, with the aim of boosting development especially in the rural sector, by empowering rural farmers for improved productivity (MARD, 2004). In most rural areas, cooperatives only enjoy nominal existence, or often lack the democratic identity where they are even minimally functional. In the list of issues that bedevil the optimal performance of cooperatives boldly stands out the stringency of capital, which has left very few options but to trail below the threshold of adequate productivity and self-reliance.

It is therefore the objectives of this study to establish the characteristics of cooperatives in the study area; determine their sources of capital; determine the amount of capital available per production cycle; and determine the factors that affect their capitalization level.

Theoretical Framework

Literature has established that co-operatives rely heavily on their members for accumulation of capital. This reliance implies that membership characteristics such as size, the individual decisions of the memberships and aggressiveness towards realizing members objectives or desire, will greatly affect their capital base. Notwithstanding other determining factors (which also affect capitalization of any other form of business), cooperation group solidarity feature will influence decision to be made by the cooperatives. This position is informed by the cooperative principals of democratic governance and equal complete participation of all members. These principals dispose the cooperative to diverse opinions coming from the members whose rights it is to air their opinions.

The coalition theoretical structure (Staatz, 1983) was developed to examine the hypothesis that the capital base of cooperatives is profoundly influenced by its structural characteristics, cooperative governance (Williamson, 1996), and other external factors such as government policies. The theory of the cooperative firm suggests the presence of transaction costs within the traditional structure (Vitaliano, 1983; Staatz, 1987). These transaction costs are generated by a set of vaguely defined property rights constraints originating from the structure of traditional cooperatives and leading to conflicts over residual claim and decision control. These property rights constraints include free-rider, horizons portfolio, control and influence costs problems; all of which do not provide members within the traditional cooperative structure with the incentives to make optimal investment decisions (Cook, 1995; Cook and Iliopoulos, 2001).

According to the coalition theory, the cooperative consists of many groups with different objectives. Each attempts to maximize their own individual utility, often at the expense of other groups. This situation is particularly relevant to agricultural cooperatives, as in Nigeria as elsewhere in the world, because costs and benefits can be allocated among groups according to a variety of rules (Zusman, 1982). The coalition decides which group will benefit and which will bear the cost of operations by setting prices for member products, offering specific services, and choosing capitalization strategies. In this context, sufficiently high transaction costs within the groups may promote *pareto* inefficient strategies. If transaction costs are higher than the increase in value resulting from the inefficient strategy, groups have no incentive to negotiate an efficient solution based on the compensation principle. Consequently, cooperative strategies will not be determined solely by the efficiency principle, but also by the initial distribution of resource and power among members (the coalition groups).

Directly linked to this is the ability to repay loans. Onyenaucheya and Ukoha (2007) found that farmers' ability to repay loans is determined by a number of factors which include the amount of loan borrowed, income, and distance between home and loan source of a farmer borrower.

METHODOLOGY

This study was carried out in Abia State Nigeria. The term Abia is coined from the four geopolitical compartments namely Aba, Bende, Isukwuato and Afikpo that make up the state at its creation in 1991. It covers a land area of 5,834 square kilometres; and lies between latitudes 07^0 00' and $08^0$10' East of the Greenwich Meridian and Longitudes 04^0 45' and 06^0 17' North of the Equator. The state is located within the tropical rain forest with luxuriant vegetation and temperature ranges of 20^0C to 36^0C which supports agricultural production. Abia State shares common boundaries with Imo State on the East, Enugu on the North, and Rivers State on the South. The State experiences two major seasons in the year: The dry season which lasts between October and March, and rainy season which stretches from April to early October. According to the 2006 population census estimates (NPC, 2007), the State has a population of 1,913, 917 decomposed into 48.78 percent males and 51.25 percent females spread into 17 local government areas. Abia State is delineated into three agricultural zones namely: Aba, Ohafia and Umuahia. Agriculture is the major occupation of the people which employs about 70 percent of the population, especially in the rural areas.

A multistage sampling technique was adopted in the selection of sample for this study. The first stage involved a random selection are agriculture from the three agricultural zones in Abia State. Three Local Government areas were randomly selected from the agricultural zone. Ten agricultural producing cooperatives were selected from each Local Government Area to give a total of 30 cooperatives.

Data were collected on the variables specified in the model through the use of structured questionnaire administered to the representatives of the cooperatives. Especially with respect to operational facilities and examination of business records shall be a source of information for the study. Data were analyzed with descriptive statistics and multiple regression analysis. A model constituting six variables was specified. The implicit form of the model is as follows:

$$CAP = f(Z_1, Z_2, Z_3, Z_4)$$

Explicitly,

$$CAP = b_0 + b_1Z_1 + b_2Z_2 + b_3Z_3 + b_4Z_4 + \varepsilon$$

where,

CAP = The amount of capital employed in production in the previous production year (Naira).

b_0 = The intercept of the function

$b_1,\ldots,b_5$ = Regression coefficients
Z_1 = Membership size (number of persons in each cooperative society)
Z_2 = Retained income (Naira) (Lagged 1 year)
Z_3 = Business expansion (years of operation of the cooperative society)
Z_4 = Access to credit (Access to credit = 1, non-access = 0)
ε = Error variable.

Four functional forms of the model were evaluated from which the lead equation was chosen on the basics of conventional principles such as explanatory power of the model (i.e. r^2 value) and the behavioural consistency of the variables with *a priori* expectations. The functional forms include linear, exponential, semi log and double log.

RESULTS

Determinants of Cooperative Financing

(a) Membership size (Z_1)

The number of cooperators a cooperative has had a regression coefficient of 5077.66 which is significant at 1% level. This implies that as the membership strength of a cooperative society increases, its capital base increases by ₦5077.66. It was shown that a greater proportion of cooperative capital was generated through membership contributions. Thus, it is also expected that a positive trend would exist between the amount contributed and the number of contributing units. In Abia State, as in other parts of Sub-Saharan Africa, income level is very low in the rural areas. Cooperative societies are groups of mainly peasant farmers whose production potentials and investment propensity are below even threshold. Thus, if the cooperatives capital base is to be strengthened, two factors emanating from the influence of this variable should be considered. The number of the contributing units, i.e. the cooperators, has to be increased. The effect will be that, through joint efforts, which the coalition theory propounds, gross benefits and risks will be shared. Under the assumption that the effects of risks are reduced when shared among a large number of people, the resulting benefit, which in this case is strong production capital, will smoothen off on the long run. Another point, which may be of very positive imperative for accumulation of large capital, is improving the income level of the cooperators. This way, the per unit contribution will be high, thus leading to increased capital.

(b) Retained income (Z_2)

The income realized by the cooperatives in the previous production year had a positive significant coefficient of 0.258. The implication is that unit increase in retained income resulted in an increase of 25.8% in production capital. This result is consistent with *a priori* expectations, since a proportion of income is ploughed back into production in the preceding year. One of the cardinal objectives of the cooperative initiative is the mutual welfare of its members. Collective profits are shared in accordance with the principles of cooperation. A proportion of such annual profits is set aside for continuity following proportions that are previously agreed upon by the members. As the proportion of retained profits increases, probably as a result of increased income from previous production or by outright agreement by the members to increase it, the capital that will be available for the next production equally increases. Thus, the emphasis here should be on whether there is an arbitrary agreement to raise the proportion of income to be ploughed back. But if this is done, dividends which the cooperators would receive would be reduced. It then follows that the members would be sacrificing present profits for future capital needs.

These issues would demand the need for external credits. In order to break the cycle of low income, poor retained profits, poor investment potentials and low capital volume, there is the need to attract external intervention in the form of credits. It was established in the earlier sections of this report that members contributed production inputs such as cassava stem, seeds, fertilizer and labour. Improved varieties of such inputs can be sourced from research institutes if the means is available, and the result would be enhanced output and higher income.

(c) Access to Credit (Z_4)

The amount of credit that the cooperatives had access to had a positive coefficient of 54706.23 that is significant at 1% level, indicating that access to credit by the cooperatives would increase their capital by per member by ₦54,706.23.

CONCLUSION

The results obtained in this study have shown that cooperatives in Abia State have similar socioeconomic characteristics. The results also showed that a greater proportion of capital is generated through membership contributions, retained income and credit. Furthermore, mean capital employed in a production cycle is very low for most of the societies. However, it was revealed that size of membership, income from the previous year, as well as access to credit were factors that determined the amount of capital cooperative could accumulate.

Since retained income was a significant determinant of capital volume, efforts at increasing income of cooperatives would be a probable option. This increase in income, accruing from sales of products, and provision of services, can only be achieved if the production of the products, which the cooperatives have comparative advantage in, is optimized. The emphasis should re-direct towards production efficiency in order to maximize use of resources. Thus, in the midst of inadequate production resources, and poor technology, cooperatives can increase their output and manage more effectively their resources by focusing their production thrust on the products that yield them greater output.

Government on their own part can enhance credit administration to agricultural cooperatives. The data generated in the study revealed that credit is the most contributing variable to the capital volume of the cooperatives; and indication that if credit is adequately available to the cooperatives, their production would be enhanced. To improve access to credit, existing credit guarantee schemes can be made more functional. Such schemes can be made farmer-friendly such that they will have minimum pre-requisites. As a group which unit components are under the pressure of low incomes and poor investment potentials, cooperatives are not able to meet with the heavy collateral requirements required to compete with the conventional credit arrangements provided by the financial and other lending institutions.

ECONOMICS OF YAM MARKETING IN AKAEZE IN IVO L G A OF EBONYI STATE, NIGERIA

C. Kadurumba

National Root Crops Research Institute Umudike
Kaduphil@gmail.com

ABSTRACT
This study presents the Economics Of Yam Marketing In Akaeze In Ivo L G A Of Ebonyi State. The objectives of the study are to determine the socio-economic characteristics of yam marketers in the study area, to determine the marketing channels of yam marketing in the study area. Primary data were used in the survey. The primary data were collected from a random sample of 80 yam marketers in Ebonyi State. The respondents were drawn from rural and urban markets in the agricultural zones of the state. The data analyzed using descriptive statistics such as frequency, percentage and Chart .The result shows that more males (58.75%) participated in yam marketing than females (41.25%) in the study area. Also, the result shows that majority of yam marketers are matured individuals (56.25%) who are in their youthful age (41-60 years). Yam marketing in the study area goes through a network of intermediaries before it reaches the final consumers. Those intermediaries are the producer, wholesalers and the retailers. The marketing of yam in the study area could be improved by reliable information on the area and provision of basic infrastructures as this will facilitate faster delivery of yam and ensure marketing efficiency in the study area.
Keywords: Economics, yam marketing, Nigeria

INTRODUCTION
Yam *(Dioscorea* spp.) is an annual tuber and monocotyledonous crop. The plant Genus comprises of over 600 species with only 10 species producing edible tuber. Six of these edible species are cultivated in Africa and only 3 of them are available in Nigeria. In Nigeria, the primary species cultivated are the white yam *(Dioscorea rotundata*), yellow yam *(Dioscorea cayensis*) and water yam (*Dioscorea alata*), (Amusa, 2000).
Yam is a popular starchy food. Nigeria is the world's largest producer of edible yams, with *Disoceara.* ro*tundata* and *Disoceara. alata* as the two most cultivated yam species in the country, Yam tubers are processed into various food forms which include pounded yam, boiled yam , roasted yam or grilled yam, etc. Yam is an extremely vital crop, not only to the domestic market but also to the export market. Domestically, it is not only a main source of income but it is a stable crop vital to food security. (Bolarinwa and. Oladeji, 2009)
Market exits when ever buyers and sellers can be in touch with one another. In modern times, buyers and seller many not necessarily meet face to face before a market exit, but a trader in one state can negotiate with another trader in another state, either by telephone , about his willingness to buy then market has been established .(okorie C. 2006). Markets are places where people buy and sell commodities (Njoku 2000). The market can be in rural or urban areas. The objectives of the study are to determine the socio-economic characteristics of yam marketers in the study area, to determine the marketing channels and Identify marketing problems of yam marketing in the study area.

METHODOLOGY
The study was carried out in Ebonyi State. The study covered one out of the agricultural zones in Ebonyi state. Multistage random sampling technique was used in selection of agric zone and respondents. One local government area was randomly selected from the three agricultural zones. Two markets were randomly selected from the L G A. The markets chosen were: Nkwogbo in Umuogbo, Orie Akaeze Ukwu. Forty yam marketers were selected randomly from each chosen market. This gave a total number of 80 Yam marketers. The primary data were collected with structured questionnaires. The data collected were analyzed using descriptive statistics such as frequency, percentage and Chart

RESULTS AND DISCUSSION
Table.1 shows that more males (58.75%) participated in yam marketing than females (41.25%) in the study area. Also, the result shows that majority of yam marketers are matured individuals (56.25%) who are in their youthful age (41-60 years). The result shows that trade of yam marketing was dominated by married people (62.5%). This implies that the trade is a source of income to many families from which they meet their basic needs. The result reveals that majority of the respondents (62.05%) had household sizes of 6-10 persons and 74 .00% of the yam marketers had one form of education or another while 26.00% had no formal education. This shows that literacy level was high amongst them and could enhance marketing technology. The level of education was identified to enhance the marketing efficiency and the marketing techniques and this was in line the findings of Obasi, (1991).

The classification of trade in the study area shows (43.75%) of the respondents were wholesalers and (37.05%) were producers while (18 .75%). This implies that the study area is a place traders can get yam in larger quantity

Marketing Channels For Yam Sold In Akaeze In Ivo LGA:

The result of the marketing channels network of the interrelationship that exited in the movement of yam in the study area from the producer to the consumer, Yam marketing in the study area goes through a network of intermediaries before it reaches the final consumers. Those intermediaries are the producer, wholesalers and the retailers. The producers are farmers in the study area who produces yam and sale in large quantities to the wholesalers from other states and wholesalers within the village, producers who sale to retailers in the village and wholesalers who sales to other major dealer from other places and wholesaler to retailer to the final consumers in the study area. A significant proportion of yam sold in the study area study area is from the farmers.

Marketing Channels of yam distributed in Akaeze in Ivo L G A

- Producers→ Wholesalers → Retailers → Consumers
- Producers → Retailers → Consumers
- Producers → Consumers
- Wholesalers → Retailers → Consumers
- Wholesalers → Consumers

Fig 1 shows the marketing channel for in the study area. This channel shows five marketing channels through which yam can be distributed to the study area from the producers to the consumers. The marketing channel involved in yam marketing in the study area shows that yam moves from the producers to the consumers, producers to the Wholesalers and from Wholesalers to the consumers. Furthermore it may likely move from producer to wholesalers who in turn sale to the Retailers, where it finds its way to the Consumers.

CONCLUSION

The study had shown the economics of yam marketing in Akaeze in Ivo L G A of Ebonyi state. The result of the survey of the socio economic characteristic of respondents showed that 58.75% were males and 43.75% were females the trade is gender sensitive and needs serious strength and 56.25% of the respondents were between the age of 41-60 years old, showing that the trade required people that can withstand the physical stress of the trade.
The marketing of yam in the study area could be improved by reliable information on the area and provision of basic infrastructures as this will facilitate faster delivery of yam and ensure marketing efficiency in the study area.

National Root Crops Research Institute (NRCRI) Umudike, PMB 7006 Umuahia, Abia State
adankejesus@gmail.com

ABSTRACT
A gross margin analysis of cocoyam production at National Root Crops Research Institute Umudike was done in 2015 planting season was carried. The experimental study showed that the enterprise is profitable. Labour constituted about 42.90% of total variable cost of production, which is the most important resource in cocoyam enterprise. One hectare cost of cocoyam production was N573,480 while total revenue was N936,400 and gross margin was N362,920. The study showed that the result of profitability analysis of cocoyam production is profitable by returning N1.63 to every N1.00 spent. There is need therefore to encourage farmers to go into rapid production of cocoyam to enhance their revenue, food security and livelihoods.

INTRODUCTION
Cocoyams (Colocasia esculenta and Xanthosoma mafia) are important carbohydrate staple food particularly in the southern and middle belt areas of the Nigeria (Asumugha and Mbanaso, 2002). Cocoyam is a stem tuber that is widely cultivated in the tropical regions of the world and is a well – known food plant which has a long history of cultivation with Nigeria being the largest producer of cocoyam (3.45mt) in the world (9.97mt) and accounting for about 34.57% of the total output (FAOSTAT, 2013). In the last decade, attention has been focused on means of eliminating food insecurity and hunger worldwide. The targets of the first Millennium Development Goal (MDG) between 1990 and 2015 are to halve, the proportion of people who suffer from extreme hunger and people, whose income is less than $1 a day (FAO, 2005).

Expansion in cocoyam production has therefore the potential of bridging the wide demand and supply gap, and enhancing the income (thereby reducing poverty) of the rural farmers, particularly the vulnerable group. Opata and Nwaeze (2009) reported that many rural people, particularly women have gained interest in the production, processing and marketing of cocoyam, essentially because of the rapid increase in its share of the urban market in Nigeria.

Resource allocation to cocoyam is significantly low when compared to crops such as yam and cassava (Okorji and Obiechina,1995; Okoye,2006). Production has not been given priority attention probably because of cocoyam's inability to earn foreign exchange and its unacceptability to the high income groups for both consumption and other purposes (Nweke, 1987; Onyenweaku and Eze,1987). The need for increased food production to meet the demand of ever-increasing population in Africa, where population growth rate is higher than the rate of increase in agriculture production had been long emphasized (World Bank, 1992).

The production is labor intensive with most operations carried out manually at the traditional level (Okoye, 2006). Zuhair and Hunter, (2000) reported that the cultivation of cocoyam is declining. To meet the demand for cocoyam, there is need to increase its production (Eze and Okorji, 2003).The study will therefore serve as a basis for information to the farmers on cocoyam profitability which is expected to drive increased cultivation of the crop.

MATERIALS AND METHODS
Six cocoyam cultivars NCe 001, NCe 002, NCe 003, NCe 004, NCe 011, NCe 012 of the *Colocasia* spp were used for the study which was carried out at NRCRI, Umudike in 2015 planting season. Data, such as resource allocation which includes; labour in mandays, inputs, cost items as well as output (yield) and value of produce were taken. Data was analyzed using the Cost and Returns analysis procedure on per hectare basis.

RESULTS AND DISCUSSION
Table 1 show that output per hectare was 4,682kg. The total value of production was N936, 400 at the cost of N200/kg for cormels and corms respectively. Total variable cost of production was N573,480. Labour constituted about 42.90% of total variable cost of production. This implies that production is labour intensive because most operations were carried out manually. This followed the findings of Okoye, (2006) and Okoye *et al*., (2004). The results show a gross margin of N362,920, indicating that cocoyam is profitable by returning N1.63 for every N1.00 spent. This excludes the fixed costs which most times are minimal and not significant due to depreciation.

Table 1: Gross Margin Analyses for Cocoyam Production at NRCRI Umudike

	Output	Unit Quantity (kg)	Price	Total
A	**Revenue**	4682	200	936,400
B	Variable Cost			
	Cocoyam setts (corns and cornel)	902	200	180,400
	Fertilizer	400	120	48,000
	Bags	20	100	2,000
	Baskets	10	150	1,500
	Total			**231,900**
C	Labour input (mandays)			
	Land preparation (Tractorization)			15,000
	Setts preparation	17	1000	17,000
	Planting	15	1000	15,000
	Weeding	$61^{\times 2}$	1000	122,000
	Fertilizer Application	13	1000	13,000
	Spraying	9	1000	9000
	Roughing	5	1000	5000
	Slashing	18	1000	18,000
	Earthening up	15	1000	15,000
	Harvesting	47	1000	47,000
	Carriage/Expenses			3,000
	Total			**246,,000**
D	Opportunity cost of variable cost at 20%			95,580.00
E	Total variable cost (B+C+D)			573,480.00
	Gross Margin (A-E)			362,920.00
	BCR=A/E			N1.63:1.00

CONCLUSION

The study estimated the gross margin for cocoyam production per ha in NRCRI Umudike. The results of the gross margin analysis showed that cocoyam production is profitable by returning N1.63 to every N1.00 spent. Farmers should be encouraged to go into cocoyam production since it is a highly profitable venture. Given that cocoyam is an important staple food in Nigeria, any attempt to increase its productivity would be a right step towards the resolution of the food crisis especially in Nigeria. Farmers are therefore encouraged to go into rapid production of cocoyam since it is highly profitable. This will enhance their revenue, improve food security and livelihoods among cocoyam farmers.

ABSTRACT
The study investigated the levels of involvement of cocoyam farmers in various cocoyam production and post harvest practices like processing, storage and marketing among farmers in Ohafia zone of Abia State. The data for the study were collected from 68 cocoyam farmers randomly selected from four communities in Ohafia zone. The data collected were analyzed by means of descriptive statistics such as frequency tables, percentages and mean-scores. The result showed that majority of the farmers were highly involved in most of the cocoyam agronomic and post harvest practices as shown by the mean scores. Land clearing ($\bar{x}$= 3.88) and planting ($\bar{x}$=3.88) had the highest involvement by farmers followed by marketing ($\bar{x}$=3.68), weeding ($\bar{x}$= 3.64), processing and harvesting activities. It was recommended that farmers should be encouraged to participate in pest and disease control activities and other areas where they showed low level of involvement in cocoyam production for increased production of cocoyam in Abia state.
Keywords: cocoyam production, post harvest, Ohafia

INTRODUCTION

Cocoyam is one of the major tuber crops in Nigeria after yam. Two major species of cocoyam cultivated in Nigeria are *Xanthosoma maffafa and Colocasia esculanta. Even though in Ghana and other countries cocoyam represents only xanthosoma maffafa while colocasia is known as taro.* The cultivation of cocoyam in most African countries including Nigeria is essentially in the hands of resource poor farmers with minimum inputs (NRCRI, 2011). The bulk of the production of cocoyam is in the south east Nigeria, as a major food crop in Nigeria especially in female headed households (Enyinnia, 2001; FAO, 2008). In some South east Nigeria, cocoyam cultivation and marketing is still neglected despite the wide adaptability, nutritional value and economic value of the crops . In Aninri Local Government Area of Enugu State where cocoyam is greatly produced in large Quantity, cocoyam is perceived as woman crop. A woman who does not have a cocoyam farm can as well be qualified as a non-farmer. Good agronomic practices should be observed throughout the period of cultivation of cocoyam for an increased crop yield, Such practices are recommended spacing (50 cm – 100 cm), used of improved varieties, weed control, use of fertilizer or organic manure, control of pest and diseases etc (NRCRI, 2008), Harvesting should be done when the crop is fully matured between 7-8 months with the following symptoms of maturity such as the yellowing of the leave, the drying of the leave, the suiting up of the corms on the ground. Delayed harvesting might cause damage of the corms. Nigeria production output of 5,143kg per hectare is low compared with 13,493kg per hectare in Japan and 13,333 kilogram per hectare in China (Ogbonna *and Nweze*, 2012). The annual output of 180 tonnes in Nigeria is as a result of poor practices and poor participation of farmers in cocoyam production practices. Investigating into the various practices and the level of farmers involvement in the activities will aid in the management of labour and other resources in production.

Objectives of the Study

The general objective of this study was to investigate farmers involvement in cocoyam production and postharvest practices in Ohafia agricultural zone of Abia state, Nigeria.
Specific objectives
1 Describe the socio economic characteristics of farmers in the study area.
2. Ascertain farmers involvement in the cocoyam production and postharvest activities
3. Identify the challenges to cocoyam production among respondents.

METHODOLOGY

The study was conducted in Ohafia agricultural zone of Abia state, Nigeria. Out of the three agricultural zones of the state Ohafia was purposively selected because the people cultivate cocoyam. Two extension blocks Umunneochi and Isuikwuato were randomly selected from the zone., followed by random selection of two circles in each of the blocks. In each of these circles, twelve cocoyam farmers were randomly selected from the list of cocoyam farmers in the area, making it a total number of 68 farmers for the study. Data collected were analyzed by means of descriptive statistics such as frequency tables, percentages and mean. A 5 point Likert scale was used to achieve the involvement value and was calculated thus 5+4+ 3 +2+1 = 15/5 = 3.0 . 3.0 means acceptance while <3.0 means rejection

RESULTS AND DISCUSSION

Table 1 shows the socioeconomic characteristics of respondents and the result showed that majority (41.17%) of respondents were between 51-60 years showing that more elders were into cocoyam production. Only 26.46% were youths between 20-40 years. The table also showed that 73.52% of respondents were married majority (81.17%) of respondents had formal education only 8.83% were illiterate, larger proportion (55.88%) were female. Majority (50.0%) of the farmers had 11-20 years experience in cocoyam farming while (32.35%) had above 20 years farming experience. Majority of the cocoyam farmers had large house hold size (61.76%) and farm size (55.88%) of 1-2 hectares per farm family. Most of the cocoyam farmers practiced both subsistence and commercial farming whereas majority (35.29) of the farmers had annual income of less that ₦100.00 per annum while many (26.47%) earned ₦500.000 thousand from farming annually. The result also revealed that 97.05% of the farmers had access to labour, 85.29% had access to land and 92.64% had access to agricultural information Table 2 revealed that majority of cocoyam farmers in Abia State were highly involved in most of the cocoyam production and post harvest activities. Land clearing and planting had the highest level of involvement with the Mean(X) of (3.88 and 3.88) followed by marketing (3.68) weeding (3.64) processing (3.62) and harvesting (3.41) activities. Farmers were also highly involved in tillage (3.32) and storage (3.35) activities. The result also showed low involvement of farmers in earthling up (2.35) erosion control (1.35) pest and disease control (2.41) and fertilizer application (2.79) as shown by the mean scores. The major constraints militating against cocoyam production among farmers were fund, poor yield high incidence of disease, unavailability of disease control chemicals as shown in Table 3

CONCLUSION AND RECOMMENDATION

The study investigated the socio economic characteristics of cocoyam farmers in Ohafia zone of Abia state, level of farmers involvement on cocoyam production/post harvest activities and the constraints to cocoyam production among farmers in the study area. The study revealed that most of the respondents were married elderly and educated farmers with over ten years farming experience. The level of farmers involvement in cocoyam production and post harvest practices was encouraging and it showed that they farmers were really into cocoyam farming. The areas where farmers showed low involvement on cocoyam production were earthening, fertilizer application and disease control. The major constraints to the farmers were fund poor yield and problem of diseases. Farmers should be encouraged to carry out all the recommended practices for increased production of cocoyam and Agricultural research should focus on the development of high yielding and disease resistant cocoyam cultivars for food security.

ABSTRACT
The study examined limitations and processing technologies of sweetpotato production by farmers in Anambra State, Nigeria. Multistage sampling techniques were used for the study. Four local governments out of the 21 local governments in the State were purposely selected due to their popularity in sweetpotato production. Two communities were selected from each local government to give a total of 8 communities that were used for the study .15 sweetpotato farmers were selected from each community using simple random sampling technique and this gave a total sample size of 120 farmers. Data were generated through a structured interview schedule. Out of 120 questionnaires distributed, only 100 were retrieved and used for analysis. Percentage, frequency, mean score and standard deviation were used for data analysis. Results show that 79% of the farmers were female and their mean age was 38yrs. Majority (58%) of the farmers were not aware of the technologies introduced to them while, some farmers were aware of the innovation. None of the farmers adopted the technologies. Too much attention on other crops with a weighted mean score 2.74, high perishability of sweet potato with a weighted mean score 2.63, inadequate finance with a weighted mean score 2.60, pest/disease infestation (2.48), high cost of sweet potato processing equipment (2.48) farmers' low knowledge on sweet potato value Chain (2.45), in adequate extension services with a weighted mean score 2.42 were identified by the farmers as the major constraints to sweet potato production technologies in the study area.
Keywords: limitations, processing and production.

INTRODUCTION
Nigeria is one of the largest producers of sweet potato (ipoema batata) in sub-sabaran African with annual production estimated at 3.46 million tons per year (Omoare, Fakoya, Fapojuwo and Oyediran, 2014). According to Okorie and Onyeneke (2012), sweet potato is an important food security crop and a short-term crop that can be consumed by boiling and mashing or frying. It could be mono-cropped or intercropping or intercropping in complex cropping systems with some staple crops like yam, and maize. A brief analysis of potato production in various countries of Africa reveals that Egypt is Africa's number one potato producer, followed by malawi while Nigeria is known to be the fourth biggest producer of potato in Africa (Ugonna, Jolaoso and Onwualu, 2013). However despite the global attention given to sweet potato with regard to food security Nigeria is still recorded number one of the world's lowest average potato yield/hectare with a value of 3.1. Potato consumption is also very low with a value of 3.2 kg per capita per year. In Nigeria, more than 85% of the potato production is done by farmers who maintain small farms and carry out their operations manually with traditional farm tools such as hoes and cutlass (Okonkwo, Amadi and Nwosu (2009). Despite the important of the sweetpotato in Nigeria as a country the crop has received so much little attention in some States due to a paucity of information on the factors limiting sweet potato production. In the light of the above, this study therefore, designs to investigate the limitations and processing technologies of sweet potato production in Anambra State, Nigeria. Specific objectives of the study were to ascertain the processing techniques being adopted by the farmers in the study area and to identify the challenges to sweet potato production in Anambra State.

MATERIALS AND METHOD
The study area for this research is Anambra State. The State is located in the South east of Nigeria. It is bounded by Delta State to the West, Imo State to the South, Enugu State to the east and Kogi State to the North. It has estimated population of 4,77,828 million people (NPC, 2006) which stretches over about 60kilometers between surrounding community. The target population for this study was all the sweetpotato farmers in the state. Multistage sampling techniques were used for this study. Four local governments out of 21 local governments in Anambra State were selected due to their popularity in sweetpotato production. Ayamelum local government, Anambra East local government, Anambra West Local Government and Awka North local government were selected.

In the second stage, two communities each from a local government were selected. Here Omor and Umumbo in Ayamelum Local Government, Nando and Igbariam in Anambra East,Nzam and Igbede in Anambra West,Achala and Uzum in Awka North local government were selected. This gave total of eight (8) communities. Third stage, 15 farmers were selected from each community using simple random techniques and this gave a total sample size of 120 farmers. Out of 120 questionnaires distributed, only 100 were retrieved and used for analysis.

Measurement of variables

To ascertain the processing techniques being adopted by farmers, six steps adoption model were used. (Madukwe, 1995, and Udemezue, 2014). The farmers were asked to show their adoption stage for the different processing technologies of sweet potato production. Total adoption score for each farmer was calculated by summing the adoption score for the variously technologies.

These were the response categories and corresponding weighted values: Not aware 0; Aware 1; Interest 2; Evaluation 3; Trial 4; Adoption 5

The challenges to sweet potato production in the study area were achieved using three point likert-type scales. The farmers were asked to indicate their levels of the challenges to sweet potato production. Their response categories were very serious =3, serious =2, not serious =1. These values were added to obtain a value of 6 which were later divided by 3 to get a mean score of 2.0. Variables with mean score less than 2 were seen as not serous while variables with mean score equal to or above 2 were seen as very serious challenges to sweet potato production in the state.

RESULTS AND DISCUSSION

Distribution of farmers According to Socioeconomic characteristics

Table1 shows that 79% the farmers were female while 21% of the farmers were male. This implies that women dominated sweet potato production activities in the study area. This result is in line with Olagunju *et al* (2013) who saw women as the dominance of sweet potato production in Ogun State, Nigeria. Majorities (53 %) of respondent were married while 10% of the respondents were single and this could be the reasons women and children were available as family labour. The average mean age was 38yrs. The indication is that the farmers were predominantly in their active age and this could also enhance their potential for investment, acceptance, adoption and application of both exotic and indigenous technologies for increased productivity. The average mean household size of the respondent was 5. The implication of this is that the farmers enjoyed a relatively large family size which is a source of labour in the farm production. About 66% of the respondents were full time farmers that combined sweet potato production with other farming crops. However, majority (49%) of the respondents acquire land by rent while about 68% of the respondent cultivated 0.1-0.499 hectare of land. The average farm size cultivated for sweet potato production was 0.23ha. This shows that sweet potato farmers in the study area were still under small scale farming. This result is in consonance with spore (2013) which observed that sweet potato is grown mainly by women on small plots of land. About 63% of the respondents used family labour while 68% of the respondent sourced agro-input from their fellow farmers.

Distribution of the farmers based on their level of adoption of sweet potatoes processing techniques

Figures in table 2 show the levels of adoption of processing techniques used by the sweet potato farmers in the study area. According to NRCRI, sweet potato could be processed into the followings; Processing of sweet potato into fermented fufu four, Processing of sweet potato into unfermented flour for use in confectioneries, Processing of sweet potato into starch and Processing of toasted sweet potato.

The findings revealed that majority (58%) of the farmers were not aware of processing sweet potato into fufu flour, 14% of the farmers were aware while 19% and 9% of the farmers were in interest and evaluation stage of the adoption process. About 45% of the respondents were not aware of processing sweet potato into flour for confessionary, 14% of the farmers were aware, 10% and 6% of the farmers were into evaluation and trial stage respectively. Similarly majority (55%) of the farmers were not aware of processing sweet potato into starch while 14% of the farmers were aware. 8%, 16% and 7% of the farmers were in interest, evaluation and trial stage of adoption process. About 39% of the farmers were not aware of processing sweet potato into toast, 23% of the farmers were aware while 38% of the farmers were in interest stage. Majority of the farmers who were not aware of the processing sweet potato into various forms revealed that they were not fully informed about the innovation by the extension workers and this characterizes one extension worker to cover a wide range of farmers at a short time. Inadequate extension services among farmers were assumed to be an impediment to adoption of new technologies disseminated to farmers. The implication of the above is that some of the farmers who said that they were aware of the innovation might not have full knowledge of it due to inadequate extension service and this could be the major reason they stopped at the trail stage of adoption process. On the other hand, another set of farmers complained about the high cost of processing equipment and this could as well be the reasons some of them did not reach trail stage. Therefore, for a farmer to adopt an innovation there should be full dissemination of the technologies by the extension workers. This finding is in agreement with Chinaka and Udemezue (2015) who saw inadequate extension services among farmers as an impediment to adoption of new technologies disseminated to farmers.

Constraints to sweet potato production and processing technologies

Figures in table3 indicate the different levels of constraints militating against sweet potato production. The constraints were categorized into very serious (3), serious (2) and not serious (1) and later ranked in descending other of the constraints. Too much attention on other crops with a weighted mean score 2.74 was ranked first, high perishability of the crop with a weighted mean score 2.63 was ranked second, inadequate finance with a weighted mean score 2.60, pest/disease infestation (2.48), high cost of sweet potato processing equipment (2.48) farmers' low knowledge (2.45), inadequate storage facilities (2.44) and inadequate extension service with a weighted mean score 2.42 respectively.

In views of the above constraints, it could be reasonable to infer that high cost of processing material, inadequate finance and inadequate storage facilities could alternatively shift farmers' attention to other crops like cassava, rice, maize among others. Scarcity and high cost of equipment restricts farmers from procuring necessary farm implement in timely manner and adoption of improved varieties may be delayed in due cost. Therefore, inadequate finance, poor storage facility and high cost of processing material greatly limit sweet potato production to a small scale level, thereby impeding the value addition of sweet potato. This result is in line with the findings of Philip, Nkonya, pender and Oni (2009) who saw inadequate finance, high cost of processing material and in adequate storage facilities as an impediment to agricultural productivity in Nigeria. Low knowledge on sweet potato, inadequate extension service and perishable nature of sweet potato were also seen as another constraints working against sweet potato farmers in the study area. Inadequate extension service could make farmers being inaccessible to some innovations because they may see such innovations as an intruder designed to impede their farming system and this could be the reasons some farmers were stagnant and static in adoption process. But with the help of extension service farmers could be persuaded and become more dynamic in decision to adopt an innovation as well as discarding his/her laggard mind in adoption process. This result agrees with Omore et al (2014) who said that inadequate extension service was a constraint to sweet potato production in Ogun State, Nigeria

CONCLUSION AND RECOMMENDATIONS

Sequel to the findings of the study, 79% of the farmers were female and the mean age was 38yr. Majority (58%) of the farmers were not aware of the processing techniques introduced to them while some farmers were aware of the technology. In the same vein, none of the farmers adopted the technologies because they were not fully informed about the technologies by extension workers. However, too much attention on other crops, high perishability of sweet potato, inadequate finance, pest/disease infestation, high cost of processing equipment, farmers' low knowledge on sweet potato value chain, inadequate storage facilities and inadequate extension services were identified as the major constraints to sweet potato production and processing in the study area. This study therefore, recommends that more land should be put into sweet potato cultivation as to increase the efficiency at which farmers operate. There is also the need to launch initiatives and enlighten the various sectors of the economy on the usefulness of sweet potato Industries like flour mills, bakeries, textiles industries among others should be enlighten and encourage exploiting the potentials of sweet potato so that farmers in the local areas would be aware of the composite use of sweet potato varieties. Farmers should be encouraged to form farmers association and cooperative to increase their chance of obtaining loan from financial institutions and benefit from various farm credit schemes. Researchers should be endeavored to develop less cost management processing equipment to farmers as to reduce the perishability of sweet potato.

ABSTRACT
This study was conducted to enlighten root and tuber crops producing households on various ways of adding value to their produce via processing and packaging in order to: increase the shelf life of their produce; enhance the nutritional content of their produce; prevent spoilage; satisfy their consumersand boost their farm income. To achieve this, the researchers consulted the post harvest technology programme of the National Root Crops Research Institute, Umudike, Abia State, Nigeria in order to gather information on innovative post harvest techniques of root and tuber crops as well as studied published materials on post harvest processing methodsof root and tuber crops with a view to bridging the knowledge gap between research institutes and farmers.
Keywords: cassava, processing, value additions techniques, root and tuber crops

INTRODUCTION
Nigeria is blessed with abundant tropical root and tuber crops. However, the potentials of these root and tuber crops in contributing to economic growth are far from being fully exploited. This is because, though the country produces root and tuber crops in large quantities, ninety-nine percent of what is produced is consumed internally in limited value forms (Eke-Okoro *et al*., 2014) hence, the country continues to import starch, flour, sweeteners and adhesives that can be made from root and tuber crops.The primary objective of the Agricultural Transformation Agenda (2011-2015) with respect to root and tuber crops is mainly to transform bulk of the root and tuber crops into value added products by adopting improved production and processing technologies thereby enhancing food security, income generation and rural economic development (Eke-Okoro *et al*., 2014). However, most post-harvest losses incurred by households involved in the production of root and tuber crops are as a result of insufficient knowledge on how to process these root and tuber crops into various value added products needed for food consumption, animal feed and industrial raw materials. Hence, this study was conducted to enlighten root and tuber producing households on how to engage in meaningful value addition in order to diversify their products and boost farm income.

MATERIALS AND METHODS
The study was conducted at National Root Crops Research Institute, Umudike, Abia State, Nigeria. Data for the study were obtained through oral interview with the section head of post harvest technology programme of the institute, as well as from other published materials on root and tuber crops processing methods.The data collected were documented and presented as flow charts for the production of value added root and tuber products as presented in the results and discussion.

RESULTS AND DISCUSSION
Method of garri preparation: Peel and wash cassava roots; grate the root into mash using cassava grater; the grated cassava mash is fermented and dehydrated by putting it in a sack and placing it on fermentation rack for 1-5 days depending on the preferred garri flavor in a given locality. Fermentation is very important because it gives garri its preferred sour flavor, and detoxifies the cyanide; sieve to remove fiber and poorly grated materials; frying is done to achieve starch gelatinization of the particle and drying; finally, the fried garri is allowed to cool, sieved and packed (Ukpabi, 2008). See fig1

Method of fufu preparation : Peel and wash cassava roots; soak in water to ferment for 2 days; remove from water and grate into mash; put the [illegible] leave for a day; de-water the mash by pressing inside a clean bag; break the pressed mash into granules; spread thinly to dry on a clean surface, preferably on a raised platform; when dry, mill into fine powder; package in an airtight container or food-grade polyethylene bag (Aniedu and Oti, 2008). See fig2

Method of cassava chip and flour preparation: Peel and wash cassava roots; grate the root into a mash; de-water the mash by pressing inside a clean bag; break the pressed mash into granules; spread thinly to dry on a clean surface preferably on a raised platform; when dry, mill into fine powder and sift; package in an airtight container or food grade polyethylene bag (Aniedu and Oti, 2008). **Note:** The whole process from harvesting of cassava to drying of the cassava granules must be completed within 24 hours for the flour to be of high quality (Aniedu and Oti, 2008). See figs 2,3,4&5

Method of starch preparation: Peel and wash cassava roots; grate into a mash; mix with a lot of clean water (about 10 times the volume of cassava mash); sieve using muslin cloth; allow the starch to sediment and decant the water; wash the cassava starch by adding water, stirring and following processes 3 and 5 two or more times; spread out in a tray to sun-dry on a raised platform or oven-dry at 50^{0c}; mill finely and package in an airtight container (Aniedu and Oti, 2008). See fig6

Method of sweet potato production : Peel and wash fresh sweet potato root, grate the root into mash, dewater the mash by pressing inside a clean bag, break the pressed mash (cake) into fine granules, spread thinly on clean trays (or black polyethylene sheet on a raised platform to prevent contamination by dust, stones) and allow to dry. When dry mill, mill finely and sift if necessary. Then package in polyethylene bags or any other air tight container (Amamgbo, 2009). See fig7

Method of yam flour production: Select fresh yam tubers, peel, wash and cut into thin slices. Parboil in water for 5 minutes, sun- dry or oven-dry at 80^{0c}. Then, mill into fine flour, sieve and package in airtight container (Ukeje *et al*., 2014). See fig8

Method of yam chips production : Select fresh yam tubers, peel, wash and chip using knife or chipping machine. Blanch in boiling water for 5 minutes, sun-dry on raised platform or oven dry at 80^{0c}, and package the dry chips for future use in food-grade polythene bag (Aniedu and Oti, 2011). See fig 9

Method cocoyam chips preparation: Select fresh cocoyam corms, wash and precook for some minutes. Peel the precooked cocoyam and slice, alternatively cocoyam corms can be fermented after washing for 24 hours without precooking. Then dry on raised platform and package for future use (Okonkwo *et al.*, 2014). See fig10

Method of cocoyam flour production: Select fresh cocoyam corms, wash with water and precook for some minutes, then peel and slice into pieces. Alternatively, fermentation is applied after washing when if corms are not precooked by soaking the chips in water for 24 hours to remove acridity. Then dry on raised platform to avoid contamination, mill into flour, sieve and store in airtight container (Aniedu and Oti, 2009). See fig11

Method cocoyam flakes production: Select fresh cocoyam corms from harvested ones. Wash the selected corms with clean water in a large bucket or dish. Boil in pressure pot or cooking drum for about 1-3 hours. Peel the boiled corms; this can be done traditionally by the use of hand or knife. Slice the peeled cocoyam with knife and sun-dry on raised platform to prevent contamination (Okonkwo *et al.*, 2014). See fig12

CONCLUSION

This study has shown that root and tuber crops can be processed into variety of value added products to boost farmers income. Hence, farmers are encouraged to utilise the value addition techniques illustrated on the flowcharts to diversify their output in order to enhance their income and living standard.

SOME ISSUES OF PACKAGING AND LABELING OF AGROCHEMICALS IN JOS, PLATEAU STATE, NIGERIA

P.Z. Chuwang & E.A. Salako.
Department of Crop Science, Faculty of Agriculture, University of Abuja
pam.chuwang@uniabuja.edu,ng

ABSTRACT
Application of agrochemicals on the Jos Plateau has become very necessary due to diminishing availability of labour and the desire of farmers to synchronize farm operations for maximum production. This study was carried out to investigate the problems that led to some mishaps in the application of the agrochemicals. The findings revealed that 26% of the agrochemical products sold to farmers are inadequately packaged and that about 29% the labels on these packages were not very legible. The result also indicated that 22% of the information read from the labels was not helpful in equipping the farmers for adequate agrochemical application.
Keynotes: packaging, labeling, agrochemicals, Jos

INTRODUCTION
Crop production in Nigeria, like many other tropical regions of the world is very heavily labour dependent in order to carry out field/cultural activities most especially when the need to time these farm cultural operations fairly precisely remains an absolute necessity for ensuring meaningful output (crop yields).
The use of agrochemicals for crop production and for agriculture generally has become very necessary not only to circumvent high cost of and scarcity of available farm labour but to synchronize field operations in order to ensure maximum productivity. These and other reasons may be responsible for the ever increasing demand for and usage of agro-chemicals in Nigeria. The apparent rise in the level of agrochemical usage has invariably increased with some negative environmental impacts (Jeong and Foster,2003;Griffins and Malburg, 2012), serious health problems (Atreya,2008; Bhandari, 2014) and great dependence on imported chemicals with attendant far reaching economic implications. It is generally believed that the recent shift in agricultural production most especially crop production to accommodate extensive usage of agrochemicals will pose these serious challenges and others that may not have been assessed adequately.
The study area [9^0, 33^I N -9,^{0}88^I N; 8^0,61 ^{I}-9^0.18^I E] located on the Jos- Plateau, is a tropical mid-altitude location, about 1500M above Sea Level and covering about 700 KM^2. The area has the potential for the production of both tropical and some temperate crops because of its heavy rainfall and moderate temperature, favorable for the cultivation of potato (*Solanum tuberosum*), wheat (*Triticum aestivum*) and barley (*Hordeum vulgare*), as well as a wide range of temperate vegetables and fruits such as celery, radish, strawberries, cauliflowers as well as apples and grapes. The moderate climatic condition has attracted a lot of animal nomads from all over West Africa, a major factor that led to the establishment of the National Institute For Veterinary Research(NVRI) located in K-Vom (09^0 , 44^I N and 08;45^I E).
In response to recent shift in agricultural policy which seems to encourage more active private sector participation, there was a noticeable increase in the introduction of some of these temperate crop varieties, which may be termed indiscriminate because it was carried out without adequate quarantine, appropriate seed certification procedure and adhering to necessary bio-safety measures. This may possibly account for some of the upsurge in some crop pests and diseases as exemplified by the recent upsurge in potato blight epidemics recorded on the Jos Plateau (Chuwang, 2014). In order to control these pests, diseases and weeds, the farmers have resorted to increased usage of all sorts of agro-chemicals with varying degrees of success and most importantly, unquantifiable levels of environmental impact. It has also been documented that synthetic chemicals used for agriculture have deleterious impacts on ground and surface water, composition of atmospheric gases, soil properties, responses of organisms to stimuli etc (Bhanbari,2014; Gregg, 2015)
Recently, there was an increase in the reported cases/incidences of food poisoning from consuming unwholesome farm produce such as cowpea and grains as well as fruits and vegetables. This unwholesomeness of the farm produce was blamed mainly on improper preservation with chemical substances. Just recently, the EU (European Union) placed a ban on the importation of agricultural food produce from Nigeria (Anon, 2013, Anon, 2015). The continuous consumption of these and other farm produce are most likely to pose danger to consumers if the issue of inappropriate agrochemical usage is not addressed.
The object of this paper is to provide some sort of information on the packaging, labelling and viability and safety of agrochemicals used for agricultural production in the Jos area. It is also hoped that this information will provide a basis for making sound decisions on the problem at hand.

METHODOLOGY

The field assessment of the farming system(s) of the study area was carried out through oral/written interviews where questionnaires were administered to 10 respondents in 10 selected locations namely *Barkin-ladi*, *Bokkos, Heipang, K-Vom, Vwang, Gassa, Mangu, Kerang, Ampang-West* and *Gindiri.* Most of these areas are located on the higher plains of the Jos Plateau, North Central Nigeria.

Information was collected included the packaging, labeling and the reliability of all the package and the composition of the active ingredients of the chemicals. Other aspects of the farming system of the area, and personal aspects of the farmer's life provided information that were also analyzed but not presented in this paper.

The data collected was analyzed statically using the simple percentage technique with the aid of MS-Excel, 2010 version. All deductions and or conclusions arrived at in this study were based on the outcome of this analysis.

RESULT AND DISCUSSION

Packaging of the agrochemicals

The packaging of the agrochemicals is as presented in Fig 1. The result shows that about 61% of the respondents affirmed that the products were very adequately packaged and about 5% reported that the agrochemicals were not properly packaged. It will be safe to assert that about 74% of the farmers felt the packaging was adequate and very adequate but the remaining 26% were of the opinion that the packaging needed to be improved upon.

The implication of this result is that the products will be prone to all sorts of abuse and deterioration due to open contact with moisture and other environmental elements. Poor packagings are indicative of possible adulteration or other forms of post-production alterations and mis-management in transit which may lead to some of the problems mentioned earlier. Farmers have reported that fertilizer used on the farm contained mainly clay or kaolin or sand this can invariably lead to crop loss or other failures in the farming system.

Labeling on Agrochemical containers

The legibility and visibility of the instructions on the agrochemical container's labels was assessed by this study and the result is presented in Fig 2. About 71% of the farmers agreed that the instructions on the agrochemical container labels were visible and legible but about 29% felt the labels were either not visible or fairly or barely visible. If the instructions cannot be fully read due to poor visibility it means that the products may not be utilized properly because most farmers rely on the instructions they can glean from the labels on the product containers. In Fig 3 we shows the level of help that the farmers obtained from these labels towards understanding the way to handle the agrochemicals.

The result showed that about 22% of the farmers did not obtain sufficient help, or none at all, from the information read from the labels on the agrochemical's containers towards a better understanding of the process of agrochemical application and utilization.

CONCLUSION

The packaging and labeling of agrochemicals sold to farmers though adequate in most cases, provided room for adulteration and deterioration due to direct exposure to climatic/environmental influence. To compound the problem, some of the agrochemical products did not have visible and legible labels on the packaging containers to provide adequate and accurate information for proper and effective application. In view of these issues some of the farmers could not obtain sufficient information to help them in the process of the correct and proper chemical utilization in their farms. It is therefore necessary machinery to be put in place to monitor agrochemicals sold on the open market to ensure that farmers derive the desired benefit from applying them.

ANALYSIS OF THE FRUITS AND VEGETABLE MARKET CHAIN IN SHOMOLU LOCAL GOVERNMENT AREA OF LAGOS STATE, NIGERIA

O. W. Olowa & O. A. Olowa
Deparment of Agricultural Education
Federal College of Education (Technical) Akoka, Lagos State
Email: olowa1@yahoo.com

ABSTRACT
The study was carried out to analyze the fruit and vegetable market chain in Shomolu Local Government Area of Lagos state. A survey of fifty marketers randomly selected in Bariga and Bajulaye markets in the area formed the sample used. A descriptive research design was used in the study and data were collected using oral interviews and a well-structured questionnaire. Data were analyzed using frequency counts, percentage, market margins, marketing channel analysis and linear regression model to identify existing marketing channels used by vegetable marketers, determine the profitability of fruit and vegetable and isolate factors that affect quantity supplied of fruit and vegetable along the market chain. The study revealed that majority (74%) of the marketers are females. The average age of the fruit and vegetable respondent was (35.5). Local government harassments, lack of support from government, poor market stall, high cost of transportation and inadequate finance were the most perceived problems of marketing by the fruit and vegetable respondents. Channels that included local markets had high total gross margins. The regression analysis showed that quantity of fruit and vegetable supplied, price of fruit and vegetable, access to market information, access to internet service and distance from the market are factors that influenced supply of fruit and vegetable in the markets. Among other things, measures that easy access to credit, reduce multiple taxes and permit on sellers are recommended.

INTRODUCTION

Vegetable constitute the most important and inexpensive component of a balanced diet, which people now realize due to their high nutritive values indispensable for the body. Originally, vegetables were collected from the wild by hunter-gatherers and entered cultivation in several parts of the world, probably during the period 1,000BC to 7,000BC, when new agricultural way of life developed and fruits and vegetables are produced seasonally, but the market requires products throughout the year. As technology improved and consumer incomes increased, it became possible to provide fresh produce year-round.

Fresh tropical fruits are on winning ground in world markets as to recent statistical figures (Babatola, 2004.). Its production has risen by 7% annually since 1997 and the bulk of these fruits (98%) are grown in developing countries. The main reason for increase in demand of tropical fruits is the growing familiarity of consumers with tropical fruits; their taste, nutritional value and cooking qualities.

The knowledge of domestic consumers of the benefits of fruits and vegetables is confined to very few varieties of fruits and vegetables. Hence, domestic demand with the exception of few widely known tropical fruits is generally small and various studies show that people generally consume fruits and vegetables on a daily basis without considering them as basic.

Abay (2007) stated that the production of fruits and vegetable is seasonal and price is inversely related to supply. During the peak supply period, the prices decline. The situation is worsened by the perishability of the products and poor storage facilities. Along the market channel, 25% of the product is spoiled. According to UNESCO (2005), lack of concerted public support, scanty information, poor understanding of how the market chain works and lack of systematic documented knowledge are main threats that hampered the benefit of the sector. Thus, comprehensive data collection along the chain is a must to envisage the direction of input-output flows. If these jeopardy are not well addressed right onwards, it is obvious the country's competitiveness would trail far behind the existing stage. Even though fruit and vegetable are economically and socially important, fruits and vegetable marketing channel and their characteristics have not yet been studied and analyzed for local markets in Lagos state. Hence, the focus of the study to investigate fruits and vegetable market chains and factors affecting fruit and vegetable supply in Shomolu Local Government Area (SLGA). The outcomes here, hopefully will narrow the information gap on the subject and will contribute to better understanding on improved strategies for reorienting marketing system for the benefit of small farmers and traders.

The main purpose of the study is to analyze the fruits and vegetable market chain and investigate the factors that influence the supply of fruit and vegetable in Shomolu local government area of Lagos state. Other objectives include to isolate the problems of fruits and vegetable marketing in the study area; to identify the major fruits and vegetable marketing channels; to identify the factors affecting the quantity of fruits and vegetable supplied to the market.

METHODOLOGY

Study Area

Shomolu is a Local Government Area in the Ikeja division of Lagos State. It is one of the sixteen LGAs of metropolitan Lagos. It is located in the northern part of Lagos city. According to 2006 population census, it has 402,673 inhabitants. Most of its inhabitants are Yorubas. It is a major nerve center for commercial printing activities in Lagos. Also because of its enormous population, it has attracted huge commercial and industrial activities. Shomolu local government area harbours several industrial and commercial enterprises. The town is plagued by problems of overcrowding, poor housing and inadequate sanitation. Other articles of trade here is the marketing of agricultural produce such as rice, fruits, beans, garri, meat, vegetables, fish etc.

Data Collection and Sampling Techniques

Survey research design was used. All the fruit and vegetable marketers in the two main markets within the local government area namely, *Bajulaye* and *Bariga* formed the population for the study. The sample for the study comprised 50 fruit and vegetable sellers from the two markets randomly selected using the Simple random sampling.

Method of Data Analysis

The data collected were summarized using frequency counts and percentages, while the marketing margin analysis was used to determine the profitability of fruit and vegetable along the market chain. A simple linear regression analysis was used to estimate the factors that affect the supply of fruit and vegetable.

2.3.1 Gross Market Margin Analysis:

TGMM= $$\frac{Cprice - Pdprice}{Cprice} X100$$

GMMp = $$\frac{Cprice - MGM}{Cprice}$$

Pdshare = $$\frac{Pdprice}{Rtlprice}$$

Where:
TGMM = Total gross marketing margin
GMMp = Producer's gross marketing margin
MGM = Marketing gross margin
Csprice = Consumer's price
Pdprice = Producer's price
Rtlprice = Retail price
Pdshare = Producer's share

2.3.2 The regression model was specified as follows:

$$Y_i = \alpha_i + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + ... + \beta_i X_i + \upsilon_i \text{ ------------------------ (1)}$$

Where: Yi = quantity of fruit and vegetable supplied to market
α_i = Intercept
$ß_i$=Coefficient of the ith explanatory/independent variable
X_i = Vector of explanatory variables
U_i = disturbance term

Hence, the equation for the quantity of fruits and vegetables supplied is: Quantity of fruits and vegetables Supplied = α_i+ $ß_1$Gender + $ß_2$Age+ $ß_3$Household size + $ß_4$Edu + $ß_5$Distance + $ß_6$ Experience + $ß_7$Quantity Supplied + $ß_8$Price + $ß_9$Internet + $ß_{10}$Market Information + $ß_{11}$ credit + Ui

RESULTS AND DISCUSSION

Problems of Fruit and Vegetable Marketing in the Study Area

The Table 1 reveals that local government harassments (74%), lack of support from government (74%), poor market stall (68%), high cost of transportation (56%) and inadequate finance (46%) were the highest problems of marketing faced by the fruit and vegetable respondents while lack of market information (28%), high costs of fruit and vegetable (28%), insufficient supply of fruit and vegetable (28%), low demand of fruit and vegetable (26%) and inadequate storage facilities (22%) were the lowest problems of marketing faced by the fruit and vegetable respondents.

Fruit and Vegetable Marketing Channels and Margins

Figure 1 presents channels through which fruit and vegetable move from the production site until they reach the final buyer. According to Teka (2009), a marketing channel involves a series of intermediaries through which fruit and vegetable pass from producers to consumers. As Figure 1 shows, the 2nd channel- Producer-local market-consumer has the highest rank. It also means that the local market will have the largest share from the sales because the goods will be sold at a price that will bring about high income.

Four marketing channels were identified for fruit and vegetable in the study area as indicated in Table 3 The results revealed that most of the fruit and vegetable goes through channel-2, followed by channel-3 and channel-4. Channel-1 accounted for the least of the fruit and vegetable in the market. The possibility here is that the producer does not make enough profit from channel-1.

Factors affecting quantity supplied of fruit and vegetable in the SLGA

In this section the factors that influence the supply of fruits and vegetable are presented and discussed. A simple linear regression models were employed to analyze the factors that affect the supply of fruit and vegetable.

Table 3 presents the determinants of the supply of fruit and vegetable. The result shows that among the eleven hypothesized determinants of market supply of fruit and vegetable, five variables were found significant. These are quantity of fruit and vegetable produced, price of fruit and vegetable, access to market information, access to internet service and distance from the market. The coefficient of multiple determinations (R^2) was estimated (0.876) and adjusted R^2 value was 0.846. This means that 87.6% of the variation in the dependent variable is explained by the explanatory variables included in the model. Furthermore, the adjusted R^2 of 84.6% which is significant further consolidated the goodness of the model. The result in table 4 shows that the quantity produced is significantly and positively related to marketed supply of fruit and vegetable at 1% significance level. The value of the coefficient for production of fruit and vegetable implies that an increase in production of fruit and vegetable by one unit per hectare resulted in an increase in farm level marketable supply of fruit and vegetable. Similarly, the result shows that the price of fruit and vegetable is significantly and positively related to marketed supply of fruit and vegetable at 10% significance level. This complied with the law of supply that price and quantity supplied are directly related. Thus as the price fruit and vegetable increase in the market, farmers will supply more quantity of fruit and vegetable to the market to get better returns for the products. A priori, access to market information is positively related to market supply of fruit and vegetable at 10% significance level. As hypothesised access to internet service affected the marketed supply of fruit and vegetable positively and significantly at 5% significance level. This might be because internet service enables the traders to have better knowledge about how to get better production and productivity, and creates awareness about new technologies. Distance from the market is significantly and negatively related with the marketed supply of fruit and vegetable at 1% significance level. As the distance from the production area to market place become farther and farther, the producers supply lesser quantity of fruit and vegetable to the market. This is might not be unconnected with the nature of the product (i.e. perishability) and the costs which are related with transportation and handling.

CONCLUSION AND RECOMMENDATIONS

This study investigated the fruit and vegetable marketing chains in Shomolu Local Government area of Lagos with the of unravelling the routes through which fruit and vegetable reached consumers in this area, the problems being faced by their sellers, the returns and factors which affect the supply of fruit and vegetable to the two prominent market in the Local Government area. The study reveals that the channel with high total gross marketing margin obtained was through producer-local market- final consumer. It also shows that quantity of fruit and vegetable produced, price of fruit and vegetable, access to market information, access to internet service and distance from the market influenced quantity of fruit and vegetable supplied to the market. Government should provide adequate market stall for the marketers to store and display their goods. Excess taxes are spread on price thus escalating prices and reducing demand/ sales, government should help streamline multiple permits and taxes imposed on fruit and vegetable sellers. Finally, Policies that ease access to loan and financial support to agribusiness should be promoted.

Table 1: Summary of problems faced by fruit and vegetable respondents

Problems	Agree (%)	Disagree (%)
Inadequate finance	23 (46.0)	27 (54.0)
Inadequate storage facilities	11 (22.0)	39 (78.0)
High cost of transportation	28 (56.0)	22 (44.0)
Insufficient supply of fruit and vegetable	14 (28.0)	36 (72.0)
Poor market stall	34 (68.0)	16 (32.0)
Local government tax collectors harassments	37 (74.0)	13 (26.0)
High costs of fruit and vegetable	14 (28.0)	36 (72.0)
Low demand of fruit and vegetable	13 (26.0)	37 (74.0)
Lack of support from government	37 (74.0)	13 (26.0)
Lack of market information	14 (28.0)	36 (72.0)

ABSTRACT
The study examined the export performance of Nigeria in the following agricultural commodities: palm oil, rubber, cocoa, cotton, palm kernel and groundnut exports. The Symmetric Comparative Export Performance Index (SCEP) was employed as analytical tool using time series data set of Food and Agricultural Organisation (FAO) that ranged from 1970-2012. The outcome of the analysis revealed that Nigeria has a high export performance in the exportation of cocoa and groundnut based on their (SCEP) indices. As such, the study recommends that priority should be accorded to the production of these crops so as to increase the quantities of these commodities available for export.
Keywords: Export performance. Competiveness. Performance Index. Agricultural Commodities

INTRODUCTION

Agricultural sector has been the foundation for development in Nigeria through food production and export of its products. According to Boansi (2014), this has influenced both domestic and international markets through forward (product market) and backward (factor market) linkages. This revealed that the agricultural sector still remains one major source of foreign earning, aside the oil sector that has played prominent role in supporting capital development projects. Akpaeti *et al* (2014) opined that prior to the deregulation of the financial sector, Nigerian economy depended solely on agricultural exports. Agriculture was the dominant sector contributing a significant proportion of the Gross Domestic Product in the 1960s. Cash crops such as cocoa, cotton, palm oil, palm kernel, groundnut, rubber and timber were the major export crops in the country.

Following oil discovering in the 1970s, the sector became neglected. Consequently, agricultural GDP fell from 63 percent in the 1970 to 20.6% in 1980 and declined further to 23.3% in 2003 (Central Bank of Nigeria, 2005). This steady decline and instability in the agricultural exports as a result of oil boom in the country has been described by the term "Dutch Disease" by researchers like (Harberger, 1983; Pinto, 1987 and Bakare, 2011). World Bank attributed this decline to the oil shocks of 1973-1979, which gave way to large receipt of foreign exchange and neglect of agriculture in Nigeria (World Bank1989). During this period, Daramola *et al* (2007) reported that agricultural exports were negligible and represented about 0.2% of total exports while an estimate of 6% of Nigerians were employed in the rural sector.

Unquestionably, Nigeria's agricultural exports have been unstable since the discovery of oil in mid 1970s with decline in agricultural output by 24.2%. From 1980, output performances has not only slowed down, but have been highly unstable (World Bank, 1989). This, coupled with the collapse of the Commodity Board affected export commodity prices, distorted macroeconomic and agricultural policies prevailing in the environment and resulted in declining agricultural outputs, dismal export performances thereby rendering Nigeria a net importer of agricultural products (Bakare, 2011, Akpaeti et al., 2014). But to what extent do can export performances be measured so as to ascertain that the agricultural outputs are declining? This brings about the question, what is export performance? Latruffe (2010), defines export performance as the ability to sell products that meet demand requirements (price, quality, quantity) and, at the same time, ensure profits over time that enable the unit under study (nation or firm) to thrive. As a relative measure, the most used index amongst the lot that comes to mind at the mention of export performance is the Balassa index (Balassa, 1965). By its original definition, the Balassa index (RCA – revealed comparative advantage) measures normalized export shares, with respect to exports of the same industry in a group of reference countries. However, definition of the index has been revised and modified such that a plethora of measures now exist (Ferto and Hubbard, 2003).

But the Balassa index was marked with flaws by deviation in the index value observed as the set of countries used as reference changes, thereby making the outcome context and reference specific and sensitive to reference definition such as (i) well susceptible to double counting between pairs of countries (ii) does not measure comparative advantage in the rigorous sense instead reflects comparative advantage based on real factor induced or distortionary induced developments in export shares (Siggel, 2007). To address the flaws in RCA of being sensitive to reference, Volratti (1991) offered three alternative specifications in its stead. These were the relative trade advantage (RTA), logarithm of the relative export advantage (ln(RXA)) and revealed competitiveness (RC). Based on these observations, the RXA which holds the same intuition as the RCA and the ln (RXA) have been used frequently in economic and business literature for assessing export performance in spite of their advantage of being less susceptible to distortions, like the RCA index of Balassa, the RXA and ln (RXA) are less informative on the performance statuses of countries in exports of respective commodities due to the respective narrow bounds.

It is upon these flaws that Boansi (2014) in his study: Comparative Performance of Agricultural Export Trade: During and Post-Agricultural Diversification Project in Ghana proposed a more appropriate technique for effectively assessing export performance. Although the suggested approach was indirectly applied by Ferto and Hubbard (2003), through the use of seven-year mean indices (for 1992-1998) in assessing Revealed Comparative Advantage of Hungary with respect to the EU, the bounds (binary) used were as well very narrow thereby being less informative. Appropriate bounds/thresholds, which are robust to minor improvements in the cardinal measures (index values) were proposed by Boansi (2014). In assessing export performance, this study will make use of that proposed by Boansi (2014), Comparative Export Performance Index (CEP), the Symmetric Comparative Export Performance Index (SCEP) and the logarithmic form of CEP. These indices are almost similar by definitions to the RXA and ln(RX) indices proposed by Vollarth (1991), with the SCEP being asymmetric form of the CEP. Although under different names, by definition, the CEP index and the SCEP have been used in past research works (including Boansi, 2013; Nwachukwu, Agwu, Nwaru and Imonikhe, 2010 and Boansi and Crentsil, 2013). In view of the significant contribution and export capacity of Nigeria in the world market, it is pertinent to analyse the export performance of these commodities. The above formed the major thrust of this paper.

MATERIALS AND METHODS

The study employed time series data on the export of palm oil, palm kernel, cocoa, rubber, cotton and groundnut for Nigeria and the world and were obtained from the database of the Food and Agricultural Organisation (FAO). The values of export were converted from US dollars to Naira, using the exchange rates for respective years. The exchange rates were elicited from Central Bank of Nigeria (CBN) Statistical Bulletin. The Data spanned from 1970 to 2012. In the analysis of the export performance of Nigeria in palm oil, rubber, cocoa, cotton, palm kernel and groundnut trade, the symmetric comparative export performance index (SCEP) as a symmetric measure of comparative export performance (CEP) was used following the method of Boansi, 2014 and stated as follows:

$$CEP = \frac{(X_{jB}/X_B)}{(X_{jA}/X_A)} \qquad (1)$$

Where:

X_{jB} = total value of export of agricultural commodity (j) from Nigeria.

X_B = total value of agricultural exports from Nigeria.

X_{jA} = total value of world exports of agricultural commodity (i).

X_B = total value of world agricultural exports.

The Symmetric Comparative Export Performance index as specified by Boansi (2014) is consequently defined as follows:

$$SCEP = \frac{(CEP - 1)}{(CEP + 1)} \qquad (2)$$

ln (CEP) = log (CEP) (3)

Among these three measures of competitiveness, the SCEP (as asymmetric measure of CEP) is perceived to provide the best picture on performance of a country by setting boundaries between -1 and +1. The closer a given country is to +1, the higher its export performance and vice versa. With a similar intuition as the [RXA and ln(RXA)], values of CEP of at least +1 and ln(CEP) give a clear definition or explanation of the terms) of at least 0 reveals competitive advantage in export.

RESULTS AND DISCUSSION

To analyse the international Competitiveness and Export Performance of Nigeria in palm oil, rubber, cocoa, cotton, palm kernel and groundnut trade, the symmetric comparative export performance index (SCEP) as a symmetric measure of Comparative Export Performance (CEP) is perceived to provide the best picture on performance of a country by setting boundaries between -1 and +1. The closer a given country is to +1, the higher its export performance and vice versa. Therefore, this study made used of the SCEP index instead of CEP index with cocoa (5.810) and groundnut (389.615) values respectively which were above +1. Table 1 reveals that, among the six commodities used in this study, only cocoa (0.706) and groundnut (0.997) indicated high export performance based on their SCEP values, which is closer to +1. From the results, it could be observed that Nigeria is highly competitive in the export of cocoa and groundnut over the period under studied. In the case of cocoa export, this is however not surprising because (Erelu, 2008) reported that at present, the production capacity of cocoa in Nigeria has reached about 385,000 metric tons per annum, an increase of 215,000 metric tons from year 2007 production level. This disposition places Nigeria as the fourth highest cocoa producing nation in the world after Ivory Coast, Indonesia and Ghana, and by implication, Nigeria competes favourably with other frontline producing nations in supplying the world market. This finding supports the finding of Nwachukwu, Agwu, Nwaru and Imonikhe (2010) in a similar study who reported that Nigeria has a high comparative advantage in the exportation of cocoa and, as such, is highly competitive.

In the case of groundnut this could probably be due to the fact that there was an upward trend in the production of groundnut in Nigeria for the period 1970-2008 according to Daramola (2007). This could be the reason why it indicated a high export performance. For the remaining four crops, which indicated low export performance by reason of their SCEP values, it shows that Nigeria has lost its market share for the export of these commodities (palm oil, palm kernel, rubber and cotton) in the world market, which has resulted in weak competitiveness of these commodities. This finding supports the work of Ijirshar (2015). It is worthy to note that Ln (CEP) could not be used to ascertain the export performance of these commodities due to its very large bounds that the values must be at least zero in order for the commodity to be said to have high export performance. From the result in Table 1, it shows that all the commodities have a high export performance which might not be true. This is why the SCEP index is chosen because it gives the best picture of a country with highest export performance by setting boundaries between -1 and +1.

CONCLUSION

The study has revealed that Nigeria has a high export performance in the exportation of cocoa and groundnut and as such is highly competitive. It is therefore absolutely necessary that Nigerian government should give these commodities top priority and farmers should be encouraged to increase their production so as to increase quantities of these commodities available for export. This will help to sustain and even increase export quantity, earn more foreign exchange and strengthen the purchasing power of our currency.

Table 1: Export performance of selected agricultural export commodities (1970-2012)

Commodities	CEP	SCEP	Ln (CEP)
Palm oil	0.048	-0.908	1.357
Rubber	0.480	-0.351	1.067
Cocoa	5.810	0.706	0.628
Cotton	0.131	-0.768	0.906
Palm kernel	0.279	-0.564	1.084
Groundnut	389.615	0.997	1.128

ABSTRACT
Locally grown Cucumber (Cucumis sativus) fruits were evaluated to highlight the benefits of storage conditions and packaging materials on the moisture content, with a view to extending the shelf life and quality. The experiment was carried out in a 3 x 4 factorial arrangement with parent completely randomized design (CRD), using three different storage conditions – wet river sand; refrigeration and the control – ambient condition; and four (4) packaging materials, namely, perforated polyethylene bags, perforated corrugated cartons, perforated plastic containers and the control (no packaging) for three (3) weeks with three (3) replications. After two (2) weeks of storage, fruits stored in corrugated cartons with wet-river sand performed significantly better ($p<0.05$) than the fruits stored with wet river sand in plastic containers (89.990 % and 89.590 % respectively). The least moisture content (85.887 %) was exhibited by fruits stored at ambient temperature in cartons. After three (3) weeks of storage, fruits stored in paper cartons with wet-river sand performed significantly better ($p<0.05$) than the fruits stored with wet river sand in plastic containers with moisture content of 89.193 % and 88.267 % respectively. The least moisture content (83.557 %) was exhibited by fruits stored at ambient temperature without packaging. Fruits stored at ambient atmospheric condition were unmarketable after 14 days of storage as there were serious defects like large yellow patches, wrinkles due to moisture loss, with undesirable off taste. All cucumber fruits stored at refrigeration conditions refrigerated were also unmarketable three (3) weeks of storage as they were frozen and had off taste due to chilling injury. The best marketable cucumbers were those stored in wet river sand in paper cartons. They remained dark green after three (3) weeks of storage, resulting in the best visual appearance of cucumber fruits. The atmosphere modification provided by wet river sand condition resulted in the enhanced and acceptable market quality of the fruits after three (3) weeks of storage.

INTRODUCTION

According to Bruhn (1995), eating quality of a fruit or vegetable is a combination of characteristics, attributes and properties that lead to enjoyment in horticulture; while consumers say that appearance and freshness are most important in initial purchase of any horticultural produce. They select products that are the appropriate colour, size and shape with proper firmness and consumers also expect horticultural produce on sale to be safe with desirable taste. Appropriate colour, shape and size are important quality criteria developed from adequate postharvest handling. A characteristic taste is desirable, as it indicates ripeness and reflects eating quality. Scars, scratches mark lower quality rating.

Attitude studies indicate that consumers tend to prefer locally grown produce, both due to perception of higher quality and to support the local economy (Zagory, 1999). Horticultural produce is viewed as a healthy food choice. In each of the last 10 years, 70 % or more consumers responding to Food Marketing Institute's annual survey indicate that they have increased produce consumption to obtain a healthier diet (Bruhn, 1995). Consumers view fruits and vegetables as good sources of vitamin, minerals and fiber; helpful in calorie control a possible cancer preventative.

Kader (1983) pointed out that losses in quantity and quality affect cucumber between harvest and consumption. The magnitude of postharvest losses in fresh cucumber is an estimated 5 to 25% in developing countries, depending upon the cultivar and handling condition. To reduce these losses, producers and handlers must first understand the pre-harvest, biological and environmental factors involved in deterioration; and secondly use the postharvest techniques that delay senescence and maintain the best possible quality.

Fresh cucumbers are living tissues that are subject to continuous change after harvest. While some changes are desirable, most are not. Postharvest changes in fresh cucumber cannot be stopped, but they can be slowed within certain limits. Senescence is the final stage in the development of plant organs, during which a series of irreversible events lead to breakdown and death of the plant cells. Fresh cucumbers are high in water content and are subject to desiccation (wilting, shriveling) and to mechanical injury.

Storage temperature and humidity are most important as they influence the senescent phases of fresh vegetables by regulating the rate of all associated physiological and biochemical processes (Salunkhe and Desai, 1984). The objectives of this study was to evaluate the optimum storage conditions, vis-a viz the packaging materials, for the extension of the shelf-life of locally grown cucumbers.

MATERIALS AND METHODS

Experimental site – Cucumbers (*Cucumis sativus*) were grown from January to April in a sandy loam shallow soil at the Horticultural Farm of Imo State Ministry of Agriculture and Natural Resources Owerri; with a monthly rainfall of 200-270cm per annum, minimum temperature of 21.14°C, maximum temperature of 29.49°C with relative humidity of 89-93% and soil pH was 6.0-7.0.

Agronomic History of Study Area – The soil had unconsolidated parent material within 1m of the soil surface. Formerly cultivated with cassava, the soil was left grass fallow for one year. The soil was treated against nematodes with Furadan 3G after which basal fertilizer application of poultry manure was applied after making the beds. Seeds were sown in well prepared raised beds with width of 100cm at spacing of 50 by 50cm^2. Cucumbers were harvested early in the morning, packed unwashed and transported the same morning to the laboratory.

Cucumbers used in the experiment were manually graded and sized with an average weight, length and diameter of 80.4 g, 136 mm and 29.4mm respectively. The fruits were sorted to eliminate bruised, punctured and damaged ones after which they were washed with clean water and air dried. There were later packaged in perforated polythene bags.

Experimental Design – the experiment was carried out in a 3 x 4 factorial arrangement with parent completely randomized design (CRD), to test the effects of the treatments on the moisture content of cucumber fruits during storage for three (3) weeks with three (3) replications.

2.3 Treatments – the cucumber fruits were subjected to three different storage conditions – wet river sand (temp. 20-25°C; RH. 85 – 90%); refrigeration (temp. 4-5°C; RH. 90 – 95%) and the control (ambient condition – temp. 30 – 35 ^{0}C; RH. 70 – 80 %); using four (4) packaging materials, namely, perforated polyethylene bags, perforated corrugated cartons, perforated plastic containers and the control (no packaging).

2.4 Data Collection – Data on moisture content were collected on a four (4) day interval. Moisture content was determined according to the methods in Abdel-Razek *et al*. (2005), using the formula:

$$\% \text{ Moisture Content} – \frac{\text{Difference in weight x 100}}{\text{Weight of sample}}$$

Analysis of variance (ANOVA) was carried out using Genstat (2000) statistical analysis software. Data interpretation was based on Wahua (1999), where significant differences were observed at 5% level of probability. Least significant difference (LSD) was used to separate and test the means for differences.

RESULTS AND DISCUSSION

Table 1 shows the effect of packaging materials and storage medium on moisture content of cucumber fruits during a three (3) weeks storage period. At the commencement of the storage, there was no significant difference between the storage or packaging materials; neither was there any between the interactions. After one (1) week after storage, fruits stored in paper cartons with wet-river sand performed significantly better ($p<0.05$) with highest moisture content (90.883 %) than fruits stored with polythene in the refrigerator (90.807 %). The least moisture content (88.500 %) was exhibited by fruits stored at ambient temperature with no packaging. After two (2) weeks of storage, fruits stored in paper cartons with wet-river sand performed significantly better ($p<0.05$) than the fruits stored with wet river sand in plastic containers with moisture content of 89.990 % and 89.590 % respectively. The least moisture content (85.887 %) was exhibited by fruits stored at ambient temperature in cartons. After three (3) weeks of storage, fruits stored in paper cartons with wet-river sand performed significantly better ($p<0.05$) than the fruits stored with wet river sand in plastic containers with moisture content of 89.193 % and 88.267 % respectively. The least moisture content (83.557 %) was exhibited by fruits stored at ambient temperature without packaging.

Postharvest practices include the management and control of variables such as temperature and relative humidity, the selection and use of packaging, and the application of such supplementary treatments as fungicides (FAO, 2009). According to El-Ramady *et al*. (2015), all fruit-vegetables, except peas and sweet corn, are susceptible to chilling injury if exposed to temperatures below 5 °C e.g., cantaloupe, lima bean, snap bean, 7.5 °C e.g., pepper, 10 °C such as cucumber, soft-rind squash, eggplant, okra, chayote, or 12.5 °C e.g., tomato, muskmelons other than cantaloupe, pumpkin, hard-rind squash. This explains why the fruits stored in paper cartons with wet-river sand performed significantly better because even though cucumber storage is best in a condition that adopts low temperature and high humidity (Abdul *et al.*, 1999), the average temperature and humidity combination offered by the refrigerator did not favour the storage quality of the cucumber but rather subjected it to chilling injury due to the temperature.

The temperature and humidity combinations offered by the wet river sand in carton ensured that the fruits stored in that condition remained fresh till the third week of storage especially because of the temperature.

The variation observed in moisture contents among the cucumber fruits in different packaging materials and storage media may be due to different humidity regimes provided by these storage media and packaging materials. According to Gorny (2001), due to the high moisture content of cucumber fruits, there is the tendency for large amounts of water loss, wilting, dryness, sensory quality decline and loss in edibility when they are placed in circumstances of relatively low humidity under the action of moisture evaporation. Although Gorny *et al*. (1998) suggested that fresh produce must be kept in a moist atmosphere as low as possible to prevent water loss; the rate of water loss depends on temperature and duration of storage and exposure to lower O_2 and or high CO_2 concentrations.

CONCLUSION

Low temperature reduces the cucumber metabolism and the high humidity keeps the moisture content of cucumber so as to keep the cucumber fresh. It is an important means to maintain the fruit and vegetable quality. Storage medium greatly affected quality of cucumber. However, among the treatments investigated in this work, the best low cost and available postharvest treatment combination for managing cucumber quality was provided by storage in perforated cartons with wet river sand. The fruits subjected to this treatment had good visual appearance, good taste and low moisture loss; they were of high quality and good marketability.

ABSTRACT
The effect of value addition on the poverty profile of agribusiness poultry entrepreneurs was carried out in Abia state, Nigeria. Abia state consists of three major agricultural zones which are Umuahia, Ohafia and Aba and they were chosen because majority of the entrepreneurs found in these zones are poultry operators. The study adopted multi-stage sampling technique in the collection of data using well-structured questionnaires and 120 (one hundred and twenty) agribusiness poultry operators were studied. Simple descriptive tools, poverty line analysis and t-test were employed in the data analysis. Results from the analysis showed that value addition in the poultry value chain significantly reduced the poverty status of the households. The study recommends that government at all levels should sit up and face the challenge so as to harness the abundant economic potentials of this sector especially in raising the standard of living of the populace through wealth and employment creation.
Keywords: Value addition, poverty profile, agribusiness, poultry entrepreneurs

INTRODUCTION

The problem of poverty has been a long standing issue in Nigeria. This is indicated by the low social status of poor living conditions of the inhabitants. The problem has been made worse over the years by the development pattern which has favored the urban modern sectors to the detriment of the traditional rural sectors (World Bank, 1996).

A recent poverty assessment survey has shown that over 70% of the Nigerian population is living on less than a dollar per day and over 50% are living below the national poverty line. The survey also revealed that poverty is especially higher in rural areas where majority of the population are resident and derive their livelihoods from agriculture (FAO, 2006). The World Bank poverty assessment on Nigeria has shown that the nature of those in poverty can be distinguished by some characteristics such as education, age, gender, employment status of the head of households, household size and the share of food in total expenditure.

In view of this, agriculture remains the best opportunity for the estimated 1.5 to 2 billion people worldwide living in smallholder households to work and trade their way out of poverty. About 85 percent of the world's farms are run by small-scale farmers, whose output supports a population of roughly 2.2 billion people (Singh, 2008). About three quarters of the world's poor (small-scale farmers or producers and wage laborers) are based in rural areas. Study show that growth generated by agriculture is up to four times more effective in reducing poverty than growth in other sectors (Bage, 2008). For example, studies have revealed that the Nigerian livestock resources consist of 13,885,813 Cattle, 34,453,724 Goats, 22,092,602 Sheeps, 3,406,381 Pigs and 104,247,960 Poultry (RIM, 1992). From these figures, poultry is about 58.72 percent of the total livestock production, which indicates the place of poultry sub-sector in the livestock industry. Poultry meat and eggs play a very useful role in bridging the protein gap in Nigeria. They are palatable and generally acceptable. This acceptability cuts across nearly all cultural religion boundaries in Nigeria. The poultry industry plays important roles in the development of Nigerian economy. It is a major source of eggs and meat which have a high nutritional value particularly in the supply of protein. Eggs are also important in the preparation of confectionary and vaccines. The poultry industry also provides employment opportunities for the populace, thereby serving as a source of income to the people. However, the poultry industry in Nigeria, as well as other developing countries of Africa, is continually characterized by low production levels (Okoli, 1991).

The importance of poultry to the national economy cannot be overemphasized, as it has become a popular industry for the small holders that have great contribution to the economy of the country. The profession has assumed greater importance in improving the employment opportunity and animal food production in Nigeria. Recognition of this fact has brought agriculture back into the international development agenda. Linking smallholders with well-functioning local or global markets ranging from local 'street markets' to formal global value chains-plays a critical part in long-term strategies to reduce rural poverty and hunger.

The value addition in agriculture derives from the value chain which encompasses all activities involving agricultural input and production, processing, storage, marketing and distribution, household and industrial consumption and export. All along the chain many problems and constraints persist. Agricultural input constraints include those relating to availability and quality of supply (e.g. land, seed, fertilizer etc). Production problems include those related to scarcity and high cost of inputs, technical production problems (low yield, pest and diseases problems) and unstable agro-climatic conditions that aggravate farmers' production risks. Others include socio-economic problems (low level literacy, pervading poverty and aging farming population).

Among approaches applied in poultry related projects and programs, micro-financing poultry value chain appears to be one of the efficient methods allowing all actors of the chains to perform smoothly and acquire necessary input and technology for their activities (production, business or trading); providing them with necessary financial source for initial investments, or working capital to start or upgrade their production and business; increasing the voice of each actors of the chain, especially the small ones, as well as of the poultry value chain as a whole. It is paid much attention to, not only by the local and national projects, but also by the international ones.

In view of the importance of poverty and the need to analyze the effect of value addition on poverty reduction, this work is set up.

METHODOLOGY

This research work was carried out in Abia state, Nigeria. The state lies between the latitude 50 03ºN to 50 07ºN and longitude 70 17ºE to 70 24ºE and it is located in the tropical rainforest zone of Nigeria. The climate is consistently hot with maxima typically being about 31ºC and minima around 24ºC with evenly distributed rainfall in moderate manner ranging from 2,000mm to 2,500mm annually (World Bank, 2000). The state covers a land area of 5,243.7 square kilometers. It has a total population of 2,845,380 comprising 1,430,298 males and 1,415,082 females (NPC, 2006).

Multistage sampling procedure was adopted in this study. The first stage involved the purposive selection of three local governments (Ikwuano, Bende and Aba-South local government areas) from each of the agricultural zones (Umuahia, Ohafia and Aba) respectively based on their relatively high involvement in poultry and poultry related activities. The second stage involving drawing a list of poultry operators from each of the local governments and followed up by the selection of 40 operators from the same, thus, the sample size of this study is 120 respondents. Simple descriptive statistics, poverty line model and t-test were employed in the data analysis.

The poverty line is given as:

PL = 2/3 * MPCHE………………..…….(1)

PCE = TCE/HHS………………...……....(2)

MPCHE = THHE/TNR……………..…...(3)

Where:

PCE = Per Capita Expenditure

TCE = Total Consumption Expenditure

HHS = Household Size

MPCHE = Mean Per Capita Households Expenditure

TNR = Total Number of Respondents

THHE = Total Households Expenditure

Households whose mean consumption expenditure falls below the poverty line are regarded as being poor while those with their expenditure above the benchmark are non-poor.

RESULTS AND DISCUSSION

Socio-Economic Characteristics of the Poultry Operators

Table (1) indicated that majority of the poultry operators are more of adults who fall within the age range of 40 years and above, representing 71%. This was followed by those within the age range of 20 - 29 representing 20%. This result indicates that youths' participation in poultry operation is not encouraging possibly due to the ever-growing rural-urban drift leaving agriculture in the hands of the aged few.

Majority of the poultry headed households are males, representing 63% while the remaining 37% are females. The marital status reveals that most of the poultry operators are married. This is shown in the table as 72%. Family size 1 - 5 had the highest representative (71%) indicating that poultry activities would be to a minimum scale. The least was between 11 and above representing only 3% of the entire population. From the result presented above, a greater proportion of 59% of the poultry operators acquired secondary and tertiary education. This implies that due to high education attainment in the state, poultry operation would be efficient and profitable. 63% of the respondents belonged to cooperative societies while the remaining 37% did not belong to any cooperative society. 37% of the respondents had business experience of 6 to 10 years which accounted for the majority. On a general case, it could be said that the respondents are reasonably experienced.

Distribution of Poultry Operators According to their Earnings

Table (2) showed that poultry operators were moderate earners. Majority of the operators earned between ₦41,000 to ₦79,000 representing 38%. This was followed by ₦80,000 to ₦119,000 representing 29%. The least was ₦1,000 to ₦40,000 representing 7%. The implication of this result is that the operators did not earn much indicating that they are low scaled.

Distribution of Respondents According to Capital Investment (Amount Invested)

The distribution of the respondents by the amount of capital initially invested in the poultry value chain business showed that a majority of the respondents representing about 71% invested less than ₦200,000 as startup capital. This was followed by those who invested between ₦200,000 and ₦299,000 representing only 13%. The least was 3% which included poultry operators who invested ₦500,000 and above. This finding shows that poultry operators are small-scaled owing to the amount of investment. This however does not preclude the fact of expanding the business considering the high demand for poultry products in the nation at large.

Analysis of Poverty Status of Poultry and Livestock Farming Households

The poultry value chain operators' households' poverty status in the state were analyzed using the three indicators- Prevalence of Poverty (Po), Poverty Depth (P_1) and Severity of Poverty (P_2). Prevalence of poverty indicates the percentage of the households falling below the poverty line; poverty depth shows the amount by which the poor fall short of the poverty line and severity of poverty is the sum of the square of poverty depth divided by the number of poor households in the sample. The result of the analysis is presented in Table 4. The prevalence of poverty among the farm households in Abia state was (0.4900) representing 49 percent of the poultry households with consumption expenditure level below the poverty line. The poverty depth was 0.0701 representing 7% whose average consumption expenditure was below the poverty line. This gap represents the percentage of expenditure required to bring poor households below the poverty line up to the poverty line. The severity of poverty index was 0.221 which represents the poorest among the poultry value chain 'operator' who require the attention of policy makers in the distribution of the standard of living indicators such as health care services, clean water and income generating activities. This finding contradicts that of Adekoya (2014) who carried a similar work in Ogun state. Prevalence of poverty was accounted for by about 78% of the farm households in comparison with the greater number of farm households which were poorer in Ogun state than in Abia state. This was further buttressed by the poverty depth and severity of poverty in the two areas which stood at 55% and 43% respectively for Ogun state and 7% and 22% respectively for Abia state. This indicates that poverty status in the study area is lower in comparison to other areas of the state, where there are less poor people.

CONCLUSION

The study showed that poultry farmers were moderate earners. Majority of them earned between ₦41,000 and ₦75,000. They also invested an average of ₦200,000 in their businesses showing that they were medium-scaled operators. The study further revealed that about 51% of the poultry operators lived above the poverty line. The results further confirmed that operators who added value to their products had higher and significant incomes in comparison to those who did not add value. From the foregoing, it is clear that value addition in the poultry value chain significantly reduced the poverty status of the households. The study recommends that government at all levels should sit up and face the challenge so as to harness the abundant economic potentials of this sector especially in raising the standard of living of the populace through wealth and employment creation. Availability of credit affected farmers' decision to add value. This is because the operators could not assess credit at affordable rates. Government in this regard should make frantic efforts in ensuring that poultry value chain operators get these credits at reduced costs. This will enhance efficiency as well as break the ravaging vicious cycle of poverty experienced by the operators.

ACCEPTABILITY OF WHEAT-SOY BISCUIT BY SCHOOL CHILDREN IN IBARAPA CENTRAL LOCAL GOVERNMENT AREA OF OYO STATE, NIGERIA

I. I. Olatunji and J. O. Olaniyan
Oyo State College of Agriculture, Igboora
Corresponding e-mail address: ibitunji@gmail.com

ABSTRACT
Enriching locally available snacks can be a viable means of alleviating temporary hunger and improving nutrient intake, thus contributing to pupils' learning capacity. this study examined acceptability of formulated snack by school children in ibarapa central local government area, oyo state. the cross sectional study involved a four-stage sampling procedure to select 520 pupils from eight schools in the study area. biscuit was prepared with wheat-soy flour in the ratios of 100:0 (control), 90:10, 80:20, 70:30 for products a, b, c and d, respectively. the snacks were subjected to sensory evaluation tests for acceptability. mean scores for overall acceptability were 4.45±0.948, 4.50±0.945 and 4.40±1.098 for products b, c and d respectively. product c (20% soyflour) with highest score and least variability was considered most acceptable. it is concluded that wheat-soy biscuit is well accepted among school children and is therefore recommended that the developed snack should be commercialized to improve nutrient intake of school children.

INTRODUCTION
Poor nutrition has been variously responsible for absenteeism from school, inattention and poor motor and cognitive development (Van, 2005; Gomez-Pinilla 2008).Under-nutrition is one of the leading causes of childhood morbidity and mortality in many developing countries. It is described as both a cause and consequence of poor human health, development, and achievement across the lifespan (Buhl, 2010; West, *et al.*, 2006). Evidence of high levels of nutritional deprivation among school children has spurred increasing global interest in their nutrition and health (Ndukwu, *et al*., 2013). Fortification of commonly consumed foods is one of nutritional intervention needed to improve micronutrient status. Biscuits are a rich source of nutrients produced off-site that is easy to pack, store, and transport. They can be served as a breakfast particularly in full-day schools, in which case they are given early in the day to alleviate short-term hunger. (Bundy, et al 2009) They are cheaper and easier to distribute than meals, and often aim to act as an incentive for increased school access, but they are less substantial and their financial value to families is lower.
The **soybean** (*Glycine max*) is a species of legume widely grown for its edible bean which has numerous uses. Fat-free (defatted) soybean meal is a significant and cheap source of protein for animal feeds and many pre-packaged meals; Soybeans produce significantly more protein per acre than most other uses of land and soybeans contain significant amounts of phytic acid, alpha-linolenic acid, and isoflavones, Soy flours are products obtained by finely grinding full-fat dehulled soybeans or defatted flakes made from dehulled soybeans. To be called soy flour, at least 97% of the product must pass through a 100-mesh standard screen.

METHODOLOGY
The study was carried out among school children in predominantly rural Ibarapa Central Local Government Area of Oyo state having its headquarters at Igbo-Ora. There are two main towns in Ibarapa Central Local Government namely Igboora and Idere consisting of ten wards. The age group of children studied was 6-12 years (being the ages of children in primary classes 1-6). The study was carried out in one school-term.
The sampling frame for this study comprised of eight schools selected from the four Local educational zones using systematic sampling technique wherein the first and seventh schools on the list provided by the LGEA were chosen for further sampling and treatments.

Product Development
Nutrient-dense biscuits were produced using rubbing-in method. The biscuits were prepared from the blend of full fat soy flour at 0, 10, 20 and 30% substituted for refined wheat flour that is 100, 90, 80, 70% refined wheat flour. The process for production of nutrient-dense Snack (biscuits) consisted of rubbing-in 150 ml vegetable oil into 1000g of flour with 0.05g salt, 35.16g baking powder, 25g sugar, 20g cocoa powder. All dried ingredients were mixed together, vegetable oil was rubbed into the flour and six eggs beaten well with 200ml water were added. All ingredients were weighed accurately by weighing balance and mixed, kneaded and rolled out into uniform sheet 1/2cm thickness and cut into round shapes with a properly shaped cutter. They were later arranged on greased trays and baked at 170 - 180^{0}C.

Determination of Acceptability of Snack Using Sensory Evaluation
In order to determine the acceptability of the new product, it was necessary to conduct a sensory evaluation using the organs of the body for taste, smell, touch and sight to evaluate the perception of respondents. (Reau

2011).The product was produced and served to the school children who form the panel of evaluators across their tiers and age groups. The choices of the pupils were depicted by "smileys" (i.e. the face scale) which is a form of hedonic scale. The designed smiley was a 5-point hedonic scale wherein the extent of acceptability is graduated in terms of liking and not liking the products.

DISCUSSION OF RESULTS

The results of the organoleptic tests showed that the Colour of Sample C (having 20% of soy flour) with a mean score of 4.73 was highest of the treatments; followed by Sample B (having 10% soy flour) with a mean score of 4.72; and lastly, Sample D (having 30% soy flour) with a mean score of 4.71. For taste, sample C had the highest value among the treatments with a mean score of 4.52; followed by Sample D with mean score of 4.49; and lastly, Sample B with a mean score of 4.48. All these samples scored lower than the control, which had a mean score of 4.60.

The Texture of sample D had the highest mean score of 4.484 which was even higher than that of the control, with a mean score of 4.48. This was followed by Sample C having a mean score of 4.48. Lastly, the mean score of Sample B was 4.41. The Aroma of Sample B had the highest mean score in the experiment group with a mean score of 4.46; followed by Sample C with a mean score of 4.45; and lastly, Sample D with a mean score of 4.41. All these treatments scored lower than the Control with a mean score of 4.49. The Appearance of Sample C had the highest score among the treatment group with a mean score of 4.45; followed by Sample D with a mean score of 4.4; and lastly, Sample B with a score of 4.36. The Control had the highest score of 4.47.

For overall acceptability, Sample C was highest with a mean score of 4.5; then sample B with a mean score of 4.45; and lastly, Sample D with a mean score of 4.40. Thus, in all Sample C (20% soy flour) emerges the most acceptable of the three enrichments. For Overall Acceptability, Sample C has the least standard error and shortest range with its convergence around the option "like a lot." It can then be safely concluded that sample C had the most Overall Acceptability.

CONCLUSION

This study concludes that under-nutrition and food insecurity was prevalent among the school children in Ibarapa Central Local Government of Oyo State, Nigeria and that biscuit is the most frequently consumed snack. Therefore biscuits were formulated and developed using locally produced food commodities wheat and soy flour at a ratio 100:0, 90:10, 80:20, 70:30 respectively The developed products were acceptable to the pupils in terms of the sensory features of taste, colour, texture, aroma and appearance. In terms of relativity, Product C ranked first in evaluating consumer acceptance of products taste, third in colour, second in texture, first in aroma and third in appearance. The overall acceptability indicated that Product C, having 20% soyflour improvement ranked first. Thus, it was considered the most acceptable

Table 1: Survey Summary

S/No	Schools	No. of Questionnaire Distributed	No. of Questionnaire Returned	Percentage Returned
1	Roman Catholic Mission School II, Igboora	75	73	97.33
2	Baptist School II, Pako	62	62	100.00

SWOT ANALYSIS OF CASSAVA VALUE CHAIN IN SOUTH EASTERN NIGERIA

H.N. Anyaegbunam, I.A, Nwokocha, A. Olaniyi, and V.N Okafor
Extension Services Programme, National Root Crops Research Institute Umudike, Abia State, Nigeria
Email: helenkol8@yahoo.com

ABSTRACT
The Presidential Initiative on Cassava, launched in Nigeria in 2003, brought cassava and its potential to the national limelight. The Initiative had as its goal the promotion of cassava as a viable foreign exchange earner and also the development of the production system to sustain the national demand. The Presidential Initiative focused its intervention on the development of production, processing, and marketing of the processed products. The study was designed to analyze the Strength, Weakness. Opportunities and Threats of cassava value chain in Anambra and Imo states. The study was purposively carried out in Anambra and Imo States based on the intensity of cassava production in the south east zone of Nigeria. Two local government areas (LGAs) and 30 respondents were selected from each of the LGAs, making it a total of 120 respondents comprising of producers, processors and marketers. Primary and secondary data were used for the study. Information was derived from secondary data and respondents using focused group discussion and interview schedule Data were analyzed descriptively and by SWOT analyses. The result of the SWOT Analysis depicted that cassava production has increased over the years due to technological advances in research but processed products are of inferior quality due to inefficient processing equipment. Diversification of cassava utilization has encouraged the development of cassava value chain and lack of mechanization contributed to drudgery in cassava production and increased utilization of labor.
Key intervention areas will involve provision and execution of adequate policy on quality of raw material and finished products and then provision of infrastructural facilities in order to promote cassava value chain development in the study area.

INTRODUCTION
Nigeria is the largest production of cassava in the world with an estimated annual production of about 54 million metric tons (FAOSTAT, 2013). About 90% of this is however consumed as food in form of garri, lafun and fufu and also 70% of cassava produced in Nigeria is processed into garri (Onabalu, 1997).Across the country, cassava production has witnessed a tremendous increase for different reasons mainly due to introduction of high-yielding and disease-resistant varieties among other factors This increase in production between 2004 and 2006 came about as a result of the interventions of the Nigerian Government and some developmental agencies. The Nigerian Government facilitated the development of new disease-resistant cassava varieties by the joint efforts of International Institute of Tropical Agriculture (IITA), National Root Crops Research Institute (NRCRI), Root and Tuber Expansion Program (RTEP), and the Federal Ministry of Agriculture, in conjunction with State Agricultural Development Programs and cassava farmers. (Sanni *et al*, 2009) The Presidential Initiative on Cassava, launched in Nigeria in 2003, brought cassava and its potential to the national limelight (Sanogo and Adetunji 2008). The Initiative had as its goal the promotion of cassava as a viable foreign exchange earner and also the development of the production system to sustain the national demand. The Presidential Initiative focused its intervention on the development of production, processing, and marketing of the processed products. The cassava market in Nigeria can be classified into two broad categories based on the nature of demand namely: the traditional food-oriented market and the industrial market. The former refers to the demand for food consumption by individuals and households while the latter is the demand for cassava for industrial purposes (Knipscheer, et al, 2007).There is increasing demand for cassava product due to rapid population increase, high rate of urbanization and increased use of cassava products in the livestock, confectionery and starch industries. A value chain process involves all the activities that are undertaken in transforming raw materials into a product that is sold and consumed (Vermeuleu *et al.*, 2008).According to World Bank (2007) ,Value chain analysis (VCA) can be defined as a method of accounting and presenting the value that is created in a product or service as it is transformed from raw inputs to a final product consumed by end users Value chain activities include direct functions of primary production, collection, processing, wholesaling and retailing as well as the support functions. In value chain system, value is added at each point in the chain .Ananmbra and Imo states produce cassava in large quantity. In-depth value chain study in the states is scanty; the study assessed the Strengths, Weakness, Opportunities and Threats of cassava value chain in the two states.

METHODOLOGY
A purposive multistage sampling technique was used in selecting states and respondents. Two states Anambra and Imo states were chosen from the five states in south eastern Nigeria based on intensity of cassava production. Two Local Government Areas were selected from each state, Awka North and Oyi for Anambra state, Ohaji

Egbema and Owerri North for Imo State respectively.30 respondents were selected from each LGA making a total of 120 respondents comprising producers, processors and marketers. Information was derived from secondary data and respondents using focused group discussion and interview schedule Data were analyzed using SWOT analyses.

DISCUSSIONS

STRENGTHS

- Available land area:
  There are available land areas for cassava production
- Adaptability:
  Cassava can adapt to different soil conditions.
- Climate:
  Conducive climatic condition leads to increased cassava production.
- Demand:
  High demand for cassava products for domestic and international markest.
- High yielding varieties:
  High yielding varieties which are early maturing and disease resistant increase output.
- Human resources:
  Over 70% of the Nigerian populace is involved in one form of agriculture or another in the rural areas
- Research and development:
  Specialists in cassava production, courtesy of NRCRI and IITA.
- Staple:
  Cassava is the staple food of most people in the study area. It can be eaten in different forms-gari, fufu, etc
- Available local resources for appropriate technology:
  Local materials are used in fabricating equipment for cassava processing.

WEAKNESS

- Fragmentation of land:
  Subsistence farming is practiced due to land tenure system that gave rise to fragmentation of land.
- Non-mechanization
  Apart from tractors that are used in farming, most operations in the farm are carried out manually and this makes farming to be strenuous and laborious resulting to low and inferior output.
- Poor infrastructural facilities:
  Poor access roads, inadequate stall and power supply hampers value chain development. Energy cost is very high and unstable
- High cost of input/ raw materials:
  Agricultural inputs are costly and when available are untimely supplied. Costs of raw materials are equally high due to poor delivery systems such as poor networks and high transportation costs.
- Inefficient market information:
  A wide gap exists between the farmers, processors and end users across the value chain. Farmers are not able to get adequate information regarding supply by the processors and vice versa. This situation results to either glut or scarcity due to imbalance between demand and supply across the value chain.
- Lack of commitment and sustainability:
  Most of the processors are not duly committed to the work. Some are on part time basis. They are usually engaged in one other work or another. This leads to decline in processing activities and eventually closure of factory.

OPPORTUNITIES:

- Development of Human Resources/ Employment
  Restive youths are skillfully developed and some other rural dwellers are employed across the value chain.
- Availability of research institute, NRCRI, is an asset for all agricultural development projects in the south east of the country.
- Production of food
  Cassava is the main staple for people in the zone and as such to makes food available to them.
- Diversification of cassava.
  Cassava can be used for different purposes such as food and industrial raw material

- Increased output
  Due to research intervention there are high yielding varieties.
- Government policy.
  Government policy of cassava initiative and 10% inclusion of cassava flour for bakery products are advantageous in increasing cassava demand.
- Urbanization
  Increased urbanization has resulted to increased demand for cassava value added products
- Collaboration and donor Agencies in cassava projects:
  This has resulted to several cassava investments.

THREATS

- Competitiveness:
  There is need to strive to compete favourably with other cassava producing zones.
- Unstable government policies:
  This thwarts the efforts of industrialists
- Need to meet domestic and industrial demand:
  Due to diversified use of cassava, the demand has increased.
- Drudgery:
  Due to non-mechanization of agricultural activities, manual labour is used and thus makes work laborious and strenuous.
- Misplacement of identity
  Most farmers are not recognized. Farmers association hsas been hijacked by politicians who described themselves as farmers.
- Poor quality products:
  Most of the agricultural products are poor in quality and thus command low market prices
- Inadequate market information:
  It leads to glut and distressed sales.
- Increased population.
  Most available lands for agriculture are used for residential building.

CONCLUSION

The study analyzed the Strength, Weakness. Opportunities and Threats of cassava value chain in Anambra and Imo states. The result of the SWOT Analysis depicted that cassava production has increased over the years due to technological advances in research but processed products are of inferior quality due to inefficient processing equipment. Diversification of cassava utilization has encouraged the development of cassava value chain and lack of mechanization contributed to drudgery in cassava production and increased utilization of labor. Key intervention areas will involve provision and execution of adequate policy on quality of raw material and finished products and then provision of infrastructural facilities in order to promote cassava value chain development in the study area

ABSTRACT
The study assessed the effect of cocoyam value addition techniques on the living condition of rural women in Ohafia agricultural zone, abia state, Nigeria. A well structured questionnaire was used to collect data from one hundred and twenty women beneficiaries of cocoyam value addition techniques in the study area. Simple random sampling was used to select 120 women beneficiaries of cocoyam training programme. Simple descriptive statistics such as mean, tables, percentages etc and student Z-test was used to analyze the data. Result showed that there is a significant effect of the training programme on the general living condition of the rural women after the training. The mean income of the respondents before the training programme was ₦9, 073. 63 and after the training programme the mean income of the respondents increased to ₦21, 930.00 implying a significant effect of the training programme on the income of the respondents. Based on the findings, government should increase the fund allocation to the National Root Crops Research Institute, Umudike for expansion of the Cocoyam Value Addition Manpower Training Programmne, increased food production and sustainability.
Keyword: cocoyam, training, programme, value addition, techniques

INTRODUCTION
Nigeria is the world's largest producer of cocoyam (FAO, 2006). The average production figure for Nigeria is 5,068,000mt which accounts for about 37% of total world output of cocoyam (FAO, 2007). Cocoyam (Xanthosoma and colocasia spp) is an important staple crop cultivated in the southern part of Nigeria (Ojiako *et al*., 2007). Being an important food security crop in Nigeria, it is variously grown by resource poor farmers, mostly women who intercrop cocoyam with yam, maize, plantain, banana, vegetables and rice (Ikwelle *et al.*, 2003). Colocasia esculenta otherwise known as taro is more popular than xanthosoma sagittaifolium, otherwise known as tannia. Cocoyam is not only used as source of food for man, industrially, cocoyam is used for production of alcohol, medicines, flour, starch and feed for livestock (Eke and Oti, 2005).
Despite the economic importance of cocoyam, its potentials have not only been overlooked but also under exploited. In order to enhance the production and consumption of cocoyam in Nigeria, the National Root Crop Research Institute (NRCRI) Umudike, Abia State, Nigeria developed nine cocoyam cultivars. They include: NX5001, NX5OO2, NX5003, NX5004, NCE002, NCE 003, NCE 004, NCE 005, and NCE 006 (Mbanaso *et al*., 2008). Enhancing the production and consumption of cocoyam will help fight food insecurity in the country. There is worsening food insecurity, even with massive food importation as evidenced by rising food import bill (Okoye, *et al.,* 2008). The National Root Crops research Institute; Umudike has had several trainings on cocoyam value addition to enhance the production and consumption of cocoyam in Abia State.
Cocoyam can be processed into several forms such as flour for soup thickening is a common practice in the food systems of South-Eastern households. Presently, the flour is finding its way into the supermarkets in beautiful packages as an emerging globalized food. It can also be consumed as chips prepared by deep fat frying like the popular potato chips. Cocoyam chips are so much delighted by children and youths as school snacks & take away. Similarly, several confectionaries such as biscuits, chin chin, flakes and balls have been produced from flours of cocoyam through various value addition technologies developed by NRCRI Umudike, Nigeria. By so doing, the consumption of cocoyam has been diversified and increased while new market frontiers are being opened. This paper therefore seeks to take a critical look at the effect of cocoyam value addition techniques on the livelihood activities of rural women in Ohafia Agricultural zone, Abia State, Nigeria.

METHODOLOGY
The study was carried out in Ohafia Agricultural zone. Ohafia agricultural zone is located in the northern part of Abia State and is made up of five locations government areas namely Arochukwu, Bende, Isuikwuato, Uzuakoli and Umunneochi. Ohafia zone was chosen for this study because it has vast and fertile land for cocoyam production. Politically, it is referred to as Abia North Senatorial zone. The zone shares a common boundary with Enugu and Ebonyi States in the north, Akwa Ibom and Cross River Sates in the east, Anambra and Imo States in the West and Umuahia Agricultural zone in the south. Ohafia Agricultural Zone is made up of five blocks namely; Arochukwu, Bende, Isuikwuato, Uzuakoli and Umunneochi. All the five blocks were purposively selected because the five blocks (Arochukwu, Bende, Isuikwuato, Uzuakoli and Umunneochi) are the major

cocoyam producing blocks in the Zone under study. From the ADP Extension Agent supervising each of the selected blocks, the list of trained women cocoyam farmers was obtained. Twenty four (24) women cocoyam value addition trainees were randomly selected from each Block making a total of 120 respondents for the study. Primary data were used for the data. A well structured questionnaire was used to collect data from 120 respondents in the study area. Both descriptive and inferential statistics were used for the study.

RESULTS AND DISCUSSION

General Living Standard

Type of Housing

From Table 1, it could was observed that before the intervention, 17% of the respondents lived in single detached room, 23% of them lived in room and parlor, 28% lived in flat with water closet and 32% of them lived in flat without water closet while after the intervention, it was observed that 13% of the respondents lived in single detached room, 21% of them lived in room and parlor, 31% lived in flat with water closet and 35% lived in flat without water closet. It is glaring that there was a clear distinction between the trainee's general standard of living in terms of housing before the intervention and the type of house they were occupying after the intervention. The simple reason being that the intervention has been well entrenched as to influence the type of house they would want to live in.

Types of Building Materials

Furthermore, 48% of the respondents lived in mud building with zinc roof while before the intervention while the percentage reduced to 20% after the intervention. While 22% of the respondents lived in block houses with zinc roof before the intervention and after the intervention the percentage increased to 55%.

Toilet facilities

The result showed that after the training, there was a reduction in the percentage of the trainees who defecated in the bushes from 27% to 17%. Those who used bucket type reduced from 15% to 14%. The reduction in the percentage of the users of bucket type and those who defecated in the bushes brought an increase in the percentage of the respondents who used pit toilets and water system from 34% to 39% and 40 % to 45% respectively. This indicated that there is an improvement and clear difference in the respondents' general living standard.

Sources of Drinking Water

As an important measure of standard of living, source of drinking water was assessed. About 25% of the trainees get drinking water from tap water before the training, while the number increased to 33% after the training. Also, there was an increase in the number of the respondents who use bore-hole from 34% to 48%. The use of well and stream/spring water was drastically reduced. There is obviously marked difference between the trainees' source of drinking water both before and after the training.

Health Service Provider

It was observed that the majority of the respondents (47% as against 33%) received medical treatments from the Clinic/Hospital/Health Centre, followed by healing through prayers by their Churches which recorded 18% as against 8% before the training. There was drastic percentage reduction in patronizing itinerant drug sellers from 17% to 4%, and consulting the traditional healers by the trainees from 17% to 5%, to attend to their health needs. Hence there was positive change observed between the trainee's health service provider before and after the NRCRI Extension Staff cocoyam value addition training programme.

Source of Lighting

Majority (46% and 35%) of the trainees have electricity and kerosene lamps as their source of lighting after the intervention respectively. This implies that the intervention influenced the living standard of the trainees since the trainee's living standards registered a remarkable improvement.

Effect of the cocoyam training programme on the Income Level of Trainees before and after the Programme

In assessing the effect of the cocoyam value addition training programme on the income of the trainees before and after the training the paired z-test was used. From Table 2, the mean income of the trainees (After) was ₦21, 930.00 while the trainees income (Before) was ₦9, 073.67 with a paired mean of N12, 856.33. This implies that the incomes of the trainees after the NRCRI Extension training on value addition are higher than their incomes before the training. Given that the variables were significant at 1% level of probability, it shows that there is a significant difference in the incomes of the respondents after the training programme. It could be inferred that the intervention impacted positively on the incomes of the trainees. This approach has been employed successfully by Ezeh (2004) and Nwachukwu (2009).

CONCLUSION

There mean income of the trainees after the training was ₦21, 930.00 while the trainee's income before the training was ₦9, 073.67, with a paired mean of N12, 856.33. This implies that the incomes of the trainees after the NRCRI Extension Staff manpower training on value addition are higher than their incomes before the training. Given that the variables were significant at 1% level of probability, it shows that there is significant difference between their incomes.Finally, it could be inferred that the intervention impacted positively on the incomes of the trainees after their training.

ABSTRACT
The study examined the factors influencing the level of income of beneficiaries of cocoyam value addition training programme by the National Root Crops Research Institute, Umudike in Ohafia Agricultural zone of Abia State, Nigeria. Primary data were collected using a well structured questionnaire which was administered on 120 respondents that were selected randomly from the list of cocoyam value addition trainees collected from ADP. Result showed that 36% of the respondents were within the age bracket of 46-55 years, 36% of them attended secondary education, 58% of them were full time farmers, 67% of them had income ranging from N50,000-69,999, 60% of them had farming experience ranging from 21-30 years and 88% of them were married. The result of the regression result showed that double-log function was chosen as the lead equation having satisfied most of the apriori expectations. Age, educational level, household size, cooperative membership and frequency of visit were the factors affecting the income level of beneficiaries in the study area. It was therefore recommended farmers should be encouraged to get basic education as this will enhance the productivity of the farmer, thereby increasing their income level.

INTRODUCTION
Cocoyam (*colocasia* and *xanthosoma* spp) is an indispensable root crop which constitutes the major staple foods of some 60 per cent of Nigerians (Oji, 1983). It plays a crucial role in the sociological, nutritional and economic development of the country (Eke-Okoro *et al.*, 2004). Cocoa yam has been in existence in Nigeria for many decades, farmers have not been enjoying good pricing of the crop. This was because people regard cocoyam as poor man's food, and there was little or no processing of this crop to make it valuable. Hence, farmer's earnings were not commensurate with the efforts they put in cocoyam production. In an effort to guide against poor earnings and encourage people to eat cocoyam, the present administration in Nigerian came up with "Cocoyam Rebirth Programme". The purpose of which is to promote the new and improved forms of processing and utilization of cocoyam for sustainable food production, income generation, increased source of medicine for diabetic patients and possible foreign exchange earnings in the country (Aniedu, 2004).

Cocoyam (*colocasia* and *xanthosoma* spp) is consumed in different forms. Cocoyam can be consumed fresh as tuber after cooking; used as soup thickener, processed into "*Achicha*", pounded as fufu, roasted in fire, and can also be fried into chips. Cocoyam has different varieties. For example, the *Colocasia Spp* is used mainly for "*Achicha"* and as soup thickener, while other *SPP's* are used, cooked pounded and roasted (NRCRI, 2004). Cocoyam varieties are rich in vitamins and may be used also as cash crop, snacks; feed for livestock or as industrial crop for production of alcohol and medicines. They are good source of carbohydrates for diabetic patients and convalescents, and fortified food for infants (Imoh 2002). Even though the nutritional quality of cocoyam compares favorably with other root crops, the status of cocoyam in its use at home is quite low. The reason for this low status range from cultural bias to the prejudice is that cultivation of cocoyam is seen as a woman's job, (NRCRI, 2010).

With this tuber crop (cocoyam) as part of the mandate crop of National Root Crops Research Institute (NRCRI), Umudike, Nigeria has become the largest producer of cocoyam in the world, and accounted for an annual production of about 587 thousand metric tonnes (FAO, 2010). The nutritional, sociological and economic relevance of cocoyam to both man and livestock cannot be overemphasized.

National Root Crop Research Institute (NRCRI), Umudike recently developed several cocoyam value added technologies aimed at addressing the high perishability of cocoyam tuber (or corms & cormels) as well as diversifying the use of cocoyam. These technologies make it possible for an array of secondary products like Bread, Biscuit Cake, Chin-Chin, Doughnut, Chips, Salad cream etc. to be derived from cocoyam flour (NRCRI News Bulletin, 2006).

Furthermore, through various processing and utilization techniques alternative uses of cocoyam have resulted in the emergence of wide array of food recipes through value addition. Thus all practices involved in diversifying the processing and utilization of cocoyam roots are termed value adding technologies. According to Aniedu (2004) these emerged as a result of rising demand for making cocoyam products available in more widely and readily usable forms. This study was therefore to examine the effect of cocoyam value addition training programme on the livelihood activities of the beneficiaries.

METHODOLOGY

The study was conducted in Abia state of Nigeria. Abia is a state in the south eastern part of Nigeria. The capital is Umuahia and the major commercial city is Aba. The commercial hub, Aba was formerly a British colonial government outpost in the region. Abia state was created in 1991 from part of Imo State. It is one of the constituent states of the Niger Delta region (Hoiberg, 2010). Abia State, which occupies about 5,834 square kilometers, is bounded on the north and northeast by the states of Anambra, Enugu, and Ebonyi. To the west of Abia is Imo State, to the east and southeast are Cross River State and Akwa Ibom State, and to the south is Rivers State. Farming in the state is determined by the seasonal distribution of rainfall. The main food crops grown are yam, cassava, rice, cocoyam and maize while the cash crops include oil-palm, rubber, cocoa, banana and various types of fruits.

There are three agricultural zones in Abia State; Ohaofia, Aba and Umuahia agricultural zones. Ohaofia agricultural zone was purposively selected because of the it is a major cocoyam producing zone in the state. Two out of five blocks in Ohafia Agricultural Zone, namely Arochukwu and Bende were purposively selected because of their involvement in cocoyam production. From the ADP Extension Agent supervising each of the selected blocks, the list of trained cocoyam farmers was obtained. Sixty (60) cocoyam value addition trainees were randomly selected from each Block making a total of one hundred and twenty respondents for the study.

ANALYTICAL TECHNIQUES

The analytical tools used were descriptive statistics such as mean, frequency, tables and percentages and multiple regression models. The models are specified as follows;

In implicit form, the model is specified as

$Y = f(X_1, X_2, X_3, X_4, X_5, X_6,)$………………………………………………….. (1)

Where;

Y = income of beneficiaries (₦)

X_1 = Age (years)

X_2 = Sex or gender (male=1, female=0)

X_3 = Years of formal education (years)

X_4 = Family size (Number of persons in a household)

X_5 = Frequency of contact by extension agents (Regular= 1, Not regular=O)

X_6 = Income level (₦)

U = error term

RESULTS AND DISCUSSION

Socio-economic Characteristics

The result in table 1 showed that 36% of the beneficiaries were within the age bracket of 46-55 years. This implies that majority of the respondents belong to the middle-aged group and are known for their physical ability, productiveness and mental alertness in learning new technologies than older farmers (Agwu, 2004). Majority (36%) of the respondents attended secondary education. According to Okoye *et al.*, (2009), educated farmers are expected to be more receptive to improved techniques while farmers with little or no education are less receptive to improved technologies. About 58% of the beneficiaries were full time farmers. This is not surprising because full-time farmers tend to be less amenable to income diversification than their part-time counterparts. Majority (60%) of the respondents had farm sizes of 9-12 persons. This is in line with the perception of Sabo, (2006) who posited that large family size necessitated respondents to learn new technologies for increasing their returns, to sustain their families. About 67% of the respondents had income ranging from N50, 000- N69, 999, 60% of them had farming experience ranging from 21-30 years. Obinne (1991) observed that experience is a major factor in the adoption of technologies and should serve as an advantage for increased investment and technology utilization. Majority (88%) of the respondents were married. This implied that majority of the beneficiaries were married. This must have been necessitated based on the need to argument family incomes in addition to their traditional roles in the family as mothers and home makers.

Factors influencing the Income Level of the Beneficiaries of Cocoyam Value Addition Training

To analyze the factors influencing the income level of beneficiaries of cocoyam value addition training, multiple regression models were estimated. The four functional forms functional forms of the regression models were tried and the lead equation was selected based on statistical and econometric criteria such as number and signs of significant variables, their conformity with a prior expectation, magnitude of R^2 and F-ratio. The result is presented in Table 2. The double-log function was chosen as the lead equation because of the number and levels of significant variables. The result showed that age, educational level, family size, membership of cooperative and frequency of contact were the significant factors influencing the income level of the beneficiaries of cocoyam value addition training of the NRCRI. Household size, membership of cooperative and frequency of contact was significant at 1% level of probability and were all positively related to the income level of the beneficiaries of the cocoyam value addition training in the study area. Age was significant at 10% level and was negatively related to the income level of the beneficiaries. Educational level of the respondents was significant at 5% level and was positively related to the income level of the beneficiaries. Age of the respondents was negatively related to the income level of the respondents, this implies that the older the beneficiaries in age, the lower the income level of the beneficiaries. This is in consonance with the findings of Odoemenem and Obinne (2010) who found that older farmers are less willing to try new innovations or take risk. Educational level of the respondents was positively related to the income level of beneficiaries in the study area. This implies that the higher the educational level of the beneficiaries, the higher their income level. The result further implied that farmers that participated in the training programme had good educational qualification.

Family size was positively related to the income level of the beneficiaries. The result implies that beneficiaries with reasonable household size could hire less labour and make use of family labour which will not attract much cost in the production of cocoyam value addition products; this will in turn increase the income level of the beneficiaries. Membership of cooperative and frequency of visit by the extension agents were positively related to the income level of the beneficiaries. This implies that being a member of a cooperative will increase the income level of the beneficiaries and frequency of visit by the extension agents will increase the income level of beneficiaries in the study area.

CONCLUSION

Based on the findings of this study, it was concluded that age, educational level, family size, cooperative membership and frequency of contact were the factors influencing the income level of the beneficiaries of cocoyam value addition training programme by the NRCRI, umudike. Education enhances participation of beneficiaries in the training programmes, hence, affecting positively the income level of the beneficiaries. Farmers should be encouraged to acquire basic education in order to enhance their productivity. Extension agents should increase their visit to farmers to enhance their access to information on value added cocoyam products.

ABSTRACT
This study carried out in Imo State in 2014 investigated the socioeconomic characteristics influencing the adoption of cassava - value - added products (CVAP) by male and female farmers in Imo State. The specific objectives were to identify CVAPs disseminated to both groups of farmers in the study area and determine factors affecting their decision to adopt CVAP. Multi-stage random sampling technique was used in the selection of male and female cassava farmers. Sample size of 150 cassava farmers comprising 75 male and 75 female who have benefited from training in value addition to cassava organized by either government or private organizations in the state were involved in this study. Instrument for data collection was a set of structured and pre-tested questionnaire. Descriptive statistics such as frequencies, means and percentages were used to analyze the socioeconomic profile of the farmers while probit regression analysis was employed to analyze factors affecting decision to adopt cassava value addition products. Result obtained show that eight major CVAPs disseminated were Garri, cassava fufu flour, high quality cassava flour, cassava chin-chin, cassava starch, cassava cake, cassava chips and cassava bread. The most adopted CVAP among the male cassava farmers in the study area was garri, with a mean adoption score value of 3.68, which was followed by cassava chips ($\bar{x}$ = 3.37) and High quality cassava flour ($\bar{x}$ = 3.34). Also, garri and cassava fufu flour, with a mean adoption score values of 4.05 and 3.18 respectively were the most adopted CVAP by the women farmers in the study area. The result of probit regression revealed that age, household size, farm size had significant influence on female farmers' decision to adopt CVAP, while age, education, farm size, farm income and membership of farmers association significantly influenced decision of male farmers to adopt CVAPs. Since these socioeconomic characteristics influenced adoption of CVAPs governments should empower farmers through provision of massive training and extension of these products, increasing access to farmland and encouraging farmers to form cooperative societies.
Keywords: value addition, cassava, probit

INTRODUCTION

Cassava (*Manihot esculenta* Crantz) is one of the world's most important food crops grown principally for its roots (Allem, 2002). Unfortunately, cassava roots are perishable, bulky and notorious for their short shelf-life due to post-harvest physiological deterioration. Consequently, over 50 percent of the harvested produce is wasted due to production and post-harvest inefficiencies (Ezedinma *et al*. 2006).

In order to reduce this wastage, it is necessary to process cassava roots into value added products within few days after harvest. However, cassava processing and value addition activities are labour intensive and productivity is usually low. The drudgery associated with traditional processing is enormous and the products from traditional processing methods are often contaminated with undesirable extraneous matter, making some of the products unhygienic and attract poor market value (Okorji *et al*., 2003). Many improved cassava value addition products and products have been developed by both national and international research centres (Aniedu *et al*., 2012). These products are aimed at increasing food forms and adding values to the crop (Nwakor *et al*, 2011). These value added products include gari, fufu, tapioca, chips, pellets, flour, alcohol, starch, high quality cassava flour (HQCF) and others (Adebayo, 2009).

These products have been extended to rural cassava farmers through direct training by specialists from research centres or through extension agents that have been trained by research centres. Aniedu, (2006), reported that such trainings have been conducted in Imo State since 2005, while Women in Agriculture (WIA) Unit of Imo State ADP have been conducting such training since 1991.

Many extension and research programs which disseminate cassava value addition products are gender sensitive, focusing more on the women, or on the other hand the family head that is usually the husbands. The presumption is that men are less economically efficient than women in post-harvest activities. Men's contributions are usually under estimated and not accorded proper recognition because of women dominance in cassava processing and value addition (PIND, 2011).

There have been studies on awareness and adoption of cassava value addition products and products in Imo State (Aniedu *et al*., 2012,) but none have looked at gender issues involved in these adoptions. Consequently there is a paucity of empirical data to support policy formulations on the subject under study. This paucity of empirical data necessitated this study on adoption level of improved cassava value addition products by both male and female farmers/processors in Imo state, Nigeria. The aspect of this study that dealt with socioeconomic characteristics that influence gendered adoption of CVAPs is presented in this paper.

METHODOLOGY

The study was carried out in Imo state. The choice of the state is purposive in the sense that it is among the states in this country that benefited from the massive training and extension of products of new and improved food forms of root/tuber crops extended to rural farmers/women groups from 2005 to date by the National Root Crops Research Institute (NRCRI), Umudike, and Imo State Agricultural Development Project (IMADP). The study adopted a multistage random sampling technique in the selection of farmers. In the first stage, two Local Government Areas (LGAs) were selected randomly from each of the three agricultural zones of the state, two communities from each of the Local Government Areas and then 14 cassava farmers were chosen randomly from each community such that 7 were male, and the other 7 were female giving a total of one hundred and sixty eight (168) cassava farmers consisting of eighty four (84) female and eighty four (84) male cassava farmers sampled for the study. However, 150 respondents' questionnaires (from 75 males and 75 females) were used for analysis. The population for the study consisted of farmers who had benefited from training in cassava value addition organized by either government or private organizations in the state.

Primary data were obtained by the use of pre-tested and structured questionnaire. The data of interest included socio economic profiles of the respondents, membership of associations, cassava value addition products disseminated and level of adoption of cassava value addition products. Descriptive statistics such as frequencies, means and percentages was used to analyze the socioeconomic profile of the farmers while probit regression analysis was employed to analyze factors affecting decision to adopt cassava value addition products.

RESULTS AND DISCUSSION

Socioeconomic Characteristics of Respondents

The distribution of male and female cassava farmers who participated in cassava value addition technology according to their socioeconomic characteristics is presented in Table 1. This result indicated a rather increasing number of the very old and aged respondents especially the female cassava farmers, while the male cassava farmers were mostly middle aged that were within the active productive work force. Age is known to be a primary latent characteristic in adoption decisions. The ability of a farmer to bear risk and be innovative has been reported to decrease with age (Nwaru, 2004). Also this has implication on agricultural production because of the ability of this segment of the population to effectively withstand the rigours, strain and stress involved in agricultural production.

The distribution of respondents according to marital status is shown in Table 1. The table revealed that majority (69.33% and 76.0%) of the male and female cassava value addition trainees respectively were married. It was observed that the married class does have access to extra financial, moral and physical supports from their spouses that could go a long way improving their production activities.

86.67% and 89.33% of male and female cassava value addition trainees respectively received formal education ranging from primary school education to tertiary school education. Acquisition of higher education by farmers would enhance improved technology adoption hence increased farm income. Education has the capacities to influence people to accept new technology and change their attitude to the desired technology. Patrick and Edna, (2002) reported that the problem of widespread of illiteracy among farmers who cannot read would hinder the understanding of information at their disposal.

The table shows that 32.0% and 36.0% of male and female cassava farmers had between 21 and 30 years of experience in cassava production. This implies that both groups of respondents were established and knowledgeable in cassava production. Farming experience affects farm managerial know-how and decision-making process. Obviously, an experienced farmer will most likely identify the relative advantage of cassava value added products. Khanna (2001) also noted that higher farming experience attainable through increased years of farming leads to higher rates of adoption of new agricultural product.

Table 1 also revealed that a good proportion (43.42%) of male cassava value addition trainees in the study area had household size of between 5 and 8 persons while a good proportion (42.67%) of female cassava value addition trainees had household sizes of between 1 and 4 persons. High cost of labour was found to be a major constraint to adoption of improved technology (Anyaegbunam *et al*, 2009). Therefore, the availability of substantial family labour may reduce the cost of labour, thereby increasing the chances of the adoption of improved products.

The mean farm size of male and female cassava value addition trainees were 1.32 hectares and 1.53 hectares respectively indicating that the respondents in the study area were mostly subsistent farmers that operated mostly on small sized farm lands. Meanwhile, Bankole *et al*., (2012) was of the view that a farmer may have positive behavior to a new technology but might have limitation due to insufficient or non – availability of farmland.

Majority (72.0% and 65.33%) of the male and female cassava value addition farmer trainees belonged to farmers' cooperative societies while 28.0% and 34.67% of both groups of respondents did not belong to farmers association. This result implies high innovativeness among the respondents due to influence of group dynamics

(Anyiro and Oriaku, 2011). Farmers communicate most frequently and effectively with those who are most similar to them. These farmers are more likely to obtain information from and be influenced in their farming practices and adoption decision by other farmers. Table 1 also shows that majority (61.33% and 69.33%) of the male and female farmers value addition trainees respectively had less regular (irregular) extension visits, 17.33% and 24.0% of them had regular extension contact while 21.33%and 6.67% of both group of respondents (male and female cassava value addition trainees) had very regular extension contact. The more, the regularity of extension contact between farmers and the extension agent, the more the farmers' awareness of recommended practices, because the agent supplies information on the mode of application or use of recommended products. Frequent contact is likely to minimize doubts among farmers (Ekpe and Obeten, 2002).

A good proportion of respondents that obtained their training on cassava value added products from Agricultural Development Programme (ADP and National Root Crop Research Institute Umudike thus confirming their statutory agenda and contribution towards massive training and extension of products of new and improved food forms of root/tuber crops to rural farmers in the country. Also the good proportion of both respondents that obtained information and training on cassava value added product from their farmers' association.

Cassava value addition products disseminated to both groups of farmers

Table 2 shows that various types of cassava value added products were introduced to both the male and women cassava farmers in the study area. Eight major types were identified which include; Garri, cassava fufu flour, high quality cassava flour, cassava chin chin, cassava starch, cassava cake, cassava chips and cassava bread. Specifically, cassava fufu flour, garri, high quality cassava flour, cassava chips and cassava starch were the most important cassava value added products disseminated to the male cassava farmers as attested by 70.7%, 82.7%, 73.0%, 68.0% and 62.7% of them respectively. The least cassava value added products extended to the male farmers were cassava chin-chin (33.33), cassava cake (38.67%) and cassava bread (49.3%).

Similarly, the most highly disseminated cassava value added product among the women farmers were Garri, cassava fufu flour, high quality cassava flour and cassava chips. Between these value added products, they were also introduced in ascending order to the following cassava value added products: cassava starch, cassava chin chin, cassava bread and cassava cake. This result implies that the predominant cassava value added products extended to farmers in the area was due to the active promotion of such products by NRCRI and ADP in the State and in alignment with major diets of the respondents.

CONCLUSIONS AND RECOMMENDATION

The work had shown that the most adopted cassava value added product among the male cassava farmers in the study area was garri, followed by cassava chips and High quality cassava flour while, garri and cassava fufu flour, were the most adopted cassava value added product by the female cassava farmers in the area. The findings further show that age, household size and farm size had significant influence on female farmers' decision to adopt cassava value added product, while the factors that influenced male cassava farmers' decision to adopt cassava value added product were age, education, farm size, farm income and membership of farmers association. Since these socioeconomic characteristics influenced adoption of CVAPs it is therefore recommended that governments should empower farmers through provision of massive training and extension of these products, increasing access to farmland and encouraging farmers to form cooperative societies.

ACKNOWLEDGEMENT

I am grateful to the management of NRCRI Umudike, my supervisors, extension agents who assisted me with data collection, and all those who in one way or the other assisted me in this project.

[2]Department of Agricultural Technology, Akanu Ibiam Federal Polytechnic, Unwana, Ebonyi State, Nigeria
E-mail: basseyessien2004@gmail.com

ABSTRACT
Jatropha curcas, a multipurpose, drought tolerant, perennial plant is one of the most important industrial plants belonging to the family Euphorbiaceae is gaining lot of importance for the production of biodiesel, income, employment and soil restoration. It is a tropical plant that can be grown in low and high rainfall areas in the farms as a commercial sole crop or intercropped or on the boundaries as a hedge to protect fields from grazing animals and to prevent erosion. This paper reviewed the importance of exploring Jatropha as an industrial crop plant to enhance diversification of the use of fossil fuel. The taxonomy, botanical description of the plant, its origin and distribution and ecological adaptation are discussed. Various propagation methods including tissue culture to get disease-free plantlets of Jatropha are reviewed. The possibilities on the exploitation of Jatropha potential for various applications have been reviewed. The paper advocates massive production of Jatropha plant to restore degraded land (waste lands) as well as reducing greenhouse emission. The paper gives an overview on the benefits of Jatropha if properly harnessed.
Keywords: Jatropha, multipurpose, oil seed, sustainable and industrial use

INTRODUCTION

Industrial crop could be referred to as crop grown for the production of raw materials and other products in the production sector, rather than food for consumption. Industrial crops when fully harnessed and utilized, impact the economy by providing raw materials and products which lessens the need for imports, increase income of the farmer and the farm sector enterprises, provide economic development activities of the rural arears.

The use of biomass to provide energy has been fundamental to the development of civilization. Biomass contributes a significant share of global primary energy consumption and its importance is likely to increase in future world energy scenarios (Vasudevan *et al*., 2005). Improved agronomic practices of well-managed biomass plantations will also provide a basis for environmental improvement by helping to stabilize certain soils, avoiding desertification, which is already occurring rapidly in tropical countries like Nigeria. *Jatropha* is a multipurpose species with many attributes and considerable potential. Nearly 40% of the land area in Nigeria is wasteland due to erosion and desertification. Importance should be given on the plantation of *Jatropha* species on wastelands, for the protection of the environment and fulfilling future energy and industrial requirements.

The wood and fruit of *Jatropha* can be used for numerous purposes including fuel. The seeds of *Jatropha* contain viscous oil, which can be used for manufacture of candles and soap, in cosmetics industry, as a diesel/paraffin substitute or extender. This latter use has important implications for meeting the demand for rural energy services and also exploring practical substitutes for fossil fuels to counter greenhouse gas accumulation in the atmosphere. These characteristics along with its versatility make it of vital importance to developing countries (Foidl and Kashyap, 1999). Jatropha, as an energy crop that grows seeds with high oil content, requires low labour inputs, does not compete with food crops and is tolerant to pests and diseases (Ogunwole *et al*, 2007, Li Guo, 2002, Baumgart, 2007, Francis *et al*, 2005). These potentials coupled with the fact that the seed oil can easily be processed to partially or fully replace petroleum-based diesel fuel (Saikia *et al*, 2009), clearly makes *Jatropha curcas* a wonder bio-fuel crop, alleviate soil degradation, erosion and desertification, soap production and environmental protection as well as increase rural income sustainability and poverty alleviation. The roots recycle nutrients and reduce possibility of erosion as well as improve soil structure and quality.

In Nigeria, desert encroachment and soil erosion are serious environmental challenges facing the nation. In a bid to ameliorate the problems, government embarked on massive tree planting campaign throughout the country and more in the northern parts (Koyejo *et al*, 2010). The fact that it takes minimum of about 4-6 years for a tree to mature enough to begin to play the intended role of windbreak, erosion control, frustrates government effort (Omolaiye, 2005).

The purpose of this review is to provide information about its potential and current development in the field of *Jatropha* research.

Geographical Distribution and Ecological Adaptation

Jatropha is believed to have originated from the Caribbean Central America and the Northern parts of South America particularly Mexico. *Jatropha* was probably distributed by Portuguese seafarers via the Cape Verde

Islands and Guinea Bissau to other countries in Africa and Asia (Heller, 1996). It is assumes that the Portuguese brought the physic nut to Asia. It is well adapted to arid and semi-arid conditions. *Jatropha* grows almost anywhere except waterlogged lands, even on gravelly, sandy, saline and stony soils. The leaves shed during the winter months form mulch around the base of the plant. The organic matter from shed leaves enhances earthworm activity in the soil around the root-zone of the plants, which improves the fertility of the soil.

Regarding climate, *Jatropha* is a warm crop found in the tropics and subtropics requiring heat, although it does well even in lower temperatures and can withstand a light frost. It will grow under a wide range of rainfall regimes from 250 to over 1200mm per annum (Katwal and Soni, 2003). In low rainfall areas and in prolonged rainless periods, the plant sheds its leaves as a counter to drought, to reduce transpiration loss. Rainfall induces flowering and, in areas of unimodal rainfall, flowering is continuous throughout most of the year. Higher precipitation is likely to cause fungal attack and restricts root growth if the soil is not well drained (Openshaw, 2000).

Jatropha Propagation Methods

Jatropha grows readily from seeds or cuttings. However, trees propagated by cuttings show a lower longevity and possess a lower drought and disease resistance than those propagated by seeds (Heller, 1996), this might have been due to trees produced from cuttings do not produce true taproots (hence less drought tolerant), rather they produce pseudo-taproots that may penetrate only 1/2 to 2/3rd the depth of the soil as taproots produced on trees grown seed. The advantage of using cuttings over seeds is their genetic uniformity, rapid establishment and early yield. The disadvantage is the scarcity of material, and the cost of harvesting, preparation, transport and planting of the woody stems compared to seeds.

There are various methods to cultivate *Jatropha*, which vary from region to region and also on climatic conditions. These are: direct seeding, pre-cultivation of seedlings (nursery raising), transplanting of spontaneous wild plants and direct planting of cuttings. Wider spacing (3m×3m) is reported to give larger yields of fruit, at least in early years (Heller, 1996).

In better rainfall or good moisture condition, the plantation could also be established by direct seeding. When establishing a physic nut crop, the survival rate can be influenced by the choice of cultivation method. Two factors are generally responsible for sprouting: the age of the plant from which cuttings are taken and the position of the cutting within the plant, it might have been due to declines of rooting ability of many woody plants with age, when the source is a seedling derived mother plant. Distal portion of the stock plants are first to exhibit this reduced rooting potential, while cuttings from the lower or juvenile regions of the plants generally maintain a higher rooting capacity than those from the upper regions (Hartmann and Kester, 1983). Jatropha can be propagated using tissue culture method to enhance seed yield per plant. Tissue cultures have been developed for the propagation and storage of selected genotypes of tropical plants (Engelmann, 1991). The tissue gets disorganized and broken down into cells which further develop into cell and finally into plantlets having roots and shoots

Utilization of Jatropha Products

Jatropha is a multipurpose plant species with many attributes and potential applications as non-energy Sources, hedge Plant, soap Making, pesticide,green Manure and Organic Fertilizers, food/Feed and as medicinal uses.

Medicinal uses

All parts of Jatropha (seeds, leaves and roots) have been used in traditional medicine and for veterinary purposes for a long time (Duke, 1985b; Duke, 1988). Uses of various parts of *Jatropha* in the treatment of disease have been presented in Table 2. Some compounds (Curcacycline A) with antitumor activities were reportedly found in this plant (Van den Berg *et al*., 1995). Substances such as phorbol esters, which are toxic to animals and humans, have been isolated and their molluscicidal, insecticidal and fungicidal properties have been demonstrated in lab-scale experiments and field trials (Nwosu and Okafor, 1995; Solsoloy and Solsoloy, 1997). The seed oil can be applied to treat eczema and skin diseases and to soothe rheumatic pain (Heller, 1996). The 36% linoleic acid (C18:2) content in *Jatropha* kernel oil is of possible interest for skincare. Furthermore, Goonasekera *et al*, (1995) showed that various solvent extracts of *Jatropha* have an abortive effect.

The oil has a strong purgative action and is also widely used for skin diseases and to soothe pain such as that caused by rheumatism. The oil is used as a cathartic purgative (Jamalgota) and for the treatment of skin ailments (Duke, 1988). The leaves and latex are used in healing of wounds, refractory ulcers, and septic gums and as a styptic in cuts and bruises. A proteolytic enzyme (curcain) has been reported to have wound healing activity in mice (Nath and Dutta, 1997; Villegas et al., 1997).

As an Energy Source

The oil from Jatropha is regarded as a potential fuel substitute. The type of fuels, which can be obtained directly from the Jatropha plant are biodiesel, charcoal, Cooking/Lighting fuel from Jatropha oil/Fuel wood

Potential conservation benefits/ Summary of Economic importance

The primary conservation benefits to be derived from production of *Jatropha* relate to improved soil restoration and management. The findings of Kumar et al. (2008), have shown that the heavy metal contaminated soil can be restored by using combination of industrial wastes and suitable bioinoculants strain (*Azotobacter*). *Jatropha* in addition to protecting crops from livestock, it reduces wind erosion and pressure on timber resources and increases soil moisture retention. Nevertheless, *Jatropha* does mine soil nutrients. *Jatropha* oil projects are expected to provide income and organic fertilizer to increase crop yields, as well as being an ecologically friendly source of alternative energy to rural farmers. However, the summary of Jatropha economic importance is presented in Fig. 1

CONCLUSION

Jatropha curcas has a great potential as a locally available and environmentally friendly source of income, fuel, manure, employment and can be used to combat other environmental hazards such as reclamation of degraded land. Although currently growers are unable to achieve the optimum economic benefits from the plant, especially for its various uses, the markets of different products from this plant have not been properly explored or quantified. Consequently, the actual or potential growers including those in the subsistence sector do not have an adequate information base about the potential and economics of this plant to exploit it commercially. It is, therefore, timely to examine the potential role that *Jatropha* can play in meeting some of the needs for energy services for rural communities and also creating avenues for greater employment opportunities.

Table 1: Alternative propagative methods

Parent materials	Advantages	Disadvantages
Seed–sown directly in the field	• Cheapest method, good taproot development	• Lower survival rate of seedlings. • Least successful method of propagation. • Poor uniformity of growth. • Variable productivity of the progeny • More weeding required in the field.
Seed–nursery raised in poly-bags	• Control of seedlings environment. • Fewer losses • More uniform plants • Disease – free seedlings selected	• Higher costs than direct seeding • Variable productivity of the progeny • Seedlings taproot development may be impaired by the poly-bags
Seed–nursery raised in seed bed	• As above • No restriction of taproot • Lower transport costs.	• Higher costs than direct seedling • Variable productivity of progeny • Higher losses at planting - out of bare root seedlings
Vegetative cuttings: ○ Planted directly in the field	• As above • Fewer losses and more uniform plants. • Mini – cutting may be done where parent materials is scare	• As above • Higher costs than planting cutting directly
Vegetative cutting ○ Nursery raised in seedbed	• As above • Lower transport costs from nursery to field	• As above • Higher losses when planted – out
Tissue culture	• Clonal • Uniform productivity • Develop taproot • Rapid multiplication of new plants	• High cost of production • Newly developed protocol not yet commercially viable

ABSTRACT
The study investigated the perception on bread made from cassava-included wheat flour in Ibadan metropolis, Oyo State. Multistage sampling technique was used to sample 120 respondents. Data were analyzed using descriptive and inferential statistics. Results revealed that 46.5% of the respondents have household size of 4-6 persons. Majority (65.8%) were aware of the existence of bread made from cassava-included wheat flour. Radio and Television provided information for 38.3% of the respondents on cassava-included bread. Most (61.7%) of the respondents disagree or strongly disagree that bread made from cassava-included wheat flour is dangerous to human health. There was no significant relationship ($p>0.05$) between age, education, household size and income of the respondents and their perception on cassava-included wheat bread.
Keywords: cassava, wheat flour, bread, perception, household

INTRODUCTION
Nigeria spent N635 Billion Naira (US$=₦156) on the importation of wheat in 2010 alone. This amounts to spending nearly N1.8 billion naira daily for wheat importation (Momoh, 2011). Nigerian wheat importation is growing at the rate of 13 percent per year and could reach 17 million metric tons by the year 2020 (Olanrewaju, 2012). Presently, Nigeria imports about 15 million metric tons of wheat flour yearly for the production of bread (Ogunbanwo *et al.*, 2008). The effect of this import on Nigeria include loss of employment to foreign nations, food insecurity, increase in food prices, trade imbalance, loss of foreign exchange over dependence on foreign goods, high domestic price of bread etc. Nigeria is planning to reduce these negative trends by partially substituting wheat with cassava for the production of composition bread. Composite flour is the name given to wheat that has been diluted with other flours (Sanni *et al.*,2004).Giami *et al* (2004) and Akubundu (2006) cited by Eddy *et al* (2007) reported that up to 20% substitution of wheat flour with cassava flour had no adverse sensory or organoleptic effect on bread. Bread with 10% and 20% of cassava flour were not significantly different in most sensory attributes. Bread baked with 10% and 20% cassava flour was rated higher in aroma, colour, general acceptability and preference to buy than wheat flour.

METHODOLOGY
The study was carried out in Ibadan metropolis, Oyo State. Ibadan lies within longitude 070 021 and 070 40E and Latitude 030 351 and 40 101 N. Ibadan is 128km Northwest of Lagos and 345km southwest of Abuja, the Federal capital territory (Udo, 1994).The study population comprise of households in Ido, Ibadan South west and Ibadan north west local government areas of Ibadan metropolis. Data were collected through the administration of structured questionnaires; multistage sampling technique was used in the first stage to purposively select three (3) local government areas to represent urban, semi-urban and rural areas. They were Ido, Ibadan North West and Ibadan South West Local Government Areas. In the second stage, five (5) communities were randomly selected from each L.G.A to give a total of fifteen (15) communities. In the third stage, eight (8) households were randomly selected from each of the communities selected for the study, giving a sample size of 120.

RESULT AND DISCUSSION
Table 1 shows the results of the socio-economic characteristics of the respondents. 53.3% were female. Many (50.8%) of the respondents had secondary education. Another 30.0% had tertiary education. Majority (69.2%) earn monthly incomes of 0-30,000 naira and were mostly self employed (60.8%).
Result of awareness and source of information on bread made from cassava-included wheat flour (Table 2) indicates that 65.8% of the respondents were aware of this bread type. This could be attributed to the high literacy level of the respondents. The electronic media (Tv/Radio) provided information to 38.3% of the respondents on cassava-included wheat flour bread.
Table 3 looked at respondents perception on bread made from cassava-included wheat flour. Most of the respondents were undecided when asked if cassava included bread gives higher calories(46%), is as good as only wheat flour bread(37.5%),is robed of protein content(39.2%). Results also show that 45.0% disagree that bread made from cassava-included wheat flour is dangerous to human health. This finding agree with report by Chukwu (2012) that, the National Agency for Food and Drug Administration and Control (NAFDAC) after considering the nutrients and health implications of cassava, concluded that the inclusion of cassava flour in

bread production is wholesome. 35.8% of the respondents were undecided if bread made from cassava included wheat flour can be kept for a very long time while 27.5% agree that it cannot be kept for long. This implies that bread made from cassava wheat flour has a short shelf life. This findings corroborates UNIDO/FGN (2006) who reported shorter shelf life of bread made from cassava-included wheat flour and mentioned this to be the reason for the failure of previous cassava inclusion in bread policy in Nigeria. Many (58.3%) of the respondents were undecided if bread made from cassava-included wheat flour is an alternative solution for celiac disease patients. This indecision is not a surprise as the respondents mostly do not have medical background. However, cassava flour by having no gluten has been of interest for many researchers for the production of non gluten bread that can be used by celiac disease patients. According to Lundin *et al.*, (1993), celiac disease is most probably an immunological disease precipitated in individuals by ingestion of wheat gliadin and recatal proteins from other cereals. Also, 49.2% of the respondents were undecided if bread made from cassava-included wheat flour can increase glycemic index. Cassava inclusion in composite flour has a positive effects on glycemic index. A recent study indicated that cassava flour had a lower glycemic index of 59.34 compared to wheat flour with a glycemic index of 70.10 among 10 diabetics patients (Fasande and Anyakudo, 2007). Majority (75.0%) of the respondents displayed favourable perception of bread made from cassava-included wheat when they disagreed or strongly disagreed that it was made for the poor. The policy of cassava inclusion in wheat was intended to put more money into the pockets of Nigerians by promoting price stabilization of bread, creation of new markets for cassava farmers, new job opportunities in the high quality cassava flour (HQCF) industry and most importantly, the reduction of amount spent on importation of wheat by about ₦335 billion annually (Gbola, 2012, Layi, 2012).
Table 4 shows the result of PPMC analyzing the relationship between selected socio-economic characteristics of the respondents and their perception on bread made from cassava-included wheat flour. There was no significant relationship ($p>0.05$) between the age, educational level, household size, and income of the respondents and their perception on bread made from cassava included wheat flour.

CONCLUSION

Majority of the respondents are aware of the existence of cassava-included wheat bread. Most of the respondents have positive perception on bread made from cassava included wheat flour. However, the presence of so many `undecided` response on data retrieved indicate lack of information and knowledge to make informed decisions by the households on technical issues such as the relationship between cassava bread, safety issues surrounding it and possible effects on the health of consumers. There is therefore the need to sensitize the general public on the obvious benefits of eating cassava-included bread, as doing so will be of immense benefit to the Nigerian economy.

DETERMINANTS OF YOUTH EMPLOYMENT IN CASSAVA VALUE ADDITION ENTERPRISES IN ABIA STATE, NIGERIA

C.N. Onwusiribe[1], F.O. Onwukwe [1] & P.E. Anaele

[1]Department of Agribusiness and Management, Michael Okpara University of Agriculture Umudike, Abia State, Nigeria
ndubuisichigo@gmail.com

ABSTRACT

The study assessed youth employment status in cassava value addition enterprises in Abia State, Nigeria. The specific objectives were to examine the socio-economic characteristics of cassava processors, determine the number of youths employed in cassava value addition enterprises, analyze the determinants of youth employment in cassava value addition enterprises, discriminate the constraints and benefits of youth involvement in cassava enterprises or other enterprises and examine the cost benefit of participating in major cassava by-products value addition. In the study area, A multistage random sampling technique was employed to selects sample technique was employed to select a sample size of 90 respondents in the study area. Data were collected through a well-structured questionnaire and analyzed using descriptive statistical tool and multiple regression. Education and availability of machines in the cassava value addition enterprises. The researcher, therefore, recommend that government should provide mechanized farm implement at a reduced rental and purchase price to encourage the youths to participate in cassava production and other farm practice in the study area.

INTRODUCTION

Cassava value addition enterprises is aimed at upgrading traditional cassava products such as garri, fufu and high quality cassava flour for domestic and international market and to develop industrial market and to develop industrial market linkages for processed cassava flour as a low cost substitute for confectionary wheat flour. Cassava value addition enterprises seek to create a new generation for cassava farmers, oriented towards to commercial production and farming as a business and to link them up to reliable demand either from processors or guaranteed minimum price scheme of the government. The activities of cassava value addition enterprises are strategized to turn the cassava sub sector in Nigeria economy into a major player in local and international starch, sweeteners, ethanol and dried chips industries by adopting improved production and processing technologies and organizing producers and processors into efficient value added chains (Nweke *et al.*, 2002). Cassava value chain activities require energy which only the youth can offer especially in the areas of planting, harvesting, peeling etc. The youth involvement in the development of cassava value chain activities becomes imperative for a sustainable sector to raise rural incomes, permit the transition of subsistent cassava farming system to a sustainable market-driven system and standardize products supply lines in West Africa.

Rural youths play a central role in cassava production processing and marketing, they are responsible for cassava production which provides additional income earning opportunities and enhances their ability to contribute to household food security (Ojuekaiye, 2001). Youth's participation in cassava production in Nigeria reduces unemployment status in the country and increases revenue generation as well as provision of raw materials for industrial development.

Youth's involvement in the cassava value addition enterprises is vital to facilitate the production of food and the improvement of nutrition, the roles of which rural youths in cassava value addition can play include a mobilization tool through which rural youth can produce both for themselves and for the communities. (Seynes, 1964), argues that such mobilization could enhance the orientation of the mind of young rural people by promoting positive attitude towards the worthy and dignity of labour, it would also promote the status of farming by giving young people opportunities, profitable enterprises and improving community through service projects execution.

The broad objective of the study is to determine the youth employment status in cassava value addition entrepreneurs in Abia State, Nigeria. The specific objectives are to:

i. Examine the socio-economic characteristics of cassava processors.
ii. Determine the number of youths employed in cassava value addition enterprises.
iii. Analyze the determinants of youth employment in cassava value addition.

METHODOLOGY

This work was carried out in Abia State, Nigeria. Abia state is a State created in 1991 was carved out from Imo State. The state is approximately within latitudes 4°, 41^{I} and 6°, 14^{I} north of the equator and longitudes 7°, 10^{I} and 8^{I}° east of the Greenwich meridian. It has seventeen Local Government Areas that are divided along three agricultural zones namely Ohafia, Umuahia, and Aba (ABSEEDS, 2005). This state share common boundaries with Ebonyi State, Rivers State, Crossriver State, Imo State, Anambra State and Akwa Ibom States . The state is selected for this study from many others because of numerous agribusiness enterprises located in the rural, suburb and urban areas.(Nto *et al.*, 2011). The multi-stage sampling technique was employed in the study. The stage was purposely selection of three (3) local government area (Umuahia North, Ikwuano ,Umuahia South L.G.A) This is because cassava production is one of their major economic activities based on a fact finding visit by the development of agriculture of those selected local government areas and the favourable climate of these zones encourage cassava production activities in cassava value addition enterprises. The second comprising of thirty (30) youth producers of cassava value added products, purposely selected from each of the three (3) local government areas; this aggregated ninety (90) respondents which formed the sample size for this study. Data for this study was collected from primary sources. The primary source is through the administration of a well-structured questionnaire which was given to the sampled youth producers of cassava value added products in Abia State.

Model Specification

Multiple regression is used thus:

$Y= b_0+b_1x_1+b_2x_2+b_3x_3+b_4x_4+b_5x_5+b_6x_6+b_7x_7+b_8X_8+\ldots+b_nx_n +ei$

Y	=	Number of youths employed
X_1	=	Age (years)
X_2	=	Educational level (years of education)
X_3	=	marital status
X_4	=	Location (urban=1, rural=0)
X_5	=	enterprise size in number both youth and others
X_6	=	experience in years
X_7	=	Access to capital (in naira)
X_8	=	processing method (automated=1, traditional=0)
X_9	=	number of machines available
X_{10}	=	number of value addition activities the youths participate
b_0	=	Constant
Ui	=	Error term
b_0	=	Constant
U_i	=	Error term.

RESULTS AND DISCUSSION

Number of Youths Employed In Cassava Addition Enterprises

The number of youth employed were analyzed and presented in Table 1, the result, shows that the majority (511.1 %) of cassava processors employs between the range of 7.11 youths in their enterprises.

Determinants of youth employment in cassava value addition were analyzed and presented in Table 2. The regression result reveals that the coefficient of determination (R^2) of 0.622, which shows that 62% variations in the independent variables. The F-ratio of 7.9761 shows that the model is positively but statistically significant. The regression parameters of the model also show the location and processing method were significant at 10% and positively related to youth participation in the cassava value addition enterprise. Most of the cassava enterprises are located in the rural and suburbs which attracts most youths with the increasing level of unemployment in the urban centres. The presence of cassava value addition enterprise in the rural areas attracts the timing youths that could have migrated to the urban centres in search of jobs. Enhanced processing methods attract most youths to participate in the cassava value addition enterprise. Youths enjoys working in an environment that promotes labour efficiency, so with the aid of machines and enhanced processing techniques youths will be employed in cassava processing enterprises. This accounts for the positive significance of availability of machines at 5% to aid and make cassava value addition lucrative for the youths.

Education and training level of the youths wets the appetite to participate in cassava value addition enterprise. Education which was statistically significant at 1% and positively related to the youth's participation in cassava enterprise enables the youths to acquire the necessary skills needed in the cassava enterprise. Number of activities youth participates in had a negative effect in youth employment in the cassava enterprises. This implies increase in labor with increase in the number of activities youths participate.

CONCLUSION

Based on the findings, the study concludes that youths I the study area participated actively in cassava production especially in the areas of planting of cassava cutting and harvesting. The study also concludes that the youths engaged in these activities for the purpose of food security, poverty reduction and income generation but were constrained by high cost of transportation, pest and disease infestation and insufficient capital.

Based on the findings of this work, the following were recommended;

1. Education of the youths should be the priority of the policy of the government.
2. Provision of credit facilities, water and other necessary infrastructure in the rural areas should be facilitated to encourage the growth of cassava value addition
3. Fabrication of cassava processing machines should be encouraged by establishment of a scheme to fabricate such machines and distribute same to cassava enterprises.

EFFECT OF PRODUCT PACKAGING ON CONSUMER BUYING DECISION OF SWEET POTATO CHIPS IN UMUAHIA METROPOLIS, ABIA STATE, NIGERIA

F. E. Ebe., K. C. Obike, & B. C. Okoye
Department of Agricultural Economics, Michael Okpara University of Agriculture, Umudike, PMB7267, Umuahia
Email: fellyebe@yahoo.com

ABSTRACT
The study assessed the effect of product packaging on the consumer's buying decision of sweet potato chips and the problems affecting the buying choice of the product. The study was carried out in Umuahia Metropolis of Abia State. Data were collected from 60 consumers through questionnaire by using random sampling method. The data were analysed with descriptive statistical tool and probit regression analysis. The result of the study showed that the coefficient of income (0.001), packaging (0.159), taste (0.043) and education (0.043) were positive and significant. This indicates that these parameters had positive influence on the consumer's buying decision of packaged potato chips. Conversely, the variable, cost (-0.003) was negatively signed, implying that cost influenced the consumer negatively on the buying decision of the packaged potato chips. The result revealed that the serious problems affecting the consumer's buying decision of packaged sweet potato chips were poor packaging, consumer's income, taste, poor marketing strategy and consumer's attitude as the means of these parameters were equal or more than 2.0. The implication of the findings is that producers and processors should be encouraged to properly package their products as this gives value addition to the goods, generate more income and help to maintain consumer's confidence on the safety of the product for consumption.

INTRODUCTION
Sweet potato (*Ipomoea batatas* L) is one of the food security crops that are gradually gaining prominence in the rural and urban markets in Nigeria. It has been found to have economic potentials in both rainforest and derived savanna zones of Nigeria (Asumugha, 1999). Globally, Nigeria is the third largest producer with China leading (106,197 million mt) followed by Uganda (2.6 million mt) (FAO, 2004). It is a major source of income to farmers especially during extended harvest period. The market values vary according to local prices. The crop is grown for both human and animals. The potato tuber can be boiled, steamed, baked, fried, chipped, canned, frozen, made into flour and starch and processed into a good number of products (Takeda *et al*, 1986a, Wolfe, 1992). The root is good source of carbohydrate as well as raw materials for the manufacturing of industrial starch, glucose and alcohol (Udo *et al*, 2005). Some important nutrients of sweet potato include carotene, vitamins B_2 and C, polyphenols, thiamins, phosphorus, niacin, iron, calcium and carbohydrate (Islam, 2006). Even the leaves are used as vegetables for human being and fodder for livestock, as they are source of protein (Onunka *et al*, 2003). Sweet potato also has the effects of protecting soil, preventing soil erosion and is used as weed suppressant in the mixture of other crops and also improves nitrogen economy of the soil (Nwaigwe *et al*, 2010).

The potato crop is used in various ways and it has been found to be economically viable, but the problems with this crop are the shortage of its life, perishability of the tubers and unstable price due to seasonality in both supply and demand. Producers and processors are making efforts in order to address the perishability of the tubers and its seasonality by adding value to the product through the processing of the tubers into potato chips and packaging of the product so that it becomes appreciable to consumers. The conversion of the potato into chips and the proper packaging are the appropriate, suitable and convenience ways of preventing deterioration of the tubers during storage. In the process of making the chips, the processors clean the potato tuber, thereafter, peel, rinse, slice, add colour protection, stew, dehydrate, blend, mould, bake and finally package them (www.potatochipsmachinery.com/new/sweetpotato-chips-machinery.htmml. Retrieved on 27th November, 2015). The dried and packaged chip can be stored up to six months or more.

The primary purpose of packaging the chip is to protect it, keep it in good condition and preserve the flavor until it reaches the consumer. The journey from the processor to the ultimate consumer may be a long one, but the product must reach the consumer with good freshness, flavor, attractiveness and appearance unimpaired (Kordylas, 1991, Mustapha *et al*, 2014). The packaging reduces the total waste of the food, promotes the products handling, visibility and differentiates it from similar products (Anikweze and Ugwuona, 2011).

Good and attractive packaging creates market value, while poor packaging can dissuade the customer from buying the product irrespective of its quality. This is because consumers most times are attracted at the first sight to the packaging style of a product and it creates value by helping customers decision making process (Terblanche, 2006, Best, 2002). Also packaging imparts unique value to products, helps consumers to choose from wide range of similar products and stimulates buying behaviour (Silayoi and Speece, 2004). Even package standing on shelf affects the consumer buying decision. In recent years, civilization has invented synthetic materials such as tin can, aluminum, foil, cellophane paper, glass, plastic etc, these make the product easier and presentable (Mustapha *et al.*, 2014). These materials are with vivid colours which convey appeals to customers; hence consumers are tempted to buy the product due to the attractive nature of the package.

Sweet potato is sold in urban markets, but the tuber of the crop is bulky, with high moisture content and deteriorates rapidly after harvest thereby resulting to losses and high marketing cost. In terms of consumption, the potato is sweet. The sweetness of the tuber often makes it undesirable for consumption; dissuade the consumers from buying the product and thereby causing low demand of the good. These characteristics make the processors to process the tuber into chips and package them for longevity. These enhance the palatability of the product, increase demand, facilitate the marketing of the sweet potato and encourage the farmers to sustain their production. Hence, this study was carried out to assess the effect of the product packaging on the consumer's buying decision of potato chips and the problems affecting the buyer's choice of the product.

MATERIALS AND METHOD

The study was conducted in Umuahia Metropolis. Umuahia is the capital of Abia State and is located in the south east geopolitical zone of Nigeria. The state capital lies between latitudes 5^0 32/ N and 5^0 53/N of the equator and longitudes 70 29/ E and 7^0 48/ E of the Greenwich meridian (en.wikipedia.org/wiki/umuahia, Retrieved on November 27, 2015). Umuahia metropolis is made up of two local government areas, namely; Umuahia North and South LGAs with a population of about 359,230 (NPC, 2006). Umuahia being an urban area has many markets, shops, highway traffic points, schools and supermarkets where sweet potato chips and many consumers of the potato chips are likely to be found.

Purposive and random sampling methods were used to select the respondents of the study. Purposive sampling was used to select the markets and shops where the potato chips are mostly sold. This is because it is not all the markets and shops in Umuahia metropolis can get the chips. The markets selected were Ubani ultra modern markets, Onu-imo market and Orie Ugba markets respectively while the supermarkets selected were Capital, Ihechukwu and Blessed supermarkets. Ten respondents were selected from each of the markets, giving a total of 60 consumers that were used for the study. Field assistants and the shop owners assisted the researchers to administer the questionnaire, the concept of the respondent was gotten before the questionnaire was administered and collected at the spot. The data were collected through questionnaire and also oral interview was used to source information from the respondents.

The data collected were analysed with descriptive statistics and probit regression model. In order to determine the factors that influence the consumer's buying decision, the probit regression model was applied. The model is stated thus:

Probit (Y^*) = $X_i\beta + \mu$

Where X

Y^* = 0 or 1 (Dummy variable index representing consumer's buying decision)

Y = Consumer's buying decision (positive = 1, negative = 0), X_i = Vector of the independent variable, X_1 = Age (years), X_2 = Sex (Male = 1, female = 0), X_3 = Marital status (Married = 1, 0 = otherwise), X_4 = Level of education (years), X_5 = Income (₦), X_6 = Packaging (Good packaging = 1, poor packaging = 0), X_7 = Cost (₦), X_8 = Taste (Good taste = 1, bad taste = 0), X_9 = Marketing strategy (Good marketing strategy = 1, poor marketing strategy = 0). In order to ascertain the problems affecting the respondent's buying choice; statistical three point scale mean was used. A three point scale was used to determine the mean. A mean score of 2.0 was taken as base of judgment. Very serious = 3, Serious = 2, Not serious = 1 and Benchmark mean = 3.0.Decision: $\geq$ 2.0 indicates serious; $\leq$ 1.9 indicates not serious

RESULTS AND DISCUSSION

The result of the probit regression analysis as presented in the Table 1.0 indicates that the chi-squared showed the overall goodness of fit of the model as it was statistically significant. The result showed that among the determinants, five variables out of nine were significant at 1.0% and 10.0% levels of significance. The detailed result showed that income, packaging and taste were positive and significant at 1.0% level of significant while education was also positive and significant but at 10.0% level of significant. This implies that these factors have positive influence on the consumer's buying decision of packaged potato chips. Therefore, the coefficients of income, packaging, taste and education 0.001, 0.159, 0.043, and 0.032 respectively means that controlling the effects of other variables, the consumer's decision to buy packaged potato chips increased by 0.01%, 15.9%, 4.3% and 3.5% for each unit increase in income, packaging, taste, and education. The positive sign in education indicates that as a consumer becomes more educated, he recognizes/appreciates the importance of packaging of products which implies that the food becomes safer for consumption as the package protects the food from chemical, physical and biological influences (Anikweze and Ugwuona, 2011). Also the positive sign shown by good packaging and taste conforms to the study by Lifu (2012) which indicated that good product packaging resulted to increase in consumer's buying decision to buy the product while good taste makes the consumer to buy more of the product. Conversely, the variable, cost was negatively signed at 1.0% level of significant. This implies that cost has a negative influence on the consumer's buying decision. It indicates that a unit increase in the cost of the packaged potato chip decreases the buying decision of the consumer by 0.3%. This result corroborates with the findings of Lenka *et al* (2010) that high cost of potato was a significant barrier to potato consumption. On the problems affecting the consumer's buying decision of packaged potato chips, the results as shown in Table 2.0 indicated that poor marketing strategy ($\bar{X}$ = 2.37), cost of potato chips ($\bar{X}$ = 2.22), taste of the chips ($\bar{X}$ = 2.15), consumer's income ($\bar{X}$ = 2.08), poor packaging ($\bar{X}$ = 2. 03) and consumer's attitude ($\bar{X}$ = 2.0) were found to serious problems affecting the consumer's choice of packaged potato chips as the mean of all the parameters were 2.0 and above. On the other hand, the problem of lack of information ($\bar{X}$ = 1.95) was not seen as a serious problem affecting the consumer's buying decision of the packaged chips in Umuahia metropolis of Abia state.

Conclusion

From the result of the study, it is clear that good and attractive packaging of sweet potato chips significantly influence the consumer's buying decision as these serve as advertisement and appeals to consumers. Not only that good packaging appeals to consumers, it protects the food, avoids its deterioration and guarantees the safety of the product for consumption. Therefore, farmers and processors should be encouraged to properly package their products as this gives value addition to the food, generates more income and helps to boost employment. In addition while embarking on good packaging, they should ensure that the quality of the food is maintained to enable them remain in the present day competitive market. Government should make it as a mark of policy that those agricultural products that are to go for a long distance should be properly packaged to ensure safety and the good health of the consumers.

EXTERNAL MORPHOLOGICAL ASSESSMENT OF THE LEAF OF EXOTIC SWEETPOTATO GENOTYPES FOR SUITABLE FOOD UTILITY TRAITS

R.M. Omodamiro, U.J. Ukpabi, S.O. Afuape, N.E. Ekeledo & E.O. Ekah

National Root Crops Research Institute, Umudike Abia State
Correspondence email: majekrachel@gmail.com

ABSTRACT
External morphology and possible culinary uses of the leaves of some exotic sweetpotato were evaluated. The fresh experimental leaves were botanically characterized and sensory evaluation of the boiled leaves was carried out. Leaves of leafy elite sweetpotato genotypes existing in Nigeria were used as experimental checks. The result of their leaves external morphology characterization showed that about 25% were of simple palmate shape while the rest were simple non-palmate. The sensory panelists observed that the leaves from some of the experimental genotypes including local and International checks (Ex-Igbariam, TIS2532.OP.1.13 and TIS8164 respectively) could be used to replace or substitute some indigenous vegetables in local food preparation. The leaves of TIS8164 can also be used for traditional packaging in the preparation of Ekpan-nkwukwo (a local Nigerian dish). The nice aroma of the exotic Julian leaves could serve as a potential substitute for some indigenous spices in local food preparations.
Key words: *Sweetpotato, edible, leaves, sensory evaluation and exotic.*

INTRODUCTION
The culinary and other attributes for processing the leaf of sweetpotato accessories is very important for end user's acceptability (Rodriguez, 1999). Though the tuberous roots of the crop serve as staples in many Nigerian homesteads, Ukpabi and Oji (1984) found that the cooked leaves were also cherished as leafy vegetables by many local consumers. The leaves serve as side dishes in Taiwan. Young leaves are eaten as leafy vegetable (Abidin, 2004). The leaves are also good sources of vitamin A, C and B2 (FAO, 1990). The leaves contain 2.4mg/100g vitamin C and 709ug/100g vitamin A (Woolfe, 1992).
Recently, National Root Crops Research Institute (NRCRI) Umudike acquired some elite sweetpotato genotypes from CIP. There is need to evaluate the culinary attributes of the elite sweetpotato genotypes.

MATERIALS AND METHODS
Sources of materials:
The experimental materials from fifteen exotic sweetpotato (NASPOT1, NASPOT 2, NASPOT 3, NASPOT 5, Costanero (1870162), Jewel (44031), Julian (440141), Salyboro (187017), Cemsa (40000), Santo-Amaro, Carrot C, CIP-199024.2, CIP-199034.1, CIP-440203, and CIP-440443 and three locals (Ex-igbariam, TIS8164 and TIS2532.OP.1.13) were obtained from National Root Crops Research Institute, Umudike the germplasm plot of Sweetpotato Programme.

Characteristics of the sweetpotato leaves:
The colour and the foliar morphology of the genotypes were visually observed and recorded.

Sensory Evaluation of the Leaves:
The respective leaves were boiled at 100ºC within 10 minutes in glass beaker (Pyrex). Seven trained panelists (graduates of food science and allied disciplines) who were conversant with local leafy vegetables were used for the sensory evaluation with a nine point Hedonic scale (Iwe, 2002). In the scale 9 represented "like extremely", 5 represented "neither like nor dislike" while 1 represented "dislike extremely".
The sensory panelists were further represented to comment extensively on the samples.

Statistical Analysis:
The obtained experimental data were statistically analyzed with the appropriate SAS computer software.

RESULTS AND DISCUSSION
Table 1 shows the foliar characterization of the experimental genotypes (leaf colour, leaf shape/ leaf size) (Dutta, 1981). The result of their leaves external morphology characterization showed that about 25% were of simple palmate shape while the rest were simple non-palmate.
The randomly selected sensory assessors generally found the experimental leaves (exotic and local checks) acceptable (Table 2) as boiled leafy vegetables (with varying degrees of liking). Table 3 shows that the leaves from some genotypes that could replace or substitute the convectional vegetables. In addition, the panelists

reported the nice aroma of Julian genotype and possible use of the leaves of TIS 8164 as a replacement for the wrapping of cocoyam slurry/ paste in the preparation of *Ekpan-nkwukwo*.

CROP PRODUCTION, PROTECTION, IMPROVEMENT AND BIOTECHNOLOGY

EVALUATION OF GROWTH PERFORMANCE AND MIXTURE PRODUCTIVITY OF INTERCROPPED SOYBEAN (*Glycine max*) AND *MORINGA OLEIFERA* AND THEIR EFFECT ON SOIL PROPERTIES IN THE GUINEA SAVANNAH ZONE OF NIGERIA

P.O. Anyaegbu

Department of Crop Science, University of Abuja, Nigeria
anyaegbupoly@yahoo.com

ABSTRACT
The trial carried out to evaluate the performance of Glycine max and Moringa oleifera under inter cropping situation and their effect on soil properties in Abuja, using a Randomized Complete Block Design with 3 replications, showed that the soil in the area was strongly acidic with pH values of 5.20 prior to planting in 2014 but became moderately acidic after the second trial in 2015 with pH ranges from 5.8 in sole crop plot of Glycine max to 6.8 in Glycine / Moringa inter crop plots. Total nitrogen was significantly reduced after the first cropping season (0.03%) but was significantly improved after the second trial (0.07%), in 2015. Elemental sodium was drastically reduced from 0.90 Cmol^{-1} to 0.38 Cmol^{-1} in Glycine max/ Moringa inter crop plots of 50,000 stands of Glycine and 10,000 stands of Moringa oleifera in 2015. In 2014, the seed yield of soybean was not significantly influenced by Moringa intercropping but in 2015, the seed yield of Glycine max in the inter crop plots was 30% greater than that obtained from the sole crop plot. Highest seed yield (0.68 tha^{-1}) of Glycine max was obtained from inter crop plot of 50,000 Soybean stands + 10,000 stands of Moringa oleifera. LER was maximum in the inter cropping system of 50,000 stands of soybean and 10000 stands of Moringa plants with 23% and 68% more yield in 2014 and 2015 than the sole crop yields of both crops. The relationship between the two plants as assessed by LEC was cordial and complementary.
Key words: Moringa oleifera, Soy bean, Land Equivalent Ratio and Land Equivalent Coefficient,

INTRODUCTION
In the Guinea savannah agro-ecological zone of Nigeria, especially in the Federal Capital Territory (FGT), Abuja, majority of the farmers grow most of their arable crops under sole cropping situation. Continuous sole cropping without adequate fertilization has led to soil fertility depletion and subsequent low crop yields (Esu, 2010). Concerted efforts by the Agricultural Development Programme (ADP) through extension service programmes and short term training occasionally organized by Ministry of Agriculture and International Institute of Tropical Agriculture, (IITA), had increased the awareness of farmers in the FCT, Abuja of the importance of intercropping system. Consequently, over 55% of them (farmers) in the FCT now practice intercropping as the major cropping system in their systems. Therefore, it becomes necessary for the farmers to adopt intercropping as the major cropping system to maximize land use output. (Tariah and Wahua, 1985). Soybean is one of the commonly grown legumes under sole cropping situation in Nigeria (Kamara, 2009). as well as tremendous potential to improve incentive of resource-poor people particularly in a developing country like Nigeria (Danshiell, 1994). Meanwhile Nigeria is the largest producer of soybean in West and Central Africa (Root et al., 1987). Thus as a result of land crises, the productive capacity of the crop in this part of the country may dwindle if the crop is not being intercropped with other crops or fallow species. In some parts of Abuja, farmers grow their crops in alleys of *Moringa oleifera.* The plant, though not a nitrogen-fixing plant, is among the known promising exotic multipurpose tree species recommended for fuel wood, fodder, food, medicinal value, soil fertility improvement, providing semi-shade, and useful in intercropping systems where intense direct sunlight could damage crops Hence, this study was conducted to evaluate the effect of *Moringa* intercropping on the yield and yield components of Soybean, the soil physicochemical properties and mixture productivity of the intercrops.

MATERIALS AND METHODS
Two experiments, one in 2014 and the other in 2014 were carried out at the Teaching and Research Farm of the Faculty of Agriculture, University of Abuja, Nigeria. Randomized Complete Block Design (RCBD) with three replicates was used in the trial. Each replicate, separated from the other by one meter path way, contained five plots. Each plot measured, 5.0 m x 4.0 m and was separated from the other by 0.5m alley. Thus, a total of 15 plots were used in the trials. The treatments of which effects were assessed include; Sole Soybean (40,000 stands/ha), 62,500 stands/ha Soybean + *Moringa*, 50,000 stands/ha Soybean + *Moringa*, 40,000 stands/ha Soybean + *Moringa*, Sole *Moringa* (10,000 stands/ha). Plants of *Moringa* were raised from seedlings. Planting of Soybean (TGX 1440 – 7t) seeds and *Moringa* seedlings was done simultaneously at the first week of August. *Moringa oleifera* seedlings were planted at spacing of 1m x 1m giving a population of 10000 stands ha^{-1} Plant population of soybean was varied; 50cm x50cm (40,000 stands ha^{-1}), 40cm x40cm (62,500 stands ha^{-1}), 50cm x40 cm (50,000 stands ha^{-1}) respectively).The plots were manually weeded at 21 and 47 days after planting.NPK 15 –15 – 15 fertilizer was applied at 200 kg/ha, three weeks after planting. Data on all the parameters collected were

subjected to Analysis of Variance (ANOVA) using Randomized Complete Block Design. Treatment means were separated with Least Significant Difference (LSD). Bar charts and Tables were used to show the trend of the results.

RESULTS AND DISCUSSION

Table 1 shows the soil physicochemical properties of the field prior to planting while Table 2 showed the soil properties after harvest in each cropping season, (2014 and 2015). The soil classified as Alfisols and mostly well drained, (Nwaka, 2012; Esu, 2010), are strongly acidic with pH values of 5.20 prior to planting in 2014 but became moderately acidic after the second trial in 2015 with pH ranges from 5.8 in sole crop plat of *Glycine max* to 6.8 in *Glycine* / *Moringa* inter crop plots. This is an indication that the cropping system was environmentally friendly. The Total nitrogen was reduced after the first cropping season but was significantly improved after the second trial, in 2015,(Tables 2 and 3). The trend was similar for all the basic cations being assessed except the elemental sodium of which value was drastically reduced from 0.90 $Cmol^{-1}$ to 0.38 $Cmol^{-1}$ in *Glycine max/ Moringa* inter crop plots of 50,000 stands of *Glycine* and 10,000 stands of *Moringa oleifera* in 2015. The result on the soil properties of the experimental area indicates that in the first year of planting, the plants did not make significant impact of the soil fertility. Obviously within the first season of planting, the *Moringa oleifera* stands may not have been established enough to contribute significantly to the soil fertility. Any contribution within the short period may have come from the Soybean component Okigbo, and Greenland (1976) had reported that Soybean cultivation has expanded as a result of its nutritive and economic importance, soil fertility enhancement through nitrogen fixation and diverse domestic usage. Shahina *et al.*, 2005) had implicated *Moringa oleifera* in soil fertility improvement and maintenance. The clay, sand and silt composition of the soil was the same even after the experiment, indicating that the physical component of the soil was not affected by the practice. Thus, the crop practice is not only environmentally friendly but sustainably maintains the soil fertility of the experimental area. , Okoruwa, (2001) reported that inter cropping involving legumes reduces soil temperature and moisture loss, which favours multiplication and growth of some soil microorganisms that will enhance foliage multiplication. In 2014, the seed yield of soybean was not significantly ($P>0.05$) influenced by *Moringa* intercropping (Table 4). Except in the intercrop plot of 625,000 stands of soybean/ 10,000 stands of *Moringa*, the seed yield of soybean was fairly the same in both sole crop plots and inter crop plots in 2014. This non significant difference in seed yield of soybean in both cropping systems in 2014 confirmed the fact that the *Moringa* component in the first few months of its establishment was unable to contribute to the soil fertility or its neighbourhood effect on the component crop. However in 2015, the seed yield of *Glycine max* in the inter crop plots was 30% greater than that obtained from the sole crop plot. While the highest ($P>0,05$) seed yield of *Glycine max* was obtained from inter crop plot of 50,000 Soybean stands + 10,000 stands of *Moringa oleifera*, the lowest seed yield was recorded in sole crop plots of soybean in 2015. In both years of cropping, the seed yield of soybean in the inter crop plot of 62,500 of soybean + 10,000 stands of *Moringa* was relatively low, being reduced by 12 % in 2015. This reduction showed that crop competition in the affected plots was very aggressive indicating that a plant population of 72,500 ha^{-1} will encourage serious crop competition for Soybean and *Moringa* inter cropping venture. Mazaheri. (1998) reported that the decrease in the formation of nitrogen at the nodules on soybean roots was attributed to competition and shading effects under inter cropping situation and the phenomenon consequently reduced the seed yield of soybean. The trend of the seed yield of soybean as influenced by *Moringa* inter cropping was the same as those of its growth characters and yield components. In 2015, the seed yield of soybean, irrespective of cropping systems, was 20% greater than that of 2014. During the second year of cropping, the *Moringa* component was well established and the non harvestable portions of it were pruned and spread as green manure. The exercise thus may have improved the fertility status of the soil to the benefit of the companion crop. Meanwhile the biomass yield of *Moringa* oleifera in both cropping systems were fairly the same in both 2014 and 2015 respectively, (Tables 5 and 6). The result on biomass weight was the same as those of the dry matter and crude oil content of *Moringa* plants. The above results on *Moringa* showed that intercropping it with Soybean has no negative effect on its growth and development rather it improved it as shown in the inter crop plots of 50,000 stands of soybean crops and 1000 stands of *Moringa* plants per hectare. Clement *et al*., (1992) and Nabavi and Mazaheri. (1998) reported that intercropping Soybean with other crops produce positive relationship that enhances yield and fixes more nitrogen into the soil. The mixture productivity of soybean and *Moringa oleifera* in the trial is shown in Table 7. The Land Equivalent Ratio (LER) values for intercropping systems (except in 62,500 stands of soybean/ 10000 stands of *Moringa oleifera* in 2014), were greater than unity in all seasons. Ikeorgu et al (1989) reported that intercropping cassava and legumes is more advantageous in terms of land economy and productivity. Averaged over the two seasons, the LER was maximum in the inter cropping system of 50,000 stands of soybean and 10000 stands of *Moringa* plants. Thus, in this cropping system, inter cropping produced 23% and 68% more yield in 2014 and 2015 than the sole crop yields of both crops. This implied that more effective use of the land occurred in this mixture population than others. The poor results obtained under 62,500 stands of Soybean and 1000 stands of *Moringa* mixture showed that competitive pressures among the component crops were high. The evidence of the good performance of the crops under the cropping system,(

50,000 stands of soybean and 10,000 stands of *Moringa*), was shown by their individual Land Equivalent Coefficient, (LEC). LEC is developed to assess the interaction and productivity potential of crop mixtures and formulating proportions, (Anyaegbu 1988). A LEC of 78% as recorded in 50,000 soybean/ 1000 stands of *Moringa* ha^{-1} in 2015 showed that the neighbourhood effects between and among the crops were significantly beneficial and involved full complementarity.

CONCLUSION

The result of the experiment showed that total nitrogen was significantly reduced after the first cropping season (0.03%) but was significantly improved after the second trial (0.07%), in 2015. The trend was similar for all the basic cations being assessed. In 2014, the seed yield of soybean was not significantly influenced by *Moringa* intercropping but in 2015, the seed yield of *Glycine max* in the inter crop plots was 30% greater than that obtained from the sole crop plot. Highest seed yield (0.68 tha^{-1}) of *Glycine max* was obtained from inter crop plot of 50,000 Soybean stands + 10,000 stands of *Moringa oleifera*. LER was maximum in the inter cropping system of 50,000 stands of soybean and 10000 stands of *Moringa* plants with 23% and 68% more yield in 2014 and 2015 than the sole crop yields of both crops. The relationship between the two plants as assessed by LEC was cordial and complementary. Thus, an intercropping system involving 50,000 stands of Glycine max and 10,000 stands ha^{-1} of *Moringa oleifera* is recommended for good seed yield of *Glycine max* and biomass productivity of *Moringa oleifera*

ABSTRACT
Moisture stress is a limiting factor in dry season crop production and this may be alleviated by manipulation of soil condition and proper irrigation scheduling. This research was conducted to determine some morphological (tuber length and tuber diameter) and yield characteristics of dry season yams produced under different pit depths, irrigation intervals and irrigation methods. The experiment was a split-split plot in randomised complete block design with two irrigation methods (M_1, sprinkler and M_2, furrow), two irrigation intervals (I_1, 3-4 and I_2, 7-day) and three planting pit depths (D_1, 20; D_2, 40 and D_3, 60 cm) as main, sub and sub-sub plot treatments, respectively, replicated thrice. The results indicated that application of all the treatments alone did not significantly affect tuber yield ($P>0.05$) but did so for all tuber morphological characteristics excepting tuber length for irrigation methods. However, there existed a significant ($P<0.05$) interaction effects of the treatments (M x I x D) on all assessed tuber morphological and yield characteristics. Irrigating the yams at a more frequent 3- day intervals under sprinkler method and planting pit depth of 40 cm ($M_1I_1D_2$) maximised tuber yield responses (31.53 t/ha). This however, produced similar yield responses to those obtained by irrigating the yams at a less frequent 7-day intervals using sprinkler method and at the same pit depth of 40 cm ($M_1I_2D_2$) (30.48 t/ha), which gave the highest tuber morphological characteristics. These results suggest that a farmer could enhance his yam yield under this production system by applying either $M_1I_2D_2$ or $M_1I_1D_2$ depending on his economic condition.
Keywords: Pitting techniques, irrigation scheduling and yam tuber characteristics

INTRODUCTION

Yam (*Dioscorea rotundata*) ranks among the major food crops of the world, occupying an area of 5 million hectares with annual production and productivity of about 50 million tonnes and 11 tonnes per hectare, respectively (FAO, 2011). Nigeria is the world's largest producer, accounting for 70 – 76 % of the total world production of yam (Wikipaedia, 2016), with an annual output of 35.017 million tonnes from 2.837 million ha (Cigar, 2011). Moisture stress in arid and semi-arid regions or during dry seasons in humid regions is an important limiting factor in crop production. However, use of irrigation techniques has been found to alleviate water stress during dry periods. Irrigation allows for a higher cropping intensity, increases crop productivity, reduces crop failure rates and guarantees higher level profit than rain-fed production. They also provide increased source of energy and food security during dry season (Onyenweaku, 1994; Pinstrup Anderson et al., 1997). Crop yields may increase by using proper irrigation scheduling and grain yield of fingermillet has been shown to be increased by more frequent irrigation intervals (Vanangamudi et al., 1990). It has been shown that, besides variation in response of applied fertilizers with different methods of irrigation, frequency of water application or more frequent irrigation intervals is different in sprinkler as in conventional furrow irrigation systems. Also, water has been found to be applied frequently in lower amounts in sprinkler irrigation as compared with heavy application under furrow irrigation (Sharma et al., 2012). Furthermore, it has been reported that sprinkler irrigation produced higher yields of potato due to better availability of moisture throughout the growth period (Pawar et al., 2002). Similarly, the "Zai" technique of planting on dug and covered up pits, otherwise referred to as pitting techniques is an indigenous technique from Burkina Faso that has been shown to improve millet yields in smallholder farms during low rainfall years in semi-arid regions (Ouedraogo and Kabore, 1996) as well as conserve soil moisture in steep lands (35 – 60 %) (Martin et al., 1996). Yams are mostly produced under rain-fed agriculture in Nigeria and/or on hydromorphic soils during the dry season mostly on mounds or ridges and scarcely in holes. Yam production under rain-fed scenario is without lots of rainfall unpredictability, especially in this era of global warming and climate change. Therefore, the dream to develop yam-based industries in Nigeria cannot be achieved if production depends on rain-fed agriculture. Dry season yam production is undertaken to complement the main-season, rain-fed production to ensure year round availability of yams in the market to meet domestic demands and encourage export. However, this is equally without lots of unpredictability as moisture stress is one of the major production constraints that constitute a threat to the sustainability of dry season yam production. Attempts at this on hydromorphic soils and suitable ecology was largely successful with water yam (*Dioscorea alata*), achieving a yield of over 24 t/ha, but this resulted in low yields of white yams (*Dioscorea rotundata*), including the hybrid ones across locations in Nigeria (4.04 – 7.39 t/ha) and at Umudike (2.31 to 15.77 t/ha) (Ikeorgu et al., 2007) despite adopting or applying all cultural production practices such as weeding, staking and fertilizer application at the recommended rate and time for ware yam production. There is therefore, the need for irrigation systems and soil manipulative strategies that improve the productivity of yam to a targeted range of 25 – 30 t/ha for meeting yam demands. The objective of this study was therefore to evaluate the potential of pitting techniques for enhancing the productivity of yams grown under different irrigation intervals and methods.

MATERIALS AND METHODS

The study was carried out during the dry season of December – April 2012 and 2013 at the irrigation farm of the NRCRI, Umudike (Lat. 05 ^{o} 29 ^{I} N and Long. 07^{o} 32 ^{I} E at an elevation of 122 m asl), a rainforest agro ecology of Southeastern Nigeria (SEN). White yam (cv Nwagba) seed of sett size of 200 $\pm$ 50 g was planted on 14th November, 2012 on a sandy clay loam at the experimental site that had previously been uniformly watered to field capacity on 12th November, 2012. The soil was a Typic Paleudult (USDA Soil Taxanomy) and exhibited, a very strongly acidic reaction, low in total N and exchangeable K, but high in organic matter content and available phosphorus (P) (data not shown). The experiment was laid out as a split - split plot in a randomised complete block design (RCBD) with three replications. The treatments comprised two irrigation methods (M_1, sprinkler and M_2, furrow), two irrigation intervals (I_1, 3 – 4 and I_2, 7-day) and three planting pit depths (D_1, 20; D_2, 40 cm and D_3, 60 cm) as main, sub and sub – sub plots, respectively. The field was mechanically slashed, ploughed, harrowed and manually detrashed and demarcated into 4m x 4m experimental plots. Planting pits were dug on the crests of the ridges at 1 m spacing and covered before planting the yams. Subsequent scheduled irrigation of the trial plots were conducted between 19th November, 2012 and 6th May, 2013, before allowing the crops to grow to full maturity under rain-fed scenario. Both irrigation methods were scheduled on the irrigation interval based on accumulated evapotranspiration replacement approach using the Modified Pennman equation at the NRCRI, AgroMet weather station. The sprinkler systems were located at the border rows between main plots and the trial plots were irrigated with a semi portable rotating head sprinklers with nozzles spaced at 12 m x 12 m. The yam tubers were harvested on 15th July, 2013 and data were collected on tuber yields and some tuber morphology (tuber length and diameter). Analysis of variance was used to assess treatment effects and means were compared using Fisher's Least Significant Difference (LSD) at 5 % probability level using GENSTAT (2003).

RESULTS AND DISCUSSION

Tuber morphology

Methods of irrigation, irrigation intervals and planting pit depths applied alone, produced significant effects on tuber length and tuber diameter except tuber length under irrigation methods (Table 1). Sprinkler irrigation (M_1) produced about 6 % wider tuber diameter than furrow (M_2) (8.498 cm) and though tuber length obtained in M_1 (29.53 cm) was not significantly (P> 0.05) different from that in M_2 (29.03 cm), it appeared to be slightly higher. The better morphological performance of the yam tubers under sprinkler irrigation could be due to a more precise control of water than furrow that allowed for more accurate management of crop – root zone soil moisture as reported by Feibert et al. (1998). Also, irrigating the yams at 7-day intervals (I_2) gave about 5 and 9 % significantly (P < 0.05 and 0.009) greater tuber length and diameter than irrigating at a more frequent 3 – day intervals (I_2) (28.72 and 8.376 cm, respectively). Similarly, top sol pit depths at 20 cm (D_1) and sub-soil depth at 60 cm (D_3), with non-significant tuber length and diameter differences between them produced about 3 and 4 % and 3 % significantly (P<0.01) greater tuber length and diameter respectively than those at sub-soil depth of 40 cm (D_2). Although D_1 and D_3 exhibited non significant differences among themselves, tuber length (29.69 cm) and diameter (8.873 cm) in D_1 were slightly higher than those (29.61 cm and 8.796 cm, respectively) in D_3. This observation could probably be due to better moisture availability from the high organic matter content (3.1 %) of the top soil (data not shown). Overall, the significant (P < 0.05) tuber length and tuber diameter responses to the independent treatments for the environmental conditions encountered could be due to differential moisture availability that existed in the irrigation intervals and pit depths. On the other hand, application of M, I and D in different combinations (that is, interaction effects of irrigation method x irrigation interval and pit depths) brought significant variation in tuber length and tuber diameter of the yams (Table 1). The highest tuber length (31.81 cm) and diameter (10.703 cm) were obtained in plots that received $M_1I_2D_2$ which was similar (P > 0.05) to those in $M_1I_2D_1$ only in terms of tuber length (31.57 cm). This suggests that sprinkler irrigation at a less frequent 7 – day interval and sub-soil depth of 40 cm produced the highest tuber morphology.

Tuber Yield

There were no significant main effects of the treatments (irrigation methods, irrigation intervals and planting pit depths) on the economic yields of the yam crop. However, interaction between the treatments (M x I x D) showed significant effect on the yam yield (Table 1). Sprinkler irrigation at a more frequent 3 – 4 day intervals and pit depth of 40 cm ($M_1I_1D_2$), which was similar to those (30.476 t/ha) from $M_1I_2D_2$ that maximised tuber length and diameter responses, including those under furrow irrigation at a less frequent 7-day irrigation intervals and pit depth of 20 cm ($M_2I_2D_1$) (30.9 t/ha), gave the highest yam tuber yield (31.53 t/ha) which significantly (P < 0.01) out yielded those from plots that received sprinkler irrigation at 3 – day irrigation intervals and 60 cm pit depth ($M_1I_1D_3$) and some others including those that received furrow irrigation at a less frequent irrigation intervals of 7 days and pit depth of 20 cm ($M_2I_2D_1$) by about 12 – 27 %. The increase in yield might be due to the higher availability of moisture under sprinkler irrigation at a more frequent irrigation interval than furrow irrigation. Pawal et al. (2002) and Sharma et al (2012) also reported similarly for potato and are consistent with the findings by Vanangamudi, et al. (1990) who showed grain yield of finger millet to have been increased by more frequent irrigation intervals.

CONCLUSION

The study found out that the yield range of yam obtained under this production system (24.73 – 31.54 t/ha, mean 28.5 t/ha) was 457 – 230 % higher than that obtained in an earlier study at the same location under hydromorphic ecology without irrigation (4.44 – 15.77 t/ha) as well as increased the average yield of yam in Nigeria (13.9 t/ha) by 105 %. Furthermore, tuber length and diameter were 2 and 6 % higher under sprinkler than furrow irrigation just as these parameters were higher at pit depths of 20 and 60 cm than at 40 cm. Also, irrigating the yams at a more frequent 3 – 4 day intervals under sprinkler irrigation and 40 cm pit depth ($M_1I_1D_2$) maximised tuber yield responses (31.54 t/ha) with similar tuber yields to those produced under same irrigation method and depth but at a less frequent 7-day intervals ($M_1I_2D_2$) which gave the highest tuber morphological characteristics. These results suggest that a farmer could enhance his yam yield and achieve the target set for meeting both domestic and export needs of yam in Nigeria by applying either $M_1I_1D_2$ or $M_1I_2D_2$ depending on his economic condition.

ABSTRACT
The causal agent of the seed rot disease of cowpea was investigated. The isolates were tested for its ability to initiate disease symptom on a relatively healthy uninfected cowpea seed. The inoculated cowpea seed were incubated at room temperature (27 – 30^{0}C) over a period of 7 – 8 days and examined daily for rot symptoms. The fungus (Sclerotium rofsii) was able to reproduce. The result shows that Sclerotium rofsii is the causal organisms of the seed rot of cowpea. The use of some plant extracts of Alchornea cordifolia and Curcuma longa to control the growth and development of the disease incitants was conducted in vitro. One disc (3mm) of the 10-day old culture of the test pathogens was transferred aseptically to the centre of the solidified PDA-Extract medium in the Petri dishes which had previously been marked underneath with 2 perpendicular lines through the centre. The Petri dishes were then incubated at 27ºC for 7 days. The radial growth of the host pathogen was measured with a meter rule along the perpendicular lines after 7 days of incubation. This experiment was laid out in a complete randomized design (CRD) made up of 4 treatments and 3 replicates. The result revealed that the crude extracts of the test plants significantly inhibited the initiation, development and spread of the fungus in cowpea. The 100% concentration of the Curcuma longa reduced the incidence of Sclerotium rofsii induced seed rot disease in the test cowpea with 83% and Alchornea cordifolia recorded 53%. Comparative to the fungicide, *there was no significant difference between benomyl (benzamidazole) 90% and 83% concentration of the extracts of Curcuma longa. The toxicity profile like in the previous in vitro assay was Curcuma longa >A. cordifolia.*
Key words: Seed rot, Cowpea and Phytochemicals

INTRODUCTION
Cowpea (*Vigna unguiculata* (L.) Walp.) commonly known as southern pea, black-eye pea, crowder pea, blackgram etc. belongs to the family Fabaceae. It is an annual legume, originated in Africa with South Africa or West Africa as its centers of speciation (SADAFF, 2009; Davis *et al.*, 2012). Its cultivation dates back to about 6 thousand years; in close association with sorghum and millet cereal farming of the West African sub-region. As a crop cowpea is widely grown in the savannas of Africa, Asia, USA and the Americas (Davis *et al.* 2012).
As a food crop, cowpea is reported as the second most important grain legume in Africa after common bean (*Phaseolus vulgaris*); and ranked among the top 5 pulse crops in the world. The crop's seeds, pods and leaves can be consumed as processed grains and vegetables (Awurum, 2000; SADAFF, 2009). One hundred grams (100 g) of cowpea seeds is reported to contain 343 KJ of metabolizable energy, carbohydrate, 59.6 g, fat, 2.1 g, protein, 23.9 g, calcium, 85.0 g, phosphorus, 438 mg, iron 9.9 mg, potassium, 1375 mg, vitamins A, 33.0 IU, C, 1.5IU, B_2, 0.2 mg, B_6, 0.4 mg, and ash 3.4 g (Infonet-biovision, 2014). Cowpea is a rich source of food for livestock and also plays important roles in erosion control and soil fertility restoration in farming systems of tropical regions through symbiotic fixation of 240kgN/ha per year (SADAFF, 2009). However, the production of this crop has been induced by heavy biotic pressures of pathogenic organisms and other health challenges (Enyiukwu *et al.*, 2014). Therefore, the objectives of the study is to isolate and identify the rot causing organisms of cowpea and to evaluate the fungitoxic effects of phytochemicals of *A. cordifolia* and *Curcuma longa* on the control of seed rot diseases of cowpea.

MATERIALS AND METHODS
The experiment was conducted at the National root crops research Institute, Umudike and College of Crop and Soil Science, Michael Okpara University of Agriculture, Umudike, Abia State Nigeria. Relatively disease – free cowpea were collected from the Michael Okpara University of Agriculture Umudike. The leave of *Alchornea cordifolia* were sourced locally and the *Curcuma longa* rhizome were collected from Minor Root Crop Programme in National Root Crop Research Institute Umudike. The organism isolate used was obtained from infected cowpea plants in the research farm of Michael Okpara University of Agriculture, Umudike. The infected cowpea seed were cut into 5mm segments, and were surface disinfected in 0.5% sodium hypochloride solution for 5 minutes and rinsed in three changes of sterile distilled water. The placed segment in PDA medium was incubated at 28^{0}C at 12 hours darkness and light for 7 days. Thirty grams (30g) of each of the ground plant extracts were dissolved in 100ml of sterile distilled water in a beaker and allowed to stand for 24hrs after which was then strained through the 4 folds of sterile cheese cloth into a beaker to obtain filtrate of 30% concentration of aqueous extract

suspension. The cultures were sub-cultured to obtain pure culture of the isolates and were tested for its ability to initiate disease symptom on a relatively healthy uninfected cowpea and the isolate were considered as pathogen.

RESULT AND DISCUSSION

Results shows that *Sclerotium rolfsii* were isolated from the seed rots of cowpea. The inoculation of the pathogen organism affected tissues leading to appearance of rot symptoms on seed of the cowpea. Two plant materials, a synthetic (chemical) and sterile water were evaluated for the inhibition of mycelial growth and spore germination of the rot pathogen (*Sclerotium rolfsii*) . The results indicated that the organisms were most sensitive to *C. longa,* while *A. cordifolia* was least fungitoxic. The extracts of the test plants showed significant difference (P<0.05) in the inhibition of the spore germination of the pathogens when compared with the control experiment. Extracts of *C. longa* recorded the best mean percentage inhibition of spore germination of the pathogen (83%) which was significantly different (P < 0.05) from extracts *A. cordifolia* (53%). The fungicide gave appreciable reduction in spore germination of the test pathogens with mean percentage of 90%. The benomyl was significantly different (p ≤ 0.05) from the plant extracts, but compared well with extracts of *C. longa.* The control (sterile water) had no effect on the spore germination of the test fungi.

Table 1: Effect of the plant extracts on the spore germination of the cowpea seed rot pathogens

National Root Crops Research Institute, Umudike PMB 7006, Umuahia, Abia State
nwankwomaxwell@yahoo.com

ABSTRACT
The experiment was conducted at the Western experimental field of National Root Crops Research Institute, Umudike Umuahia Abia State in 2014 and 2015 respectively the objectives to was to select high tuber yielding cultivars as parents, to define the accessions into sexes, to select parents that flowers profusely, to determine the intensity of flowering among the cultivars, and to select cultivars with high flowering intensity for inclusion into the germplasm for breeding purposes. Twelve water yam cultivars were used. Each cultivar was planted in a 4 by 5m plot at a planting distant of 100cm between ridges and 100cm between plants and the plots were replicated four times. Data collected were on: tuber yield, flowering intensity, number of male and female plants that flowers, Number of leaf axils/nodes per plant, Number of male (staminate spike) flowers on the leaf-axils/nodes per plant, Number of female (pistillate spike) flowers per plant and Sex of the yam plant. The result indicated that Cultivars with total number of tubers less than the grand mean and total fresh tuber weight lower than the grand mean of 26.25 and 22.82t/ha respectively were not selected as parents. and that cultivars with profuse flowering having the score 4 were selected as male parents while Sakata with 38 number of tuber per plot and 19.5t/ha fresh weight of tubers were selected as the only female water yam plant. These cultivars would be included in the germplasm for D. alata improvement programme.
Keywords: Parents, tuber yield, flowering intensity, germplasm and hybridization

INTRODUCTION
Yam in general is one of the major carbohydrate staple foods for the people of Nigeria and to a large extent for people in West Africa. There are six major yam species cultivated in West Africa namely: *D. rotundata, D. alata, D. dumetorum, D. cayenensis, D.esculenta* and *D. bulbifera* (Onwueme and Sinha, 1999). *Dioscorea alata* is one of the major yam species in the family *Dioscoreaceae* (Okoli,1986). *D. alata* is very important in terms of food quality and when compared with other yam species is fraught with many problems which range from low genetic improvement, poor food quality in terms of dry matter content, biotic and abiotic factors which make it prone to pests and diseases (Onwueme and Sinha, 1999). One of the major problems is low dry matter content, and attack by diseases such as anthracnose, Yam mosaic diseases and pests such as yam beetles. Some of these problems could be solved by breeding, however, Egesi (1998) noted that poor flowering and seed setting limits the introduction of valuable genes from some germplasm with desirable attributes. The introduction of desirable genes will be possible with a good choice of parents. Parents with desirable attributes could be selected through screening of parental stock (Okoli, 1986). Therefore the objectives of this work was to: to select high tuber yielding cultivars as parents, to define the accessions into sexes, to select parents that flowers profusely, to determine the intensity of flowering among the cultivars, and to select cultivars with high flowering intensity for inclusion into the germplasm for breeding purposes.

MATERIALS AND METHODS
The experiment was conducted at the Western experimental field of National Root Crops Research Institute, Umudike Umuahia Abia State in 2014 and 2015 respectively.. The average weight of each sett was 300g. The land was prepared with tractor. The soil at the site of evaluation was well drained deep clay sandy loam and a mean annual rainfall of 1500mm and mean sunshine hours of 5.5 per day. Twelve water yam cultivars were used Each cultivar was planted in a 4 by 5m plot at a planting distant of 100cm between ridges and 100cm between plants and the plots were replicated four times. Farming operations such as weeding and staking were carried out. However, no fertilizer was applied to avoid the crop growing very vegetative which will delay flowering and fruit set.

Data collection: Data collected were on: tuber yield, flowering intensity, number of male and female plants that flowers, Number of leaf axils/nodes per plant, Number of male (staminate spike) flowers on the leaf-axils/nodes per plant, Number of female (pistillate spike) flowers per plant and Sex of the yam plant, .

Data analysis: The number of tubers per plant were counted and recorded at harvest, All tubers per plant were weighed after harvest and Analysis of variance was used to determine the variability in fresh tuber yield and mean tuber yield were separated using standard error of means. Fresh weight was measured in tonnes per hectare. Number of flowered male and female yam plants was calculated in percentages, Sex score, using scoring procedure outlined by Orkwor et al (2000) were as follow:1 = absence of flower, 2 = presence of either male or female flower, 3 = male yam plant, 4 = female yam plant, 5 = monoecious, male flower > female flower , 6 = monoecious, female flower > male flower.

Flowering intensity were determined using the formula derived by (Orkwor, et al 2000). Flowering intensity for Male Flowers

$$\frac{\text{Total number of staminate spike flowers}}{\text{Total number of nodes}} \times \frac{100}{1}$$

(ii) Female flowering intensity;

$$\frac{\text{Total number of pistillate spike flowers}}{\text{Total number of nodes}} \times \frac{100}{1}$$

Scoring for flowering intensity was carried out after calculation using the percentage for the scoring as follows: 0 =(0.0%) = No Flower, 1 = (1 – 25%) = low flowering intensity (sparse), 2 = (26 – 50%) = Medium flowering intensity (moderate), 3 = (51 – 75%) = High flowering intensity, 4 = (76 – 100%) = Profuse flowering

RESULTS AND DISCUSSION

The result on number of tubers and fresh tuber weight is presented on Table 1. There was high significant (P<0.01) variation in the total number of tubers produced by the water yam plants. Number of tubers varied from 20.0 (TDa02/00019) to as high as 55.0 (TDa/00194) per plot. Also this variety had the highest number of ware tubers per plot (Table 1). Four of the varieties evaluated produced less number of tubers per plot even lower than the general mean of 26.25 numbers of tubers per plot. According to Nwankwo (2012), number of tubers per plant per plot is a function of yield and the first thing a farmer considers while assessing for a high yielding varieties. Varieties with high number of tubers per plant per plot should be considered for selection while selecting for parents for inclusion in the hybridization programme of *D. alata*. Also considered is the tuber weight. Significant (P<0.05) variability existed in the total fresh tuber weight produced by the water yam varieties. The total weight of tubers varied from 17.0t/ha (TDa02/00019) to as high as 42.3t/ha (TDa00/194) with a general mean of 22.82t/ha (Table 1). However, 7 out of 12 of the water yam cultivars evaluated produced total fresh weight of tubers lower than the general mean of 22.82t/ha and may not be considered as good candidate for selection as parents for inclusion in the hybridization programme.

Flowering intensity, Flowering pattern and Sex of the water yam plant: The result of the Flowering intensity, Flowering pattern and Sex of the water yam plant (*D. alata*) are presented in Table 2. The result indicated that all the water yam plants with the score 2 under the sex of yam plant flowered as either male or female yam plant. One variety (Sakata) with the score 4 flowered as female water yam plant which represent 8.3% while 91.7% with the score 3 were male water yam plants (Table 2). The following water yam plants flowered profusely with the score 4 under flowering intensity: TDa/96/01168, TDa00060, TDa1166, TDa02/00019 and TDa/00194, and were selected for inclusion as parents in the hybridization programme for *D. alata*. The female water yam plant (Sakata) had high flowering intensity with the score 3 and should be selected as female flowering water yam plant for inclusion in the hybridization programme.

The number of nodes and the number of male and female flowers arising from the axil are used to calculate the flowering intensity of the male and female yam plants (Orkwor et al., 2000). Yam plants that flowered profusely were given the score 4 which indicated that the flower production was much between 76 -100%, while those that were scored zero. produced no flowers. Low or sparse flowering were given the score 1 (that is between 1 - 25%). Five of the male yam plants flowered profusely with the score of 4 while the only female yam plant (Sakata) scored 3 which indicated flower production of between 51 - 75% and was regarded as high flowering intensity. Therefore male and female water yam plants that flowered highly intensive (score 3) and profusely (score 4) were selected as parents for hybridization programme (Table 2).

CONCLUSION

Cultivars with total number of tubers less than the grand mean and total fresh tuber weight lower than the grand mean of 26.25 and 22.82t/ha respectively were not selected as parents. Based on the result obtained, the following male water yam cultivars TDa02/000194 with 55 number of tubers per plot and 42.3t/ha fresh weight of tubers, TDa96/01168 with 41 number of tubers per plot and 28.2t/ha fresh weight of tubers, and Abanaoyibo with 31 number of tubers per plot and 23.1t/ha of fresh weight and profuse in flowering having the score 4 were selected as male parents while Sakata with 38 number of tuber per plot and 19.5t/ha fresh weight of tubers were selected as the only female water yam plant. These cultivars would be included in the germplasm for *D. alata* improvement programme.

Email: eddynwaogu2012@yahoo.com

ABSTRACT
The capacity of biochar, applied alone and in combinations with varying levels of NPK fertilizer, to improve the productivity of low fertility soils of Southern Guinea Savanna using ginger as a test crop, was evaluated in a field study conducted in 2015 at the research farm of the National Root Crops Research Institute, Nyanya Sub-Station, Abuja. Treatments comprised five biochar rates (0, 1, 2, 3, and 4 t/ha) factorially combined with four rates of NPK fertilizer (0, 75, 150, 300 and 450 kg/ha). Soil amendments with both bio-char and NPK fertilizer significantly improved ginger plant height and rhizome yield responses relative to absolute control. Both ginger plant height and fresh rhizome yield increased significantly with increasing rate of biochar application and NPK fertilizer rate. Optimum ginger plant height was recorded on plots treated with 3 t/ha biochar beyond which there was a gradual decline in height. Highest yield response was achieved using 300 kg/ha NPK fertilizer rate.
Keywords:Fertilizer, Bio-char, Performance and Ginger

INTRODUCTION
Maintaining an appropriate level of soil organic matter and biological cycling of nutrients is crucial to the success of any soil management program in the humid tropics. Cover crops, mulches, compost, or manure additions have been used successfully, supplying nutrients to crops, supporting rapid nutrient cycling through microbial biomass, and helping to retain applied mineral fertilizers better. The benefits of such amendments are, however, often short-lived, especially in the tropics, since decomposition rates are high (Lehmann and Rondon 2006) and the added organic matter is usually mineralized to CO2 within only a few cropping seasons. Organic amendments therefore have to be applied each year to sustain soil productivity. Management of black carbon (C), also referred to as bio-char, may overcome some of the limitations in organic manure use in crop production and provide an additional soil management option. Bio-char is a solid material obtained from the thermochemical conversion of biomass in an oxygen-limited environment. The objectives of this study are (i) to assess the effects of bio-char and NPK fertilizer amendments on the growth and yield responses of ginger in the Southern Guinea Savanna ecology of Nigeria; (ii) to determine the optimum rate of bio-char applied alone or in combinations with inorganic NPK fertilizer for sustainable ginger yield in the Savanna.

MATERIALS AND METHODS
The study was conducted in 2015 at the research farm of the National Root Crops Research Institute, Nyanya Sub-Station, Abuja, Nigeria (Latitude 09º 04' N; Longitude 07º 37' E) with an altitude of 426 m above sea level. The soil of the experimental site was a kaolinitic hyperthermic oxic paleudult (USDA) with loamy sand topsoil texture. Selected physico-chemical properties of the soil used for the study before imposition of treatments are shown in Table 1. The site used for the experiment had earlier been put to continuous cultivation for eight years and recently cropped for three years with maize and maize/cassava crop mixture before the trial was initiated. Pre-cropping analysis of some physical and chemical properties of the soil was done using standard methods as reported by International Soil Reference and Information Centre (2002). Treatments comprised five levels of Bio-char (0, 1, 2, 3, 4 t/ha) in factorial combinations with four inorganic NPK fertilizer rates (0, 150, 300, 450 kg/ha). The Bio-char used for the study was made from thermo-conversion of Avocado tree under oxygen-limited condition. Both the bio-char and the NPK fertilizer treatments were applied into the soil by manual incorporation during land preparation using a spade. Land preparation (slashing, ploughing and harrowing) was done by use of a tractor. The land was demarcated into plots measuring 2 m x 2 m. Inter plot distance was kept at 0.5 m. The treatments were laid out on the demarcated plots in a randomized complete block design with 3 replications. The plots were planted with 20 g Yellow ginger (UG 1) rhizome setts at a population of 250,000 plants/ha. The plots were kept weed-free throughout the duration of the study. Weeding was done by rouging. Data on ginger plant height and fresh rhizome yield were collected and analyzed statistically using analysis of Variance (ANOVA) according to the procedures for Randomized Complete Block Design as reported by Gomez and Gomez (1984).

RESULTS AND DISCUSSION
Table 1 shows some selected properties of both the bio-char and the soils of the site used for the study. The soil of the experimental site was of low fertility classification as illustrated by its low values of Total N, changeable K, Ca, Mg and medium level of organic Carbon. Soil amendments with both bio-char and NPK fertilizer significantly influenced ginger plant height (Table 2). Ginger plant height increased increasingly with increasing

rate of biochar application up to 3 t/ha beyond which there was a gradual decline in height. A similar trend was observed with respect to rhizome yield (Table 3). With increasing rates of biochar application, rhizome yield response of ginger was positively and progressively linear until some maximum was reached at 3 t/ha biochar rate, above which yield response tended to be negative. Averaged over the four NPK fertilizer rates evaluated, the highest mean plant height response of 82.3 cm and highest mean rhizome yield of 18.8 t/ha were recorded with the application of 300 kg/ha NPK fertilizer rate. The results of this study in Table 3 are implicating the fact that addition of nutrients using inorganic fertilizers is essential for high ginger productivity and that it also increases the positive response of the bio-char amendment in the low fertility soils of Southern Guinea Savanna ecology. This assertion is corroborated by the observed significant interaction effect between biochar and NPK fertilizer with respect to ginger plant height and rhizome yield responses (Tables 2 and 3). Conventionally in ginger production, inorganic NPK fertilizer is usually applied during ginger planting. Between the time fertilizer is applied and the time it is taken up by ginger, fertilizer nutrients can be leached out of the soil by excess rainfall, consumed by weeds, or metabolized by microbial activity in the soil. But when biochar and NPK fertilizer are complementarily applied, biochar helps conserve fertilizer nutrients by storing them within its matrix and making the nutrients available when they are needed by the ginger crop plant. This happens because of a property in biochar, known as enhanced cation exchange capacity (CEC) as a consequence of the large surface area of biochar particles. CEC is a measure of a biochar's capacity to retain positive ions, such as ammonium and potassium cations, in an exchangeable form that is available to plants. The lower ginger plant height response recorded at biochar rate > 3 t/ha may be ascribed to nitrogen limitation. Nitrogen availability decreases through immobilization by microbial biomass at high C:N ratios occasioned by higher biochar application rates (Lehmann et al., 2003b). This observation is in agreement with the report of Glaser et al, (2002) who found higher crop yield responses at lower biochar application rates. However, other growth-limiting factors may be responsible as well.

CONCLUSION

Combined application of biochar and NPK fertilizer improves the relative efficiencies of the two amendment materials to improve ginger growth and yield relative to when they are sole-applied. Optimum growth and yield responses of ginger are achieved using 3 t/ha biochar rate on a soil amended with 300 kg/ha of NPK fertilizer.

EFFECT OF NITROGEN FERTILIZATION ON THE VARIETAL YIELD RESPONSE OF YAM UNDER MINISETT TECHNOLOGY IN THE GUINEA SAVANNA ECOLOGY OF NIGERIA

E.N. Nwaogu

National Root Crops Research Institute, Nyanya Sub-Station Abuja, Nigeria.
Email: eddynwaogu2012@yahoo.com

ABSTRACT
Relative effects of nitrogen fertilization on the yield response of three yam varieties mostly preferred by farmers in the Southern Guinea Savanna ecology of Nigeria were assessed under yam minisett technology. Treatments comprised three yam varieties (Meccakusa, Pepa and Yangode) in factorial combinations with five rates of Nitrogen fertilizer in form of Urea (0, 15, 30, 45 and 60 kg N/ha) laid on a Randomized Complete Block Design with three replications. Results showed that contrary to farmers' belief, N fertilization had significant influence on the tuber yield of yam as it resulted to a progressive increase in both tuber number and tuber yields relative to when no N fertilizer was applied. Application of 45 kg N/ha maximized the number and yield of seed yam tuber production. Across all N fertilizer rates studied, Meccakusa variety proved most superior in terms of yield increase due to N fertilization with 31 and 106 % higher yields over Yangode and Pepa respectively.
Keywords: Fertilization, Yield, minisett and Yam

INTRODUCTION
Yams, particularly white yam (*Dioscorea rotundata spp.*) are a valued starchy staple for many communities in Nigeria. Yam plays important roles in the livelihood of people especially those from the yam producing belts of Nigeria. Apart from being the major source of carbohydrate food intake, its role in the socio-cultural life of many households in Nigeria is very remarkable. It is used in celebrating important cultural festivals, chieftaincy title taking and payment of bride price. Yam is eaten boiled, roasted, fried or pounded and eaten as food. Yam can also be processed into flour and used in making different food forms. Nigeria is the world's leading producer of yams and Ghana is Africa's leading exporter. Despite the importance of yam, research and support for yam production in Nigeria has been limited and current average yields of 13.9 t/ha represent a fraction of the yield potential of 20 t/ha (Onyenweaku, 2015). Major constraints to yam production in Nigeria are low yield due to poor soil fertility accentuated by scarcity of reliable planting material. The minisett technique introduced in the recent past by NRCRI in collaboration with IITA for rapidly multiplying seed yams has so far not been widely adopted by farmers because the technology did not provide for proper understanding of the specific effects of fertilizer elements in the yam production chain. As a result of this information gap, smallholder yam farmers hold a strong belief that inorganic fertilizer application in seed yam production, especially N-based fertilizers, decreases yam tuber size and causes easy tuber rot under storage. This belief among smallholder yam farmers has not been validated scientifically. The objective of this study therefore, is to evaluate the impact of nitrogen fertilization on the tuber yield response of different yam varieties in the Southern Guinea Savanna ecology of Nigeria.

MATERIALS AND METHODS
The study was conducted in 2015 at Adunu Village in Paiko Local Government Area of Niger State, Nigeria. The soil used for the study was of loamy sand texture with total N, available P, exchangeable K, Ca and Mg contents of 0.18 %, 10.0 mg/kg, 0.22, 2.3 and 1.6 cmol/kg respectively. The organic C content of the soil was 2.8 % with a slightly acidic pH value of 6.4. Treatments comprised three varieties of yam mostly preferred by farmers in the Southern Guinea Savanna (Meccakusa, Pepa and Yangode) in factorial combinations with five rates of Nitrogen fertilizer in form of Urea (0, 15, 30, 45 and 60 kg N/ha equivalent to 0, 33.3, 66.6, 99.9, and 133.2 kg/ha of urea). Basal applications of P (20 kg P /ha equivalent to 47 kg P_2O_5/ha) and basal K (50 kg K/ha equivalent to 60 kg K_2O) were made to all the plots excepting the absolute control treatment. The treatments were laid out on 3m x 5 m ridged plots prepared using a tractor. Both N fertilizer treatments and the basal P and K fertilizers were applied 2 months after planting (MAP) of yam. The plots were kept weed free throughout the duration of the study. Weeding was done manually using a weeding hoe. All other important agronomic practices for yam production were carried out. Data on weight, number and grade of seed yam tubers produced were collected and analyzed using analysis of Variance according to the procedures outlined for randomized complete block design by Gomez and Gomez (1984). Treatment means with significant effects were separated using the Least Significant Difference method at 5 % level of probability ($P \geq 0.05$).

RESULTS AND DISCUSSION
The results in Table 1 show that N fertilization has significant influence on the tuber yield of yam. There was an observed progressive increase in tuber yields with increase in the rate of N fertilization irrespective of yam variety.

Highest interactive tuber yield response of 12.5 t/ha given by Meccakusa was obtained with the application of 45 kg N/ha. This figure represented a 331 % yield increase over the mean tuber yield value of 2.9 t/ha obtained from the three yam varieties receiving no N fertilizer application (Table 1). Tuber yield response varied among the three yam varieties evaluated. Across all N fertilizer rates studied, Meccakusa variety proved most superior over Yangode and Pepa in terms of yield with 31 and 106 % yield increases respectively. Growing yam with nitrogen fertilizer application resulted in increased number of seed yam tuber production relative to when no N fertilizer was applied (Table 2). Mean number of seed yams produced per plot increased significantly as the quantities of N fertilizer applied increased. Application of 45 kg N/ha appeared adequate for maximizing the number of yam tuber production under the conditions of this experiment. Further increases in the Quantity of N fertilizer beyond this rate did not however translate to increased number of seed yam, suggesting possible physiological imbalance in which fertilizer N did not favour seed yam production. Application of N fertilizer had a significant influence on the weight of different categories of seed yam tubers produced (Table 3). Significantly higher numbers of ware yam (yams weighing from 1 kg and above) and seed yam A (i.e. yam tubers weighing from 500 g to 999 g) was produced with the application of 45 kg N/ha while application of 65 kg N/ha favored production of higher number of seed yam B (i.e tubers weighing from 100 g to 449 g). Averaged over all N fertilizer rates evaluated, Meccakusa variety produced significantly heavier seed yam A followed by Pepa while Yangode gave heavier ware yam tubers.

CONCLUSION

Contrary to farmers' belief, N fertilization has significant influence on the tuber yield of yam as it results to a progressive increase in both tuber number and yields relative to when no N fertilizer was applied. Such increases in number and yield of seed yam tubers were more with increasing rates of application irrespective of yam variety. Under the conditions of this experiment, application of 45 kg N/ha maximized the number and yield of seed yam tuber production. Across all N fertilizer rates studied, Meccakusa variety proved most superior in terms of yield increase due to N fertilization with 31 and 106 % higher yields over Yangode and Pepa respectively.

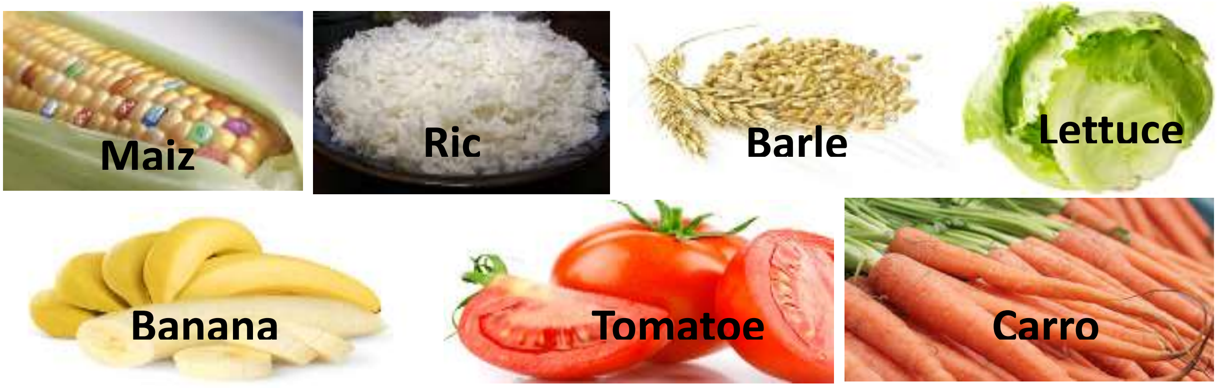
ABSTRACT
Biotechnology is offering innovative possibilities for engineering crops to produce not just food, but drugs, vaccines and enzymes. Often, crops are being engineered so that a vaccine can be delivered through the direct consumption of leaves, fruits, or other parts, without the cost and inconvenience of extracting the proteins and delivering them via pills or injections. But of concern are the possibility of accidental contamination of food or livestock feed with genetically modified crops containing edible vaccines and the potential of transgene escape and fertilization of nonpharmaceutical crops. However, a possible strategy to circumvent these problems would be to engineer proteins so that they do not become biologically active until after they are extracted and further processed in a laboratory.
Keywords: Pharmaceuticals, crops, bane.

INTRODUCTION
It is now 39 years since the concept of commercial potential of gene manipulation was conceived by Robert Swanson and Herb Boyer. Seven years later, precisely in 1983, the first transgenic plant was engineered by Rob Horsch. The two events (1976 and 1983) marked the beginning in our long scientific journey towards today's achievements in the plant and agricultural biotechnology revolution (Altman, 2003; Ubalua, 2009). One of the earliest commercial applications of gene-manipulation techniques was the production in bacteria of human proteins with therapeutic applications. Not surprisingly, the first such products were recombinant versions of proteins already used as therapeutics: human growth hormone and insulin. Prior to the advent of genetic engineering, human growth hormone was produced from pituitary glands removed from cadavers. Not only did this limit the supply of the hormone, but in some cases, it resulted in recipients contracting Creutzfeld-Jackob syndrome. By contrast, the recombinant approach resulted in unlimited supplies of safe material. Another milestone in recombinant DNA technology is in 'biopharming' which refers to the use of transgenic animals and plants to produce recombinant therapeutics. Presently, plants are being turned into factories producing not just food, but drugs, vaccines, enzymes, and antibodies. The first step in using crops to produce pharmaceutically active proteins is the synthesis or isolation of genes that code pharmaceutical proteins, followed by the transfer of those genes into the DNA of crop plants. In most cases, the crop-produced pharmaceutical protein is extracted, purified and possibly modified further before it is administered to humans or livestock. In some instances, crops are engineered so that a vaccine can be delivered through the direct consumption of leaves, fruits, or other parts, without the cost and inconvenience of extracting the proteins and delivering them via pills or injections (Sala et al., 2003). Although they may open doors to less expensive and more-ready available drugs, there is concern regarding the potential for contamination of human food and livestock feed, as well as environmental harm. The potential benefits, concerns and principles of pharmaceutical crops are hereby discussed.

Benefits of pharmaceutical crops
One of the most exciting aspects of recombinant DNA technology is that it permits the design, development, and isolation of proteins with improved operating characteristics and even completely novel proteins (Wilkinson *et al*., 1984). Plants are a useful alternative to animals for recombinant protein production because they are inexpensive to grow and scale-up from laboratory testing to commercial production is easy (Ma *et al*., 2005). Transgenic plants can potentially express any foreign gene, whether that gene is derived from bacteria, yeast, other plants or even animals. The scope for exploitation and improvement is virtually limitless and gene-manipulation techniques have therefore given the biotechnology industry a new lease of life. Some of the potential products of transgenic plants include blood thinner, hemoglobin, insulin, growth hormones, cancer treatments, and contraceptives. Products already in the pipeline include plant-produced vaccines for hepatititis-B, cholera, rabies, HIV, malaria and influenza. Lipase, a digestive enzyme used to treat patients with cystic fibrosis is currently being developed in genetically modified maize (corn) (Sala *et al*., 2003). Arthritis and other autoimmune diseases are also targets for plant-produced vaccines (Sala *et al*., 2003). Maize, bananas, tomatoes, carrots, and lettuce are major targets for edible vaccine production because these foods can be eaten raw (Fig. 1), thereby avoiding the protein denaturation that typically occurs during cooking (Sala *et al*., 2003). Moreover, plants are an attractive alternative because they could potentially produce greater yields. This is especially important for monoclonal antibodies (such as etanercept, which is used to treat rheumatoid arthritis) (Elbehri, 2005). Grain crops are usually favoured because protein yields from the large seeds of maize, rice, and barley (Fig. 1) are

typically much higher than those obtained from leaves and other vegetative parts. In addition pharmaceutical proteins can remain stable in dried grain for several years compared with the much-reduced stability of these same proteins in leaf tissue. Another major benefit of utilizing plants is the reduced risk of disease transmission. There is concern that producing drugs via mammalian cell cultures or animal milk could facilitate the movement of certain viruses to humans.



Concerns of pharmaceutical crops

The aims of biotechnology industry goes hand in hand with those of conventional breeders, but offers the possibility of importing useful genes from distant species that could not be used for breeding. The initial focus of plant biotechnology was on improving agronomic traits, i.e. the protection of crops against pests, pathogens and weeds and thus increasing yields. Herbicide generally affects processes that are unique to plants, e.g. photosynthesis or amino acid biosynthesis. Both crops and weeds share these processes and developing herbicides that are selective for weeds is very difficult. An alternative approach is to modify crop plants so that they become resistant to broad-spectrum herbicides, i.e incorporating selectivity into the plant itself rather than relying on the selectivity of the chemical. Two approaches to engineering herbicide resistance have been adopted. In the first, the target molecule in the cell either is rendered insensitive or is overproduced. In the second, a pathway that degrades or detoxifies the herbicide is introduced into the plant. For example, glyphosate is a non-selective herbicide that inhibits 5-enol-pyruvylshikimate-3-phosphate (EPSP) synthase, a key enzyme in the biosynthesis of aromatic amino acids in plants and bacteria (Table 1).

Insect pests represent one of the most serious biotic constraints to crop production. Typical insecticides are non-selective, so they kill harmless and beneficial insects as well as pests. For these reasons, transgenic plants can express toxins that are selective for particular insect species. Unlike other *Bacillus* species, *Bacillus thuringiensis* (Bt) produces crystals during sporulation, comprising one or a small number of ~130 KDA protoxins called crystal proteins. These proteins are potent and presumed to be specific. The specificity reflects interactions between the crystal proteins and receptors in the insect midgut. In susceptible species, ingested crystals dissolve in the alkaline conditions of the gut and the protoxins are activated by gut proteases. The active toxins bind to receptors on midgut epithelial cells, become inserted into the plasma membrane and form pores that lead to cell death (and eventual insect death) through osmotic lysis. Unfortunately, the toxins overtime affects both targets (corn borer) and non-target organisms like monarch butterflies, bees etc. The primary concern associated with pharmaceutical crops is the accidental contamination of food or livestock feed with edible vaccines (Elbehri, 2005, Kirk *et al*., 2005). Transgenes can escape when pollen from pharmaceutical crops drifts into and fertilizes fields of nonpharmaceutical crops. Alternatively, if seeds are left behind in the soil following harvest, "volunteer" pharmaceutical plants could establish themselves in subsequent growing seasons, possibly in mixture with nonpharmaceutical crops. Even if production is limited to non-food crops, potential risks would remain. Pollen, fine particles of leaves that are crushed during harvest, and possibly even runoff water contaminated with proteins from decomposing plants, could expose people and wildlife that live on or near pharmaceutical-producing fields to the transgenic material. Birds, insects and other wildlife can consume pharmaceutical crops, regardless of where they are grown or what species they are. One possible strategy to avoid these problems would be to engineer proteins so that they do not become biologically active until after they are extracted and further processed in a laboratory. Tissue-specific expression of pharmaceutical proteins may also reduce or eliminate certain avenues of exposure (such as the possibility of exposure via pollen inhalation), and gene deletion technologies could potentially be used to remove transgenes from certain tissues (such as pollen) to reduce the possibility of transgene spread (Keenan and Stemmer, 2002). If transgenes could be contained, regulations could be much more permissive about which traits are allowed in crop plants. On the other hand, if transgenes will inevitably escape and spread – a more cautious approach about which traits are allowed to be developed in crop plants has to be adopted.

CONCLUSION

The future of pharmaceutical crops will require thoughtful input from environmentalists/ecologists, public health experts, and medical researchers – as well as from those who genetically engineer these crops.

Table: 1: Mode of action of herbicides and method of engineering herbicide–resistant plants

Herbicide	Pathway inhibited	Target enzyme	Basis of engineering resistance to herbicide
Glyphosate	Aromatic amino acid biosynthesis	5-Enol-pyruvylshikimate-3-phosphate (EPSP) synthase	Overexpression of plant EPSP gene or introduction of bacterial glyphosate-resisitant *aro* Agene.
Sulphonylurea	Branched-chain amino acid biosynthesis	Acetolactate synthase (ALS)	Introduction of resistant *ALS* gene
Atrazine	Photosystem 11	Q_8	Introduction of mutant gene for Q_8 protein or introduction of gene for glutathione-S-transferase, which can detoxify atrazines

ABSTRACT
The field experiment was conducted in early cropping season of 2014 at the Teaching and Research Farm of Imo State University, Owerri, to evaluate the effect of priming on seedling emergence of turmeric seeds. The experiment was laid out in a randomized complete block design with seven treatments and three replicates. The treatments were seeds of turmeric soaked for 12hours in water, seeds soaked for 24hours in water, seed soaked for 48hours in water, seeds soaked for 12hours in moringa leaf extract, seeds soaked for 24hours in moringa leaf extract, seeds soaked for 48hours in moringa leaf extract and non-soaked seeds. The result revealed that priming had significant effect ($P \leq 0.05$) on number of days to 50% seedling emergence and emergence speed. Interms of seedling emergence the seeds soaked for 48hours in 100% crude MLE had the least value of 92%. The value was statistically similar to the values obtained from the seeds soaked for 24hours in 100% crude MLE (96%) and that of non-soaked seeds (93%). All other treatment gave 100% seedling emergence. The non-soaked seed gave the least emergence speed (60% /day) and the highest number to 50% seedling emergence (47 days).
Key words: Turmeric, priming, seedling emergence, water and moringa leaf extract.

INTRODUCTION

Turmeric *(Curcuma longa L.)* is a rhizomatous herbaceous perennial plant of the ginger family *Zingiberacea* (Chan *et al.*, 2009). It is a low growing tropical herbaceous plant, which forms many long thin rhizomes. It is best known as one of the ingredients used to make curry. Turmeric is rich in the yellow food pigment called *Curcuminoid* (6%) and essential oils which accounted for 5% (Nunes, 1989). In Indian systems of medicine, turmeric is used to some extent as stomach tonic and blood purifier (http//myfolia.com). It is a relief for rheumatoid arthritis (http://myfolia.com). Poor seedling emergence and establishment is one of the major abiotic constraint encountered by resource poor farmers (Muhammad *et al.*, 2013). The decline rate of seedling emergence was found to be obvious, varying with crop species and cultivars. Improvement in seedling emergence is an active area of research and efforts are being made to improve seed germination in various economically important crops (Suleman *et al.*, 2011). Seed priming is an effective tool to minimized time between germination and emergence which resulted in synchronized emergence (Harris *et al.*, 2002). Bradford (1986), stated that seed priming is a pregermination treatment in which seeds are held at low water potential to allow imbibitions by preventing radical extension. Different techniques have been carried out for seed priming, like hydropriming, matripriming, osmopriming, hardening, osmohardening and hormonal priming (Basra *et al.*, 2005). This is to improve the germination rate, field emergence, seedling vigour, stand establishment and economic yields in many crops (Farooq *et al.*, 2008). Seed priming enhances speed and uniformity of germination (Khalil *et al.*, 2010), extend many biochemical modification which are basically needed for starting germination process via dormancy breaking, hydrolysis, enzyme creation and seed imbibitions (Asgedon and Becker, 2001). The general purpose of seed priming is to hydrate partially the seed to a point where germination processes are initiated but not completed. Hydropriming is a sample low cost method of seed priming that requires no sophisticated equipment and gives results which are easy to see (Foti *et al.*, 2008). Hydropriming encounters available soil moisture dryness to endow plants with greater tolerance to subsequent stress exposure (Patanea *et al.*, 2009). In hydropriming, seeds are soaked in water for usually overnight, followed by drying. Due to imbibitions, seeds take short time to germinate (Hartman *et al.*, 2002). However, non-primed seeds take longer time with relation to soil moisture for imbibitions. Therefore, it is suggested that seed germination might be increased by hydropriming technique (Hartman *et al.*, 2002). Among the seed priming treatments, hydropriming is in the control of farmer (without chemicals) and could be employed to accelerate germination, seedling growth and yield of many yield crops under normal and water stress conditions (Muhammad *et al.*, 2013). Hydropriming practically ensures rapid and uniform germination accompanied with low abnormal seedling percentage (Shivankar *et al.*, 2003). *Moringa oleifera* leaf extract has the potential to promote plant growth hence; it is used as a natural plant growth enhancer (Basra *et al.*, 2011). The leaves of *M. oleifera* are rich source of protein, zeatin, ascorbate, phenolic compounds, calcium, vitamins and potassium (Basra *et al.*, 2011). *Moringa oleifera* extract as a plant growth promoter influences plant growth in several ways and also promotes defense mechanism against abiotic stresses by harmonizing the plant growth regulators (PGRs) endogenous concentration (Wasif *et al.*, 2012). *Moringa* is increasingly becoming popular among communities in Zambia for uses such as a food supplement, as a weaning food in children and for medicinal purposes (Phiri and Mbewe 2010). Stakeholders such as the health sector are promoting *Moringa* as a food supplement while others such as the water sector are promoting *moringa* for water treatment (Phiri and Mbewe, 2010). Nigeria has favourable climate condition for turmeric production. However, there is a dearth of available information on its agronomic and processing requirements to harness its production. The problem associated with the production of this crop is late maturity (i.e. it matures within 7-9 months) which can be attributed to late sprouting. There is need to use low cost techniques such as hydropriming and *moringa* leaf extract to enhance early sprouting which will shorten the maturity period and hence enhances seedling development. The objective of the study was therefore to ascertain the effect of priming on seedling emergence of turmeric.

MATERIALS AND METHODS

Location

The experiment was carried out in the planting season of July-October of 2015 at the Teaching and Research Farm of the Faculty of Agriculture and Veterinary Medicine, Imo State University, Owerri. The location lies between the latitude of $5^0$10'N and $6^0$0'N and longitude $6^0$35'E or $7^0$28'E within the South-East rainforest agricultural zone of Nigeria. The environmental conditions are characterized by a temperature above 27^0C, average annual rainfall of 2500mm and relative humidity of 85% during the rainy seasons (NIMET, 2010).

Experimental Material/Land Preparation

Moringa oleifera leaves were collected from Ikwerre, Rivers State. Turmeric rhizomes were collected from Imo State University, Farm.

Land Preparation /Experimental Design

The experimental field was cleared and all debris was completely removed from the site. The experimental design used was Randomized Complete Block Design with three replications and six treatments and control. The area of the experimental field was 10m x 5m ($50m^2$) which was partitioned into plots each separated by 1m space and a total of twenty-one (21) plots were made.

Preparation of Extract /Treatment Application

The *moringa oleifera* leaves were air-dried and grounded mechanically with Electronic blending machine after which 10g of the grounded *moringa* leaves was added in 50cl of water and was allowed to stay overnight after which the mixture was sieved. The turmeric rhizomes were soaked in water at three(3) different time durations which were 12hours -24hours and 48hours. Turmeric rhizomes were also soaked in 100% crude MLE at three(3) different levels of time duration which were 12hours, 24hours and 48hours and non-soaked turmeric. The soaking of turmeric rhizomes in *moringa leaf* extract and water was serialized into different levels of time duration which formed the different treatments as follows:

T_1 = Seeds soaked for 12hours in water, T_2 = (Seeds soaked for 24hours in water)
T_3 = Seeds soaked for 48hours in water T_4 = (Seeds soaked for 12hours in 100% crude MLE)
T_5 = Seeds soaked for 24hours in 100% crude MLE
T_6 = Seeds soaked for 48hours in 100% crude MLE T_7 = (Non-soaked turmeric).

Sowing

The turmeric rhizomes were planted on beds at the rate of one seed per hole, at a plant spacing of 30cm x 50cm and at a shallow depth of 4cm for easy sprouting. All the necessary cultural practices were done in all the plots.

Data Collection: The experiment was monitored and data was collected on the following parameters;

Percentage Seedling Emergence: This was calculated using the formular below;

$$\frac{Sg}{St} \times \frac{100}{1}$$

Sg = the total emerged seeds, St = the total number of seeds planted

Number of days to 50% Emergence: This was the counting of number of days from sowing till 50% of planted seeds emerged in days.

Emergence Speed: This was calculated using the formular as applied by Delouche, J.C. and Baskin, C.C. (1980).

$$\sum \frac{Number\ of\ seedlings\ emerged}{Number\ of\ days\ taken} x \frac{100}{1}$$

RESULTS AND DISCUSSION

Percentage Seedling Emergence (%)

The effect of seed priming on percentage seedling emergence of turmeric *(Curcuma longa)* is shown in table 1.The result showed that seed priming had significant influence on emergence of turmeric. The highest percentage seedling emergence (100%) was obtained from seeds soaked for 12 hours in water; seed soaked for 24hrs in water, seeds soaked for 48hours in water seeds and soaked for 12hours in *moringa* leaf extract seeds. The value was statistically similar to seeds soaked for 24hours in *moringa* leaf extract (Table 1). But the least value (92%) was obtained from seeds soaked for 48hours in *moringa* leaf extract was significantly similar ($P \leq 0.05$) to the value (96%) obtained from the seeds soaked for 24hrs in 100% MLE and non-soaked seeds (Table 1).

Number of Days to 50% Emergence of Turmeric

Statistical analysis of data showed that seed priming significantly affected the number of days to 50% emergence. Number of days to 50% seedling emergence of seeds soaked for 12hours in water, 24hours in water, 48hours in water, 12hours in *moringa* leaf extract, 24hours in *moringa* leaf extract, 48hours in *moringa* leaf extract, and non-soaked seeds were 12days, 13days, 14days, 15days, 12days, 12hours in *moringa* leaf extract, 24hours in *moringa* leaf extract, 12days and 47days respectively. The 47days obtained from non-soaked turmeric was significantly higher than all others (Table 2). The values obtained from other treatment were statistically similar ($P \leq 0.05$) (Table 2).

Emergence Speed (% /day)

The effect of the priming treatments on emergence speed was shown in table 2. The value (86%/day) obtained from seeds soaked for 12hours in water was the highest which differed significantly ($P \leq 0.05$) from 60%/day obtained from the non-soaked seeds. But all the values obtained from other treatments were statistically similar ($P \leq 0.05$) (Table 2).

The result obtained from the research work revealed that seed priming had significant effect on percentage seedling emergence. The days to 50% emergence was significantly affected by priming. The seeds that were primed reached 50% emergence earlier than non-soaked seeds. The reason for the early emergence of the primed seeds might be attributed to the fact that primed seeds imbibed water, breaks dormancy and revive seed metabolism faster, resulting in reduction in number of days to 50% emergence. This result is in conformity with the findings of Asgedon and Becker (2001) who reported the extension of many biochemical modifications and enzymes creation by primed seeds. The seeds that were primed had higher emergence speed than non-soaked seeds. This result is a reflection of the fact that seed priming enhances speed and uniformity of germination as reported by Khalil *et al.* (2010). Priming of turmeric is highly recommended for early seedling emergence.

Table 1: Effect of Seed Priming on Percentage Seedling Emergence of Turmeric

Priming Treatments	Percentage seedling emergence (%)
Seeds soaked for 12hours in water	100^{a}
Seeds soaked for 24hours in water	100^{a}
Seeds soaked for 48hours in water	100^{a}
Seeds soaked for 12hours in 100% crude MLE	100^{a}
Seeds soaked for 24hours in 100% crude MLE	96^{ab}
Seeds soaked for 48hours in 100% crude MLE	92^{b}
Non-soaked seeds (control)	93^{b}

Mean in the column, having the same letter(s) are not significantly different at ($P \leq 0.05$), according to Duncan Multiple Range Test

Table 2: Effect of Seed Priming on Number of Days to 50% Emergence of Turmeric

Priming Treatments	N0. of days to 50% emergence (%)	Emergence speed (%/day)
Seeds soaked for 12hours in water	12^{b}	86^{a}
Seeds soaked for 24hours in water	13^{b}	82^{a}
Seeds soaked for 48hours in water	14^{b}	80^{a}
Seeds soaked for 12hours in 100% crude MLE	15^{b}	82^{a}
Seeds soaked for 24hours in 100% crude MLE	12^{b}	85^{a}
Seeds soaked for 48hours 100% crude MLE	12^{b}	80^{a}
Non-soaked seeds (control)	47^{a}	60^{b}

Mean in the column, having the same letter(s) are not significantly different at ($P \leq 0.05$), according to Duncan Multiple Range Test

ABSTRACT
The study was conducted to assess the responses of growth and yield of taro var. Coco-India [Colocasia esculenta (L.)] to NPK Fertilizer and Poultry manure rates at umudike, south Eastern Nigeria in 2014 cropping season. The experiment was laid out in 4 x 4 factorial in randomized complete block design (RCBD). Factor A comprises 0, 150, 200 and 250 kg/ha levels of NPK fertilizer while Factor B consists of 0, 5, 10, and 15 t/ha levels of poultry manure. A total of 16 treatment combinations with 3 replicates were obtained. Data were collected on growth and yield parameters and analyzed using analysis of variance (ANOVA). The results showed that significant effects of treatments varied across the intervals of measurement. Though, non-significant, the highest yield was obtained with application of 250kg/ha and 15t/ha of NPK fertilizer and the poultry manure, respectively.
Keywords: Growth, yield, cocoyam, NPK fertilizer, poultry manure

INTRODUCTION

Taro var. Coco-India (NCe 001) has deep green coloration with erectophylous growth habit. Its petiole and petiole junction are brownish green and brown, respectively. Also, its corm shape is oval with smooth skin, and deep green flesh coloration. Coco-India produces suckers ranging from three to ten per plant (Orji and Ogbonna, 2015). Taro is a plant with a broad, beautiful, nutritious strong leaf shaped like a huge heart. There are more than 200 cultivars of taro, selected for their edible corms and cormels, or their tropical looking ornamental foliage. The taro plant has a triple value in that the stem may be used as salads, the tubers provide easily digested starch, with the leaves are used as a green vegetable. Taro root is often used in a similar fashion to a potato, but in fact has better nutritional qualities than a potato. It has almost three times the dietary fiber, which is important for proper digestive health and regularity. Fiber can also fill you up and make you feel less hungry with fewer calories. This study is aimed at determining the effects of NPK fertilizer and poultry manure on growth and yield of taro var. Coco-India at Umudike.

MATERIALS AND METHODS

An on-farm trial on taro var. Coco-india was carried out at Research and Training Eastern Farm, Michael Okpara University of Agriculture, Umudike. Umudke lies on a longitude 07° 32' E and latitude 05^0 29' N with altitude 122 m above sea level. This study was carried out between June and December, 2014 cropping season. A piece of land with a dimension of 11m× 38 m was cleared. The land was ploughed, harrowed and ridged with a tractor. The ridges were converted into plots of bed manually. Each plot of bed measuring 2 m × 3 m with a gap of 0.50 m and 1.0 m within and between the plots, respectively was created. Twelve cornels with an average weight of 17.5g each were planted with planting space of 0.5 m × 1.0 m. The experiment was laid out in 4 x 4 factorial arrangement in randomized complete block design (RCBD) in which NPK 15:15:15 fertilizer formed Factor A with four levels - 0, 150, 200, 250 kg/ha while poultry manure formed Factor B with four levels - 0, 5, 10, 15 t/ha. There was a total of 16 treatment combinations with three replicates. Weeding was done at 3 WAP and 12 WAP. Data were taken on the following crop attributes: Number of suckers/plant, number of leaves/plant and on yield and yield components. The field data collected were subjected to analysis of variance (ANOVA) using Genstat 12 edition. F-LSD was applied to detect significant difference between two means (p=0.05).

RESULTS AND DISCUSSION

Main effect of zero application of NPK fertilizer rate was significant ($p \leq 0.05$) on the number of suckers/plant at 12 WAP while poultry manure rate of 10 t/ha application was also significantly ($p \leq 0.05$) produced higher number of suckers/plant (Table 1). Zero application of NPK fertilizer rate gave the highest number of suckers/plant relative to other treatment levels. The interaction between fertilizer rate and poultry manure rate was significant with 10 t/ha of poultry manure application only giving the highest number of suckers per plant (15.20) compared to other interactions while zero application of the treatment factors (control) gave the least number of suckers/plant (2.70). NPK fertilizer rates differed significantly ($p \leq 0.05$) on the number of leaves/plant across the period of data collection. Greater number of leaves/plant was produced at 12 WAP when NPK fertilizer was not applied (Table 1). Also, poultry manure rate significantly ($p \leq 0.05$) produced the highest number of leaves/plant at 12 WAP when 15 t/ha was applied. More so, the interaction between NPK fertilizer and poultry manure rate was significant at all the sampled period (Tables 1). The main and interaction effects of NPK fertilizer and poultry manure rates did not significantly ($p \geq 0.05$) influence the number of cormels/plant at harvest, although 250kg/ha and 5t/ha levels of NPK fertilizer and poultry manure, respectively produced higher number of cormels/plant (Table 2). Also, 150kg/ha rate of NPK fertilizer x 10 t/ha rate of poultry manure interaction gave higher number of cormels/plant (Table 2). In the same vein, NPK fertilizer and poultry manure treatments and their treatment combinations did not differ significantly on the weight of cormels/plant, nevertheless peak rates of the two factors produced weightier cormels/plant than other levels. The main effects of NPK fertilizer and poultry manure rates were non-significant ($p \geq 0.05$) on the weight of corm/plant, although 150kg/ha rate of NPK fertilizer with zero application of poultry manure produced greater weights of corm/plant (Table 2). But, the rates of NPK fertilizer x poultry manure interaction significantly ($p \leq 0.05$) influenced the weight of corm/plant with a combination of 150kg/ha rate of NPK fertilizer and zero application of poultry manure giving weightier corm/plant than other treatment levels. On the hand, total yield (kg/ha) was not influenced by main and interaction effects of both factor, nevertheless, higher total yield of Coco-India was obtained from plots where NPK fertilizer rate of 250kg/ha and zero application of poultry manure were added (Table 2). In the same vein, a combination of 50kg/ha rate of NPK fertilizer and 15 t/ha rate of poultry manure gave higher total yield (kg/ha) which amounted to 11.40% over the control yield.

The significant effect of NPK fertilizer rates on the number of suckers and leaves/plant was in response by poor nutrient soil that required fertilization more than cation base-saturated soils as reported by Mare and Modi (2009) who asserted that application of NPK fertilizer improved growth and yield of cocoyam. In the same vein, Orji and Ogbonna (2015) observed increase in the number of suckers and leaves per plant with application of 150 kg/ha and 200 kg/ha rates of NPK fertilizer in Nsukka plants in 2008 and 2009 cropping seasons, respectively (Tables 1). Also, Hamma *et al*. (2004) reported increase in the number of suckers and leaves per plant with the application of 10 t/ha rate of poultry manure. Significant interaction effects of NPK fertilizer in combination with poultry manure could be caused by positive interaction between the two factors which resulted in the production of higher number of suckers and leaves plant. Non-significant effects of NPK fertilizer and poultry manure on the yield and yield components of taro could be attributed to weather, soil conditions, and slow mineralization of poultry manure which might have nullified treatment applications.

CONCLUSION

Despite non-significant effects of NPK 15;15:15 fertilizer rates on the yield of taro variety Coco-India, I would still recommend 250kg/ha rate to farmers at Umudike as it still gave the optimum yield. However, more years of poultry manure experiments are still required on taro production to confirm this research report.

Table1: Effects of NPK Fertilizer and Poultry Manure rates on number of suckers and leaves/plant at 12 weeks after planting (WAP)

NPK Fertilizer	**poultry manure Rate (t/ha)**

ABSTRACT

A field experiment was conducted during the 2014 wet season at the Agricultural Research Station, Institute for Agricultural Research farm, Wasai-Minjibir in Kano (12^0 8.58'N, 8^0 40.46'E), 500m above sea level in the Sudan savanna ecological zone of Nigeria to evaluate the growth and yield response of sweet sorghum to NPK levels (Sorghum bicolor (L.) Moench. sub-spp saccharatum) varieties. The treatments consisted of three varieties of sweet sorghum (SSV NTJ2, SSV Ex-Daura and SSV Ex-Garki), and four NPK levels (0, 200, 300 and 400 kg ha^{-1}) which were combined and laid in a randomized complete block design (RCBD) and replicated three times. The result showed that application of 400 kg ha^{-1} of NPK significantly increased grain weight per ear, stalk and grain yields (129.12g), (40.4 t ha^{-1}) and (2.7 t ha^{-1}) and is comparable to 300 kg NPK ha^{-1} rate. Similarly application of 400 kg ha^{-1} of NPK gave superior growth parameters such as plant height (291.6 cm) and crop dry weight (260.3g) compared to other rates of application. The SSV NTJ2 variety had higher plant height (271.3 cm), crop dry weight (205.17g) than SSV Ex-Daura or SSV Ex-Garki). While SSV NTJ2 variety had the highest grain weight per panicle (88.56g), there were not significant differences among the test crop in terms of stalk yield. From the study, it could be suggested that a farmer may use SSV NTJ2 variety with the application of 300 kg NPK ha^{-1} in the Sudan savannah ecological zone to grow sweet sorghum crop that is now nearing extinction.

INTRODUCTION

Sweet sorghum [*Sorghum bicolor* (L) Moench. *sub-spp saccharatum*] belongs to same species as grain sorghum, grass sorghum and broom sorghum. It is similar to grain sorghum but has sugar-rich stalks (Doggett, 1970). It is a crop that is well adapted to sub-tropical and temperate regions of the world and it is both water and nutrient efficient. Sweet sorghum has good tolerance to drought, water lodging and salinity (Almondares *et al.*, 2008). It can be grown in areas of low fertility and unpredictable rainfall (Van-Oosteroma *et al.,* 2001). It is a C4 plant with a high biomass yield and good nitrogen used efficiency (Gardener *et al.*, 1994). Sweet sorghum has the potential to be a good alternative feedstock for ethanol production. It is a multi-purpose crop which can be cultivated for simultaneous production of grain from its ear-head as food and feed ingredients, sugary juice from its stalk for making syrup, jaggery or ethanol, the bagasse and green foliage as an excellent fodder for animals, as organic fertilizer or for paper manufacturing. It is special purpose sorghum with rapid growth and has wider adaptability (Reddy and Sanjana, 2003). The grain contains 11.3% protein, 3.3% fat and 56–73% starch, relatively rich in iron, zinc, phosphorus and B-complex vitamins and the high tannin, an anti-oxidant, makes it a beneficial source of nutrition and medicine (Gnansounoua *et al.* 2005). Nitrogen, Phosphorous and Potassium (NPK) are the most important nutrients that influence the growth and yield of crops, sweet sorghum inclusive. Most of the crop growing soils in Sudan savannah are deficient in these nutrients (Burns *et al.*, 1991). Global warming, energy crises and environmental pollution have become a source for concern, adversely affecting agricultural production with consequences on food security issues. Developing this multi-purpose crop could play important role in promoting food production, livestock husbandry, energy source, sugar and paper making, leading to jobs creation. The study was undertaken to investigate rates of NPK for optimum productivity of sweet sorghum.

MATERIALS AND METHODS

The study was conducted during the 2014 wet season at the Agricultural Research Station, Institute for Agricultural Research farm, Minjibir-Kano (12^0 8.58'N, 80 40.46'E), 500m above sea level in the Sudan savanna ecological zone of Nigeria during the 2014 rainy season in Sudan savanna ecological zone, where annual rainfall averaged 600 mm is received between May and September. Soil type is a semi drain ferruginous tropical sandy loam. The results are presented in Tables 1 and 2. The treatment consisted of three sweet sorghum varieties SSV NTJ2, SSV Ex-Daura and SSV Garki and four NPK levels (0, 200, 300, and 400 kg ha^{-1}). Treatment combinations were laid in RCBD and replicated three times. Gross and net plot sizes used were 18m^2 and 12m^2. The test crops were obtained from IAR sorghum breeding unit. SSV NTJ2 is an improved and early maturing, while the other two varieties SSV Ex-Daura and SSV Ex-Garki are local land races sourced from Daura in Katsina and Garki in

Jigawa States respectively. Planting was carried out in mid-May and thinning was done at three weeks after sowing (WAS), while manual hoe weeding was done at 3 and 6 WAS. The NPK treatments, using 20:10:10 compound fertilizer, was applied in two split doses as per the treatment rate to each main plot at 3 and 6 WAS. Data collected were subjected to analysis of variance (ANOVA) using SAS software package (SAS, 2002). Means were separated using Duncan Multiple Range Test (DMRT) method at 5% level of significance (Duncan, 1955).

RESULTS AND DISCUSSION

The response of sweet sorghum to NPK was significant on both growth and yield characteristics such as plant height, number of leaves per plant, plant dry weight, grain weight per ear, stalks and grain yields during the trial period.Table1 shows the response of sweet sorghum to NPK on plant height (cm), number of leaves per plant and plant dry weight (g) of sweet sorghum. Application of 400 kg NPK gave significantly the highest plant height, which was similar to 200 and 300 kg ha^{-1} application rates. Thus by implication, for each increase in the NPK level from 0 to 400 kg ha^{-1} there was corresponding increase in the plant height with statistical similarities. The response of the sweet sorghum varieties however, showed a different trend where SSV NTJ2 produced the tallest plants while Ex-Garki produced the shortest. Application of 300 kg ha^{-1} NPK resulted in significantly higher number of leaves per plant than other rates of application. The result further revealed that the control recorded the lowest leaves number. SSV NTJ2 recorded the highest number of leaves per plant though was similar to other varieties, a situation that shows similarities in response to NPK by all varieties. Application of 400 kg ha^{-1} of the NPK significantly increased the crop dry matter and was comparable with the 300 kg ha^{-1} rate; the control and the 200 kg ha^{-1} were similar but significantly much lower. Response to NPK as portrayed in grain weight per ear, stalk and grain yields are shown in Table 2. The application of 300 and 400 kg ha^{-1} NPK were similar in all the three parameters (grain weight, stalk and grain yields) and significantly higher than other rates; consistently the control recorded the lowest responses of all. Response of SSV NTJ2 to NPK was the highest in grain weight per ear, stalk yield and grain yield, compared to other varieties during the trial period. Though NTJ2 response was higher than SSV Ex-Daura in stalk yield, the difference was not significant. Sudan savanna soils are low in organic content of C and N attributable to low vegetative cover and annual bush burning prevalent in many farming communities in the zone, thus the need to supplement crop growing with fertilizers (Buah, 2009). In the present study, the growth parameter such as plant height, number of leaves per plant and dry weight responded significantly to the different rate of NPK applied (200, 300 and 400 kg NPK ha^{-1}) which was in tandem with the report of Alagarsamy (1995). Plant height, number of leaves and other growth characters increased progressively with increase in NPK, which may be due to the effect of on cell division and tissue elongation which consequently led to increase in number of node and internode elongation as well as proper root formation that enhances soil nutrient absorption (Leible, 1991). The enhanced vegetative growth of sweet sorghum resulted in significant response of yield parameters such as grain weight ear^{-1}, stalk yield and grain yields. The increase in these parameters could be linked to higher assimilate partitioning and dry matter production for grain filling with increased NPK application as reported by Mosier (2004). SSV NTJ2 superior response with regards the yield traits may have been in its ability to efficiently use the production resources compared to other varieties.

CONCLUSION

Sweet sorghum growing has almost gone extinct in the Sudan savannah zone as a result of neglect, however, this study has shown that just like its family member, the grain sorghum, its growing can be successfully revived given it significant response to NPK. Farmer in the Sudan savannah can grow sweet sorghum successfully, especially the SSV NTJ2 variety, with application of 300 kg ha^{-1} NPK in the ecology.

ETHANOLIC EXTRACTION OF TOXICITY OF PLANT EXTRACTS AGAINST COWPEA SEED BRUCHID *Callosobruchus maculatus*(F.) (coleoptera: chrysomelidae) ON MUNGBEAN (*Vigna radiata* (L.) Wilczek) STORAGE

L. A. Chukwu

Agricultural Technology Department, Akanu Ibiam Federal Polytechnic Unwana
Email: **lwangachukwu@gmail.com**

ABSTRACT
A laboratory study was conducted at Crop Science Laboratory of Michael Okpara University of Agriculture Umudike, to determine the toxicity of ethanolic extraction of Piper guineense fruits, Dennittia tripetala fruits Allium sativum bulbs, Zingiber officinale rhizomes against the cowpea seed bruchid Callosobruchus maculatus (F.) (Coleoptera:Chrysomelidae) on stored mungbean (Vigna radiata(L.)Wilczek) seeds. The experimental design was a completely randomized design with three replications. 0.5,1.0,1.5,2.0g rates of the different extraction was admixed with 20g of mungbean seeds placed in plastic containers. The effect of the treatments were assessed on insect mortality at 48, and 96hours, oviposition 7days, adult emergence on 14days after infestation, and seed viability test at the expiration in each of the experimental plots. The results showed that plant extracts were effective in controlling insect infestation by recording significantly higher performance when compared with the control. Piper guineense provided the best protection for stored mungbean at 2.0/20g compared with the other treatments, followed by Allium sativum. Dennittia tripetala and Zingiber officinale were almost the same in their performance. Plant extracts did not affect the viability of the seeds. The results obtained suggest that the plant extracts possess insecticidal properties and can be utilized in protecting stored mungbean from C. maculatus infestation since they are environmental friendly, cheaper than synthetic insecticides and safer for humans.
Keywords: Mungbean, *Callosobruchus maculatus, Piper guineense, Allium sativum, Dennittia tripetala, Zingiber officinale* and Toxicity

INTRODUCTION
Grains are however, very susceptible to infestation by insect pests belonging to two main orders, Coleoptera (beetle) and Lepidoptera (moth), micro-organisms and to rodent pests in storage. These pests are responsible for losses of grains in storage amounting to several millions of US dollars annually. They are thus, a major threat to the food security programme of any nation, particularly developing countries where the storage of agricultural produce is handled mainly by poor resource farmers. Food legumes occupy a prominent place in the nutrition level of families because their edible seeds form a cheap alternative source of protein in their diets especially in Africa (Okosun and Adedire, 2010). Mungbean (*Vigna radiata* (L) Wilczek) belong to the family Fabaceae. It is an annual erect plant reaching a height of about 0.15-1.25m. It is a good source of proteins, carbohydrates, and vitamins for mankind all over the world. Mungbean are widely grown as a tropical and subtropical crop. It is a low input crop and it is priced for its seeds which have high protein level, easily digestible and is consumed as food. Because of its non-flatulent behaviour (digestibility) and high protein level, it has an edge over other pulses(Ghafoor *et al.*, 2003). Mungbean is attacked by different species of insects, but sucking insect pests*(Ahids craccivora, Empoasa spp.,Cicadella viridis* and *Bemisia* tabaci-white fly) are the major insects (Isman,2008). A serious postharvest pest of mungbean is the bruchid, *Callosobruchus maculatus* which can infest the crop in the field before harvest then develop during storage. The protection of crop plants and seeds from pests and diseases has been achieved in industrialized countries almost through the application of chemical control means. Plant extracts or their potent derivatives such as derris, rotenone, pyrethrum, nicotine, sabadilla, physostigmine, quassin or azadirachtin, have been used as insecticides for decades (Sarfraz and Keddie, 2005). Botanical pesticides are of interest to organic farmers because the chemicals are natural products, hence easily biodegradable and are often thought of being safe to handle and use on food products. The objective of this research work was to evaluate the toxicity of ethanolic extraction of some plant extracts against the bruchid *C. maculatus.*

MATERIALS AND METHODS
The laboratory study was conducted at the Crop Science Laboratory College of Crop and Soil Sciences, Michael Okpara University of Agriculture Umudike. Bruchid beetles used for the study was obtained from naturally infested stored Cowpea collected from Umuahia main market, Abia State, and reared in the laboratory on dry susceptible brown cowpea, in plastic buckets covered with muslin cloth held with rubber bands to ensure aeration and prevent escape of the beetle. The plastic buckets was kept at an ambient temperature and relative humidity (28$\pm$30C and 75$\pm$5% r. h).The sexes of bean beetle *C. maculatus* was determined by examining the elytral pattern (Southgate et al., 1975). The different plant extracts used were obtained from Umuahia main market, Abia State. They are; Guinea pepper (*Piper guineense* Schum and Thonn), Pepper fruit (*Dennittia tripetala*), Garlic (*Allium*

sativum) and Ginger (*Zingiber officinale*). The dried plant extracts were separately ground using a HP kitchen hammer mill. The powders were sieved into particle size of 300um with a British laboratory test standard sieve and kept in air tight containers prior to use (Okonkwo and Okoye, 1996). Each of the plant extracts were weighed into four dosages of 0.5, 1.0, 1.5 and 2.0g and added to 20g wholesome mungbean seeds in plastic containers with tight fitting, but perforated lids for aeration. Different weights of plant powder extracts, were mixed with 5ml of ethanol. The suspension was vigorously stirred and left for 16hours before filtering with muslin cloth to get the filtrate. Then 20g of clean and wholesome (uninfested) mungbean seeds were steeped in the filtrate of the different concentration for 30 seconds and quickly removed to air dry for 5hours. The treated mungbean seeds and the control were placed inside plastic containers and four freshly emerged bruchids (1-2 day old) 2 females and 2 males were introduced into each container which was tightly covered with muslin cloth and firmly screwed by the lid.

RESULTS AND DISCUSSION

The mean percentage mortality of *C. maculatus* treated with ethanol extraction of the plant extracts on Mungbean is presented in Table 1. The result indicated that the plant extracts significantly ($P \leq 0.05$) caused adult mortality of the bruchids, 48 hours post treatment compared with the control (Table 1). *P. guineense* had the highest percentage adult insect mortality with 18.30%, while *Z. officinale* and *A. sativum* had the least with 11.70% and 11.70% respectively the plant extracts did not differ significantly from each other in their mortality effects on adult *C. maculatus* ($P < 0.05$). Table 1, also shows the mean percentage mortality of adult *C. maculatus* exposed to ethanol extracts 96hours after Infestation. All the plant ethanol extracts had higher mortality ($P \leq 0.05$) of adult *C. maculatus* than the control. *P. guineense* had the highest mortality with 55.00% which was significantly different ($P \leq 0.05$) from others, followed by *A. sativum, D. tripetala* and *Z. officinale* with 48.30% 43.30% and 43.30% respectively. There was highly significant dosage effects observed in the ethanol extracts when compared with the control. ($P \leq 0.05$). The effect of treating mungbean seeds with some ethanol extracts on oviposition by *C. maculatus* is shown in Table 2. There were highly significant reduction on oviposition in all the treated samples when compared with the control ($P \leq 0.05$). *P. guineense* had the best protectant action among the plant ethanol extracts with mean oviposition count of 58.73% which was significantly different from other plant extracts ($P \leq 0.05$). *A. sativum* had 62.53% which was not significantly different from *D. tripetala* and *Z. officinale* with 63.47% and 63.80% respectively ($P \geq 0.05$). The mean oviposition reduction effect of the different dosages was highly significant ($P \leq 0.05$) compared with the control The dosage of 2g/20g mungbean seeds had the least oviposition count with 46.17% which was significantly different from 1.5g, 1.0g and 0.5g/20g mungbean seeds with53.08%, 59.42% and 67.83% respectively ($P \leq 0.05$). This is also an indication that higher dosages reduced oviposition more. In Table 3, adult emergence count of *C. maculatus* on mungbean seeds treated with some plant ethanol extracts. Adult *C. maculatus* emergence was significantly suppressed by all the plant extracts ($P \leq 0.05$) when compared with the control. *P. guineense* gave the highest suppression effect with mean adult emergence count of 37.20 which was significantly different ($P \leq 0.05$) from other plant extracts. *A. sativum, D. tripetala* and *Z. officinale* were statistically the same with 40.67, 41.67 and 43.60 respectively. Table 3. also shows percentage germination of mungbean seeds treated with plant ethanol extracts. There were no significant difference among the mean of the ethanol extracts on percentage germination of mungbean seeds treated, but they differed significantly ($P \leq 0.05$) with the control. *A. sativum* had the least percentage germination count with 38.67%, while *Z. officinale* had the highest percentage germination count with 41.33%. The dosage effect on percentage germination were highly significant ($P \leq 0.05$) when compared with the control. The higher the dosage the more the percentage germination count. The result of the experiment indicates that all the ethanol extracts were insecticidal to the bruchids. *P. guineense* were significantly different from other extracts used in all the dosage due to stronger contact toxicity. Longer exposure of the insects to treated seeds with ethanol extracts 96 hours enhanced the insecticidal activity and mortality became more pronounced above 60%. Dosages per 20g seeds consistently caused higher adult mortality in *P. guineense* and *A. sativum* than in *D. tripetala* and Z. officinale. Mortality trend was in line with (Emeasor, 2005). Benner (1993) reported that extraction of insecticidal plant extracts with appropriate solvents often concentrates the active material and makes their potency readily detectable. Oviposition by the bruchids was significantly suppressed by all the ethanol extracts. Oviposition was significantly suppressed by *P. guineense* more than other extracts. The adult emergence of the bruchids were significantly suppressed by the ethanol extracts compared with control ($P<0.05$). Adult emergence suppression was highest at 2.0g dose with *P. guineense* having the best suppression. The ethanol extracts did not affect the viability of the seeds.

CONCLUSION

The ethanolic extraction of all the plant extracts proves insecticidal against *C. maculatus*. Piper guineense performed best among the plant extracts used. 2.0g/20g gave the best protection. Plant extracts are therefore recommended for grains in store as they are natural products, hence easily biodegradable, ecological friendly and being safe to handle better than synthetic.

ABSTRACT
The experiment was conducted at the screen house and field of National Root Crops Research Institute (NRCRI), Umudike with the aim of determining the varietal response of selected landraces for enhancing the multiplication ratio of yam tuber through vine cuttings for seed yam production, to select the variety /varieties that responded best to vine cuttings survivability ratio for seed yam production and to determine 'over all seed yam' production. Single micro-tubers of size 100g from white yam varieties was planted in each of the 20 polybags measuring 8 x 12cm filled with sterilized top soil and arranged in the screen house. Vines were cut one node and planted in black polybags of size 5 x 6cm filled with sterilized topsoil and later transplanted to the field until harvested. The following data were collected: number of vines collected from each yam plant every 3 months after planting (MAP), for 9 months, number of plants transported to the field, percentage field establishment, number of tubers per plant and per variety, tuber length and tuber diameter, The result indicated that the variety with the highest number of vine cuttings per stand were Gbagu and TDr89/02665 with 56 vine cuttings per stand respectively and yielded 56 and 58 tubers each with average of one tuber per stand as against the natural method of one tuber at planting and one tuber of seed yam at harvest. A total of 180 yam plants from 9 varieties, cloned up to 461 yam plants gave tuber yield totaling 39,166,560 tubers for seed yam production within one year when compared with the control, only one tuber was produced within the same year. This indicated that vine cuttings could be used to enhance the rate of tuber multiplication of yam varieties for commercial seed yam production.
Keywords: vine cuttings, clonning, multiplication ratio, seed yams and commercial seed yam

INTRODUCTION

Yams have long been vegetatively propagated through seed tubers or through tuber setts. However, Sadik and Okereke (1975) reported the possibility of propagating yams through botanical seeds although this method has not increased the multiplication ratio of single yam plant. Therefore, seed tubers, tuber setts and botanical seeds are still limited in the application of tuber yam multiplication for ware tuber yam production. Many researchers such as Njoku, in 1968, and Martins and Gaskins also in the same year (1968) had demonstrated that yams can be propagated by vine cuttings. According to Vander Zang and Fox (1981), vine cuttings could be used for ware yam production in *Dioscorea alata* field. They reported that vine cuttings are able to produce roots within 3 - 4 weeks after planting. The bud in the leaf axil when cut with the vine and planted, first produce roots and then a new shoot or multiple shoots, tuber initiation followed and bulk and the whole physiological processes continued and end when the plant senescence. All researchers have been working on vine cutting for seed tuber /ware yam production however; very few number who had worked on vine cuttings for seed tuber multiplication have left their work unreported. Therefore this study aimed at determining the varietal response of selected landraces for enhancing the multiplication ratio of yam tuber through vine cuttings for seed yam production, to select the variety /varieties that responded best to vine cuttings survivability ratio for seed yam production and to determine 'over all seed tuber for ware yam production.

MATERIALS AND METHODS

Screen house activity: The experiment was conducted at the screen house and field of National Root Crops Research Institute (NRCRI), Umudike in 2014 and 2015 seasons. Single micro-tubers of size 100g from white yam varieties were planted in each of the perforated 20 plastic buckets measuring 8 x 12cm filled with sterilized top soil and arranged in the screen house. They were watered twice a week with watering can until they sprout. The vines were trained on ropes to the top of the screen house. The vine tips were cut back at two months after planting to induce lateral branching. Three competitive yam plants from each variety were tagged and vine cuttings were collected from lateral branches of the tagged yam plants 3 months after planting (MAP) and for every 3 months for a period of 9 months. The vines were cut one node and planted in black polybags of size 5 x 6cm filled with sterilized topsoil. After 4 weeks after pre-sprouting (root initiation and shoots), the potted vines were transplanted to the field. Also one perforated plastic bucket of same size filled with sterilized top soil was planted with one micro tuber of the same size using the national check (TDr89/02665) and was used as control. At time of transplanting to the field, the potted yam plant used as control was transferred to the field and planted.

Field activity: The area for the experiment was slashed, ploughed, harrowed and ridged. The ridges were spaced 1.0m apart. Planting was on the crest of the ridges at 0.3 x 0.1m apart in a plot for each of the varieties collected for a period of 9 months. Each variety constituted a plot and the 9 varieties constituted a block while the 3 months interval constituted replicates. (that is each 3 months interval is a replicate, for the 9 months were 3 replicates). The clone seedlings in the 9 varieties were laid out in a Randomized Complete Block Design (RCBD. The Sprouted vine plants were trellised with ropes to enable the yam plants to climb up. Fertilizer application was N P K 15: 15:15, applied 8 weeks after being transplanted and 9cm round the base of each clone seedling in the field. The whole plots were kept weed-free throughout the growth of the yam clone seedlings with hand-hoe. Hand rouging was done toward harvesting which took place when the yam plants senescence. All agronomic practices such as pests and disease control were carried out as at when due.
Data Collection: Data collected from the clone seedlings at harvest from each variety in the field were: number of plants transplanted to the field, percentage field establishment, number of tubers per plant and per variety, tuber length and tuber diameter.
Data analyzes: Data collected after logarithmic transformation using log base ten were statistically analyzed using Analysis of variance and means were separated.

RESULTS AND DISCUSSION

Number of vine cuttings produce per variety: The result for the mean ratio of vine cuttings per variety, Number of Sprouts, Mean number of tubers per variety and Size of tubers for the two years combined are presented in Table 1. The result on Table 1 showed significant ($P<0.05$) variation in the ratio of vine cuttings to one stand of potted variety. Therefore ratio of 9 stands of various yam varieties yielded 504 vine cuttings. That is 9 yam stands : 504 vine cuttings which was equivalent to 1 yam plant : 56 yam plants. When compared to the control, the number of yam plants yielded was 1 yam plant : 1 yam plant. The ones that sprouted and were planted in the field were 465 yam plants; however, 461 yam plants survived in the field and the tubers produced were harvested.
Number of tubers per clone per variety: The results of number of tubers per clone per variety, size of tuber and number of tubers harvested are presented in Table 1. There was significant ($P<0.05$) variation in the number of tubers yielded by the vine cuttings. The result of the number of tubers per variety, and size of tubers are presented in Table 1. Total number of tubers harvested from the cloning of the various 9 yam plants was 472 tubers, which was in the ratio of 9 stands to 472 tubers. This gave a grand mean of 1 yam plant to 52.4 tubers. When compared to the control where one tuber was planted without cutting into setts, only one tuber was harvested for planting as seed yam. However, the variety with the highest number of vine cuttings per stand were Gbagu and TDr89/02665 with 56 vine cuttings per stand respectively and yielded 56 and 58 tubers each with average of one tuber per stand (Table 1). However, the mean length of tuber was 28.7cm and diameter was 4.2cm which indicated that the size of the tubers produced by the vine cuttings was large enough to be used as seed yam (Table 1).
Multiplication ratio of the cloned vine cuttings: The multiplication ratio of the cloned vine cuttings with the twenty stands per variety of the yams planted in the Screen house are presented in Table 2.
One stand of yam plant can be cloned to obtain many yam plants to enhance the rate of seed yam multiplication for commercial purposes. The result in Table 2 indicated that with a total of 180 yam plants from 9 varieties, cloned up to 461 yam plants gave a total yield of 39,166,560 tubers for seed yam production within one year when compared with the control, which produced only one tuber within the same year. This indicated that vine cuttings could be used to enhance the rate of tuber multiplication of yam varieties for commercial seed yam production. Seed yams are used for the production of ware yams (table yam and ceremonial yam). The mean ratio of vine cuttings of 1 yam plant to 52.4 number of tubers as against the control which is 1 yam plant to 1 tuber of yam is an indication that the vine cutting had high multiplication ratio than using tubers in seed yam production..

CONCLUSION

The result indicated that the variety with the highest number of vine cuttings per stand were Gbagu and TDr89/02665 with 56 vine cuttings per stand respectively and yielded 56 and 58 tubers each with average of one tuber per stand as against the natural method of one tuber at planting and one tuber of seed yam at harvest. This showed that vine cuttings could be used for rapid multiplication of yam tubers for commercial seed yam production. A total of 180 yam plants from 9 varieties, cloned up to 461 yam plants gave tuber yield totalled 39,166,560 tubers for seed yam production within one year based on this study. However, when compared with the control, only one tuber was produced within the same year. This indicated that vine cuttings could be used to enhance the rate of tuber multiplication of yam varieties for commercial yam production.

ABSTRACT

In order to determine the effect of hydro-priming as seed enhancement method in three pepper species, a laboratory experiment was conducted. Seeds of Capsicum annum, Capsicum frutescences and Capsicum chinense were hydro-primed and drawn at 0,2,4,6 and 8 hrs and were further dehydrated under natural air drying conditions at 0, 6, 12, 18, and 24 hrs. The experiment was a factorial laid out in Completely Randomized Design with three replicates. Data collected on seed germination test were subjected to analysis of variance and means were separated using Tukey's HSD test at 5% probability level. Species, hydro priming time and drying hour had considerable effect on seed germination. Seeds of C. annum as well as seeds of C. frutescences gave higher seed germination. Seed lot, irrespective of species, hydro primed for 0 and 2 hours showed higher seed germination Also, seeds of C. annum hydro primed for 8 hrs and air dried for 6 and 12 hrs had highest germination of 92 - 97 % while C. annum seed soaked for 6 hrs and air dried for 24 hrs showed higher germination. Capsicum frutescences seeds hydro primed for 8 hrs and air dried for 6 hrs had enhanced germination data and therefore recommended. C. chinense seeds found with lower germination suggests the presence of dormancy in the seeds and may require further studies on how to break the seed dormancy.

Key words: Seed quality, seed improvement, seed priming and seed dormancy

INTRODUCTION

Pepper, *Capsicum spp,* is one of the most cultivated vegetable and spices crop worldwide and plays important role as a constituent in many food industries. Pepper was the first plant to be domesticated and cultivated in the western hemisphere (Bosland, 1996). *Capsicum spp* is a native of tropical and subtropical America and may comprise up to 30 species among them are five major cultivated species which are *Capsicum annum*, *Capsicum frutescence*, *Capsicum pubescence*, *Capsicum pendulum* and *Capsicum chinese* (Moscone *et. al.*, 2007). In order to improve field emergence and uniformity, priming treatment may be applied. During priming, treated seeds are allowed to take up water and start (part of) their germination related processes, but emergence of the radical is prevented to avoid the loss of desiccation tolerance that is needed for subsequent drying, storage, and marketing of the treated seeds. Priming treatments are used to synchronize the germination of seeds (Heydekker *et. al.*, 1973). Seed priming is pre-sowing treatment that involves the controlled hydration of seeds, sufficient to allow pre-germination metabolic events to take place but insufficient to allow radical protrusion through the seed coat (Heydekker *et. al.*, 1973). This technique has been used is some vegetable seeds to increase the germination rate, total germination and seedling uniformity, mainly under favourable environmental conditions (Misra and Dwibedi, 1980; Basra *et. al.*, 2005). Hydro-priming is a pre-sowing priming technique in which seeds are soaked in aerated distilled water as a priming medium, and does not require any special technique or equipment, thus, it is probably the simple and inexpensive technique of seed priming (Adebisi *et al.*, 2014). Although priming is one of the physiological methods, which improves seed performance and gives faster and synchronized germination (Sivritepe and Dourado, 1995), but there is little information on the benefit of hydro priming on seed quality of three pepper species grown in Nigeria. Therefore, a study was initiated to determine the effect of hydro priming in enhancement of seed quality in three *Capsicum* species.

MATERIALS AND METHODS

Seed material and source: Three *Capsicum species*(*Capsicum annum*, *Capsicum frutescence*, and *Capsicum chinense)* commonly grown in Nigeria were selected for the study and sourced from the National Horticultural Research (NIHORT) ,Ibadan, Oyo State, Ibadan, Oyo State, Nigeria.

Experimental design and treatments: The experiment was a factorial arrangement made up of seventy-five treatments and three replicates each making a total of 225 experimental units laid out in a Completely Randomized Design (CRD). The factors investigated were five hydro-priming durations, five drying period and three *Capsicum species*.

Hydro-priming treatment: Seed samples of three *Capsicum species* were sterilized using sodium hypochlorite (NaOCl) before priming. After sterilizing, the seeds of each species were divided into three replications with each replicate containing twenty-five seeds for each hydro-priming duration. Seventy-five seeds in three replicates for each hydro-priming duration were placed in net bags and then suspended in an aquarium tank containing distilled water and then drawn at 0, 2, 4, 6 and 8 hrs.

***Artificial drying of primed seeds**:* After priming seed lots were air dried for 0, 6, 12, 18 and 24 hrs before germination test under ambient conditions.

Seed quality assessment:

Standard Germination**-** Twenty-five seeds replicated three times from each species were placed in Petri-dishes lined with moistened paper towels at 25ºC in an incubator. Germination counts of normal seedlings were recorded from 4th day and subsequently at two days interval till the 14th day after sowing (DAS). The number of normal seedlings (visibly emerged radicle) was expressed in percentage following the procedure of ISTA (1985) thus:

$$SG = \frac{\textit{Number of seeds germinated after 8 days}}{\textit{Number of seed sown}} \quad X \quad 100$$

Data analysis

Data collected were transformed using arcsine transformation prior analysis. Data were analyzed using SPSS statistical software package for analysis of variance and treatment means were separated using Tukey's HSD test at 5% probability level.

RESULTS AND DISCUSSION

Table 1 presents the effect of hydro priming duration on seed germination of three Capsicum spp. The result reveals that seed of *C. annuum and C. frutescences* hydro primed for 0 hour (without priming) recorded highest value of 82% while *C. chinense* had the lease value (57%.) Similarly, *C. annuum* and *C. frutescences* seeds hydro primed for 2 hrs showed higher germination values of 76 and 74%, respectively. On seeds hydro primed for 4 hrs, the highest value was recorded in *C. annuum* (85%)< followed by *C. frutescences* (67%) while *C. chinense* had the lowest value, Also, seed primed for 6 hrs recorded highest germination of 83% in *C. annuum*, followed by 65% in *C. frutescences* while *C. chinense* gave lease value However, after 8hrs hydro priming time, *seed* of *C. annuum* showed highest germination (87%), followed by *C. frutescences* with 69% while *C. chinense* had the lease value.

The effect of drying time after hydro priming on seed germination of three *Capsicum* spp. is shown in Table 2. The result reveals that at 0 hrs of drying time, *C. annuum* and *C. frutescences* had higher values of 66 and 67%, respectively while *C. chinense* recorded lower value. After 6 hrs of drying time, seeds form *C. annuum* recorded highest germination value of 73% followed by *C. frutescences* (64%) while *C. chinense* gave the least value. At 12hrs of drying time, *C. annuum* seed air dried for12hrs was significantly highest in germination value (76%) closely followed by *C. frutescences* with 63%. Similarly, after 18 hrs drying time, *C. annuum* and *C. frutescences* showed highest germination of 66% while *C. chinense* gave lease value. For 24 hrs of dehydration time, *C. frutescences* had the highest value of 62%, followed by *C. annuum* whereas *C. chinense* gave the lease value of 16%.The effect of hydro priming time and drying duration on seed germination of three *Capsicum* spp. is shown in Table 3. The data show that seeds of *C. annuum* hydro primed for 0to 8 hrs as well as C. *frutescences* and thereafter dehydrated for 0 hour had statistically higher values of germination. Seed of *C. frutescences* primed for 2 and 4 hrs in water and dried for 0 hrs had intermediate germination performance of 73 and 65%, respectively. Likewise, seed of *C. chinense* hydro primed for 0 and 2 hrs with 0 hr dehydration also had intermediate germination performance of 62 and 67 %, respectively. Similarly, seeds of *C. annuum* hydro primed for 8 and 12 hrs and dehydrated for 6 hrs recorded the highest seed germination of 97 and 88%, respectively whereas seeds of *C. frutescences* had intermediate values in most cases except at 8 hrs of hydro priming with a lower value of 69%. In the same Table 3, unexpectedly, seed from *C. chinense* soaked in water for 0 to 8 hrs and air dried for 6 hrs had lease germination of between 38 and 57%. Also, seed of *C. annuum* hydro primed for 8 hrs and dehydrated for 12 hrs showed the highest value of 92%, though was not significantly different from values obtained under 0 to 6 hrs of priming as well as 2 hrs of priming with *C. frutescences*. Seed of *C. annuum* soaked in water for 6 and 0 hrs and dehydrated for 18 hrs recorded highest germination of 93 and 90%, respectively. Similarly. seeds of *C. annuum* and *C. frutescences* hydro primed for 8 hrs as well as seed of *C. frutescences* hydro primed for 2 hrs had intermediate germination performance of between 73 and 81 % while *C. chinense* in most cases had lowest values. Similarly, *C. annuum* seeds hydro primed for 6 and 8 hrs and dehydrated for 24 hrs had highest values of 92 and 86%, respectively which was not significantly different from 84% recorded at 4 hrs of hydro priming. However, seeds from *C. frutescences* hydro primed from 0 to 8 hrs had intermediate germination performance of between 66 and 74 % while seeds from *C. chinense* hydro primed from 0 to 8 hrs and dehydrated for 24 hrs in most cases had lease values of between 33 and 56%.

The result of the study indicated that hydro priming and drying periods significantly influenced seed germination of the three *Capsicum species.* The differential responses among the species for the seed germination could be due to differences in genetic make-up of the species. Significant differences in seed quality characters due to variation in genetic constitution have been reported by Adebisi *et, al.(* 2013) in *Capsicum spp*. Earlier observation by Adebisi *et al*. (2014) showed that differences in the periods of soaking and drying were responsible for variation observed in seed germination of eggplant genotypes. On the main effect of species across hydro priming and drying time, seed obtained from *Capsicum spp*. had highest seed germination, closely followed by seeds from *C. frutescences* while seeds from *C. chinenese* showed least value. On the hydro priming effect, seeds soaked for 0 to 2 hrs had highest seed germination while seed germination did not respond to differences in drying hours. On the effect of hydro priming time and *Capsicum spp, C. annuum* had the highest seed germination of between 76 and 86% under each of the soaking times. Seeds of *C. frutescences* hydro primed for 0 and 6 hrs recorded highest germination of between 72 and 82% while *C. chinense* had a consistent low values at each of the hydro priming hours. For the effect of hydro priming and drying duration, seeds that were hydro primed for 0 and 2 hrs were observed with highest germination of 71% while subsequent higher hydro priming time of between 4 and 8 hrs resulted in lower germination values under each of the drying periods. Seeds of *C. annum* dried for 6 and 12 hrs after hydro priming retained highest germination of between 73 and 76 % while other species had lower values at various drying times.

However, seeds of *C. annum* hydro primed for 8 hrs and dried for 6 and 12 hrs had the highest seed viability of between 92 and 97% while the same seed-lot hydro primed for 6 hrs and dried for 18 and 24 hrs were found with higher values of 93%. Also, seed of *C. frutescences* hydro primed for 0 to 2 hrs and dried for 0, 6, 12 and 18 hrs had high germination of between 73 and 89% why *C. chinense* seed hydro primed for 0 to 8 hrs and dried for 0 to 24 hrs had lower germination of between 33 and 73 % compared to other two species.

CONCLUSION

This study has shown that seeds of *Capsicum species* could be hydro primed for 0 hour and 2 hrs and dried for 0hr (no drying) for improved seed germination. However, *Capsicum species* seeds hydro primed for 8 hrs and dried for 6 hrs had improved germination data and therefore could be adopted. *C. annum* seed hydro primed for 8 hrs and dried for 6 and 12 hrs had improved germination compared to other species but *C. chinense* seed found with lease germination values suggests the presence of dormancy in the seeds. Therefore, it requires further studies on how to break the seed dormancy.

ABSTRACT

Research trial was conducted during the 2014 cropping season at National Root Crops Research Institute, Umudike in the rain forest zone of south eastern Nigeria to determine the effect of relative time of introduction of garden egg on sweetpotato/garden egg system (Ipomoea batatas)/garden egg (Solanum gilo) intercropping system. Two varieties of sweetpotato NR 05/022and (TIS 87/0087) planted at spacing of m1 x 0.30 m each were intercrop with garden egg at 1 spacing of 1m x 1 m different times. The experiment was laid out in a randomized complete block design (RCBD) replicated three times with 13 treatments which comprised Sole NR 05/ 022 sole TIS 87/ 0087 sole garden egg , simultaneous garden egg + NR 05/ 022, simu.GE + TIS 87/ 0087, GE4 WAP + NR 05/ 022 (4 weeks after planting) GE 2 WAP + NR 05/022, GE 4 WAP + TIS 87/ 0087, GE 2 WAP + TIS 87/ 0087, GE 4 WBP + NR 05/022 (weeks before planting), GE 4 WBP + TIS 87/ 0087, GE 2 WBP + NR 05/ 022 and GE 2 WBP + TIS 87/ 0087. Data of sweetpotato were collected on vine length/plant, number of leaves/plant 10 WAP, and yield (t/ha) at 16 WAP. Data on garden egg were collected on plant height, number of leaves/plant, number of branches/plant at 10WAP and fruit yield (t/ha). Piecemeal harvest of garden egg fruits was done between 10 to 16 WAP. The land equivalent ratio (LER) was also computed for sweetpotato and garden egg to measure land productivity. Data collected were subjected to analysis of variance. Results indicated that vine length, number of leaves and root yield (t/ha) were significantly ($p<0.05$) higher in sole cropping and simultaneous planting of each of the two varieties of sweetpotato with GE than other times introduced. There were no statistical differences among the other times of introduction. GE growth and yield followed the same trend. Simultaneous GE + UMU/SP1, GE +UMU/SP1 4WAP and GE +TIS 2 WBP gave the highest land equivalent ratio (LER) values of 1.29, 1.14 and 1.16, respectively indicating yield advantages of growing the two crops together at those times.

Keywords: Time of introduction, sweetpotato, garden egg, intercropping, yield

INTRODUCTION

Intercropping is an agricultural practice of growing two or more crops simultaneously on the same field during a growing season, in definite pattern or arrangements. Intercropping can be defined as a multiple cropping system where two or more crops are planted in a field during a growing season. It is a type of sustainable agriculture that is more efficient in the use of resource, for the benefit of human and is in balance with the environment (Eskandari, 2012). It is one of the most widespread traditional agricultural practices by West Africa farmers which provide food and income at different periods of the year for the family (Emede and Adegoke, 2011). Time of introduction of crops in the field is an important factor in crop production, because it affects growth, development and yield. Any crop that do not complete its vegetative phase or planted earlier than required will not yield well because growth and yield is a function of time. Intercropping of crops can be planted simultaneously, before and after each of the component crops. Muoneke *et al*, (1997) and Ofori and Stern, (1987) reported that in intercropping there is simultaneous planting, early planting and late planting of one of the component crops. Sweetpotato *(Ipomoea batatas* (L.) Lam) family of *Convolvulaceae* is one of the world's widely grown crops. In sub-Saharan Africa, the high productivity of sweetpotato per unit area and time is the basis for its choice as a principal crop in agriculture campaigns towards food security and poverty alleviation (NRCRI, 2005). When the vines spread out, conserve soil moisture, improves soil fertility, control weed and erosion (Anuebunwa, 2000). Nigeria is the third largest producer of sweetpotato after China and Uganda (Kathryn *et al*, 2012). With production over 3.5 million t annually from 1.03 million ha (FAO, 2008), sweetpotato is now prominent in our farming systems and rapidly becoming staple food in Nigeria. Garden egg *Solanum gilo* (L.) belongs to the family of *Solanaceae* is a fruit vegetable crop. It is a traditional vegetable crop in Africa and has potential to improve nutrition, boost food security, and generate income, foster rural development and support sustainable land use (NRC, 2006). It is also used in many traditional ceremonies like village meetings, wedding, child naming, burials and other festivities. Garden egg is usually grown in mixed cropping systems. In south east agro ecological region of Nigeria, it is seen in homestead farms staggered arrangement with food crops like yam, cocoyam maize, fluted pumpkins. Intercropping garden egg/maize or with other food crops in some parts of Nigeria. Sweetpotato/ garden egg are compatible crops in intercropping systems (Ebeniro et al, 2015), and time of introduction is an important factor in farming operations therefore the objective of this study is to determine the best time of introducing garden egg in sweetpotato/garden egg intercrop in rainforest of Nigeria.

MATERIALS AND METHODS

This work was conducted at National Root Crop Research Institute (NRCRI), Umudike experimental farm in 2014 cropping season. The soil is acidic and well drained sandy loam. The study was conducted on land that been fallow for 2 years (2011/2013) after yam crop. Land was cleared, disc ploughed, harrowed and ridged. The experiment was laid out in a randomized complete block design. The plot size was 6 m x 4 m (24 m^2) and replicated 3 times. Treatments consisted of two varieties of sweetpotato NR 05/022 light orange flesh, TIS 87/0087 white flesh and garden egg (GE) Ngwa large planted at different times. The 13 treatments were sole NR 05/ 022, sole TIS 87/ 0087, sole garden egg, simultaneous garden egg + NR 05/ 022, simultaneous garden egg + TIS 87/ 0087, weeks after planting (WAP) GE 4 WAP + NR 05/ 022, GE 4 WAP + TIS 87/0087, GE 2 WAP + NR 05/022), GE 2 WAP + TIS 87/0087, weeks before planting (WBP), GE 4 WBP + NR 05/ 022, GE 4 WBP + TIS 87/0087, GE 2 WBP + NR 05/ 022 and garden egg 2 (GE 2 WBP + TIS 87/0087). Sole crops of sweetpotato and garden egg were planted for the computation of the productivity parameters of intercropping systems. Sweetpotato were planted on the crest of the ridge at 1 m x 0.3 m to give a population of 33,333 plants/ha. Garden egg seeds were raised in nursery beds and transplanted into at 4 to 6 WAP. Garden egg seedlings were planted midway between the crest and base of ridges at 1m x 1m to give a population of 10,000 plants/ha. Weeding was carried at 4 WAP, 300kg/ha of NPK 15: 15: 15 and 5 t/ha of poultry manure were applied in all the plots at 4 WAP. Insecticide (Karate) was applied at 6 WAP before flowering of garden egg. Data on sweetpotato were collected on vine length/plant, number of leaves/plant, number of branches at 10 WAP, root yield/plant in (g) and yield t/ha at 16 WAP. The land equivalent ratio (LER) was also computed for sweetpotato and garden egg. Data on garden egg were collected on plant height, number of leaves/plant, number of branches/plant at 10WAP, no of fruit/plant and fruit yield t/ha. Piecemeal harvest of garden egg fruits was done between 10-14 WAP. The data were subjected to analysis of variance using GENSTAT DISCOVERY EDITION 1(Lawes Agricultural Trust. 2003) and means were compared using Fisher's least significance difference (LSD) at 5% level of probability.

RESULTS AND DISCUSSION

The results indicated that vine length, number of leaves and root yield (t/ha) of sweetpotato, sole NR 05/ 022 and SIM GE + NR 05/ 022 had the highest value which were significantly different from other times. Intercropping GE 4 WAP + NR 05/ 022 had root yield of 19.30(t/ha) which differed significantly from other times of planting while GE 4WBP + TIS 87/0087 gave a yield of 6.88(t/ha) which is the lowest. For garden egg plant, plant height, number of leaves and fruit yield (t/ha) were influenced by planting of time. Sole garden egg and simultaneous planting of garden egg + 2 varieties of sweetpotato were positively influenced than other periods of planting. GE 4 WBP + NR 05/ 022 gave fruit yield of 2.80 (t/ha) while the lowest fruit yield of 1.84 (t/ha) was from GE 4 WAP TIS 87/ 0087. The low yields obtained in garden fruits were due to pests' infestation at the point of flowering and fruiting. Land equivalent ratio showed that planting garden egg + sweetpotato showed that the GE4 WAP + NR 05/ 022 and GE 2 WBP + TIS 87/0087 1.14 and 1. 16 respectively while the lowest was from GE 4 WBP + NR 05/ 022 that was 0.92 which could be as a result of pest problem. The high yield obtained in sweetpotato root could be attributed to that both the space and growth resources were utilized by sweetpotato. Time of planting component crops in intercropping systems affects growth and yield of crops. The results obtained in the study agreed with the work of Njoku *et al*, 2010 that sole crop and simultaneous planting of crops in intercropping gave higher yield than other time of planning. In intercropping earlier sowing of component crops usually established, grown better and yield well.GE 4 WAP + NR 05/ 022 and GE 2 WAP + NR 05/ 022 yield well. Muoneke *et al*, 1997 in their studies reported that yield of component crops increased when sown earlier and late sowing date decreased yield of one of the component crops. Umana, 2007 also said that yield and yield components of intercrop is reduced with delayed time of introduction in the system. Planting earlier in the season increased yield as in GE 4 WAP + NR 05/ 022 that is sweetpotato planted 4 weeks before planted garden egg gave the highest root yield and GE 4 WAP + NR 05/022 garden egg planted 4 weeks before planted NR 05/ 022. Land equivalent ratio obtained in the study is the same with the work of Ebeniro *et al*, 2015 showing that the system was productive than sole cropping.

CONCLUSION

In intercropping garden egg + sweetpotato, early introduction of both crops were better than late planting. Also simultaneous planting did well than late planting.

ABSTRACT
Postharvest decay is the major factor limiting the extension of storage life of most vegetables .Biological control of postharvest diseases of fruits and vegetables is a new area of research. Biological control using microbial antagonist is a promising alternative to fungicides to control postharvest disease. Intensive research efforts have been made to isolate, screen and test the efficacy of biocontrol agents under laboratory and semi-commercial conditions that could serve as alternative strategies which are safe, effective, economical and needed for control of postharvest diseases. The alternative methods are needed because of concern about environmental contamination and human health risks associated with fungicide residues and because the widespread use of the chemicals in commercial packing houses which has led to the proliferation of resistant strains of pathogens.
Keywords: Antimicrobial, Bicarbornate salts, Neem extracts and Rot Pathogens

INTRODUCTION
Selected organic and inorganic salts are active anti-microbial agents and have been used widely in the food industry. Among these, Sodium bicarbonate and Potassium sorbate are used for controlling pH, taste and texture and they also exhibit broad-spectrum anti-fungal activity and have efficacy against oral pathogens (Miyasaki *et al*., 1986; Karabulut *et al*., 2001) and against aerobic and anaerobic bacteria and yeasts that are food borne (Corral *et al*., 1998). Neem (*Azadiratcha indica*) extract contains the concentrated form of active or principle compounds found in neem. Neem extracts can be used in different industries like agricultural, herbal and pharmaceutical industries to manufacture quality natural products. Neem extracts are also used as an effective and safe method to control pests and plant pathogens and also lack any residual problem (Quarles, 1994; Thacker, 2002). Diseases that infect crop after harvest and on storage are postharvest diseases. These postharvest diseases increase loss in yield, reduce quality and quantity of crops, depreciate nutritive value, cause low market demand, introduce poisons to crops and increase food insecurity. These do not encourage farmers who have worked all hard from planting to harvesting and meet doom at storage. There should be solution to these postharvest storage diseases, and the difficulties in obtaining fungicides and application machinery, and their high cost for small-scale farmers which make it almost impossible for farmers to effectively control these diseases. Ethanobotanical studies have shown that most of the plants we see as wild herbs or weeds are of medicinal value to humans. Moreso, the synthesized chemicals used as fungicides are discouraging for use and they may have side effects on both the crops and animals that consume the crops (Torigan *et al*., 2001). Thus, more emphasis should be laid on the use of biological disease control and natural herbs in disease management because they are cheap, available and with no residual effect on the environment. This study examined the possibility of using bicarbonate salts and neem (*Azadiratcha indica*) leaf extract to inhibit postharvest rot pathogens of crops.

Components and action of Neem
Neem (*Azadriatcha indica*) leaves, locally called dogoyaro or ochonyeogwo is a medicinal plant. Its liquid can be extracted and then used to prevent or reduce diseases, or used in the storage of crops after harvest. Extraction of these herbs can be done by cooking in water, squeezing or grinding, after which it is dissolved in water. Neem oil or extract is effective against rots, mildews, rusts, scab, leaf spot and blight. Scientific review papers also show that neem possess insect growth regulatory effect. Neem is also known to contain over 100 biologically active constituents that can be used in various agricultural formulations, and antiviral compounds (Quarles, 1994; Thacker, 2002). According to Anon (1990), there is considerable emphasis placed on the development of neem pesticides based on azadiratcha, which is the most widely evaluated neem compound. The seeds are known to have the highest concentration of azadiratcha and are most effective. Neem also contains several active ingredients and they act in different ways under different circumstances. Neem products are unique, in that they are not outright killers, instead they alter an insect behavior or life processes in ways that can be extremely subtle (NRC, 1992). Azadiratcha is thought to be the most bioactive ingredient found in the neem tree; however, such speculations may be due to it having been investigated more thoroughly than other compounds (Quarles, 1994; Thacker, 2002). Neem products are generally sold as emulsifiable concentrates (EC) but Copping (2001), reported that there is no known incompatibilities with other crop protection agents. Neem seeds control several types of soil pests and pathogens. It is for instance, notably effective against nematodes. Other neem compounds, nimbin

and nimbidin have been found to have antiviral activity. They control viral diseases of crops and livestock (NRC, 1992). Nimbidin is the primary component of the bitter principles obtained when neem seeds are extracted with alcohol. It occurs in sizeable quantities about 2% of the kernel (Anon, 1990). Neem extracts can be applied in many ways; they may be employed as sprays, powders, drenches or diluents in irrigation water or sub-surface irrigation system. It can be applied either as dusts or sprays (NRC, 1992).

Botanicals in Disease and Pest Control

There was a considerable interest in the use of sodium bicarbonate (NaHCO3) and potassium bicarbonate (kHCO3) for controlling various fungal diseases in plants (Karabulut et al., 2003; Smilanick et al., 2006). Bicarbonates were found to suppress several fungal diseases of potato (Nehal et al., 2009), cucumber (Ziv and Zitter 1992). Spraying plants with NaHCO3 solution provided good control of several plant diseases (Horst et al., 1992; Arimoto et al., 1997; Palmer et al., 1997; Janisiewicz and Peterson 2005). Also, spraying with KHCO3 solution provided the most effective protection against plant diseases (Fallik et al., 1996; Smilanick et al., 1999, 2006). Sodium and Potassium bicarbonate combined with oil were effective in controlling plant diseases (Horst et al., 1992; Ziv and Zitter 1992). The potential of bicarbonate salts for the control of postharvest pathogens has been demonstrated in citrus (Arimoto *et al*., 1977), carrots (Punja *et al*., 1993), bell pepper (Fallik *et al*., 1997) and melon (Aharoni *et al*., 1997). Smilanick *et al*., (1999), found that the effectiveness of sodium bicarbonate (SBC) and carbonate improved significantly when the treatment was followed by the application of the fungicide imazalil or the biocontrol agent *P. syringae* Ese – 10. The combination of bicarbonate or carbonate with *P. syringae* was synergistic. Hot water (HW) treatments have been well studied for the control of postharvest decay of citrus fruits (Schirra *et al*., 2000). Treatments with sodium carbonate (SBC, NaHCO3, baking Soda) provided satisfactory control of green mold on lemons (Smilanick *et al*., 1995, 1999) and oranges (Smilanick *et al*., 1997, 1999; Palou *et al*., 1999) and blue on oranges (Palou *et al*., 2001). On the evaluation of the use of sodium bicarbonate (SBC), potassium sorbate (K-sorb) and yeast antagonists for decreasing postharvest decay of sweet cherries by Karabulut *et al*., (2001), it was reported that SBC was more effective than K-sorb and yeast antagonists in controlling the decay of sweet cherries. SBC at a concentration of 2% showed potential for controlling postharvest disease of sweet cherry during air, MA and shelf life.

Gamage *et al*., (2003), researched on the use of sodium bicarbonate and *Candida oleophila* to control anthracnose in papaya during storage and reported that both (*C. oleophila* and 2% NaHCO3) can be used together for treatment of papaya fruit. However, the reduction of anthracnose severity was significantly ($P<0.05$) higher in fruits subjected to a combination of sodium bicarbonate and *C. oleophila*, suspension than in fruits dipped in either sodium bicarbonate or *C. oleophila* suspension. In Hot water (HW), sodium carbonate (SC) and sodium bicarbonate (SBC) treatment for the control of postharvest green and blue molds of *Clementine mandarins*, it was reported that HW dips at 45 or 50^0C for 60 0r 150s, did not effectively control either green or blue mold, a 150s dip in 3% SC at 50^0C, controlled totally both green and blue molds of mandarins without noticeably injuring the fruit (Palou *et al*., 2002). In the shelf-life estimation of Fuji apples II, the behaviours of recently harvested fruits during storage at ambient condition by Varela *et al*., (2008), he reported that Fuji apples kept at normal atmosphere for 91 days until consumption; from day 70 of the storage, the apples showed external skin damage as a result of the non-controlled atmosphere storage. Excess or too low relative humidity can have detrimental effect on fruits during storage; if the humidity is too low, it causes dehydration of the tissues leading to shriveling. Also, sensory rejection of the edible part of the apple because of the eating quality loss, would not be the reason for the end of shelf-life in this case, instead, physiological deterioration leading to the rejection of the entire fruit before consumption would be the determinant of shelf-life.

Effects of Bicarbonate salts on postharvest rot pathogens of Potato

The suppressive effect of sodium and calcium salts applied individually or combined with the yeast *Saccharomyces cerevisiae* (CBY) against *Alternaria solani* the causal agent of early blight disease of potato was evaluated under laboratory, green house and field conditions (Nehal *et. al*., 2009). In vitro test a complete inhibition in fungal growth was observed at concentration of 30mg/ml both sodium bicarbonate and calcium chloride. In pot experiment under artificial infestation with pathogenic fungus, application of sodium bicarbonate or calcium chloride significantly reduced the early blight incidence and severity by increasing their concentrations. Their most effective concentration were 30mg/ml that reduced the disease incidence by 50 and 62.4% respectively. Superior effect of sodium bicarbonate or calcium chloride in disease reduction was observed when they combined with CBY. Study on antifungal activity of some salts on growth and dry rot development of fusarium solani (Mart.) Sacc.(Mohammed et al., 2013). In the study, antifungal activity of some salts ammonium phosphate, potassium carbonate, potassium bicarbonate, sodium carbonate and sodium bicarbonate was investigated against Fusarium solani. In vitro, inhibition of the growth rate was evaluated after 7 days in PDA media. The result exhibited the salts had inhibitory activities on the growth rate of this fungus. Ammonium phosphate indicated the largest inhibition (92.2%) followed by potassium carbonate (54.92%), potassium bicarbonate (46.14%), sodium carbonate (42.60%) and sodium bicarbonate (42.3%).

Effects of Neem extract on postharvest rot pathogens of sweetpotato

Suleiman and falaye (2013) reported that neem leaf extract was effective in suppressing mycelial growth of Aspergillus niger in sweetpotato at higher concentrations (30% and 40%) and the percentage inhibition at ther various concentrations was determined. In the study, isolation and identification of of the fungi associated with rotten sweet potato root was carried out and the diseased portion of the rotted tubers were scrapped and inoculated on PDA at 27+ 2^0C, subcultured to obtain pure culture. A. niger was isolated from the rotten portion and identified based on morphological characters and pathogenicity tests.

In the in vitro and in vivo experiment to control postharvest rot pathogen of sweetpotato (Opara and Agugo 2014), neem oil inhibited growth of sweetpotato soft rot both in the in vitro and in vivo trials but performed much better in the in vivo experiment than oil extracts of the other leaves used and sterile water (p> 0.05). The antifungal effect of different concentrations of neem and moringa seed extracts on wet rot disease of sweetpotato was conducted (Tijani et al., 2013). Moringa and neem seed extracts each with four varying concentrations (30, 60, 90 and 120g/L) were evaluated along with carbendazim and untreated sweetpotato served as the control. The result showed that neem seed extract was significantly (P<0.01) better than the moringa seed extract in controlling the disease. It inhibited radial mycelial growth of *Rhizopus stolonifer* and also reduced the weight loss of sweetpotato caused by *R. stolonife*r. The effectiveness of the two plant seed extracts compared favourably with carbendazim.

CONCLUSION

The study revealed that there exist a potential in natural plant products for the control of crop diseases and if fully exploited they can replace chemical pesticide in the control of crop diseases. Hence, the use of natural plant products or botanicals is a strategy particularly well suited to assist small-scale farmers farmers of the tropics who generally lack financial resources and technical expertise required to use chemical control methods effectively, hence the purpose of the research being investigated.

ABSTRACT
Field experiment was conducted during 2013/2014 dry season at the Research farm of Institute for Agricultural *Research (I.A.R) Ahmadu Bello University Zaria located at Kadawa Sudan savannah to study the growth and yield of grains amaranth (Amaranthus cruentus L..) as controlled by sowing method and seed rate under irrigation at Kadawa. The treatments consisted of three sowing methods (drilling, broadcasting and dibbling) and five seed rates (1 kg, 2 kg, 3 kg, 4 kg and 5 kg/ha) combined factorially in a randomized complete block design and replicated three times. Sowing method had no significant effect on plant height and leaf area index of the crop, however, drilling method had the higher values for stem diameter, panicle length, grain weight per panicle and grain yields. Drilled and dibbled plants had larger diameter compared to broadcast amaranth while at later stage of growth larger diameter was obtained in dibbled stands. No significant differences were noted due to varied sowing methods on plant height and LAI. A significantly taller plants were noted when 3 kg/ha seed was used resulting in taller plants that were at par with other rates except 5 kg/ha that gave shorter plants. In addition 3 kg/ha resulted in plant with longer panicle which was at par with 2 kg/ha seed rate. Heavier panicle weight per plant was recorded when 2 kg/ha seed was used, whereas 1 and 5 kg seed / ha resulted to reduction in panicle weight. Higher grains weight per plant and yields per hectare were recorded when 2 kg/ha seed was used which was at par with other rates except 1 kg/ha that recorded least grains output. Based on the result of this finding it was observed that drilling method using 2 kg/ha seed rate could be used for the cultivation of grains amaranth under irrigation at Kadawa , Sudan savannah agro ecological zone of Nigeria.*
Key words: Sowing method, seed rate and grain amaranth

INTRODUCTION
Amaranth is a vegetable crop belonging to the family Amaranthaceae. It is a native to South America and Mexico the crop is now widely distributed and cultivated in tropical and subtropical countries under irrigation and rainfed conditions (Husssaini, Y.(2002) Raemaekers, 2001). There are over 60 known species of Amranths of which only few are cultivated for their grains or vegetative part. Prominent among which are *Amaranthus hypochondriacus*, *Amaranthus cruentus* and *Amaranthus caudatus* (Anon, 1984). Amaranth requires good land preparation both dry and rainy season cropping.. A bed of 90 cm wide and 20 cm height is required during the dry season and under rainfed condition the bed can be raised to 30 cm or above to faciliatate drainage. Amaranth can cultivated by direct seeding or by transplanting. Seeds are either broadcast or sown in rows 10-20 cm apart. Amaranth is an important nutritious crop grown for home consumption and local sales The crop is traditionally planted using broadcasting or drilling method; with little or no attention to appropriate seed rate resulting to wastage of scarce seeds scanty. The crop has high economic values and literature on planting method and seed rate is. The present study was conducted to determine the appropriate seed rate and sowing method for efficient growth and higher yield of grain amaranth under irrigation.

MATERIALS AND METHODS
The study was conducted during 2013/2014 dry season at the research farm of the Irrigation Research Station Kadawa of the Institute for Agricultural Research, Ahmadu Bello University located in the Sudan Savannah ecological zone of Nigeria (11º 39'N, 80º 27'E and 500 m above sea level). The treatments consisted of five seed rates (1kg, 2.kg, 3 kg, 4 kg and 5kg/ha) and three sowing methods (drilling, broadcasting and dibbling) and were factorially combined in randomized complete block design (RCBD) and replicated three times. The gross plot size was 4m x 3m ($12m^2$).and the two central ridges ($6\ m^2$) served as net plot. The experimental site was harrowed and ridged to fine tilth. After plot demarcation the ridges were later flattened into raised beds. The seeds of grain amaranths mixed with clean sand were drilled, broadcast or dibbled on their respective beds as per treatments. After sowing the beds were mulched and irrigated regularly. Weeds were controlled manually by hoeing and regular hand pulling. The data collected were subjected to statistical analysis of variance (ANOVA) to test significance of treatment effects as described by Snecdector and Cochran (1967). The means obtained were compared using Duncan's multiple range test DMRT (Duncan, 1955).

RESULTS AND DISCUSSION

Table 1 shows the effect of sowing method, seed rate and their interaction on plant height,stem diameter and leaf area index (LAI) of grain amaranth at Kadawa during 2013/2014 dry season. The result showed no significant differences in plant height and LAI due to varied sowing methods during the sampling periods. The effect of seed rate on plant height of the crop was significant at 10 WAS, in which 3 kg seed/ha resulted in the production of taller plant that were statistically at par with those from 1, 2 and 4 kg seed/ha but taller than n those obtained from 5 kg seed/ha. The shortest plants produced by 5 kg seed/ha were in turn statistically similar to those from 1, 2 and 4 kg seed/ha. There was no significant interaction between the sowing method and seed rate on plant height throughout the sampling periods.The effect of sowing method on stem diameter was significant in which drilling resulted in larger stem diameter throughout a sampling periods which was at par with dibbling method. The least stem diameter was observed in broadcast stands which in turn were at par with drilled amaranth at 10 WAS. No significant interaction was recorded between sowing method and seed rate on stem diameter during the experimental period. No significant differences were noted on LAI due to different sowing methods throughout the sampling period and similar observation was made when different seed rates were used. No significant interaction was recorded between sowing method and seed rate on LAI. Table 2 shows the effect of sowing method, seed rate and their interaction on panicle length, panicle weight per plant and grains yield. of amaranth at Kadawa during 2013/2014 dry season. A significant effect of sowing method on panicle length was observed, where drilling and dibbling method resulted in longer panicle compared broadcasting method. The effect of seed rate was significant on panicle length where 3 kg seed/ha produce longer panicles that were at par with other seed rates except 1kg seed/ha which gives shorter panicle. There was no significant interaction between sowing method ad seed rate on panicle length. A significant effect on grain weight per plant when different sowing methods were used was observed. Drilled and dibbled amaranth had higher grains weight per plant and lower weigh per plant was recorded in broadcast amaranth.. Seed rate of 2, 3 and 4 kg/ha produced similar and higher grains weight per plant and the was least produced by 1 and 5 kg/ha seed rate. No significant interaction was recorded between sowing method and seed rate on grains weight per plant. A significant effect of sowing method on grain yield per hectare was observed where amaranth sown by drilling method had higher grain yield per hectare when compared to broadcast and dibbling methods which were at par with lower grains output. Seed rate had significant influence on grains yield /ha, where 2 kg seed//ha produce higher yield which was at par with other rates except 1kg seed/ha which gives least yield. The least grain yield observed 1kg seed/ha was in turn statistically similar with that at 3, 4, and 5 kg seed/ha. No significant interaction was recorded between sowing method and seed rate on grains yields.

The taller plant with longer and heavier panicle in drilled amaranth stands could be attributed to uniform seed distribution that ensure good and timely germination that reduced competition with weed at early stage of growth compared to broadcast method, that had over crowded stands resulting in serious competition for nutrient and space. This agreed with the findings of Putman (1990) who stated that broadcasting method increase the risk of poor plant stands, increase in uneven germination and competition with weeds at early stages of growth. Similarly, Olofintoye *et al* (2011) observed that grain amaranth plants compete excessively with each other when sown at closer spacing leading to smaller grain per panicle. The variation on grains yield due to sowing method might be attributed to a number of plants per plot that determine their rate of growth potential. Due to more plants /stands germination was delayed in dibbled and broadcast plots. Similarly, overcrowded stands in weaker plants that matured and produced seeds earlier at the expense of vegetative growth, hence reduction in yield potential of the plant as observed in least yield in dibbled plots. This is in conformity with findings of Gimplinger *et al* (2006) that stated higher plant population pressure drastically reduced the growth and yield characters of grain amaranth. The high yield obtained from 2 kg seed/ha and beyond could be attributed to high plant population, however, the yield attributing characters like panicle length were comparatively more in other rates hence the reason for similarity in yield. This was further indicated by lower yield obtained when 1 kg/ha seed rate was used resulting in the production of shorter panicle.. Also O'Brien and Price (2008), have pointed that low planting density in grain amaranth resulted in large heads and vice versa. Svirtkis (2003) reported that, in grain amaranth seed rate of 2-4 kg/ha with row spacing of 5 cm gave the highest yield in Lithuania. Seed rate had no significant effect on leaf area index at both locations during the experimental period. This could be due to wider leaves coverage of the soil nutrient and light interception. In the cultivation of grain amaranth, the recommended sowing density varies considerably worldwide, depending on number of factors such as the environment, production system and variety involved. (Weber, 1990,and Olofintoye *et al (*2015).

CONCLUSION

In conclusion, based on the result of this investigation it was observed that drilling method and 2 kg/ha seed rate could be used for the cultivation of grains amaranth under irrigation at Kadawa, Sudan savannah agro ecological zone of Nigeria.

ABSTRACT
The importance of cocoa in Nigerian economy could not be over-emphasized. The crop has contributed immensely to Nigeria's gross domestic product and has provided employment to the populace especially in cocoa producing belt. In view of this, this study which determines the characteristics of Theobroma cacao is pertinent. Simple random sampling technique was used to select 104 cocoa farmers from four cocoa producing States in Nigeria, the States include Osun, Ekiti, Abia and Cross-River. Structured questionnaire was used to collect information from the respondents. The information collected was analysed using descriptive analysis. The result shows that majority (74.04%) of the cocoa farmers in the study area were male while 85.58% of the farmers were having formal education. Most farmers (69.35%) indicated that the breed of cocoa on their farms fruits at the age of four years while 50.96% of the farmers signified that the cocoa trees on their farms do not resist to blackpod disease. In most cocoa farms, variations such as number of pods per tree, pod size, tree size, pod colour and bean size were observed among the cocoa trees in the same farm. The study recommended that a breed of cocoa needs to be developed that will be resistant to blackpod disease and that the period of first fruiting will be reduced.
Keywords: *Theobroma cacao,* characteristics and blackpod disease

INTRODUCTION

Cocoa (*Theobroma cacao*) came into the West African sub-region from Brazil, and was specifically introduced into Nigeria from Fernando Po (present day Equatorial Guinea) by Chief Squiss Ibannigo in 1874 (Ayorinde, 1966). Other sources of introduction include trade agents, Ministries of Agriculture and Research Institutes (Opeke, 1987). Government of Nigeria developed an interest in the cultivation of cocoa since 1887 when cocoa seedlings from the old Botanic Garden at Ebute-Metta (Lagos) were sent to Ibadan for trial. This explains how cocoa cultivation gained its first and earliest impetus around Ibadan, Oyo State of Nigeria which produced the bulk of Nigerian cocoa up to the early twentieth century. Cocoa cultivation later spread to various parts of Western Nigeria. At present, cocoa is grown in most parts of Southern Nigeria extending from areas having 1,100mm annual rainfall towards the North to areas having 2,500mm annual rainfall towards the coast (Sanusi, 2006). Estimation put Nigerian cocoa acreage at 10,000 acres (4,000 hectares) in 1912 and this increased to over 300,000 acres (120,000 hectares) by 1930 (Olayemi, 1974). Planting continued at a high rate from 1930 to 1945 by which time about 1,000,000 acres (400,000 hectares) had been planted (Adesimi and Ladipo, 1979) with the acreage of the main cocoa-producing region (that is, the former Western Region) reaching a peak of 56,000 acres (22,400 hectares) in 1936 alone (Olayemi, 1974). It remained at this level until the late fifties when further planting and black pod and pest control led to further and rapid increase in its cultivation (Olayemi, 1974). Climatic compatibility of cocoa with the Nigerian environment coupled with successful combination of cocoa with arable crops by peasant farmers equally promoted the thriving of cocoa in Nigeria (Adegeye, 1977). By the early 1970s, Nigeria became the second largest cocoa producer in the world with an annual output of about 270,000 tons (Aigbekaen 2004, Sanusi and Oluyole, 2005). However, with the advent of the oil boom of the 1970s, activities in the cocoa sub-sector experienced a decline. Particularly, cocoa acreage actually declined for most part of the 1980s when some cocoa farms were abandoned (ICCO, 1999). Investigations have attributed the travails of the Nigerian cocoa industry to the price paid to farmers, scattered small holdings in different locations and the old age of the existing cocoa trees (Olayemi, 1974 and Oduwole, 2000). Adegeye, (2000) observed that most of the cocoa farms were established over 40 years ago and as such the trees were ageing. Obviously, cocoa production is hampered by various problems that range from biological to environmental, socio-economic to institutional. This includes land tenure, ageing cocoa trees, low/poor yielding varieties, unavailability of inputs and chemical, persistent increase in the cost of production, lack of adoption of new technologies, political instability/inconsistencies in government policies (Fashina, 1999, Oduwole, 2004, Oduwole 2000, Adegeye 1974). Having realized this, Nigerian government decided to put some institutional efforts in place, such efforts include cocoa trade liberalization, cocoa rehabilitation programme and distribution of improved cocoa varieties to farmers at subsidized rate. With these efforts, some abandoned plots were rehabilitated and a few new plantings were carried out from mid-1980s to most part of the 1990s thus increases cocoa hectarage. Estimation put the current cocoa hectarage at about 600,000 to 700,000 hectares (Fashina, 1999 and Aigbekaen, 2004). In order to sustain cocoa production, there is a need for increased production which could be through programme aimed at increasing productivity. One of such programmes is rehabilitation programme to replace older tree-stocks. Higher standards of husbandry and better disease management and pest control systems, may also enable farmers to limit the damage caused by pests and diseases. Moreover, scientific research may provide effective and environmentally sound solutions to those losses and contribute to the future assurance of cocoa supplies (Sanusi and Oluyole, 2005). A cocoa tree growing on fertile soil can live for a hundred years or more and may yield well throughout its life. However, the highest cocoa yields are achieved between 15 and 25 years and that a profitable life span may be 50 years but as from the twenty-sixth (26th) year, yields decline gradually and production cost rise steadily (Montgomery, 1981). In order to further buttress these claims, this study was carried out to determine the characteristics of cocoa trees among cocoa farms in Nigeria.

METHODOLOGY

The study was carried out in Southern Nigeria. Simple random sampling technique was used to select four cocoa producing states within the study area. The randomly selected states were Osun, Ekiti, Abia and Cross-River. One hundred and four cocoa farmers were randomly selected from the four cocoa producing States. Structured questionnaire was used to collect information from the respondent farmers. Some of the information collected from the farmers include the socio-economic characteristics of the farmers and the characteristics of cocoa trees on their farms. The cocoa trees' characteristics investigated include (i) Length of first fruiting of cocoa trees after transplanting (ii) Undesirable qualities of cocoa trees on their farms and (iii) Variations among cocoa trees on their farms. The information collected was analyzed using descriptive analysis such as frequencies and percentages.

RESULTS AND DISCUSSION

Socio-economic characteristics of cocoa farmers

Table 1 shows the age distribution of the farmers. The table shows that only 10.5% of the total farmers were below 30 years of age. Hence, not many youths were engaged in cocoa farming. The implication of the finding is that the present old farmers may be difficult to get replacement at the time when they are incapable to continue with the work. Regarding the gender distribution of the farmers as shown on table 2, findings from the table showed that there were more male headed households than female headed households. The dominance of the male over the females may be attributed to the fact that male children are considered in the inheritance of farm land in the study area. Also, females are involved in off-farm activities such as buying and selling of farm produce, storage of crops and packing of farm produce. While their males counterparts were highly involved in tree crop production most especially cocoa in the study area. This is in consonance with Adamu *et al* (2006), who stated that majority of rural women engaged in off-farm activities such as packing of farm produce, buying and selling farm produce, storage of crops among others. Also cocoa production requires routine management practices that are considered too strenuous for the female to cope with. Results from table 3 showed that respondents with formal education were more (85.58%) in the study area. This shows that most of the farmers had formal education .This is in consonance with Orisasona *et al* (2016) ,who stated that majority of the farmers are literate and hence the ability to adopt new innovation that can bring about increase in input use efficiency. Education is a form of human capital; hence it could impact positively on household ability to take good and well informed production. Regarding the marital status, the findings revealed that 1.92 percent of the respondents were single while 88.46 percent were married. The large percentage of those who were married connotes that marriage is highly cherished by the people of the study area and could lead to increase in household size which implies that there is the likelihood that there could be more family labour available to farming households. As regards the farm size as shown on table 5, a high proportion of the respondents (75.96%) had not more than ten hectares of farm while only 24.04% of the total respondents had more than ten hectares of farm. This however shows that most of the respondents were small scale cocoa farmers.

Characteristics of *Theobroma cacao*

Table 6 shows the farmers' response to the length of first fruiting. It could be observed on the table that 69.35% of the farmers indicated that the breed of cocoa on their farms fruits at the age of four years while only 0.96% indicated that their cocoa fruits at the age of seven. The finding shows that the old variety (Amelonado) which takes longer years to fruit is gradually becoming extinct among cocoa farmers, hence they are responding well to the new technologies in cocoa production by replacing the old varieties with the new varieties which fruits earlier. However, only two farmers indicated that they had a breed on their farms which fruits at the age of two. This should be among the varieties that were recently released to cocoa farmers by Cocoa Research Institute of Nigeria. Table 7 shows the farmers' response on what is not preferable on the breeds of cocoa that are available on their farms. The finding shows that 50.96% of the total farmers indicated that the breeds of cocoa on their farms are not resistant to blackpod disease. This is quite obvious as blackpod disease is one of the most prevalent disease affecting cocoa farms in Nigeria (Oluyole, 2010). However, 24.04% of the farmers indicated that they are not satisfied with the number of seeds per pod while 9.62% of the farmers indicated that the breeds of cocoa on their farms are too tall. A tall cocoa tree is a disadvantage as it may be difficult to harvest pods on them. Meanwhile, 15.38% of the farmers listed late yielding as what they dislike in the breed of cocoa on their farms. Table 8 shows the variations among the cocoa trees on their farms. It could be observed on the table that 14.83% of the farmers observed variations among the tree size of cocoa on their farms, some cocoa trees were long while some were short. Also, 19.91% of the farmers observed differences in the number of pods per tree; 19.49% observed variations in the pod size; 16.10% took note of the differences in the pod colour while 10.59% of the farmers observed differences in cocoa bean size on their farms. However, 12.29% and 4.25% of the total farmers noted variations in the resistance to diseases and pests respectively.

CONCLUSION

Based on the findings in the study, the following conclusions were drawn:
1. Most cocoa farmers in the study area are old. This however could have implication on their productivity since at old age there would be no much strength to do farm work as farm work is very tedious.
2. Majority of the farmers are small scale farmers with total farm size of not more than 10 hectares.
3. In most cocoa farms in the study area, the breed of cocoa that is present there fruits at 4-5 years of age.
4. The breed of cocoa in most cocoa farms is not resistant to blackpod disease and the number of seeds per pod is not satisfactory.
5. In most cocoa farms, variations such as number of pods per tree, pod size, tree size, pod colour and been size were observed among the cocoa trees in the same farm.
However, the study recommends the following:
Youths should be encouraged into cocoa farming, this is quite imperative in as much that they would take over from the old farmers. The encouragement package could be in form of the provision of soft loan to the youths. Incentives should be given to farmers to enable them expand their farm size. Furthermore, a breed of cocoa needs to be developed that that will be resistant to blackpod disease and that the period of first fruiting will be reduced. However, the recently lunched eight cocoa breeds by Cocoa Research Institute of Nigeria would solve the problems as the breeds are resistant to blackpod disease and they fruit at two years.

ABSTRACT
The study was conducted to investigate the constraints of scientist engaged in agricultural biotechnology research in Ibadan metropolis. A multistage sampling technique was used for this study. Data were collected through the administration of structured questionnaire.The data were summarized using Descriptive statistics, Likert Scales and Chi-square. Majority of the respondents were 21-40years old (79.7%), had HND/B.Sc (54.21%), had worked for 1-10years (66.7%), sourced information mostly from Journals (44.1%), were mostly engaged in tissue culture research (33.9%). Serious constraints to agricultural biotechnology research include unstable electricity supply (64.41%) and poor government funding of biotechnology research (55.91%). There was a significant relationship between the personal characteristics of the respondents and constraints faced on agricultural biotechnology research except their sex ($p<0.05$). It is recommended that training up to PhD level be provided through grants for scientist involved in agricultural biotechnology research, regular seminars/conferences be organized for the scientist, more funding from the government and the private sector be made available and extension strengthened to convey research findings to farmers.

Keywords: Agricultural Biotechnology, Constraints, Scientists and Research

INTRODUCTION
Agricultural biotechnology include range of tools that scientist employs to understand and manipulate the genetic make-up of organisms for use in the production or processing of agricultural products(FAO, 2004).In animals, agricultural biotechnology has been used to manipulate the physiology and the genetics make up of farm animals to enhance their performance or to get novel products.The manipulation of reproductive physiology of farm animals include artificial insemination and embryo transfer and those have enabled diverse usage of superior dams and sires (Ransom et al., 1996). In plants, agricultural biotechnology applications have aided in several plant breeding and propation techniques for improvements of food production world over (Nuffield Council on Bioethics, 2003). Some of such examples include tissue culture (Ammonety and Essebey 2003), anther cultures, protoplast cultures, production of Fi hybrids and marker assisted selection.Agricultural biotechnology research has potential to contribute to food security through increase yields, producing healthier crop varieties that can withstand drought and heat, enhancing nutritional and medicinal value and improving storability (UNmillennium project,2005b) biotechnology promises to contribute to world food demands as well as deliver a range of environmental, health and economic advantages (Wheeler, 2005).This study aims to investigate the constraints of agricultural biotechnology research in Ibadan metropolis, south western Nigeria.

METHODOLOGY
The study was conducted in Ibadan metropolis, Oyo state. Ibadan lies within longitude $07^0 02^1$ and 07^0 40E and latitude 03^0 35^1 and 4^0 10^1N Ibadan is 128km North West of Lagos and 345km southwest of Abuja, the Federal capital territory (Udo,1994). Multistage sampling techniques was used for the study.In the First stage, five (5) research centres were purposively selected because they have a mandate covering agricultural biotechnology research. They were National Institute for Horticultural Research (NIHORT), Cocoa Research Institute of Nigeria (CRIN), National Centre for Genetic Resource and Biotechnology (NACGRAB), Forestry Research Institute of Nigeria (FRIN) and Institute of Agricultural Research and Training (IAR&T). International Institute for Tropical Agriculture(IITA) was not selected because it is funded internationally. In the second stage, a list of all the research personnel in each institute involved in biotechnology research was generated and all the personnel used for this study. The sample size for this study was fifty nine (59). Data were collected through administration of structured questionnaires. Data collected were summarized using descriptive statistic such as frequencies, percentages,bar and pie chart. A 4 point Likert scale was used to measure constraints and chi-square analysis (SPSS, 2008: version 17) was used to test the hypothesis.

RESULTS AND DISCUSSION
Table 1 shows the results of the personal characteristics of the respondents. About half of the respondents were males(50.8%), majority were in the age bracket of 21-40 years(79.7%),Mostly had HND/B.Sc as educational qualification(54.2%).Majority of the respondents had between 1-10years experience on the job(66.1%) and are

majorly Christians (72.9%). Having mostly HND/B.Sc, holders in various research facilities indicates a predominance of staffs in need of further training for their M.Sc and P.hd. Result from Fig 1 indicates that majority of the respondents source information on agricultural biotechnology research from journals (44.1%). Another 25.4% source their information from the internet. Just 13.5% got information regularly from seminar/workshops and conferences attended on agricultural biotechnology. Sourcing information from journals and internet shows individual attempts of scientists at accessing information. That is okay, but not good enough. Workshops, conferences and seminars provide a for a where scientist, whether from the National Agricultural Research Institutions or Universities can meet to exchange information on agricultural biotechnology. Michelson et al., (2003) suggested workshops, seminars and conferences to enhance better sharing of information on agricultural biotechnology.Table 2 shows the respondents activities in Agricultural Biotechnology Research. Most were engaged in tissue culture research (33.9%).Another 22.0% are involved in tissue culture and fermentation research. A few of the respondents were involved in tissue culture and development of biofertilizer(11.9%). Just 1.7% are involved in tissue culture and in-vitro technique for breeding.This result support findings by Al-Hassan (2003) who reported that Nigerian infrastructure in tissue culture research is strong but relatively weak in molecular biotechnology.Nwalozie *et al*., (2006, based on Byerlee and Fischer, 2002) used three tiered model to categorize the capacity of national agricultural research systems (NARS). Type 1: "having molecular biology and plant breeding capacity", type II: "with limited molecular biology but solid plant breeding capacity", and type III: "having limited capacity overall". Although African NARS vary significantly in capacity, most fall into lower level type III. Table 3 reports the constraints of the respondents on Agricultural Biotechnology Research. Serious constraints include; Lack of modern agricultural biotechnology laboratories and facilities (52.3%), poor government commitment to funding biotechnology research (55.9%), poor extension delivery mechanism to take the products of biotechnology research to farmers (59.3%) and unstable electricity supply to research stations (64.4%).Other constraints were lack of trained manpower for biotechnology research (39.0%), poor access to information and communication technology by scientist (47.5%) and investors not funding biotechnology research and development in Nigeria(42.4%). These findings agree with Maturuka (2009) who reported that in Africa, agricultural productivity suffers from under-investments in agricultural research, education, farm mechanization, and infrastructure (such as roads, electricity and irrigation).Also, Scooner (2005) in a study stated that Africa (Nigeria inclusive) is under threat from decreasing capacity as a result of inadequate government investment and a series of external imposed conditionality's. On poor extension delivery being a constraint, Davis et al.,(2004) stated that public education is a major task of extension worldwide, and is one potential strategy to inform diverse audiences about agricultural biotechnologies. If so, extension must take a pro-active leadership role and formulate innovative strategies to address the issue of transferring the research finding on agricultural biotechnology and educating the end users to adopt innovations in biotechnology. Also,agricultural extension has a great role in improving the linkage between public and private sectors involvement in agricultural biotechnology. Public-private partnership is more effective mechanism for converting the potential of biotechnology in producing products that improve productivity and economic conditioner of agricultural sector (Seyed *et al.,* 2011). Table 5 shows the result of the chi-square analysis of the personal characteristics of the respondents and the constraint faced in agricultural biotechnology research. There was a significant relationship ($P<0.05$) between Age, marital status, religion, education level and years of experience of the respondents and the constraints faced in agricultural biotechnology research. However, no significant relationship ($p>0.05$) exist between sex of the respondents and the constraints faced in agricultural biotechnology research.

CONCLUSION

Agricultural biotechnology research in the study area is constrained by poor academic qualifications of the researchers, poor infrastructure available for conducting biotechnology research generally and especially in the area of molecular biology, poor government funding and inadequate extension service support.

VARIATION IN FARMERS POTATO TUBER YIELD IN ON-FARM TRIALS IN JOS PLATEAU, NIGERIA

A.K. Danbaba, D.M. Lenka & A.J. Lang

Potato Programme, National Root Crops Research Institute, P.M.B 04, Vom, Plateau State, Nigeria
Email:danbabaanthony@yahoo.com

ABSTRACT

Exploratory surveys have identified many constraints to potato production in Jos Plateau. These include late blight disease, bacteria wilt, low yield, low soil fertility and poor cultural practices. Local and three improved potato varieties were used in on-farm trials in the Jos Plateau Nigeria. Seven Local Government Areas were covered to remedy some of the production constraints. Six farmers were used in each location/site. A randomized complete block design (RCDB) was used in all the locations. Results indicated that variation exist among the varieties and locations. Varieties connect performed significantly better than the others in all the location. Mean tuber yield of variety connect (19.25tlha) out yielded the local variety (8.11tlha). Bassa Local Government recorded the highest tuber yield of variety connect than the rest of the LGAS. However, the ranking of varieties varied across locations. Except for variety Queen Anne all the improved varieties yielded more than the Local one. Implications of these results on future on-farm potato studies are discussed.

Keywords: Variety, locations, tuber yield, and on-farm

INTRODUCTION

In the past few years, several improved potato cultivars have been introduced into Jos Plateau Nigeria. In on-station and multi-location experiments, these introduced cultivars have produced yields more than local varieties. The superiority of these cultivars under farmer's condition has not been demonstrated. In Nigeria (Jos Plateau) on farm experiments with potato began a couple of years ago. In general. These trails are highly variable. This variability in yield is cause mainly by differences in management practices (methods of land preparation, weeding frequency, planting and harrowing time) from one farmer to the other (Ngeve, 1994), plot size, fertility levels rainfall distribution, shade, pest and disease incidence (Mutsears and Walker, 1990). This variability is control by the use of uniform blocks and applying all non- treatment operations as weeding equally each plot in a trial (Gomez and Gomez, 1983). The difference observed in each farm is done in such a way as to better understand the farmer's condition of production (Simba, 1989). The objective of this research therefore were to monitor the performance of three newly introduced potato cultivars under variable farmer conditions so as to get an appraisal of yields under sole cropping situations, to determine farmer assessments of the new varieties and to determine feed back to on-station research

MATERIALS AND METHODS

Site Selection and Characterization: Six villages were chosen in each of the seven Local Government Areas of Jos Plateau namely Jos east, Jos South, Bassa, B/Ladi, Mangu, Bokkos and Pankshin. The six villages were selected and considered a representative milieu within the Area of diagnostic survey. The site selection exercises started as early as March after Land Clearing but before the ridges were made. An Area of 5mx6m was pegged out within each farm and the farmers were asked to complete the land preparation. All farms selected consisted of Land where potato have not been planted for 5years, with no fallow period due to land scarcity. The method of land preparation was remark ably similar and consisted of slash and burn and the construction of ridges. The sites were located in the expansive Jos Plateau Area. The soils are uniform, shallow and highly- leached medium soils. Colour of the top soils ranged from dark brown to brown depending on the organic matter accumulation. The sub soils varied from high brown to near white at depth. All sites were, therefore, susceptible to severe moisture stress during the dry season. The topography of the experimental plots was fairly flat or gently sloppy. The trial sites were therefore, located on slopes of varying degrees, sites were characterized by low soil fertility. Soil fertility was rated as low, medium, or high, depending on the vigor and growth of the crops in each farm.

Planting

At planting, each farmer was supplied with tubers of improved potato varieties, connect, Caruso and Queen Anne. the farmers supplied their own local varieties, all cultural practices were those of the farmers. Intervention by researchers was committed to observations and data collection on tuber yield at harvest after 3 months. The data were subjected to analysis of variance from each individual environment were analyzed, using ANOVA for tuber yield only according to steed and Torrie (1980). Data were subjected to combined statistical analysis across environment using the procedure of little *et-al*, (1996).

RESULTS AND DISCUSSION

The combined analysis of variance is presented in Table 1. The table showed that there was a highly significant genotypic difference indicating that the evaluated cultivars differed in their genetic potential concerning tuber yield. The first order interaction (L×V) did not show any significant difference for tuber yield indicating that the cultivars did not differ in their ranking when grown at different locations, this agrees with the results of Yildrum and Caliskan (1985). There may be no need to repeat the experiment. The findings of the present study fulfill the basic requirements for stability analysis, for the tuber yield studied . The data in Table 2 indicates clearly that tuber yield showed significant differences among the evaluated varieties and reflected a large amount of variability. The variety connect produced the highest tuber yield and was followed by Caruso with a significant difference of 19.25tlh and 11.50lha respectively, while Queen Anne gave the lowest tuber yield of 5.82tlha. As for the average effect of the different environments on mean tuber yield data in Table 3, showed that tuber yield was highly affected by the environment and appeared to be sensitive for their changes. Total yield of cultivars range from 28.91t/lha for connect at Bassa, to 0.68t/lha for Queen Anne at Mangu. The studied varieties indicated their adaptation which reflected the highly magnitude of genotype x environment interaction. Data on table 4 showed the on-station versus on farm potato tuber yields. Tuber yield obtained from multi-site on-station trials were compared with farmers yields in on- farm trials, there was virtually no difference between on-station and on-farm yields of improved varieties. However, the local varieties sustained a significant yield reduction in farmer's field.

Farmer Assessment

In almost all farms, connect was unanimous first choice of farmers over Caruso and Queen Anne. The reasons for choosing connect were#;

- High plant canopy and competes well against weeds
- High resistance to late blight disease.
- It has high yield potentials.
- It has relative big tuber size

CONCLUSION

Improved cultivars out-yielded Local varieties except Queen Anne at on-farm both Local and improved cultivars produced yields at on farm comparable with on-station and mulilocational sites this suggest that the reported low yields of both improved and local at farmer level varieties may be due to inadequate farm management, that is if properly maintained most of the varieties could give better yields. Okonkwo et-at. (1970) reported that at least two properly timed weeding were necessary it potato most farmers were seen to weed only once, this might also have been responsible for the observed low yields of both improved and local varieties. On –farm potato results of different locations were higher in some locations than others. This is probably because of difference in soil fertility, because some of the sites were newly opened at Bassa, where pressure on land is acute and as a result land is really left fallow for up to 3years. From the results presented in this study, it is our suggestion that high yielding verities such as those screened and developed by the pototа programme of National Root crops research instate, athough possessing many desirable characteristics such as disease and pest resistance, have a competitive advantage over local landraces which may result in increased peasant potato production Nigeria

ANTI-SECRETORY AND ANTI-MOTILITY EFFECT OF *Solenostemon rotundifolius* LEAVES ON EXPERIMENTAL RAT INTESTINE

[1]C.I. Harbor, [2]I.I. Ijeh & [2]O.C. Ohaeri

[1]Biotechnology Program, National Root Crop Research Institute Umudike, Nigeria
[2]Department of Biochemistry, Michael Okpara University of Agriculture Umudike, Nigeria
Email: chinma_h@yahoo.com

ABSTRACT
The anti-secretory and anti-motility activities of Solenostenom rotundifolius leaves were investigated in experimental animal intestine. Castor oil an enteropooling inducer was used to cause the accumulation of fluid in the small intestine of albino rats, graded doses of Solenostemon rotundifolius (300mg/kg, 500mg/kg and 1000mg/kg) were administered prior to castor oil treatment. Their effect on gastrointestinal transit of charcoal meal and enteropooling activity in the albino rat intestine were measured and compared with that of a standard drug, loperamide given at 2mg/kg body weight. All doses of S. rotundifolius significantly ($p<0.05$) reduced the intestinal fluid accumulation comparable to that of loperamide; and S. rotundifolius at 300 and 500mg/kg significantly ($p<0.05$) delayed the charcoal meal intestinal transit. These results were comparable to that of loperamide. These results suggest that S. rotundifolius leaves could be used to treat hypersecretoy and hyper motility disorders
Keywords: Anti-secretory, rat intestine, anti-motility, effect, solenostemon rotundisfolins

INTRODUCTION

Solenostemon rotundifollius (common name Hausa potato) is a small herbaceous annual crop with a succulent stem (15-30cm), thick leaves and pale violet small flowers. It has aromatic smell and small dark-brown tubers which clusters at the base of the stem. The tubers are believed to be the source of staple energy in the past but it is now being replaced by more starchy food and only been consumed as a supplementary energy food especially when income is lean. Boiled leaves of *S, rotundifolius* is eaten as a pot herb and in ethnomedicine used for the treatment of dysentery, blood in urine and eye disorders (Enyiukwu *et al.*, 2014; Sugri *et al*, 2013). Dysentery is a gastrointestinal disorder caused by micro organisms; it is characterised by hyper intestinal secretion and motility, accompanied by faecal urgency and incontinence (diarrhoea). Diarrhoea is an important health problem in children where it is the major cause of mobility and mortality accounting for more than 5-8 million deaths annually (Ladaporn *et al*, 2010); any anti-secretory and anti-motility drug will go a long way in the management of diarrhoea. In recent years there is a growing interest in the use of herbal remedies for the management of many ailments diarrhoea inclusive; in view of this the World Health Organisation (WHO) has advocated for the study of traditional medicine practice for effective diarrhoea management and prevention (Mukherjee *et al.*, 1995). Various scientific diarrhoea models have been developed to be used to ascertain the ethnomedicinal use of plant materials for the control of diarrhoea episodes. These models include the *in vivo* reduction in castor oil, induced diarrhoea; reduction in charcoal meal intestinal transit time and the enteropooling test. In this study we are investigating the reduction in charcoal meal intestinal transit time and the enteropooling activities of *S, rotundifolius* leaves.

MATERIALS AND METHODS

Drugs: Loperamide (Square pharmaceuticals Ltd., Bangladesh), Castor oil

Chemicals: All chemicals and reagents were of analytical grade and were mainly products of Sigma-Aldrich.

Plant material: Fresh leaves of *S. rotundifolius* were collected in the month of October, 2014 from the demonstration farm of National Root Crop Research Institute Umudike and identified by experts in the Institute. The leaves were dried under room temperature, milled into powder and extracted with ethanol by continuous extraction using Soxhlet apparatus. The extract was evaporated at room temperature and gave a yield of 2% of a semi solid ethanol extract.

Animal: Male albino rats (65-120g) obtained from the animal facility of the Faculty of Biological Sciences, University of Nigeria, Nsukka were acclimatized to normal laboratory conditions for two weeks, fed with standard rodent pellet and water *ad libitum*. All animal experiments were in accordance with the National Institute of Health Guide for Care and Use of Laboratory Animal (Pub No. 85-23 revised 1985)

Effect of *S. rotundifolius* on castor oil-induced fluid accumulation and electrolyte secretion

Following the method of Dicarlo *et al*. (1994), albino rats selected without discrimination were divided into four groups of six animals each and fasted for 18h before the test but had free access to water. Animals in group I received loperamide (2 mg/kg) and served as the standard while groups, II, III and IV received 300, 500 and 1000 mg/kg of *S. rotundifolius* respectively and one hour after treatment, all the animals received 1ml castor oil orally.

One hour after castor oil administration rats were sacrificed and the small intestine removed from pylorus to cecum, after ligating the ends, and weighed. Intestinal content was milked into graduated measuring cylinder, the volume was measured and the intestine was re-weighed. The difference between full and empty intestine was calculated.

Effect of *S. rotundifolius* on small intestinal transit time of charcoal meal in rats

The effect of *S. rotundifolius* on gastrointestinal motility was assessed using the charcoal meal method of Mascolo *et al*. (1994) with slight modification. Ggastrointestinal transit was calculated for each animal as the percentage distance travelled by the charcoal meal in ratio to the total length of the intestine:

$$\text{Gastrointestinal transit} = \frac{\text{Distance moved by charcoal meal}}{\text{Whole length of small intestine}} \times 100$$

The inhibitory effect of *S. rotundifolius* on gastrointestinal transit was calculated relative to the control:

$$\%\ \text{Inhibition} = \frac{\text{Distance moved by control} - \text{Distance moved by test}}{\text{Distance moved by control}} \times 100$$

RESULTS AND DISCUSSIONS

The acute toxicity of the extract of *S. rotundifolius* had earlier been established to be <5000mg/kg. The small intestine is both an excretory and absorptive organ. Castor oil produces changes in intestinal mucosal permeability to electrolyte and water leading to diarrhoea. In the intestinal mucosa recinolic acid is liberated from castor oil causing irritation and inflammation of the intestinal mucosa an the release of prostangladins which induces hypersecretion (Ammon *et a*l., 1974). Water and sodium are absorbed in the small intestine by the coupled transport of Na^+ and glucose or Na^+/amino acid across the intestinal brush boarder by the Na^+/glucose symporter and Na^+/amino acid symporter respectively with water flowing down the concentration gradient (Field, 2003). The enteropooling test showed decreased weight and volume of the intestinal content which is suggestive of inhibition of intestinal secretion and increased absorption of intestinal water and electrolyte; and by implication increased absorption of intestinal solute. The study on intestinal transit time reveals a delay in the animal treated with *S. rotundifolius* at 300mg/kg and at 500mg /kg when compared with the control but this inhibition is not comparable with that of the standard drug. Delay in intestinal motility is suggestive of diarrhoea control as delay in intestinal motility allows for further absorption of water from the faeces and reduces the watery texture of feaces.

CONCLUSION

The studies showed that *S. rotundifolius* leave extractreduced castor oil induced intestinal secretion and hypermotility, therefore the plant could contain some bioactive principles which can be explored for the management of intestinal disorders such as diarrhoea.

ABSTRACT
The use of DNA fingerprinting as a quick technique for monitoring contamination and quality control of drought tolerant maize varieties released in Nigeria was considered to ensure quality seeds reach farmers for maximum benefits of combating losses from drought spell. Relying on DUS (distinct, unique and stable) phenotyping characteristics to monitor seed production from the breeder seeds through the foundation seeds to the certified seeds that finally get to farmers, could be time consuming and expensive. In this study, 39 drought tolerant maize varieties comprising of 14 breeder seeds, 11 foundation seeds and 14 certified seeds were examine using 40 SSR markers. Twenty eight (28) SSR markers were polymorphic across the 39 varieties and generated a total of 51 alleles. The polymorphic information content (PIC) values obtained for the polymorphic SSR markers varied from 0.11 to 0.39 with an average of 0.27. The percentage variability in seeds produced by the KNARDA (4), SeedProject (4) and Premier seeds (5) Nigeria limited was very low and non-significant. Genetic distance (GD) among all pairs of the breeder seeds ranged from 0.16 to 0.65 while it was 0.13 to 0.75 among all the varieties combined. This showed that the breeder seeds were distinctly different from each other. The foundation and certified seeds from the other sources showed minimum or no contamination and conformity to their parent breeder seeds. Thus, DNA fingerprinting was shown to be an effective and quick technique to compliment DUS phenotyping in ensuring seed purity and quality control.

INTRODUCTION

Maize is the number one cereals crop in Nigeria in terms of production and consumption. It is consumed more than other traditional cereals due to its superior grain yield and versatility of its recipes. With an annual estimated increase in population of 3%, about 4.5 million new mouths need to be provided for every year. Maize is a highly input-responsive crop with high water-use efficiency making it highly prone to yield losses from drought stress. Efforts to mitigate the danger of drought threatening the livelihoods of over 60 million people in Nigeria depending on maize as staple crop lead to the initiation of the Drought Tolerant Maize for Africa Projects (DTMA). DTMA is a project run by CIMMYT and the International Institute for Tropical Agriculture (IITA) in 13 countries of eastern, southern and West Africa: Angola, Benin, Ethiopia, Kenya, Malawi, Mali, Mozambique, Nigeria, Tanzania, Uganda, Zambia, and Zimbabwe and Ghana. The goal of the DTMA projects which is to develop DT varieties in order to cushion the effect of climate change has so far been gaining grounds (La Rovere *et al.*, 2010). Several adaptable DT Maize varieties-OPV synthetics and Hybrids (farmers preferred) have been released in Nigeria by the collaborative efforts of Institute for Agricultural Research (IAR) Samaru and the International Institute of Tropical Agriculture (IITA) Ibadan (Ado *et al.*,2007). The released varieties have been deposited in the National Center for Genetic Resource and Biotechnology (NACGRAB) and various genebanks of other NARS (IAR and other collaborating institutions) that developed them. The varieties are to be disseminated and promoted for adoption by farmers to mitigate the effects of extreme weather and other climatic events in drought prone areas especially Sokoto, Katsina, Kano and Borno State. For these purposes there is the continuous and consistent need for the production of breeder seeds, foundation seeds and certified seeds of these materials. These seeds are of high purity, and quality. The conventional practice of DUS phenotyping as recommended by the International Union for the Protection of New Varieties of Plants (http://www.upov.int/en/publications/tg-rom/tg002/tg_2_6.pdf [verified Feb. 2013]) to ascertain purity and uniformity of seeds during production by breeders and before certification by the National Agricultural Seed Council (NASC) requires a lot of labour, land, time and costs and the right environments. Genotyping as an alternative offers a relatively cheaper, time saving and less labour for breeder and foundation seeds quality control (Warburton *et al.,* 2010). This will facilitate seeds certification by the NASC and purity monitoring and maintenance during breeder and foundation seeds production. The objectives of this research are therefore to fingerprint/ genotype some of the released Drought Tolerant Maize varieties in Nigerian and to use the genotyping data for monitoring the purity and quality of seeds produced by different seed producing agencies in Nigeria.

MATERIALS AND METHODS

The list of the 39 drought tolerant maize varieties used in this study, comprising of 14 breeder seeds, 11 foundation seeds and 14 certified seeds are shown in Table 1. Seeds were obtained from IAR maize breeding program, Kano State ADP (KNARDA) and SeedCo and Premier Seed companies.

DNA Extraction

Seedlings were grown in the green house for 3 weeks after which fresh leaf tissue of 15-20 seedlings of each varieties was harvested and stored in eppendorf tubes at -80°C for total genomic DNA extraction. The modified Dellaporta *et al*. (1983) cTAB method was used with some modifications to extract DNA. The quality and quantity of DNA was determined by NanoDrop spectrophotometer machine (ND-100 Technologies, Wilmington, Delaware, USA).

SSR PCR and electrophoresis

A total of 38 SSR maize primers selected from the 52 core SSR primers described by Warburton *et al*. (2002), were used for PCR amplification of the released DT Maize varieties in sets of 14 breeder seeds, 11 foundation seeds, and 14 certified seeds (Table1). The primers were chosen from the MaizeGDB database (http://nucleus.agron.missouri.edu/cgi-bin/ssr_bin.pl) based on the bin locations, which provides a uniform coverage of all the ten chromosomes in the maize genome. Primer names and chromosome loci (Bin number) of the SSR loci evaluated are included in Table 2. All the primers were diluted to a working concentration of 5 μM with sterile water and stored at -20°C. PCR conditions and gel visualisation were performed as described by Senior et al (1998). Variable "touch down" PCR profiles, annealing temperatures (65-55°C, 70°C-63°C and 60°C-50°C) were used for different SSR primers. The SSR loci amplified were separated on 2% (w/v) superfine agarose gels (Amresco). The gel was stained with ethidium bromide solution and photographed under UV light attached to a gel documentation system (Bio-Rad, Hercules, CA). Allele sizes of amplified fragments were scored on the basis of size in comparison with DNA molecular weight markers. Clear polymorphic SSR fragments (bands) were scored in a binary form of 1 or 0 for presence or absence of the band, respectively.

Data analysis

PowerMarker (Liu and Muse, 2005) was used to calculate standard diversity statistics of observed heterozygosity, gene diversity (D or expected heterozygosity), mean number of alleles per locus (A) and polymorphic information content (PIC). The differences between the seed sources were studied using the analysis of molecular variance (AMOVA) according to Weir (1996) with Arlequin V3.01 (Excoffier et al., 2005). Further analysis of the breeder seeds separately and together withal the other seed types were conducted using clustering method and Principal Co-ordinate Analysis (PCoA). The clustering method is implemented in the PowerMarker V3.25 software which estimated Euclidean genetic distance from allele frequencies (Kaufman and Rousseeuw, 1990). Cluster analysis was performed using the genetic matrices generated by the Euclidean distance method to reveal the patterns of genetic relationships among genotypes. Dendrograms were constructed based on neighbour joining using the software MEGA version 5 (Tamura *et al.*, 2011). The 3D (three dimension) representation of the genetic relationships among the breeder seeds of the studied varieties was done using PAST software version 1.18 (Hammer *et al.*, 2001) and STATISTICA version 6.0 software (StatSoft, Inc., 2001).

RESULTS AND DISCUSSION

The 39 drought tolerant maize varieties comprising of 14 breeder seeds, 11 foundation seeds and 14 certified seeds were investigated using 40 SSR markers. Twenty eight (28) SSR markers were polymorphic across the 39 varieties and generated a total of 51 alleles (Table 1). The polymorphic information content (PIC) values obtained for the 18 polymorphic SSR markers varied from 0.11 to 0.39 with an average of 0.27 (Table 1). This was similar to reports by Adeyemo *et al.* (2011) for yellow maize inbred lines. The number of polymorphic alleles per locus ranged from 1 to 3 with a mean of 2.06 being lower than 4.9 for 40 U.S maize inbreds reported by Lu and Bernardo (2001) suggesting that the varieties were less diverse than the panel of inbred lines studied in Lu and Bernardo (2001) and that they shared more common alleles due to selection for drought (Banziger *et al.*, 1999). Genetic distance (GD) values among all pairs of the breeder seeds ranged from 0.16 to 0.65 while it was 0.13 to 0.75 among all the varieties combined. Gene diversity estimate (D) which is a measure of inbreeding/ heterozygosity (Table 2) ranged from 0.0625 for SM13 to 0.2188 for SM27 (breeder seed), 0.0938 for SM12FS and SM15FS to 0.2188 for SM19FS, 0.1250 for SM18KN, between 0.0625 for SM28SP to 0.1563 for SM27SP and between 0.03 for OBA7 to 0.0938 for OBA5. The higher the value of D the more the heterozygosity. Consequently, hybrid seeds from premier seeds had the least D because they are hybrid varieties, followed by seeds from SeedProject then, KNARDA. Results of AMOVA showed that all the varieties obtained from IAR/ABU Zaria (14BS and 11FS) had significantly high intra and inter population variability (Table 3). The breeder seeds were less heterozygous than the foundation seeds which was probable due to some sort of selection in the course of rouging off types during breeder seed production. The percentage variability in seeds produced by the KNARDA (4), SeedProject (4) and Premier Seeds (5) Nigeria limited was very low and non-significant. The within individual variation of Premier seeds was the least validating the fact that there were hybrid seeds. The low values for the within population variation for these varieties from KNARDA (5.23%), Seed Project (3.90%) and Premier seeds (4.71%) complied with fact that there were fewer genotypes in these sets as compared to seeds from IAR/ABU

Zaria (38.8%). Heckenberger e*t al.* (2002) had also reported genetic differences between different sources of the same cultivar, including inbred lines and doubled haploids using molecular markers.

CONCLUSION

DNA fingerprinting confirmed that the released DT maize varieties were distinctly different from each other. The quality of seeds for farmers' use (i.e. certified seeds) produced by Agricultural Development Agency (KNARDA) and two seed companies (SeedProject and Premier Seeds) were in conformity to their parent seeds (foundation seeds). Seeds from Seed Projects and Premier seeds, though, they were produced under trade names of Obasuper, were derived from DT maize breeder seeds maintained by Institute for Agricultural Research (IAR) Ahmadu Bello University. The effectively of DNA fingerprinting for purity and quality assessment of seeds in the production chain is, thus ascertained and therefore recommended for routine quality assurance during seeds certification and production.

ABSTRACT
In soybean breeding, the focus of attention has been developing cultivars with high and stable yield. Genetic diversity evaluation among varieties is importance and a prerequisite in breeding programme. The objectives of this study were to assess the diversity of soybean accessions at morpho-physiological traits and to identify the correlations among the traits. Results show significant variation amongst varieties for most traits. Positive and significant corrections were observed between yield and some morphological traits while the correlation between yield and physiological traits assessed were not significant. The positive and significant correlations obtained from this study can be helpful information for selection in soybean breeding program.
Keywords: Yield, Variation, morpho-physiological traits, soybean varieties.

INTRODUCTION
The soybean (Glycine max (L) Merrill) is the world most important protein crop. Primary centre of soybean origin is North-eastern China (Popovic, 2010). Primary constituents of soybean seed include about 40% protein, 20% oil, 30% of carbohydrates, 10.5% mineral (Osho and Dashiell, 1998). In soybean breeding, the focus of attention has been on developing cultivars with high and stable yield with increase protein, and oil content (Hollung *et al.*, 2005; Violic *et al.*, 2010). Inspite of the best efforts to improve the soybean varieties, the yield of this crop remains low. Several studies have been made to understand their performances which mainly include the contribution of various yield components towards yield (Mehta *et al.*, 2000, Chettri, 2003; Jian *et al.*, 2007). To improve the chances of selection for various characters within the different parent, genetic diversity among genotypes regarding to agro-morphological and physiological characters can be expected to provide information about genetic relationships. The assessment of genetic diversity is important not only for crop improvement but also for efficient management and conservation of germ plasm resources (Tahir *et al*, 2011). In the selection of diverse parental combinations, it is invaluable to estimate accurately the genetic diversity for generating segregated progenies with maximum genetic variability. Since yield is influenced by different characters, selection of yield per se does not give sufficient confidence for selection of genotypes. Hence, agro-morphological and physiological traits and correlation analysis would provide important information about the degree of relationship among important crop traits and can be used as an index to predict the yield response in relation to the change of particular trait. To understand the physiological bases of yield differences among the genotypes in soybean, it is essential to quantify the component of growth and the relevant variables which is useful in crop improvement. Also a number of factors, such as genotype variations have high impact on seed chemical composition (Cicek, 2001). It is important to evaluate agronomic and quality traits and study correlations among the traits. Knowledge of significant correlation either positive or negative between agronomic and quality traits could be of direct use in improving both kinds of traits in soybean. The objectives of this research include; determining variation in morphological and physiological characteristics of selected soybean varieties, the relationship between morphological characteristics, yield and yield components and the relationship between physiological characteristics and yield of selected soybean

MATERIAL AND METHODS
This study was performed on 16 varieties of soybean. The experiment was conducted in June 2012 at the research farm of Michael Okpara University of Agriculture, Umudike. The design was 2 x 6 factorial experiment arranged in a randomized complete block design (RCBD) replicated three times. Soybean varieties used include: NCRI Soy 16, TGX 1831-32F, TGX 1921-4F, TGX 1485-1D, TGX 1908-3F, TGX 1835-1E, TGX 1987-62F, NCRI Soy 8, TGX 1956-1F, TGX 1802-1F, TGX 1448-2F, TGX 1844-4E, TGX 1885-8F, CAMEROON LATE and TGX 1923-2E collected from National cereals Research Institute (NCRI) Badeggi, Niger State. The entries were shown in spacing of 60cm between rows and 20cm between plants. The collected morphological data consisted of plant height (PH), leaf length (LL), number of leaves (NL), number of branches (NB), number of pods per plant (NP), number of seed (NS) per plant, seed size (SS), dry matter weight (DMW), dry seed weight (DSW), dry pod weight (DPW).

In physiological identification, chrolophyll contents were determined using method described by Sartory et al, (1994) using modification by Francis et al, (2007). Leaf area and leaf area index were also determined by disc method (Watson, 1952). Analysis of variance was performed for all traits in order to test the significance of variation among varieties. For statistically different traits ($P \leq 0.05$) means were separated using Standard Error Difference (SED). Correlation analysis was conducted to detect the functional relationships between the yield and other traits. Computations were done using Genstat statistical software and SPSS statistical software version 17.0.

RESULTS AND DISCUSSION

Agro-morphological trait analysis; stem girth (SG) of different soybean varieties ranged from 0.217cm in TGX1831-32F to 0.388cm in CAMEROON LATE (Table 1) and did not differ significantly($p \leq 0.05$). Chiezey and Odunze (2009) reported significantly wider stem girth in fertilized soybean plant compared with the unfertilized plant. Variation in plant height due to variety was not significant). Leaf length of soybean did not vary significantly ($p \leq 0.05$) with variety. Leaf length of TGX 1923-2E was the longest but was not significantly different from those of 5 varieties (Table 1). Number of leaves per plant differed significantly with soybean varieties and ranged from 10.81 cm in TGX 1485-1D to 24.67 cm in CAMEROON LATE, followed by TGX 1923-3E which was significantly leafier compared to other varieties (Table 1). Result also showed that there were no significant differences amongst the varieties in number of branches per plant. Leaf area (LA) ranged from 329 cm in TGX 1831-32F to 536 cm in CAMEROON LATE (Table 1) and varied significantly. Leaf area index (LAI) of the varying soybean varieties ranged from 4.91 cm in TGX 1831-32F to 11.04 cm in TGX 1921-4F (Table 1). Variation in LAI in this result confirms the report of Chiezey and Odunze (2009) who reported that variation in leaf area index of the two soybean varieties indicates more light interception for photosynthetic activity; hence high assimilate accumulation (Chiezey *et al*, 2001). Dry matter of soybean varied significantly ($p \leq 0.05$) with variety (Table 1) and ranged from 6.54 in TGX1831-32F to 17.20 in TGX1844-4E (Table 1). Lui et al, (2004) and DeBruin and Pederson (2008) also reported significant variation in dry matter of soybean varieties in south east China and Lowa USA respectively.

Dry matter production depends largely on solar radiation intercepted over the growing season and interception of radiation depends on leaf area and leaf area index (Chiezey and Odunze, 2009). TGX1844-4E with high dry matter also had large leaf area indicating the influence of leaf area on leaf dry matter. Number of pods per soybean plant differed significantly ($p \leq 0.05$) and ranged from a mean of 18.3 in TGX1835-1E to 53 in CAMEROON LATE (Table 1). Liu et al (2004) also reported significant differences in number of pods of soybean and observed that number of pods were higher in high yielding varieties. The dry pod weight of soybean varieties ranged from 4.79g/plant in TGX1831-32F to 13.06g/plant in TGX1448-2F. The dry pod weight of the sixteen soybean varieties varied significantly ($p \leq 0.05$). Seed size of plant varied from 0.3850 cm in CAMEROON LATE to 0.4867 cm in TGX1956-1F (Table 1). Amadi and Ifenkwe (2001) reported significant differences between seed weight of soybean due to variety effect in a trail conducted at Saminaka Kaduna state while Mohammed et al, (2014) reported none significant variation in seed weights of soybean treated with fertilizer. Number of seeds/plant had significant differences ($p \leq 0.05$) amongst soybean varieties in number of seed per plant. This ranged from 31.8 in NCRI SOY16 to 89.3 in CAMEROON LATE (Table 1). Ikeogu and Nwofia (2013) reported highly significant ($p \leq 0.01$) variation in number of seeds/ plant of soybeans evaluated at Umudike and Amakama. Thangana *et al*, (2013) also reported significant differences in seed number due to variety. Variety effect on seed yield was highly significant ($p \leq 0.05$) with highest yield of 7.95g/plant in TGX1448-2F and lowest of 3.31g/plant in TGX1921-4F (Table 1). Variation in seed yield of soybean has been reported by various authors (Amadi and Ifenkwe, 2001; DeBruin and Pedersen, 2008; Thangana, et al., 2013; Ikeogu and Nwofia, 2013). Yield is a complex quantitative character governed by large number of genes and highly influenced by environment. Hence the selection of superior varieties based on yield is very difficult. For a rational approach towards improvement of yield, selection has to be made for the component of yield. Association of yield components and yield may be assumed as special importance for the bases of indirect selection. Positive and significant correlations were observed between yield and growth traits; LL (0.37*), NL (0.35*), PH (0.34*), SG (0.28*) (Table 2) and between yield and yield components; $DMW_{(g)}$ (0.84*), NFP (0.77*), NP (0.76*), NS (0.85*) Table 3. This suggests that these traits are good attribute for selection for crop improvement.

Physiological Traits Analysis

Three pigments (carotene, chlorophyll a and chlorophyll b) total chlorophyll and total nitrogen were assessed. Result showed that there were significant differences ($p \leq 0.05$) among soybean varieties in each of these attributes. Fritschi and Ray, (2007) separated soybean accessions into distinct groups based on their chlorophyll a/b ratio. However, chlorophyll a was positively and significantly associated ($p \leq 0.05$) with chlorophyll b, total chlorophyll and total nitrogen respectively (Table 4)

CONCLUSION

From the results, leaf length, number of leaf, dry matter weight, dry pod weight, number of filled pods, number of seeds varied significantly ($p \leq 0.05$) soybean varieties. Seed yield showed high positive, significant association with dry matter weight, dry pods, number of seeds, leaf length, number of leaf, plant height and stem girth. This result highly indicated the importance of these characters for selection in soybean improvement. None positive and significant association between seed yield and pigments assessed indicated that chlorophyll is not a direct determinant of yield in soybean.

IMPROVING ROOT YIELD AND TOTAL CAROTENOID CONTENT OF ORANGE FLESHED SWEETPOTATO USING INTEGRATED NUTRIENT MANAGEMENT

E.O. Anedo, J.M. Emetole, C.V. Agu & I.F.Olaleru

National Root Crops Research Institute Umudike, P.M.B.7006 Umuahia Abia state
Email: emmaanedo@gmail.com

ABSTRACT
This study was conducted to determine the effect of integrated nutrient management on root yield and total carotenoid content of orange fleshed sweetpotato at Umudike Southeastern Nigeria. The experiment was a 5x4 factorial laid out in randomized complete block design (RCBD). The treatment comprises of five levels of composite manure (Pig manure, cowdung and poultry manure) applied at the rate of 0, 2, 4, 6 and 8t/ha and mineral fertilizer (NPK 15:15:15) applied at the rate of 0, 200, 400 and 600kg/ha. Combined application of mineral fertilizer and composite manure significantly (p<0.05) increased the total and marketable root yield of orange fleshed sweetpotato. Application of 4t/ha composite manure + 400kg/ha NPK gave the highest root yield of 15.90t/ha relative to control. The carotenoid content increased generally with increasing rate of the treatment combinations with application of 8t/ha composite manure + 200kg/ha NPK giving the highest total carotenoid content of 733.2µg/g. From the results obtained, application of 4t/ha composite manure + 400kg/ha NPK is recommended for good root yield while application of 8t/ha composite manure + 200kg NPK is recommended for farmers who wish to improve the carotenoid content of orange fleshed sweetpotato.
Keywords: Composite manure, mineral fertilizer, root yield, orange fleshed sweetpotato and carotenoid

INTRODUCTION

The orange-fleshed sweet potato varieties are gaining great attention as a means of reducing common health related problems in low income communities associated with vitamin A deficiency. The varieties are believed to be the least expensive source of dietary vitamin A available to poor families (Laure *et al*, 2013). This is due to their high nutritive value of beta-carotene content, a precursor to vitamin A synthesis (Ukpabi *et al*, 2012). The high yielding orange-fleshed sweet potato varieties are fertilizer responsive (Nedunchezhiyan *et al*, 2010). Applications of inorganic fertilizers have been reported to increase root yield (Nedunchezhiyan and Reddy, 2002). But hampers the quality of sweet potato (Nedunchezhiyan *et al*, 2003). Better sweet potato root quality was observed at optimum amount of nitrogen supply especially through organic sources (Nedunchezhiyan *et al*, 2003). B-carotene content of the root though governed by the genetic factor, Agronomic factors like source and quantity of nutrients significantly influenced the content (Nedunchezhiyan, *et al*, 2010). According to Nedunchezhiyan and Reddy, (2002), sweet potato gets nutrients throughout the growing period when there is integrated use of inorganic (immediately available) and organic (slow mineralisation) source of nutrients which leads to higher yield attributes. However, there is limited information on the integrated use of Composite manure (poultry manure, Cowdung and swine waste) together with mineral fertilizer on improving the root yield and total carotenoid content of orange fleshed sweetpotato in southeastern Nigeria.

MATERIALS AND METHODS

The experiment was conducted at the Research farm of National Root Crops Research Institute Umudike, southeastern, Nigeria. The experiment was a 5x4 factorial laid out in Randomized Complete Block Design (RCBD). The plot size measures 3m x 3m with 0.5m separating the plots and 1m separating the replicates. Materials for the experiment comprises of Composite manure (cowdung, poultry droppings, pig manure) and mineral fertilizer (NPK 15:15:15). Equal weights (72kg each) of the three animal manures were bulked together and applied to the plots at the rate of 2, 4, 6 and 8t/ha with 0t/ha as control. They were factorially combined with 0, 200, 400 and 600kg/ha of NPK 15:15:15 giving a total of 20 treatment combinations replicated three times. The animal manures were applied to the plots one week before planting. While mineral fertilizer was applied at 4 weeks after planting. The test crop orange fleshed sweet potato variety Umuspo 1 was obtained from sweetpotato programme of NRCRI, Umudike. All agronomic practices recommended for sweetpotato production were carried out.

The storage roots were harvested at 16 weeks after planting and graded based on weights as Marketable roots (>100g), unmarketable roots(<100g)(Levett,1993).The total root yield was also computed. The carotenoid analysis was done using the method described by Rodriguez-Amaya and Kimura (2004) and calculated using the formula:

Total carotenoid µg/g = {[$A^{1\%}$ x volume (ml) x 104 x DF]/ [A12 1cm x Weight of sample]}

Where:

A: = Absorbance

Volume: Total volume of extract

$A^{1\%}$ 1cm: Absorbance coefficient of β- Carotene in petroleum ether (2592).
DF = dilution factor and multiplied by 100 to get the carotenoid content in μg/100g. Statistical analysis of data generated was performed using Genstat Discovery Edition using the procedures of factorial experiments. Significant means were separated using Fishers least significant difference (F-LSD) at 5% level probability.

RESULTS AND DISCUSSION

Effect of composite manure and mineral fertilizer on the total root yield orange fleshed sweet potato.

The result of the effect of composite manure and mineral fertilizer on the total root yield of orange fleshed sweet potato is presented in table 1. The results obtained showed that the interaction of composite manure and mineral fertilizer significantly ($p<0.05$) increased the total root yield of orange fleshed sweet potato relative to the control. The highest mean root yield of 15.90t/ha was recorded with the application of 4t/ha composite manure + 400kg NPK. The higher root yield obtained with the application of composite manure and mineral fertilizer in this study might be as a result of improvement in the physicochemical properties which leads to the release of nutrients for crop uptake. Similar results were reported by Agyarkor *et al*, (2014) with incorporation of organic manure and NPK on sweetpotato yield; Akinmutimi, (2014) with application of Cocoa pod husk ash and NPK on the yield of sweetpotato; Onunka *et al*, (2012) with application of organic and inorganic manures on root yield of sweet potato; Asawalam and Onwudiwe, (2011) with complementary use of Cow dung and mineral fertilizer on sweet potato; Yeng *et al* (2012) with integrated application of chicken manure and inorganic fertilizer on growth and yield of sweet potato.Santhi and Selvakumari (2000) have proposed that the addition of organic manure sources to chemical fertilizer could increase the yield of crops through improving soil productivity and higher fertilizer use efficiency.

Marketable Root yield

The results of the effect of composite manure and mineral fertilizer on the marketable root yield of orange fleshed sweetpotato are presented in table 2. The interaction of composite manure and mineral fertilizer significantly ($p<0.05$) improved the marketable root yield of orange fleshed sweet potato relative to the control. The highest marketable root yield of 13.97t/ha was obtained with the application of 4t/ha composite manure +400kg NPK. The improved marketable root yield obtained with the combination of composite manure and mineral fertilizer could be as a result of improved soil physicochemical properties leading to the release of nutrients for the uptake by the sweet potato. The result is in line with similar results by Yeng *et al*, (2012) who obtained higher marketable root yield of sweet potato with integrated application chicken manure and inorganic manure. Hartemink, (2003) reported poultry manure in combination with mineral fertilizer increased the marketable root yield of sweetpotato.

Effects of composite manure and mineral fertilizer on the carotenoid content of orange fleshed sweet potato

The results of the effect of organic manure and mineral fertilizer on the carotenoid content of orange fleshed sweet potato are presented in table 3. The result shows that the application of organic manure singly and its combination with NPK significantly ($p<0.05$) increased the carotenoid content of orange fleshed sweet potato. The highest carotenoid content of 733.2 ug/g was obtained with the application of 200kg/ha NPK with 8t/ha of organic manure. Applications of organic manure singly at 8t/ha gave a total carotenoid content of 726.6 ug/g. The increase in the carotenoid content might be due to increased soil fertilization. Similar results were reported by Gichuhi *et al*, (2013) with application of different rates of broiler litter on Beauregard sweet potato; Moumouni *et al*, (2013) with application of organic and mineral fertilizers on antioxidants, polyphenolic and carotenoid contents of orange fleshed sweet potato; Neduchezhiyan *et al*, (2010) with application of farmyard manure in sweet potato; In addition kipkosgei *et al*, (2003) working with black night shade observed that B-carotene content was significantly increased depending on the type and the level of fertilizer applied. Nedunchezhiyan *et al*, (2010) noted that B-carotene content though governed by the genetic factor, agronomic factors like source and quantity of nutrients significantly influenced the content. Also the increase in the carotenoid content of the orange fleshed sweetpotato might be as a result of improvements in the total nitrogen contents of the soil. Ukom *et al*, (2009) reported that N fertilizer application significantly increased the carotenoid and crude protein content of sweetpotato with increasing N application up to 120 Kg/ha.

PESTICIDES AND SAFE FOOD CROPS PRODUCTION IN NIGERIA

A. Anyim

Ministry of Agriculture, Umuahia, Abia State
Email: anyimalozie@gmail.com

ABSTRACT
The use of pesticides in crop production is sine-qua-non to accelerated food production despite its danger to humans, environment etc. Pesticides can be safe if they are used carefully for prescribed purposes and by trained hands. This paper reviews the benefits of pesticide usage in crop production and measures necessary for the production of safe food crops for local consumption and export.
Keywords: Pesticides, Safe food and Crops

INTRODUCTION
In Nigeria, it is estimated that crop losses due to pests and diseases of some cultivated crops are within the range of 10-100% (Table 1). Besides, average losses due to storage pests have been estimated at 30% (Ezueh, 1983; Anyim, 2013) and in severe cases may lead to as much as 100% damage (Egwuatu, 1986; Anyim, 2013). These losses in most cases begin with the sowing of the seed and continue throughout the phases of production, storage and processing. The huge losses attributable to these pests aggravate the food deficit situation in Nigeria and elsewhere and drastically reduce the financial returns to farmers and their export earnings. Consequently, this precarious situation has often called for the use of plant protection measures, especially synthetic pesticides which have been valued for their effectiveness. Hence, the apparent stability in the world's food crop production is attributable to the use of pesticides to check the ravaging effect of the different types of pests and diseases on crops and crop products (Amadioha *et al*, 2004). Pesticides can be defined as substances or mixture of substances for preventing, destroying, attracting, repelling, or controlling any pest including vectors of human or animal disease, unwanted species or plants or animals causing harm during or otherwise interfering with the production, processing, storage, transport or marketing of food, agricultural commodities, wood and wood products or animal feed stuffs, or substances which may be administered to animals for the control of insects, arachnids or other pests in or on their bodies. The term includes substances intended for use as a plant growth regulator, defoliant, desiccant or agent for thinning fruit or preventing the premature fall of fruit. Also used as substances applied to crops either before or after harvest to protect the commodity from deteriorating during storage and transport. The term normally excludes fertilizers, plant and animal nutrients, food additions, and animal drugs (FAO, 2007). Table 2 lists the most important groups of pesticides currently used for pests control in crop production. These pesticides contain nerve poisons of the organochloride, organphosphaste, carbamate and pyrethroid groups. They affect a wide range of pests. However, in recent years, highly active pyrethroids have been developed, replacing the more toxic organochloride, organophosphate and carbamate products. However, if not properly used, pesticides can cause serious problems, foremost among these is toxicity with an estimated 3,000,000 or more cases of pesticide poisoning annually, 20,000 of which proved fatal and cause pollution of soils, water and air, with as yet unknown long term consequences for human, wild life and the environment (Emeribe, 2008). On the other hand, pesticides can be safe if they are used carefully as prescribed (Amadioha *et al,* 2004).

Table 1: Estimates of crops losses due to pests and diseases of the principal food crops in Nigeria.

CROP	% Losses caused by	
	Pests	**Diseases**
Cereals	15 – 25%	10 – 20%
Grain Legumes	10 – 95%	_
Roots & tubers	12 – 90%	20 – 100%

Source: Adapted from Anyim, 2004

Table 2: Major Chemical groups of pesticides used in crop production

S/N	Chemical Group	Action and effects	Examples (trade name)	Rate (g ai/ha)	Activity
1.	Organo-Chlorines	Nerve poison. Damages fat layer around nerve fibre. Muscle convulsions; internal organ functions disrupted	Endosulfan (Thiodan, Thionex) gBHC (Gammalin)	750 1000	Stomach, contact; broad spectrum Stomach, contact; broad spectrum, persistent.
2.	Organo-Phosphates	Nerve poison. Anticholinesterase; Muscle convulsions; Internal organ functions Disrupted	Monocrotophos (Nuvarcon, Azodrin) Pirimiphos-methyl (Actellic) Dimethoate (Rogor, Perfecktion)	500 500 Seed 10 ppm 400	Contact, systemic, broad spectrum Same same
3.	Carbamates	Nerve poison. Anticholinesteerase. Muscle convulsions; Internal organ functionsdisrupted	Carbofuran (Furadan) Pirimicarb (Pirimor)	500 200	Contact, systemic; Broad spectrum. Contact, fumigant; Specific aphicide.
4.	Pyrethroids	Nerve poison. Damages fat layer around nerve fiber. Muscle convulsions; Internal organ functions disrupted.	Cypermethrin (Cymbush, Sherpa,) fenvalerate (Sumicidin) Deltamethrin (Decis)	50 100 12.5	Stomach, contact; broad spectrum. Same Same.

Rationale for the use of pesticides in food crops production

According to the population projections of the World Bank, the world's population will increase from 6 billion in 1999 to 7 billion people in 2020 (Anyim, 2013). Absolutely, the consequences of the population's increase will not be far-fetched since all these people will also have to be housed, dressed and, above all, to be fed. Therefore, to narrow the gap between food production and human population growth in Nigeria, pesticides have remained a veritable instrument in farmers' effort to contend with pests and their consequent reduction in food production (Anyim, 2013). It is also important to note that in 2006 and 2007, the world used approximately 5.2 billion pounds of pesticides, with herbicides constituting the biggest part of the world pesticide use at
40%, followed by insecticide (17%) and fungicides (10%) (EPA, 2007). The U.S used approximately 1.1 billion pounds of pesticides, accounting for 22% of the world total (EPA, 2007).

Benefits of using pesticides

The overall benefits of using pesticides to control the various pest species and diseases of food crops in Nigeria and elsewhere cannot be over emphasized. Even though, recently, both the public and press have increasingly focused on the negative impacts of agricultural, urban, industrial and residential pesticides. However, there are substantial benefits to farmers and indeed, the society. The benefits are of two levels – primary and secondary. The primary benefits are direct gains from the use of pesticides while the secondary benefits are effects that are more long term (Cooper and Dobson, 2007).

Primary Benefits

(a) Pesticides are the most effective means of controlling pests and plant disease vectors in many circumstances. Pesticides can save farmers' money by preventing crop losses to insects and other pests. It permits more and crops varieties to be grown, reduces manpower requirements, mechanical cultivation, saves time, save cost etc (Emeribe, 2008). For example in the U.S, farmers get an estimated fourfold return on money they spend on pesticides (Helfrich *et al* 1996). Kunicki (2001) also found that not using pesticides reduced crop yields by about 10%. Similarly, in Nigeria, Anyim (2003) found that insecticides significantly increased the yield of soybean with 48% yield reduction in the control. Also. Ogunwolu (1992) found out that insecticide application significantly reduced pod and seed damage and consequently increased the seed yield of cowpea.

(b) Pesticides help to control human and livestock disease vectors and nuisance organisms. For example, they are used to kill mosquitoes that can transmit potentially deadly diseases like West Nile virus, yellow fever and malaria. Pesticides can protect animals from illness that can be caused by parasites such as fleas. Pesticides can prevent sickness in humans that could be caused by mould food or diseased produce.

(c) Pesticides protect private, public and commercial buildings from structural damage associated with termite infestations. Uncontrolled termites can damage structures such as farm houses etc.

(d) Pesticides are used in grocery stores and food storage facilities to manage rodents and insects that infest food such as grain.

Secondary effects

(a) Pesticides usage enhances farm and agribusiness revenues in our communities. Invariably, the nutrition and health of our people will be improved while food safety and security are assured.

(b) Nationally, the workforce productivity and export revenue increases. Government may be partially dependent upon the jobs and tax base that pesticide manufacturers, distributors, dealers, commercial applicators and farmers provide.

(c) In the long run, the use of pesticides stabilizes the national crop production which will in turn shape the national agricultural economy.

Risks involved in pesticide usage

Although there are human benefits to the use of pesticides, some also have drawbacks, such as potential toxicity to humans and other animals. According to the Stockholm Convention on Persistent Organic Pollutants, 9 of the 12 most dangerous and persistent organic chemicals are pesticides.

Therefore, Pesticides if incorrectly used can:

(a) **Be of potential hazard to the user, general public and animals including livestock**

Pesticide exposure can cause a variety of adverse health effects, ranging from simple irritation of the skin and eyes to more severe effects such as affecting the nervous system, mimicking hormones causing reproductive problems and also causing cancer. Moreso, since chlorinated hydrocarbon pesticides, dissolves in fats and are not excreted, organisms tend to retain them almost indefinitely (Anyim, 2013).

(b) **Cause damage to the local ecology and environment**

Pesticide use raises a number of environmental concerns. Over 98% of sprayed insecticides and 95% of herbicides reach a destination other than their target species, including non-target species, air, water and soil (Miller, 2004). Pesticides are carried by wind to other areas, potentially contaminating them. In addition, pesticide use reduces biodiversity and nitrogen fixation destroyed habit (especially for birds) (Palmer *et al* 2007) and threatens endangered species (Miller, 2004).

(c) **Damage beneficial organisms**

There is a wide range in the toxicity of pesticides to various natural enemies. So, if a choice is available, opt for the one that is least toxic to important natural enemies. Also, pesticide use contributes to pollinator decline (Haefeker, 2000; Hackengberg, 2007).

(d) **Encourage pest resistance**

Pests can develop resistance to the pesticide when used continually and the pest becomes immune to it, necessitating a new pesticide. Alternatively, a greater dose of the pesticide can be used to counteract the resistance, although this will cause a worsen of the ambient pollution problem. The development of resistance is due to selection of resistant individuals from populations in each succeeding generation and the gradual genetic development of resistant strains.

Measures Necessary for Safe Crop Production

There is no doubt that the use of pesticides in crop production is sine-qua-non to accelerated food production. However, it has been noted with utmost interest that outside its valued effectiveness, pesticides poses great danger to humans, environment and especially food production. Therefore, to avert the adverse side effects of pesticides on crop production, the following measures must be adopted.

(a) **Use of genuine pesticides**

I advocate that pesticides dealers or Crop Life Nigeria accredited distributors to ensure its genuineness. That is why it is conventionally recommended that pesticide users must not buy pesticide which does not have a label or National Agency for Food Administration and Control (NAFDAC) registration number printed on the label. The product label indicates direction for use, protective equipment to be used, active ingredients of the product, WHO hazard symbols, warnings, date of manufacture, date of expiration etc.

(b) **Correct use of pesticides**

It is of paramount importants to note that pesticides exclusively meant for field application must not be used on stored foods, especially grains. Although stored products pesticides may be a bit expensive, but it is advisable to use them in storing grains since they are safer to use for that purpose and will not pose problems to the user and eventual consumer of the grains if all necessary precautions are fully obeyed (Okunade, 2006).

(c) **Use of certified pesticide applicators**

It is unfortunate to note that some untrained hands have infiltrated fumigation programmes in agricultural farms and residential areas. I suggest that relevant Ministries, Institutions, Agencies such as the State Ministries of Agriculture, the Federal Ministry of Agriculture and Rural Development (FMARD), Research Institutes, Universities of Agriculture etc should mount qualitative training programmes for pesticide users and applicators. At the end, only certified applicators, who have passed an examination may purchase or supervise the application of pesticides, especially restricted ones.

(d) **Enforcement of ban on banned, restricted and adulterated pesticides**

The Consumer Protection Council (CPC) and NAFDAC should intensify efforts and expand their dragnet to ensure that all banned, restricted and adulterated pesticides are not used in crop production. Agricultural dealers, farmers or pest control agents found marketing or using these products should be prosecuted according to the existing laws, if any. Also, all registered pesticides should be renewed every 15 years to ensure they meet the proper standard.

(e) **Effective use of Agricultural Extension Agents to disseminate proven pest control technologies**

Currently, the Agricultural Development Programmes (ADPS) in the country are running a Unified Agricultural Extension System, in which case, every aspect of agriculture is covered. These trained Extension Agents should be empowered by the various state governments to extend effectively proven pest control technologies, especially on safe use of pesticides by farmers. Besides, with the training they have received, the Extension Agents are in a better position to discourage farmers or consumers and indeed, the general public from eating treated seeds, meant for planting and so on.

(f) **Observing the appropriate waiting period for pesticides to degrade**

It is not advisable to consume grains treated with pesticides immediately because of the inherent toxic effect. The truth is that consumers must wait for a particular period of time before consumption, this is called waiting period and the length of this period depends on the type of pesticide used, mode of the application etc. (Okunade, 2006). For example grains treated with pirimiphos methyl should be left for at least 6 weeks while grains treated with only fumigant (e.g Aluminium phosphide) could be consumed after exposure to air for about 4 hours and the content of the piece of paper/cloth removed.

(g) **Establishment of maximum residue levels (Tolerances) of pesticides**

The tolerance level of the different classes of pesticides must be established at registration to guide scientists, plant protectionists, farmers, pesticide applicators etc. Therefore, NAFDAC should use all the necessary tools at its disposal to ascertain the maximum amount of pesticide residue that may legally remain on or in treated crops.

(h) **Rodent poisons should not be used near stored grain**

Rodents are mobile creatures and can poison the food by walking over poison and after that spreading it over the food, if it is kept near it. Under normal conditions, acute poison must be used outside, not in stores containing foodstuffs. Besides, acute poison must be handled by an experienced person, who is aware of the precautions to be taken to avoid accidents. More so, other workers or occupants in the stores should be duly informed before placing poison baits. Dead rodents should be removed immediately with the aid of suitable materials to avoid contact with bare hand. It is also necessary to keep rodent poison away from the reach of children. However, I advocate that rodent poison can be used only when other means (hygiene, rodent-proofing, trapping etc) have failed.

(i) **Use of alternatives to synthetic pesticides**

Currently, the use of alternatives to synthetic pesticides is being advocated for safe crop production. Miller (2004) noted that alternatives to pesticides are available and include methods of cultivation, use of biological pest control (such as pheromones and microbial pesticides), genetic engineering and methods of interfering with pest breeding. The use of alternative to pesticides has been effective in some countries. For example, Sweden has halved its use of pesticides with hardly any reduction in crop yield. In Indonesia, farmers have reduced pesticides use in rice fields by 65% (Miller, 2004).

(j) **Applying Good Agricultural Practices (GAP) to integrated pest management (IPM)**

GAP from crop production perspective, incorporates the use of all proven crop husbandry techniques in such a combination as to enhance the optimum crop production. Consequently, its application in IPM will minimize the effect of pest damage by a combination of cultural, biological and chemical control, use of quality tested and NAFDAC registered pesticides, well timed, accurately applied, at Economic Threshholds (ETs) which is the population density at which control measures should be initiated to prevent pest population from reaching the economic injury level. (Fig. 1).

The economic injury level (EIL) is the population density that will cause economic damage (Fig. 1) while economic damage is the amount of injury which will justify the use of artificial control measures. Thus, below ET, the target population is economically innocuous while at ET, the population attains pest status, requiring crop or grain protection measures. Thus, IPM aims at developing non chemical methods of pest control which are environmental safe and less disruptive of the ecological system while at the same time enhancing sustained safe crop yield.

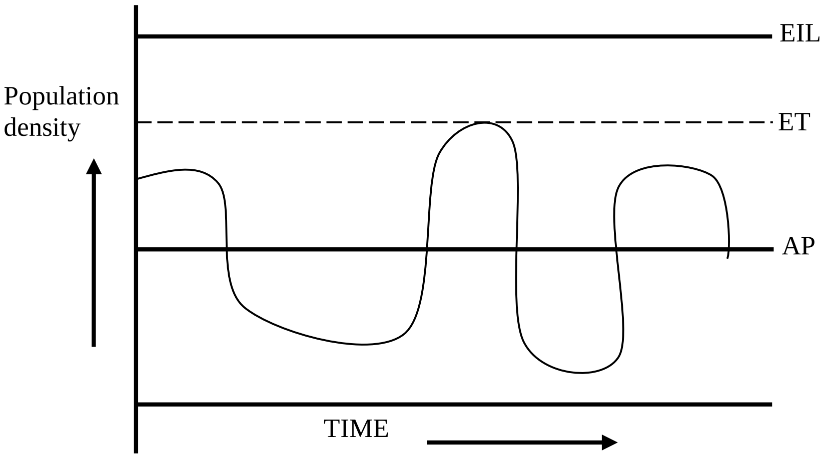

Fig.1: Pest population oscillations in a habit.
Legend
EIL-Economic injury level
ET-Economic threshold
AP-Average population

(k) **Obeying rules governing pesticide application in the field or store**

To ensure good results with minimum risk every pesticide applicator must obey and take the following rules into consideration:

i. Wearing of protective clothing (high cotton overall, gloves, boots etc)
ii. Following instructions given on the label religiously
iii. Making sure that the spray tank rests comfortably on your back for every work.
iv. Keeping weather conditions in mind to avoid spray drift.
v. Spraying should be done either in the morning or in the evening since there is less wind and spray solution less likely to evaporate.
vi. Spraying should be done at the time of the day at which organism to be destroyed is most active.
vii. Keeping other people and animals away from the area when spraying. Besides, when working with moderately toxic to extremely toxic pesticides, it is advisable to work in pairs so that help can be summoned promptly in the event of an accident.
viii. If a spray nozzle becomes blocked during use, never blow it clear by mouth. Clear it with brush or with water.
ix. Never eat, drink or smoke when applying a pesticide.
x. After application any remaining spray solution which is not needed to treat other fields should be sprayed onto a field which has already been treated.
xi. Tidy the environment. Do not leave empty containers well sealed after use and then safely stored away, especially out of reach of children.
xii. Spraying equipment (e.g. Knapsack CP15 etc) and protective clothing should be well cleaned after use and allowed to dry.
xiv. Wash yourself with soap and water.
xv. Keep record of which fields have been sprayed and when.
xvi. Also, take into consideration the safety period between spraying and harvesting etc.

CONCLUSION

The whole effort, so far, has been to highlight the rationale for using pesticides in crop production, its threat to life and measures that will ensure the production of safe food.

ABSTRACT

The experiment was conducted in 2015 cropping season at National Root Crops Research Institute Umudike to evaluate the effect of different stake lengths, varieties and time of harvest on root yield and some morphological traits of Cassava. The need for increased planting material for farmers and the continuous emergence of new improved cassava varieties call for low cost low impute technology to supply the farmers need hence this experiment. There were two stake lengths, three varieties and two time intervals of harvest. Stem girth, plant height, root yield were some of the parameters used to evaluate their performance. The results showed that stem girth of the varieties differed significantly and increased significantly with time of harvest (p< 0.05). Stake length, time and their interaction significantly affected final height at harvest. Time of harvest and variety positively influenced stem girth while stake length and time of harvest positively influenced root yield. It was concluded that time of harvest and variety are important variables for consideration for increasing planting materials for farmers and that cassava stakes should be harvested from 12 MAP. From this trial also TME 419 is recommended for increased cutting production when planted with full stake length (25 cm) or medium (12.5cm) stake length in a slanting position.

Keywords: Stake Lengths, Cassava Varieties, time of Harvest and Roots

INTRODUCTION

Cassava (*Manihot esculenta* Crantz) is the 5th most important food crop in the world and most important source of energy in the diet of Africans. Nigeria is the largest producer of the crop in the world with over 45 metric million tons (FAOSTAT). It has its origin from South America. The importance of Cassava cannot be over-emphasised; it provides food for over 800 million people (FAO, 2007). Because of its relatively high productivity under conditions of erratic rainfall and low soil fertility, about 250 million Africans depend on it as food. In 2007 more than 117 million tons was produced in Sub Saharan African and used for fresh consumption and processed foods (Phillips et al., 2006). Seeds are the foundation of Agriculture and the most important input. In Nigeria seed industry is still developing especially in crops like cassava whose botanical seeds are not consumed nor popularly used for planting. According to Ekwe (2012), most private companies seem not to be interested in the multiplication, distribution and marketing of cassava varieties. Cassava, being vegetative propagated, has a relatively low multiplication ratio and thus cannot compete vigorously with grain crops, which have very high multiplication ratios. One cassava plant can only generate about 10 stem cuttings (IITA 1998). Also, the one-year-long period of producing cassava planting materials has a comparative cost disadvantage over that of the grain seeds, which are produced in 3-5 months. Furthermore, the large hectares required to produce substantial quantities of cassava stems as well as the bulkiness of the planting materials usually require significant sums of money for transportation which often discourage private companies from investing in production, distribution and marketing of cassava stem cuttings to rural farmers. The need for more improved methods to increase cassava production to reduce the above impediments should be a continuum in research. Rapid multiplication of cassava cuttings using 2-3 nodes requires administering some preventive chemical treatments on the stems against diseases and pests, preliminary nursery care, transplanting of the sprouted stakes and efficient management. Use of half of the recommended stake length of 25cm and comparing the performance when harvested over time intervals becomes a viable option as it does not involve the above mentioned processes. Stake lengths are known to influence the yield of the crops in terms of planting materials and consumable roots (Anselem *et al*., 2000) Variations in yield of different cassava varieties have been reported (Richardson, 2011.) Investigations on the effect of stake length, orientation and variety on yield have been carried out by different researchers giving various results, without recourse to time of harvest. Time of harvest is known to play an important role in the performance of cassava. Cassava is said to be ready for harvest after six or seven months from the time of planting depending on variety and the purpose of harvest. Ebah-Djedji *et al*, (2012,) reported that harvest period has effect on starch dry matter from the tuberous roots of improved cassava varieties. The objective of this work is therefore to determine the performance of new varieties of cassava when planted with half of the recommended stake length and harvested at two different time intervals on root yield and some morphological traits.

MATERIALS AND METHODS

The study was carried out at block A3 western farm of National Root Crops Research Institute Umudike. Umudike located on latitude 4° 15' and 7° N and longitude 52° 91'and 7° 33' E of the equator with an elevation of 122m above sea level. The site of the experiment was slashed, ploughed, harrowed and ridged The blocks used for this research work was maintained in a two year rotation but in the penultimate year the block was planted with cassava and fertility enhanced by inorganic fertilizer. The dominant weed on the land before clearing was *Panicum maximum,* the pre planting soil analysis was also done but not presented .The soil is moderately acidic high in organic matter with appreciable percentage base saturation and classified sandy clay loam. The experimental design was Randomized Complete Block design in a factorial fashion. The factors were: two stake lengths of 25cm and 12.5cm, respectively, 3 varieties of cassava namely NR8082, TME419 and Umucas 37 designated v1, v_2, v_3, and two times of harvest 10 and 12 months after planting (map) also designated T_1 and T_2. The stake lengths were designated F (25cm) as the recommended and M (12.5cm) as medium, half of the recommended length. The experiment was replicated three times. The plot length was $16m^2$. Each cutting was inserted into the soil at the crest of the ridge with about one third of the cutting above the ground at an angle of about 45^0 .The planting distance was 1m within the plants and between the rides giving a population of ten thousand plants ha^1. The experiment was planted on 3rd June 2015, germination count was taken on 17th of June 2015, weeding was done on 22nd July while fertilizer (NPK 15:15:15) was applied on the 29th of July 2015 (8wap) at the rate of 600kg/ha. The second weeding was done followed by under-brushing. Data were taken on root weight (kg/plot), plant height (cm), saleable root number, total root number, stem girth and stem yield. Root and stem yields were taken from the entire plot (gross) while eight stands were randomly selected and measured for the stem girth. Data collected were subjected to analysis of variance (ANOVA) according to the procedure for RCBD experiment using Genstat discovery edition.

RESULTS AND DISCUSSION

Stem Girth

The effect of stake length and time of harvesting on stem girth of three varieties of cassava is shown on table 1. The result showed that stem girth of the varieties differed significantly and increased significantly with time of harvest ($p< 0.05$). The interaction between stake length and variety was also very highly significant. There was no significant difference in girth between the two stake lengths. The interaction between stake length time and variety were not significant ($p<0.05$). Stem girt is one of the most neglected parameters for the assessment of the performance of cassava in the field. This accounts for how resistant the stem can be to moisture loss which increases root initiation and subsequent survival of the plant. It has been reported that the root yield of the cassava stem is positively related to the stem girth (Eke Okoro et al., 2005) and less planting material will be required when stakes of greater girth is used for planting. Onunka et al (2012) in a trial to determine the nutrient requirement for optimum performance of new cassava varieties found the stem girth significant at 8 MAP instead of 4 and 6 map indicating a direct proportional relationship between time and stem girth in cassava stem production.

Plant Height at Harvest

The effect of stake length and time of harvest on plant height of cassava varieties at harvest is presented on table 2. The result showed that only stake length and time of harvest were very highly significant ($p< 0.05$) while the interaction between stake length and time was significant ($p<0.05$) amongst all the parameters evaluated. Umucas 37 (v3) recorded the highest mean height of 2.45 m closely followed by TME 419 (2.441m) .The difference in height was not significant. The least was NR8082 with a mean height of 1.86m.Harvesting at 12 MAP gave the highest mean height of 2.14m significantly different from 10 MAP of 1.950m.The significant increase in plant height at 12 MAP implies increase in quantity of planting materials available to the farmer. This result is in line with the findings of Onunka et al (2012) who observed that prolonged time of harvest in cassava resulted to increase in height. This also results to better mature planting materials as premature stakes may lead to poor establishment and subsequently low yield of both root and stakes.

Root Yield

The effect of stake length and time of harvest on root yield is shown on table 3.In this result stake length was very highly significant while variety was very significant ($p< 0.05$) on root yield .Full length stakes significantly out yielded the medium stakes 34.8 and 27.7kg per plot respectively. There was no significant difference in root yield in terms of time of harvest but NR 8082 V1 out yielded the two other varieties. Full stake length out yielded the medium stake probably because of the advantage of having more nodes exposed which produced more sprouts and subsequently more leaves and greater photosynthesis for carbohydrate formation. Furthermore the many nodes exposed by full stake lengths lead to more sprouts that increases stem production.

CONCLUSION

As result of poor seed system in Nigeria and the nature of cassava, seed supply is likely to be a hindrance to cassava production. Efforts should be geared towards developing new varieties and other improved agronomic practices than reducing the recommended stake length for planting. Cassava matures from about 6map but for increased stem and root production harvesting should be from 12 map as observed from this work.

ABSTRACT
A field experiment was conducted at the Crop Research Farm of the University of Calabar located in the Calabar coastal humid forest area of Southeastern Nigeria to determine the effectiveness of agronomic iodine biofortification in two popular and widely cultivated elite cassava varieties (TME 419 and TMS 30555) in Nigeria. Different rates (0, 2.5, 5.0 and 10 kg KI/ha) of Potassium Iodide (KI) were applied to cassava at 10 weeks after planting. Yield parameters measured were tuber number plant^{-1}, tuber weigh (kg plant^{1}) and tuber yield (t ha^{1}). Effectiveness of Iodine biofortification was determined by evaluating Iodine concentration (mg kg^{1}) in the freshly harvested cassava tuberous roots and processed cassava products (garri and fufu). Results obtained indicated that tuber number and weight plant^{1} and yield ha^{1} were not significantly ($p \leq 0.05$) influenced by iodine application. However, there was significant ($p \leq 0.05$) positive correlation between the rate of Iodine applied and the amount retained in fresh tuber flesh and processed products in both varieties with fresh tuber containing higher Iodine than the processed products. TMS 419 exhibited stronger iodine retention capacity (r = 0.91 – 0.92) than TMS 30555 (r = 0.82 – 0.85) in both raw and processed products, indicating effective agronomic biofortification at 10 kg KI ha^{-1}.

INTRODUCTION

Iodine is an essential micronutrient required in human health and like other micronutrients such as Fe, Se, and Zn, it is usually consumed below the recommended range by majority of the people in developing countries who subsist largely on carbohydrate staples which are poor in these nutrients (Zhu *et al*, 2003; McWilliams, 2011). Nutrient iodine is required in the thyroid gland for the production of the hormone thyroxin which regulates basal metabolic rate and supports normal growth and development. Iodine plays such a vital role in the body such that its deficiency has been identified as a strong causal factor in hypothyroidism (sluggishness), obesity and enlarged thyroid gland, commonly known as goiter (Abraham *et al*, 2002).The human body lacks the ability to synthesize iodine and can it can only be supplied to the body through food intake. Iodine deficiency disorders are preventable and treatable and the use of iodized salt is the most common inexpensive iodine supplementation strategy in human diet but this is still a challenge in most parts of the world (Zhu *et al*, 2003) as high salt intake is detrimental to health and is commonly associated with hypertension which is among the deadly *silent* killer diseases. Iodine requirement can be met through food diversification and consumption of different kinds of fruits, vegetables and animal products, but this approach is expensive and uneconomical to the target households which are usually chronically poor and simple and affordable alternatives such as agronomic biofortification of popular staples like cassava which provides dietary energy for over 800 million poor people world-wide (FAOSTAT, 2012; CARDI, 2013; Howeler *et al*, 2013). The objective of this experiment was to determine the optimum KI rate for effective agronomic biofortification in cassava to enhance its nutritional profile.

MATERIALS AND METHODS

Study Area

A field experiment was conducted at the Crop Research Farm of the University of Calabar located in the Calabar, Nigeria in 2012 to 2013 cropping seasons. The area is characterized by distinct dry and wet seasons which last from November/December to March/April and April/May to October/November, respectively. The minimum temperature is about 23 oC and maximum temperature is 33 oC while annual rainfall ranges between 2000 – 2500 mm and relative humidity of 75 - 90 % (Afangideh *et al*. 2010).

Plot Preparation and Experimental Design

The land was cleared and tilled manually using a machete and spade respectively. Unit plots measuring 4.0 m x 4.0 m (16.0 m²) separated by 1.0 m alley ways were marked out in blocks spaced 1.0 m apart.

The experimental design used was a 2 x 4 factorial involving two varieties of elite cassava varieties (TME 419 and TMS 30555) and four rates (0, 0.25, 0.5 and1.0 kg KI ha^{-1}) of Iodine as Potassium Iodide (KI). Experimental plots were arranged in randomized complete block design with three replications.

Planting of cassava
Mature and healthy cassava stems cut to 20 cm length were planted in the plots in the first week of August 2012 and 2013. Stands were established 1.0 m apart each way to give 10,000 plants/ha.

Application of Iodine and fertilizer
Potassium was applied as potassium Iodide (KI) by banding around individual plants ten weeks after planting (10 WAP), which coincided with period of storage root initiation when nutrient absorption is maximum (Alves, 2002; El-Sharkawy, 2004). Fertilizer N:P:K 15:15:15 was applied at 200 kg ha $^{-1}$ was applied to the field 3 MAP in both 2012 and 2013.

Soil analysis
Analysis (IITA, 1979; 1989) of the composite surface (0 – 30 cm depth) soil samples randomly taken with a soil auger at the site showed pH 4.7, total – Nitrogen 0.637%, Av Phosphorous 177 mg kg $^{-1}$, while exchangeable K, Ca, Mg and ECEC were 0.08, 0.70, 0.40 and 3.19cmol kg $^{-1}$ respectively; with organic carbon content of 4.02% and zero soil iodine content.

Data collection, analysis and evaluation of cassava iodine content
Yield parameters assessed were number of tubers (plant $^{-1}$ and plot $^{-1}$), tuber weight (plot $^{-1}$ and plot $^{-1}$) and tuber yield (t ha $^{-1}$), while the iodine content in tuber flesh and processed cassava was determined using the x-ray fluorescence method (Allen, 1989). Data was analyzed using analysis of variance (ANOVA) and significant ($p \leq 0.05$) means were compared using Duncan multiple range test (DMRT).

RESULTS AND DISCUSSION
The cassava varieties did not differ in their response to iodine fortification in terms of the yield parameters evaluated neither did iodine rates significantly ($p \leq 0.05$) influence them in 2012 and Variety and rate interaction was insignificant. However, 10 kg KI ha^{-1} produced more tubers while 5 kg KI ha^{-1} produced heavier tubers and higher tuber yield plot^{-1} than other KI rates (Table 1). The cassava varieties TME 419 and TMS 30555 did not also vary in tuber production, tuber weight and tuber yield in 2013. Tuber production was also not affected by KI rates while tuber weight and yield were all significantly ($p \leq 0.05$) influenced by application of potassium (Table 2). Potassium application resulted in reduced cassava tuber weight which reduced progressively as KI rate increased and was lowest at the highest KI rate, followed by 2.0/2.5 kg KI ha^{-1} and highest in the control with the tuber weight difference of 8.56 kg plant^{-1} between the control and highest KI rate. Plot yields followed the same trend with tuber weight giving correspondingly highest and lowest tuber yield in zero and highest KI rate, respectively with yield difference of 9.17 t ha^{-1} higher in zero KI plots. Iodine retention in cassava tuber flesh and processed cassava products presented in Table 3 showed iodine content increased in all products in both varieties as the application rates were increased. In the 2012 crop, iodine content was double in plants that received the least dose of the nutrient compared to those that did not receive iodine application. Iodine contents in tuber and processed cassava were higher in 2013 than the 2012 indicating that the nutrient was retained in the tissues of the crop. However lower concentrations were found in processed products than in the raw tuber. This result is in tandem that obtained by Smolen and Sady (2011) and Stzetelski *et al* (2009) who similarly obtained significantly higher iodine retained in carrot storage roots and radish with increasing iodine levels. Effective rate for agronomic biofortification for TME 419 was 2.5kg/ha, while that of TMS 30555 is 10kg/ha. TME 419 variety showed a stronger positive relationship between the iodine rates applied and the amount retained in processed and raw cassava than TMS 30555 (Table 4) implying that different cassava varieties probably have different capacities to retain iodine.

CONCLUSION
Though iodine application to cassava suppressed tuber yield, increased product quality obtained through agronomic iodine biofortification could compensate the yield reduction and should be promoted.

Table 1: Influence of rates of iodine application on yield in two cassava varieties (2012)

ABSTRACT

This study was carried out at Cocoa Research Institute of Nigeria (CRIN) Headquarters, Idi-Ayunre, Ibadan Southwestern Nigeria, Latitude 7º25'N and Longitude 3º25'E on evaluation of organic coffee production using three levels cocoa pod husk (CPH). There were four treatments comprising of 100,200 and 300 kg/ha of CPH and the control (no fertilizer) applied to coffee seedlings on the field. The cost price of CPH per kilogram at CRIN's Crop Processing Unit is #200 which translate to 20,000, 40,000 and #60,000/treatment/hectare respectively. Four coffee seedlings planted three meters apart were used per treatment. The plot was laid out using Randomized Complete Block Design (RCBD) and replicated three times given a total of 48 stands. Treatments were randomly allocated, 6 months after field establishment. Data on morphological parameters such as Plant height, stem diameter, number of leaves and leaf area were collected from 3 months after transplanting (MAT) for periods of three years (36 months), while berry yield from different treatments were collected for periods of 2 years (24 months). Data collected were subjected to statistical analysis of variance and LSD was used to separate the means that were significant. Results obtained showed that the three levels of cocoa pod husk significantly (P<0.05) enhanced morphological parameters (plant height, stem diameter and leaf area) of coffee from 6 MAT to 36 MAT relative to the control. Cocoa pod husk (CPH) applied at 200kg/ha CPH gave the highest plant height, stem diameter and leaf area from 9 MAT compared to other organic manure levels and the control. Also, 200 kg/ha produced the highest coffee berry yield relative to other levels of CPH application and the control in both 2014 and 2015. 200 kg/ha CPH also increased the plant height, stem diameter and leaf area of coffee by 28 %, 18 % and 13 % respectively compared with the control, but when compared with 300 kg/ha CPH treatment, it also increased plant height, stem diameter and leaf area of coffee by 22 %, 17 % and 10 % respectively. Again, 200 kg/ha CPH enhanced coffee berry by 10 % and 9 % compared with the control plot in 2014 and 2015 respectively, when compared with 300 kg/ha CPH, it increased coffee berry yield by 7 and 6 % in 2014 and 2015 respectively. 200 kg/ha CPH performed best while 100 kg/ha CPH performed least. Therefore, 200 kg/ha CPH is recommended for organic coffee production. Instead of other treatment as cocoa pod husk ,readily available with or no cost incurred by the farmers compare to the use of inorganic fertilizer which is scarce, costly hazardous to soil micro-ecology

INTRODUCTION

After oil, coffee is the most valuable traded commodity worldwide, with global retail sales estimated to be US$ 90 billion. Brazil is the largest word's coffee producer, followed by Vietnam and Colombia (Davies *et al*., 2006). Coffee is the major export product of some countries such as Uganda, Burundi, Rwanda and Ethiopia. About 70 % of the world crop is grown on smallholdings smaller than 10 ha and hence it is often a family business that provides maintenance for over 25 million people worldwide (Fassio and Silva, 2007). Among some 100 species of the *Coffea* genus, only C. *arabica* L and C. *canephora* (robusta coffee) are economically important worldwide, with these species being responsible for about 99 % of world bean production (Davies *et al*., 2006). Coffee is today grown in more than 60 tropical countries of the world and accounts for a significant part of the foreign exchange earnings of many of them (Baumann, 2006). Coffee cultivation began in the ninth century in Africa and since most varieties of coffee are naturally intolerant of direct sunlight coffee was originally grown under shade trees, most often fruit and nut trees which also helped to replenish the soil with valuable nutrients and allowed the land to remain fertile generation after generation. Shades land be-reported to be beneficial to coffee. (Famaye 2000; Famaye and Agboola 2003). Williams (1989) reported that coffee is cultivated in more than 20 states in Nigeria on over 500,000 ha with the highest concentration at Mambilla Plateau, Taraba State. It is also an important source of foreign exchange to Nigeria. In the beginning all coffee was organic and shade grown. Beginning in the 1970s full sun coffee varieties were developed to increase productivity by allowing coffee plants to be grown closer together. As a result chemical fertilizers and pesticides had to be used to compensate for the lack of nutrients being added back to the soil. These types of chemicals harm the soil, surrounding wildlife, adjacent water, the farmers themselves and the taste of coffee. (Famaye, 2005)

Increasing awareness of damage to our environment and our health through harmful production methods has led to greater demand for organic products. Although organically produced consumer goods still account for a small percentage of all grocery sales and organically-grown coffee sales currently represent about 1% of the United States of America market for coffee/beans ((Famaye, 2005). Organic coffee farming encourages sustainability, multilayer crop production and a rich array of wildlife. Organic coffee farming encourages beneficial insects and a healthier more resistant crop. The considerable potential for improving organic coffee and yield through application of organic materials is widely recognized (Adejobi *et al.*,2011; Agboola and Adeoye,1990; Rayer and Chiroma,1990; Adu-Daapah, 1994; Moyin-Jesu, 2002. Owaiye (1993) and Michori, (1981) reported that residue mulch materials including grasses and farm wastes were efficient in improving coffee yield, while Obatolu (1995) reported the use of cocoa pod husk (CPH) as fertilizer for coffee. The objective of this study therefore is to evaluate the performance of coffee on the field using three levels of Cocoa Pod Husk (CPH) as organic fertilizer in view of economic reality without the aid of artificial chemical substances .

MATERIALS AND METHODS

A field experiment was conducted at Cocoa Research Institute of Nigeria (CRIN) Ibadan. The location is on Latitude 7°25'N and Longitude 3°25'E, Alfisol in rain forest zone of Southwestern Nigeria. The annual rainfall is between 1200-1500 mm. The maximum temperature ranges between 26 to 35^{0}C with an average of about 30.1^{0}C. Relative humidity ranges from 50 to 89 % with an average of 79 %.

Soil sample and analysis

Soil samples were collected from 0-30 cm depth on the site, mixed thoroughly and the bulked samples were taken to the laboratory, air-dried and sieved to pass through a 2 mm screen for chemical analysis of particle size which was determined by the hydrometer method (Kettler *et al.*, 2001) and organic carbon content (OC) by the potassium dichromate oxidation method (Zhang *et al.*, 2001). Soil pH was read on pH meter (1:1 water). Soil potassium (K), calcium (Ca) and magnesium (Mg) were extracted with 1MNH_4 OAC, PH_7 and were determined with flame photometer; Mg was determined with an atomic absorption spectrophotometer. The total nitrogen (N) was determined by the Microkjedahl method (AOAC, 1990). Soil P was extracted by the Bray P1 extraction and measured by the Murphy blue coloration and determined on a spectronic 20 at 882um (Murphy and Riley, 1962)

Processing and analysis of cocoa pod husk used for the experiment

The cocoa pod husk (CPH) used for the experiment was obtained from the Crop Processing Unit of Cocoa Research Institute of Nigeria, Ibadan at the rate of ₦200/kg. This translated of ₦ 20,000, ₦ 40,000 and ₦60,000/treatment/hectare. The CPH was air dried for 3 weeks under the shade, later ground into powder form (< 2 mm sieve) using hammer mill and packed in 50 kg bags for application on the field. Two grammes (2 g) of the organic fertilizer (CPH) was analyzed by Moyin-Jesu (2012) for nutrients composition according to standard procedures (IITA, 1992).

Collection of coffee seeds and depulping

Diseased free coffee seeds were collected from the coffee plantation of Cocoa Research Institute of Nigeria (CRIN) in early September, 2011 and depulped. The selected berries were soaked in water over night and harsh parchment removed. The berries were washed further in water to removed mucilage and the clean coffee berries were air dried under shade.

Pre-nursery and nursery establishment

In late September 2011, air-dried seeds were sown in boxes (90 x 60 x 30 cm) after filling the seed boxes with river sand. The seed boxes were thoroughly watered and kept under shade. The watering was discontinued because rain was steady at that period of time. The seeds of coffee germinated about 6 weeks after sowing. The bulk soil taken from the site (0-30 cm depth) was sieved to remove stones and plant debris and 2.5 kg of the sieved soil was placed into a polybags (25 x 15 cm) in 2011 and 2012. The germinated coffee seeds were transplanted in to polybags filled with top soil. Watering was done immediately to prevent transplanted seedlings from wilting and this continued for one week till proper establishment. A shade was constructed over the polybags containing the germinated seeds to prevent scorching by sun. Hand weeding was done at 2, 5, 8 and 16 weeks. No chemical spray in both pre-nursery and nursery stages. The seedlings were transplanted into the field, 20 weeks after sowing.

Field experiment

Field was conducted in Cocoa Research Institute of Nigeria (CRIN), Ibadan Headquarters. The experiment was conducted between 2012 and 2015. It was laid in Randomized Complete Block Design (RCBD) with 3 replications. The site was cleared and lay-out of the experimental site (Measurement, pegging and holing) was carried out before planting. Plantain suckers were planted at 3.0 x 3.0 m apart as a shade crop for the establishment of coffee seedlings. The experiment had four treatments comprising of four coffee stand applied with 100 kg/ha CPH, 200 kg/ha CPH, 300 kg/ha CPH and the control (No CPH application). Coffee seedlings were transplanted 3.0m apart. Treatments were imposed 6 months after transplanting of coffee seedlings into the field.

Data collection

Data were collected on the growth parameters of coffee seedlings such as: Plant height measured in centimeter using a meter rule on the surface and the tip of the main stem; Stem diameter was measured in centimeter with the use of Vernier'Caliper 30 cm above the ground level and leaf area (Leaf area meter). Coffee berry yield, obtained in the first 2 years of fruit bearing were also evaluated. The results were subjected to statistical analysis of variance and LSD was used to separate the means that were significant.

RESULTS AND DISCUSSION

The chemical properties of CPH used in the experiment are represented in Table 1: CPH was indicated to be high in N, P, K, Ca, and Mg. The higher P, K, N, Ca and Mg for CPH agreed with the fact that plant derived materials including those of cocoa and kola pod husk increased P, K, Ca, Mg, and yield of vegetables, rice, millet and maize (Owolabi *et al*., 2003). The plant height, stem diameter and leaf area of coffee seedlings under different levels of CPH treatment are presented in Tables 2, 3 and 4. The application of cocoa pod husk at different levels increased significantly (P<0.05) the growth parameters of coffee seedlings compared to the control treatment with the exception of 3 MAT (Tables 2, 3 and 4). This might've been due to slow released of this organic fertilizer that are peculiar to organic matter contained in it. Cocoa pod husk (CPH) applied at 200kg/ha CPH gave the highest plant height, stem diameter and leaf area from 9 MAT compared to other organic manure levels and the control. Also,200 kg/ha CPH also increased the plant height, stem diameter and leaf area of coffee by 28 %, 18 % and 13 % respectively compared with the control, but when compared with 300 kg/ha CPH treatment, it also increased plant height, stem diameter and leaf area of coffee by 22 %, 17 % and 10 % respectively. This study showed that CPH, a seemingly waste product of cocoa could be used to produce organic coffee and increased availability of N, P, K, Ca and Mg in soil and their uptake by coffee plants thereby leading to enhanced growth performance of coffee. Poor growth of coffee as a result of low nutrient status of soil N, P, K, Ca, and Mg was generally observed in no treatment plot. This observation is in agreement with the work of (Moyin-Jesu, 2007). Which identified deficiency symptoms of yellow coloration, purple coloration and marginal burning of leaves signifying N, P, K deficiencies in tropical Africa soils. Also, 200 kg/ha produced the highest coffee berry yield relative to other levels of CPH application and the control in both 2014 and 2015. Again, 200 kg/ha CPH enhanced coffee berry by 10 % and 9 % compared with the control plot in 2014 and 2015 respectively, when compared with 300 kg/ha CPH, it increased coffee berry yield by 7 and 6 % in 2014 and 2015 respectively. These yield results authenticate the importance of organic fertilizer in crop production. These results have shown clearly that organic manures are capable of enhancing tree crops yield such as coffee (Michori, 1998; Obatolu, 1991), teak (Fagbenro, 1998), tea (Ipinmoroti and Adeoye, 2002; Ipinmoroti *et al*, 2004). Ojeniyi and Adejobi, (2002); Adejobi *et al*.,(2015 a and b), Ayeni *et al*.,(2008 and 2009) also found that wood ash, cocoa pod husk ash increased growth parameters and yield of crops such as amaranthus , tomatoes, pepper, kola and cashew seedlings and yam. It has also been observed that leaf chlorophyll, K: Na and C:Na ratio of organic manure treated crops were found to be higher than NPK treated crops. These contents might have been responsible for better growth, yield and yield quality for crops under organic treatments compared to NPK treatment (Adeniran, *et al.*, 1999; Alabi and Odebina, 2001).

CONCLUSION

The results indicated that the CPH applied at 200 kg/ha increased the plant height , stem diameter, leaf area and coffee berry yield. The organic manure applied at 300 kg/ha CPH might have been too much as the coffee may not be able to take more nutrient after 200 kg/ha CPH that seemed to be the optimum required for good growth of the coffee as recorded in all the morphological parameters at 36 MAT. The 100 kg/ha CPH treatment was however higher in growth parameters than 300kg/ha CPH but not adequate as the 200 kg/ha CPH treatment was higher than 100 kg/ha CPH. However there was no significant difference in both growth parameters and yield of coffee between 100 kg/ha CPH and the control. The better performances of 200kg/ha CPH indicate no loss of nutrient or in-adequate when applied. Since organic coffee farming encourages sustainability, healthier more resistant crop, create environment friendly. However, treatment with 200kg/ha CPH with highest growth and yield will be more profitable than other treatment. 200 kg/ha CPH that gave the highest morphological parameters and highest berry yield which increases production efficiency of farmers could be recommended for coffee farmers instead of other treatments in organic coffee production in Nigeria.

ABSTRACT
Field experiment were conducted during the 2008 and 2009 wet seasons at the experimental farm of the National Root Crops Research Institute, Umudike, Potato programmes farm, Kuru (Lat 09^0 44' N and Long 08^0 44'E and with an elevation of 1,239.4m above sea level) in the Northern Guinea Savanna ecological zone of Nigeria. The experiment was conducted to determine the effects of various rates of nitrogen (0, 60 and 120 kg N/ha), wood ash (0, 2.5 and 5.0 t/ha) and intra – row spacing (20, 30 and 40 cm) on the growth and yield of potato. A split plot design was used where the factorial combinations of N and intra- row spacing were assigned to the main plots, while wood ash was assigned to sub plots. The treatments were replicated three times. The result revealed that application of 60 – 120 kg N/ha and 2.5 - 5.0 t/ha wood ash enhanced net assimilation rate and total tuber yield. Application of wood ash at 5.0t/ha significantly influenced net assimilation rate and total tuber yield. The use of 30 or 40cm spacing resulted in higher net assimilation rate and total tuber yield compared to 20 cm spacing.
Keywords: Potato, wood ash, nitrogen, intra-row spacing and net assimilation

INTRODUCTION
Potato (*Solanum tuberosum* L.) is a tuber crop it belongs to the family *Solanaceae*. It ranks fourth as the world's economically valuable food crop after rice (*Oryza sativa*), wheat (*Triticum aestivum*) and maize (*Zea mays*) (USDA, 2014).Crop nutrition is a basic requirement in potato production, especially on the Jos Plateau, where continuous cropping has greatly depleted the soil of the major native nutrients such as N, P and K (Okonkwo *et al.,* 1995). The mineral fertilizers are scarce and costly, and in most cases beyond the reach of the resource – poor farmer. Wood ash has some fertilizer value, the amount varying somewhat with the species of wood ash being used (Hillary, 2009). Wood ash contains nutrients that were taken up from the soil by the tree in question. It may improve crop growth and yield through provision of phosphorus, calcium magnesium and potassium if applied as fertilizer (Jerome, 2004). N is an indispensable plant major nutrient, without it growth is retarded, leaves will turn yellow and reproductive growth is impaired while intra – row spacing in plant give room for the plant to express its potential as competition for space may lead to etiolation (Hillary,2009). It is therefore, the objective of the study, to evaluate the effects of wood ash, nitrogen and intra- row spacing on potato growth and yield.

MATERIALS AND METHODS
Field experiment were conducted in 2008 and 2009 rainy seasons on the National Root Crops Research Institute, Potato programme farm, Kuru, in the Northern Guinea savanna ecological zone. Kuru is located on latitude 09^0 44'E and longitude 08^0 44'N, 1,239.4 m above sea level, with an annual rainfall of 1,289.89 mm distributed across 150 days within the months of May to October. Potato variety; Nicola, was used as test variety. The soil is a sandy loam and of feralgilic origin, Treatments were: nitrogen (0, 60 and 120 kg ha^{-1}), wood ash (0, 2.5 and 5.0 t ha^{-1}) and intra – row spacing (20, 30 and 40 cm). Factorial combination of nitrogen and intra – row spacing was assigned to main plot while wood ash was allocated to sub – plot. The gross plot size was 4 x 6 m (measured 24 m^2) while the net plot size was 2 x 6 m (Measured 12 m^2) consisting of two inner ridges .The experiment was laid out in a split plot design replicated three times. Planting was done on the crest of the ridges spaced 100 cm apart while the intra – row spacing was 20, 30 and 40 cm. Planting was carried out on 3rd may, 2008 and 16th may, 2009. The wood ash used in this experiment was from African birch (*Anogeissus leocarpus* L.) plant, and was incorporated on the crest of the ridges at planting. Urea fertilizer was applied manually by side banding, two weeks after planting (WAP). Weeds were controlled with pre-emergence herbicide, (combination of Alachlor – EC at 1.92 kg a.i ha $^{-1}$ and Atrazine 500Sc at the rate of 4kg a.i ha^{-1}) using CP-15 knapsack sprayer at a pressure of 2.1kg cm^{-2}; and by hoe weeding at 4 and 8 WAP. Tubers were harvested manually by lifting, using garden fork. Five stands were selected and harvested; and their tubers were counted to determine the mean number of tubers per plant. The weight of the randomly selected tubers were determined using electronic balance; model TH – 5000 with capacity 5000g x1g/200 oz .Net assimilation rate was measured at 3 weeks interval beginning at 3 WAP. Tubers harvested from the net plots (12m^2) were weighed, and later the yield/net plot was expressed in tones per hectare. Harvested tubers from each net plot were weighed and yield per hectare was determined and expressed in tones per hectare. The data collected were statistically analyzed using analysis of variance (ANOVA) according

to the method described by Gomez and Gomez (1984), and the treatment means were separated using Duncan's multiple range test (Duncan, 1955).

RESULTS AND DISCUSSION

Net Assimilation Rate (NAR)

Nitrogen, wood ash and intra – row spacing significantly influenced NAR in both years (Table 1). At 3 – 6 WAP in 2008, 60 and 120 kg N/ha produced similar and greater NAR than the untreated control. At 3 - 6 WAP in 2009, NAR increased with increasing nitrogen rate from 0 – 120 kg N/ha. At 3 – 6 WAP in 2008 0 and 2.5 t/ha wood ash resulted in similar but lower NAR than 5.0 t/ha rate. In 2009, NAR by 2.5 and 5 t/ha wood ash rate were at par and statistically higher than by 0 t/ha at 3-6 WAP. At 6 – 9 WAP, 5.0t/ha wood ash produced higher NAR than the untreated control. At 3 – 6 and 6 – 9 WAP in both years, increasing intra – row spacing spacing of potato from 20 – 40 cm correspondingly increased NAR. The interaction of N, wood ash and intra – row spacing on NAR of potato was not significant at any of the two sampling periods in both years.

Total Tuber Yield

The effects of nitrogen, wood ash and intra – row spacing of potato on total tuber yield is presented in (Table 2). Nitrogen, wood ash and intra –row spacing significantly affected total tuber yield. In 2008, N at 60 and 120 kg N/ha increased total tuber yield over the control. In 2009, 60 kg N/ha yielded more than the control and 120 kg N/ha. Total tuber yield increased with N rate from 0 – 120 kg N/ha in 2009 and the combined data.

In 2008, 2.5 and 5.0 t/ha wood ash increased total tuber yield over the untreated control. In 2009, tuber yield increased with wood ash rate, while in the combined data, the 2.5t/ha level produced greater tuber yield than the control.

Effects of Wood Ash on Growth and Yield

The significant positive response of potato to the application of wood ash in these trials explained the importance of the material as a source of P and K as earlier reported by Beukema and Za'ag (1990) and Harris (1992). Net assimilation rate increased with progressive rise in wood ash up to the maximum applied rate of 5.0t/ha. This is in consonance with the findings of (Obi, 2000, Obi and Ekperegin 2001, Ojeniyi *et al.*, 2001, Ojeniyi and Adejobi, 2002, Reula and Janssen, 1976) who reported that wood ash is an effective source of plant nutrients such as Calcium, Phosporus, Potassium, Magnesium and other secondary elements. Wood ash is also a fast liming material that rapidly dissolves and neutralizes acid soil, apart from providing plant nutrients (Jerome, 2004). Sokoto *et al*. (2007) reported positive effect of wood ash on sweet potato. Each of K and P has a specific role in potato growth and development and absence of any in the soil may retard potato growth and decrease yield. P and K deficiency in soils of Nigerian Savanna had been occasionally reported in some areas on the Jos Plateau most especially intensely or continuously cultivated farms (Okonkwo *et al.*,1995). However reports by Ogbolu (1991), Ojeniyi *et al*. (2001) and Ojeniyi and Adejobi (2002) contradicted findings in this present study. They reported that wood ash was not as effective as fertilizer for vegetables and cassava. Also, in this study, Net assimilation rate increased with wood ash rate in 2009. This confirmed reports of Nyobe (1998) and Awodun and Ojeniyi (2005) who observed that application of wood ash increased availability of Phosporus and Potassium and their uptake in groundnut and recommended 4 t/ha of wood ash for groundnut production, while Sokoto *et al.*(2007) recommended 6 t/ha of wood ash for Sweet Potato production under irrigated conditions. Therefore, it is not surprising that the growth, and consequently yield responded positively to increasing wood ash rate. In this study, presence of N influenced leave expansion, DM accumulation and total tuber yield of potato which is in consonance with report of Okonkwo *et. al,* (1995).

Effect of Nitrogen on Growth and yield

NAR in the two years increased with increasing rate of N at 3 WAP. This could be attributed to the low N status of the soil of the experimental site, (Appendix 1). This is in consonance with reports that N in the presence of P and K stimulate canopy growth, development of leaves and branches, and need to be available from seedling emergence to flowering so as to promote rapid canopy development, haulm weight, stollon growth, as well as increase potato leaf area index, relative growth rate and final yield of Potato crop (Chapman and Carter, 1976; Okonkwo *et al*.,1988; Juzl, 1990 and 1991; Huett and Dattmann 1991; Rogozinska and Pinska, 1991; Zrust and Mica, 1992,). In this study, the significant response to applied N, by the growth parameters enumerated above and total tuber yield explained the importance of N on growth and development of Potato crop which is in agreement with (Beukema and Za'ag 1990 and Harris, 1992) who indicated that N influence positively, vegetative growth of potato and maximize total tuber yield.

Effects of Intra – row Spacing on Growth and Yield.

The growth character was significantly and positively influenced by intra – row spacing in the two years of trial. The use of 20 cm intra- row spacing gave the tallests but less robust in terms of leaf, branch and stem production, this is in consonance with the report by Ifenkwe and Allen (1978) who reported that increasing plant density reduced NAR, number of auxiliary branches, leaves per plant and dry weight of leaves, stems, underground parts and tuber/unit area, and also Sevensson and Naglicker (1995), who reported that using intra – row spacing of 10 cm and 20 cm in potato gave lower number of main stem with low number of branches than rows spaced 20 cm with resultant low NAR. This is probably because with 20 cm intra –row spacing, there was competition between plants, for solar radiation which led to low NAR due to etiolation; plants grew narrower with less branching. At the letter stage for stands spaced 40 cm plants had enough space for vegetative growth and branching and overtook the 20 cm stands. The degree of vegetativeness of the plant in terms of shoot and branch number per plant confirmed the positive correlation between leaf number and NAR. Higher NAR means higher DM production, hence more production of branches with wider intra – row spacing. This finding is in consonance with the finding of Harris (1992) who reported that larger LAI and higher NAR permitted investment of more dry matter through its effect on the amount of intercepted radiation which inturn maximized total tuber yield. This in turn might have resulted in high DM, which invariably translated itself through the shoot dry weight produced.

CONCLUSION

The result revealed that application of 60 – 120 kg N/ha and 2.5 - 5.0 t/ha wood ash enhanced net assimilation rate and total tuber yield. Application of wood ash at 5.0t/ha significantly influenced net assimilation rate and total tuber yield. The use of 30 or 40cm spacing resulted in higher net assimilation rate and total tuber yield compared to 20 cm spacing.

Table 1: Effects of nitrogen, wood ash and intra-row spacing on net assimilation rate and total tuber yield of potato during 2008 and 2009 cropping seasons.

ABSTRACT
Generally, farmers in Nigeria consider sweetpotato to be difficult to store. There are limited storage and curing methods especially at smallholder farm levels that could enhance the storability of sweetpotato roots at post-maturation. Therefore, it becomes expedient to devise strategies that will ensure the availability of sufficient sweetpotato roots post-harvest. A study was conducted at National Root Crops Research Institute (NRCRI), Umudike with the aim to evaluate pre-harvest curing and hilling-up on in-ground storability of fresh roots. The experiment was laid out as a split plot in a randomized complete block design, replicated 3 times. The main plot treatments comprised 7 varieties (UMUSPO1, UMUSPO3, Kwara, Ex-Igbariam, Butter milk, TIS87/0087, TIS8164), while 4 storage methods (Cured, Uncured, harvest after 1 month and 2 months) formed the subplot treatments. In most cases there were significant differences among varieties with UMUSPO3 (OFSP) and UMUSPO1 (OFSP) producing high yields (17.7 and 13.3t/ha respectively) compared to other varieties. Yields obtained at cured (9.3t/ha), uncured (9.1t/ha) and left 1 month in-ground unharvested (9.2t/ha) were not significantly different from each other but superior to those left in-ground unharvested for 2 months (7.6t/ha). Overall, there were varietal differences on level of susceptibility to weevil and rot incidences. Butter milk and UMUSPO1 in most cases recorded high rot losses compared to other varieties especially at 2 months unharvested. Also in most cases low weevil and rot losses occurred at cured, uncured and 1 month unharvest compared to when storage roots were left in-ground for 2 months unharvested. Conversely high weevil incidence occurred with UMUSPO1 and 3 compared with other varieties. UMUSPO1 and 3 are shallow rooted varieties and that may account for their susceptibility to high weevil attach. In general, there were advantages of these storage methods in prolonging the storability of roots with low pest and disease incidence. Further studies on quality assessment and acceptability of the storage roots under prolonged storage are recommended.

Keywprds: In-ground curing, Storage methods and Sweetpotato roots

INTRODUCTION
Low storability of fresh roots of sweetpotato has been a major problem in sweetpotato production. This is as a result of deterioration caused by mechanical injury during harvesting, physiological changes with the plant and infection by decay organism and pest infestation. Storage can be improved by adopting careful harvesting of the roots to avoid injury or bruises. Where damage or bruises occur, it can be cured to allow the bruise or injury to heal before storage. However, in Nigeria, farmers engage in piece meal harvesting of storage roots to avoid low prices associated with the peak of the harvesting due to glut. But when roots are left in the soil especially during the dry season, losses occur due to weevil attacks notably *Cylas punticolis*. These insects reach the roots through cracks in the dry soil (Stathers, et al, 2003) and the damage in most cases predisposes the roots to rots. Though rots and weevil incideces on sweetpotato roots have been reported sufficiently (Arinza, 1985. , Onifeda, et al., 2004), there is dearth of research work on improving in-ground storability of sweetpotato roots. The objectives of this study therefore will be to evaluate the effect of sweetpotato defoliation and earthen up on curing and in-ground storabilty of fresh roots on storability of fresh roots over time.

MATERIALS AND METHODS
The experiment was conducted at Umudike station in 2013 and 2014 cropping season. The trial was laid out as a split plots in randomized block design and replicated 3 times. The main plot treatments measuring 8 x 4.5 m comprised of 7 varieties (Butter milk, UMUSPO3, UMUSPO1, Kwara, TIS87/0087, TIS8164 and Ex-igbariam), and 4 storage methods (Cured, Uncured, harvest after 1 month and 2 months) with the dimension of 2 x 4.5m formed the subplot treatments. The cured treatment was defoliated one week prior to harvesting to allow the storage roots to harden. The uncured treatment was defoliated and harvested the same day while the treatments which were harvested 1 and 2 months after maturity were defoliated and earthen up and left for 1 month and 2 months before harvesting. Data were collected on root yield, weevil infestation, and rots. These were analyzed statistically using Genstat statistical package. Cultural management of the experiment as recommended were carried out.

RESULTS AND DISCUSSION

There were significant differences among varieties with UMUSPO3 (OFSP) and UMUSPO1 producing average high yields of 17.2 and 13.3t/ha respectively compared to other varieties in most cases in 2013 and 2014 (table1). There was however no significant difference between cured, uncured and when left in the ground for 1month before harvesting. This suggests that a farmer can delay harvesting for one month to escape the glut period and target high price. The result in 2014 followed the same trend but for the inconsistency in storage method. There was no significant effect of storage method on yield of varieties in 2014. The incidences of rots were evident when roots were left in the ground for 1 or 2 months before harvesting (Table2). More roots developed rots (6.0% and 12.3%) when left in the ground for 1 or two months before harvesting for both seasons. Butter milk in most cases recorded the highest storage losses (13.4%) compared to other varieties. There was low rot incidence when the roots were cured and uncured and harvested at maturity. Weevil infestation (2.3 and 6.7% for 1MAS and 2MAS respectively) was significantly high in most cases when harvesting was delayed (Table 3). Generally, UMUSPO1 had a high significant value (6.0%) of weevil infestation compared to other varieties with TIS8164 recording the lowest (0.7%) value. When roots were left in the soil for 1 or 2 months after maturity, 5% and 3% weevil infestation occur but this value is not too high to cost much economic damage to the yield.

CONCLUSION

Sweetpotato weevil (Cylas puncticollis) has been a major problem to farmers and its actions predisposes roots to rots thereby causing yield loss and low market value. This investigation revealed that sweetpotato roots can be left in the soil for 1 month or more with minimal damage. For in-ground storage methods, sweetpotato plant should be defoliated and ridges or mounds hilled up to close the cracks that could create access for weevils to get to the roots. Storing the roots in-ground following the procedures discussed will prolong storage of roots more than 1 month after maturity to enable the farmers harvest storage roots when need. Also varietal characteristics might have contributed to susceptibility to weevil attach. The two varieties (UMUSPO1 & 3) with high incidence of weevil are hallow rooted and as such more prone to weevil attach as a result of their exposed roots. Sweetpotato breeders may evaluate for deep rooted genotypes that may root beyond soil medium that weevils may have access to. However, more research is recommended to investigate the nutritional quality of the prolonged stored roots.

EVALUATION OF CASSAVA LEAF LITTERS AS A SUPPLEMENT WITH INORGANIC FERTILIZER FOR SUSTAINABLE PRODUCTION AND YIELD OF CASSAVA

S.C. Njoku, S.P. Abah, E. Ukenyi & C. Okpara

National Root Crops Research Institute, Umudike, Abia State, Nigeria
E-mail: **Sallynjoku@yahoo.com**

ABSTRACT
A field experiment to evaluate the potentials of cassava leaf residue in sustaining cassava production under a continuous cropping system as an alternative to the use of inorganic fertilizer was carried out in 2011/2012 cropping season at the experimental field of National Root Crops Research Institute, Umudike. The various fertilizer treatments used were sole application cassava leaf residue, sole application of NPK fertilizer at the rate of 400kg/ha, combination of cassava leaf residue and 200kg/ha NPK as well as no fertilizer application which served as a check. Three varieties of cassava (TMS98/0510, TMS98/0581 and TMS96/1632) were used to determine the effect of these fertilizer applications on cassava varieties. The two-factor experiment was laid out in a randomized complete block design with three replications where cassava was planted in 1m x 1m distance in a 4m x 5m experimental unit. Variety, fertilizer rates and some of their interactions had a significant (P<0.05) effect on some of the growth and yield attributes of cassava measured. TMS98/0510 had a significant higher performance than the other varieties, whereas; cassava leaf residue in combination with 200kg inorganic fertilizer application was higher than the other fertilizer treatments. Therefore, cassava leaf residue can serve as an alternative and readily available source of nutrients for cassava production and sustainable soil fertility.
Keywords: Cassava leaf litters, inorganic fertilizer, sustainable production, yield and cassava

INTRODUCTION
Cassava (*Manihot esculenta* Crantz) is the most widely consumed root crop of the tropics (Nweke *et al.*, 1994; Henry 1995). It is a major food source for more than 500 million people in Africa, Latin America and Asia. It is mainly cultivated for its starchy roots with a world production estimated at 152 million tons (FAO, 1996). The total area harvested is about 16 million hectares with 60%, 24% and 16% in Africa, Asia, and Latin America respectively (Bonierbale *et al.* 1997, FAO, 2002). The storage roots are the basic component of the carbohydrate diet and the leaves are consumed as the preferred green vegetable in many parts of Africa, providing protein, minerals and vitamins (Hahn, 1989). Approximately 71% of world cassava production is utilised for human consumption, while the rest is for animal feed and industrial uses (Sarma and Kunchai, 1991).Cassava leaves have potential that can help in sustainable cassava production through its contribution to soil fertility. Considering the constant practice of farmers having to plant and harvest the same piece of land yearly due to inadequate farm land, and with the present high cost of fertilizer. There is, therefore, the need to carry out agronomic practices that can sustain cassava production on the same piece of land. This work aims at determining the contribution of cassava leaf residue to sustain a new crop on the same piece of land as well as contributing to soil improvement.

MATERIALS AND METHODS
Three cassava varieties of specific growth and branching habit were used for treatments of the following cassava leaf residues and inorganic fertilizers as supplement: no cassava leaf residue as control, application of cassava leaf residue alone, application of cassava leaf residue + 200kg inorganic fertilizer and application of 400kg inorganic fertilizer, alone as control in a randomized complete block design (RCBB) with 4 replicates. For the first year of the experiment, planting was done and basal application of inorganic fertilizer carried out in all the plots to ensure good growth and performance of the cassava for the following year work. At harvest of the first year work, the plots were weeded to dispose other leaves other than cassava leaves , the stem and stalk of cassava was removed leaving the cassava leaf only on the needed plots. The leaves were allowed for some time on the plots before the field is prepared for the subsequent cropping. This work will be done for three years on the same piece of land. Data were analysed using Microsoft excel and GenSTAT.

RESULTS AND DISCUSSION
Effect on Germination Count
Varieties affected the establishment rate of cassava but not the fertilizer application and the interaction between the two factors. The three varieties were statistically different in their rate of establishment in the field. TMS98/0510 had the highest establishment rate than the other varieties. Although not significantly different (P>0.05), there was a recorded higher plant establishment count in the check than the fertilizer treatments.

Effect on Vigour

Cassava Vigor was significantly affected by varieties and fertilizer treatments (P<0.05), but not their interaction. TMS98/0510 was the most vigorous of all the varieties used. The mean fertilizer treatment effect on vigor showed that there was an increased vigor with application of fertilizer treatments compared to when there was no fertilizer application. However, the combined application of organic manure and NPK fertilizer at the rate of 200kg/ha (Organic manure+20kg NPK) and sole application of NPK fertilizer at the rate of 400kg/ha were the same.

Effect on number of Tuber

The number of tubers was significantly influenced by the different fertilizer treatments as well as the varieties. There was no significant interaction effect between the two treatment factors. The variety TMS98/0510 had a higher and significant number of roots than the other two varieties. The fertilizer treatments had higher number of roots than the check. The combination of organic and inorganic fertilizer at 200kg/ha supported the highest number of roots than the other fertilizer treatments. Number of roots in TMS98/0581 increased with the addition of organic manure (sole), Organic +200kg NPK and 400kg NPK.

Effect on weight of Tuber

The analysis of variance showed that the tuber yield of cassava was significantly (P<0.05) affected by the varieties of cassava but not with the fertilizer treatments as well as their interactions. TMS98/0510 had the highest tuber yield followed by TMS98/0581 and TMS96/1632 in a decreasing order. Addition of fertilizer treatments had higher yield than the check where no fertilizer was applied. The combination of organic and 200kg of NPK fertilizer had the highest tuber yield than other fertilizer treatments. This combination was highest with TMS98/0510 and the sole addition of 400kg NPK although not significant, reduced yield.

CONCLUSION

The use of cassava leaf residue in maintaining soil fertility has great potential in sustaining cassava production. However, the combined application of cassava leaf residue and inorganic fertilizer at the rate of 200kg/ha proved to be very effective. This therefore, suggests a 50% reduction in the cost of inorganic fertilizer application. TMS98/0510 had an outstanding growth and yield performance in all the parameters measured and should be made available to cassava end users for enhanced cassava production.

Table 1: Effect of the inorganic and organic on the germination count of cassava varieties

Treatment	TMS 98/0510	TMS 98/0581	TMS 96/1632	Mean
No fertilizer	31.75	21.75	22.75	25.42

ABSTRACT

A Pot experiment were conducted at Umudike Southeastern Nigeria to study the effects of different sources of biochar on growth parameters and leaf/pod nutrient composition of Okra (Abelmoschus esculentus moench). The biochar treatments were prepared from eleven (11) different feed stocks which comprised – bone (BN), Cocoa pod (CP), Cow dung (CD), Goat dropping (GD), Palm bunch (PB),Pig waste (PW), Poultry droppings (PD), Rice mill husk (RMW), Saw dust (SD), Mucuna flagellipes shell (MFP), Wood shaving (WS) and a mixture of all the feed stocks mixed together (MFB) and one control (Ctrl) making it 12 treatments in all. The treatment were applied at the rate of 3 t / ha (equivalent to 86g) in 10kg of soil weighed into poly bags and replicated 4 times using completely randomized design (CRD). Parameters measured were plant height number of leaves at 2, 4, 6 and 8 weeks after planting (WAP) and nutrient composition (N, P, K, Ca and Mg) of okra leaf/pod at 8WAP. The results obtained from the study showed that application of different sources of biochar significantly increased number of leaves, plant height and leaf/pod nutrient (N, P, K, Ca, and Mg) content of okra over the control. Though pots amended with mixed feedstock biochar (MFB) gave best result both in plant height, number of leaves at 2, 4, 6, and 8 WAP (5.62, 14.50, 28.90, and 41.20cm) and nutrient composition of okra, Nitrogen (4.20%), Phosphorus (1.10%), Potassium (3.80%), Calcium (0.72%) and Magnesium (0.48%).

Keywords: Biochar, Nutrient Composition, Growth and Okra

INTRODUCTION

In tropical country such as Nigeria, high cost and scarcity of fertilizers hinder fertilizer use by most resource poor farmers in the rural areas. Hence, attention has shifted to the conversion of organic wastes into biochar for plant nutrition. Biochar is a solid product material produced during a process known as pyrolysis from the thermo-conversion of biomass under little or no oxygen for use in soils as an amendment Lehmann (2009). A lot of studies have been carried out on the direct application of organic wastes for crop production. However the fertilizing values of these wastes when converted to biochar have not received much attention in the tropics. This is not the case in the temperate countries, where use of organic waste biochar have been shown to improve soil physio chemical properties and nutrient status of okra. Novak *et al*., (2009) and Gaskin *et al*., (2008). On lowly fertile soils of Oklahoma, biochar was found to improve the soil chemical properties, growth parameters and nutrients composition of okra. Laird *et al*., (2010). A study was carried out on an Ultisol of umudike in Abia state, Nigeria to investigate the effect of biochar sourced from different organic wastes on growth characteristics and nutrient composition of okra an important tropical and sub-tropical vegetable grown for its leaf/pod.

MATERIALS AND METHODS

The study was carried out at Umudike, Ikwuano LGA of Abia state southeastern Nigeria. Umudike is located on latitude 05° 29' N, longitude 07° 33' E and 122m above sea level. The climate is essentially humid tropical with an average annual precipitation of 2164mm. There are two distinct seasons; the rainy season which starts in March/April and ends in October. Then the dry season which starts in November and ends in March subsequent year (NRCRI Meteorology Centre, 2015). Soil samples were collected at the depth of 0 - 15cm, air dried, crushed and sieved with 5mm sieve then ten kilograms (10kg) of the soil were weighed into experimental polyethylene bag properly labeled and laid out in Completely Randomized Design (CRD). The treatments (biochar) were prepared from 11 different feed stock/sources - Bone (BN), Cow dung (CD), Cocoa pod (CP), Goat droppings (GD), Palm bunch (PB), Pig waste (PW), Poultry Dropping (PD), Rice mill wase (RMW), Saw dust (SD), Mucuna flagellipes (MFP), Wood shavings (WS), Mixed feedstock biochar (MFB) using a slow pyrolysis drum method. The biochar were applied at the rate of 3t/ha with its grams equivalent of 86g. The 12 treatment and one control were randomly assigned to the container and replicated four times to give a total of 52 pots. The treatments were applied and mixed thoroughly with the soil, moistened and allowed to equilibrate for 1 week. Okra seeds (Var. NH 99/28) obtained from National Agric. Seed Council Umudike Regional Office were planted 4 seeds per pot and later thinned to two plants per stand after two weeks. Plant height and number of leaves were determined at 2,4,6 and 8 weeks after planting (WAP); using meter rule. The plants were uprooted, washed, oven dried at 65°C., grinded and digested for nutrients extraction using double acid extraction method by Udo *et al*., (2009). Total Nitrogen (N) was determined my micro Kjeldahl method, Phosphorus (P) was determined by Vanado-molybdate colorimetry on spectrometer, Potassium (K) was determined by flame photometer while Calcium (Ca) and Magnesium (Mg) were determined by titrametric method as described by Udo *et al.,* (2009). Data were subjected to analysis of variance for CRD experiment, significant treatment means were separated using the least significant difference at 5% probability level.

RESULTS AND DISCUSSION

Table 1 show the effect of different sources of biochar on okra height at 2, 4, 6 and 8 weeks after planting (WAP). Plant height increased significantly ($P < 0.05$) across the weeks during the experiment as a result of applying different source of biochar. Okra treated with MFB gave the highest value on plant height across the weeks of the experiment (2, 4, 6 and 8 WAP) (5.63, 14.50, 28.90 and 41.20cm) while the lowest value on plant height were recorded on pots with no treatment (control) (5.03, 13.48, 24.03 and 35.67cm). Data on number of leaves in response to different source of biochar were presented in Table 2. Different sources of biochar increased number of leaves compared with control across the weeks. MFB and MFP gave the highest value on number of leaves across the weeks 2, 4, 6, and 8 WAP (5, 8, 9 and 11) followed by poultry droppings (PD) (4, 8, 9 and 11) while pot with no treatment had the lowest value on number of leaves (3,6,8 and 10). Table 3 contains data on okra nutrient. Different source of biochar increased N, P, K, Ca and Mg contents significantly ($P < 0.05$) relative to the control. The highest value of N, P, K and Ca were obtained from okra treated with MFB (4.20, 1.10, 3.80 and 0.72%) followed by PT (N, P, K and Ca) (3.72, 1.22, 3.6 and 0.65%). Though okra treated with BN gave the highest value on Mg (0.80%) while the control gave the lowest value across all the nutrient (N, P, K, Ca, and Mg) (1.95, 0.28, 1.80, 0.41 and 0.22%). The increase in plant height, number of leaves and nutrient content (N, P, K, Ca, and Mg) of okra due to application of different source of biochar is in accordance with result obtained by Lehmann (2009), Gaskin et *al* (2008) and Laird *et al* (2010).

CONCLUSION

It is concluded that biochar from different source has fertilizing effect in production and can serve as an alternative to the expensive fertilizer for most small-holding farmers.

ABSTRACT
American yam bean (Pachyrhizus spp) (AYB) has been successfully introduced in some African countries with exciting results. Fourteen AYB accessions were received from CIP Lima Peru. The objective was to assess the performance of twelve American yam bean accessions under Nigerian environmental conditions in order to identify and select adapted genotypes with high yield and acceptable culinary qualities. Twelve accessions - 209039, 209016, 209013, 209037, 209019, 209015, 209038, 209018, 209041, 209045, 209042 and 209044 were planted in the field on the 30th of May 2014 in a randomized complete block design with two replications. Results obtained show that percentage emergence (3WAP) ranged from 30% in accession 209041 to – 93.3% in accession 209018. Tuber skin colour ranged from cream, dark cream to purple while tuber flesh colour was mostly milky to milky white. Number of tubers/m² ranged from 0.33 in accession 209045 to 4.17 in accession 209015. Tuber yield ranged from 0.03 to 1.7kg/m² and there were significant differences between accessions. Based on tuber yield, 5 accessions 209013, 209015, 209016, 209018 and 209019 were selected for further evaluation. Yields obtained showed that these selected accessions have the potential to serve as alternative sources of calories to help feed increasing population.

Keywords: *Pachyrhizus spp*, yield, genotypes, rotenone and growth attributes

INTRODUCTION

American yam bean (*Pachyrhizus spp*) (AYB) has been successfully introduced in some African countries (Zanklan *et al*. 2007; CIP, 2014a) but not in Nigeria. Its tubers can be eaten raw or processed into a number of products including garri (Padonou *et al*., 2013). These products are iron dense and have good iron bioavailability (CIP, 2014b). An important characteristic of yam bean Pachyrhizus is the presence in the matured seeds of the isoflavoniod called rotenone, an insecticidal compound. The presence of high levels of rotenone and pachyrhizide make seeds of AYB toxic and unsuitable for human consumption (Zanklan, 2003). Fourteen accessions of AYB were received from International Potato Centre (CIP), Lima in March, 2013. The accessions were received in the form of true seeds. The objective was to assess their performance under Nigerian environmental conditions in order to identify and select adapted genotypes with high yield and acceptable culinary qualities.

METHODOLOGY

Twelve accessions - 209039, 209016, 209013, 209037, 209019, 209015, 209038, 209018, 209041, 209045, 209042 and 209044 were planted in the field on the 30th of May in a randomized complete block design with two replications. Planting distance was 1m inter-row and 0.3m intra-row, giving a population density of 33,333 stands per hectare. No fertilizer was applied. Weeding was manual. Harvesting was carried out in December, 2014. Data were collected on some growth and tuber yield attributes. Nematode symptoms were also assessed. Data was statistically analyzed using genstat software (discovery edition).

RESULTS AND DISCUSSION

Growth Attributes

Data on some growth attributes of AYB are presented in table 1. Percentage emergence (3WAP) ranged from 30% in accession 209041 to – 93.3% in accession 209018. Plant vigour scored on a scale of 1-5 ranged from 1(Very poor) to 5(Highly vigorous). There was a variety of growth habits from erect to creeping and from determinate to indeterminate types. Even within an accession, plants varied in these attributes. Field outlook of some accessions are shown in Fig 1.

Tuber Yield Attributes

Some tuber yield characteristics of AYB are presented in table 2 while freshly harvested tubers are shown in fig 2. Tuber skin colour ranged from cream, dark cream to purple while tuber flesh colour was mostly milky to milky white. Number of tubers/m2 ranged from 0.33 in accession 209045 to 4.17 in accession 209015. Accession 209015, differed significantly from many other accessions in number of tubers/m2. Tuber yield ranged from 0.03 to 1.7kg/m² and there were significant differences between accessions. Zanklan (2003) reported differences between tuber fresh yield of accessions of *Pachyrhizus ahip* but did not find significant differences between numbers of tubers. He however reported significant differences between numbers of tubers in *Pachyrhizus tuberosus.*

CONCLUSION

Based on tuber yield, 5 accessions were selected for further evaluation at 3 different locations in 2015. These accessions are 209013, 209015, 209016, 209018 and 209019.

ABSTRACT
Roots and tubers provide a substantial part of national food supply and are also an important source of animal feed. This paper relied on secondary data and information to review efforts to increase production of root and tuber crops in Nigeria with emphasis on Root and Tuber Expansion Programme (RTEP) and Research based programmes. RTEP was found to have had a very strong positive impact on production, processing, marketing and utilization of root and tuber crops especially cassava and yam. Farmers took advantage of technologies disseminated through RTEP to expand their acreage and increase productivity which ultimately increased income and reduce poverty amongst participating farmers and communities. The potentials of research based programmes like YIISFWA, HarvestPlus, NEXTGEN, amongst others to enhance production of root and tuber were highlighted. It was suggested that future intervention strategies for root and tuber crops expansion intensification, mechanization, value addition and product development, strengthening extension delivery and advocacy, improvement of rural infrastructure and encouraging the production of minor roots and tubers
Keywords: Root, Tuber, Expansion and Nigeria

INTRODUCTION
Root and tuber crops are grown for their underground modified, thickened root or stem. Those with modified tuberous and fleshy primary or secondary roots are simply referred to as roots (Cassava, Sweetpotato) while those plants with modified thickened tuberous stems are referred to as tubers (eg Yam, Potato, Livingstone potato). Rhizome are underground, horizontally enlarged shoot, more or less fleshy when fresh (eg ginger, turmeric). The principal root and tuber crops of Nigeria are cassava (*Manihot esculenta* Crantz), yam (*Dioscorea* spp.), sweet potato (*Ipomoea batatas* L.), potato (*Solanum* spp.) and cocoyam (*Colocasia* spp. and *Xanthosoma sagittifolium*). Root and tuber crops of minor importance in Nigeria include Livingstone potato (Rizga) (*Plectranthus esculentus*) Hausa potato (*Solenostemon rotundifolius*), and Polynesian Arrowroot (Amora) (*Tacca leontopetaloides* Kuntze). Ginger (*Zingiber officinale L*) and Turmeric (*Curcuma longa* L) are rhizomatous spices. Root and tuber crops share some common characteristics but are also very dissimilar in many respects (Table 1). They differ in plant architecture, maturity period, temperature, soil and fertility requirements and storability.

Table 1: Characteristics of Root and Tuber Crops

Characteristics	Cassava	Potato	Sweetpotato	Ginger	Taro	Yam
Growth period (months)	9-24	3-7	3-8	9-12	6-18	8-11
Annual or perennial plant	per.	ann.	Per.	per.	per.	ann.
Optimal rainfall (cm)	100-150	50-75	75-100	140-200	250	115
Optimal temperature (°C)	25-29	15-18	>24	13-29	21-27	30

Source: Adapted with modification from Kay, D.E., 1973. Tropical Products Institute, London, as presented in Horton 1988.

Roots and tubers provide a substantial part of the world's food supply and are also an important source of animal feed. They also provide some minerals, essential vitamins, and proteins in variable amounts. In most traditional diets vegetable soups, meat, groundnuts, grain legumes and fish are good sources of protein and are frequently used to supplement root crops and compensate for their protein deficiencies. In some parts of Africa the diet is supplemented with the tender leaves of sweet potato, cassava and cocoyam which are rich sources of protein, minerals and vitamins (Hahn, 1984). The aggregate value of yam, cassava, potato and sweetpotato exceeds all other African staples, including cereal crops (cereals annually producing on average 169 million tons on 108 million ha of land) (Saginga, 2015). Figures 1, 2 and 3 show trends in area under cultivation, yield/ha and production respectively of five major root and tuber crops grown in Nigeria from 1990-2013 (Source: FAOSTAT downloaded 17th July, 2016).

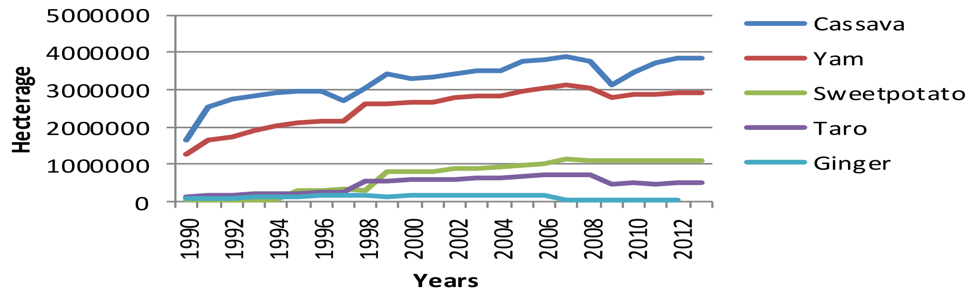

Fig 1: Area under cultivation of Major Root and Tuber Crops in Nigeria

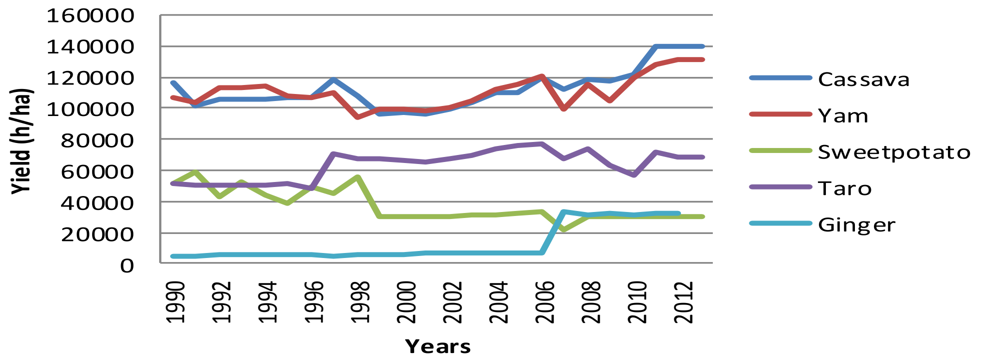

Fig 2: Trend in Yield of Major Root and Tuber Crops

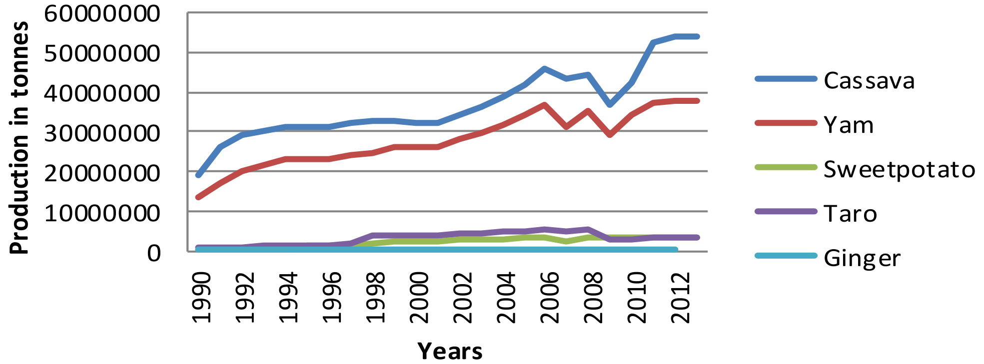

Fig 3:Trend in Production(t) of Major Root and Tuber Crops in Nigeria

Government intervention and the efforts of non-governmental organizations in the root and tuber crop subsector have led to a number of measures that support the production, processing and marketing of root and tuber crops especially cassava, dating back to the 1970s. These include government programmes such as the National

Accelerated Food Production Programme (NAFPP), Operation Feed the Nation (OFN), the Agricultural Development Projects (ADPs), Cassava Multiplication Programme (CMP), Root and Tuber Expansion Programme (RTEP), Presidential Cassava Initiative (PCI), Agricultural Transformation Agenda (ATA), the development of the National Agricultural Research Systems and their close collaboration with the International Institute of Tropical Agriculture (IITA) and other international agricultural research centres and activities of oil companies and church organizations. Through these efforts, appreciable progress has been made in genetic improvement, agronomic practices, root storage and in the development of processing technology and rural infrastructure. For example, National Root Crops Research Institute Umudike in Collaboration with IITA have developed and released 43 improved cassava (Okonkwo, 2015), 19 yam, 3 sweetpotato and 2 potato varieties to farmers. In addition, many rapid seed multiplication techniques, agronomic and post-harvest management packages have also been developed. Concerted efforts have also been made to create awareness, and extend these improved practices to farmers. While these programmes especially CMP, PIC, RTEP and ATA led to significant expansion in the production and utilization of cassava only RTEP cut across other root and tuber crops and as a result will form the main focus of this paper.

Root and Tuber Expansion Programme (RTEP)

RTEP was launched in 2000, drawing on lesson learnt from Cassava Multiplication Scheme (CMS) but effective disbursement of the loan commenced in 2002 (FAO, 2001, Adeniji, 2006). The total project cost of USD 36.09 was funded by IFAD loan USD 23.6 million; US$ 7.18 million from Federal Government of Nigeria; USD 5.85 million from State Governments. This phase of the project ended in 2010 with Federal Ministry of Agriculture and Water Resources (FMAWR) through its Federal Department of Agriculture as the implementing agency (FAO, 2010a). The long-term objective of RTEP is to commercialize root and tuber production to improve the living conditions, income, food security and nutritional health of the poorest smallholder households in the programme area. It particularly targets small-scale farmers with less than 2 hectares of land per household. The programme used the existing extension service system to introduce improved varieties of roots and tubers and better cultivation techniques. Since women play a major role in cassava and other food crop production, processing and marketing, the programme encourages them to participate in research trials and demonstrations (Adeniji, 2009; IFAD, 2010). Specific programme objectives include: developing improved root and tuber production technologies to increase productivity; multiplying improved planting material; developing processing techniques and marketing activities; and collaborating with NGOs to provide training to farmers (FMANR, 2006, Adeniji, 2009). Twenty six states in the root and tuber crops-growing belt participated in RTEP. The overall target group was about 5.2 million small holders with less than 2 to 3 ha of land holding per household in Nigeria (PIM 2001 in Ibrahim and Onuk, 2010). The activities include multiplication and distribution of improved root and tuber planting materials and adding value to root and tuber crops by processing, marketing and linking fabricators with processors (Okeh et al., 2014). In addition, actions and strategies to strengthen downstream activities, check incidences of low prices in producing communities, bridge income disparities, and enhance employment were also incorporated into the programme (Olusegun et al, 2015).

Impact of RTEP

The programme improved the availability and access to new varieties of planting materials, and has also enhanced the processing and marketing of products. It introduces trade policies to expand the breadth of demand for root and tuber products, and cassava in particular. It also helps targeted communities purchase equipment for processing (IFAD, 2010). As a result of RTEP, farmers increased the area under cultivation of root and tubers especially cassava. Tijani and Thomas, (2011) reported as shown in Table 3 that percentage of farmers in Remo area of Ogun State who cultivated between 1 — 3 hectares increased from 50.0% to 71.1%, while farmers with less than one hectare reduce from 38.9% to 28.9% before and after RTEP intervention respectively. This was evident in most other communities that participated in the project as shown by other reports (Mgbakor et al., 2013). In addition, farmers took advantage of RTEP to increase production (Ater et al., 2006, Tijani and Thomas, 2011). Before the intervention the percentage of farmers who had yield of less than 1 ton was 77.8% but with the introduction of RTEP, the percentage of farmers who produced between 2 - 4 tons shoot up from 22.2% to 84.4%. Olusegun et al, (2015) reported that adoption of RTEP increased yield and crop income by a range of about 13.00 to 18.52 metric tons and ₦39,705 to ₦42,133 respectively.

Increased production due to RTEP was not just as a result of expansion of land area under cultivation but also from increased productivity due to awareness, availability and utilization of improved varieties and healthier planting materials. RTEP had a positive impact by widening and improving crop varieties and production; field evidence has shown a relatively high adoption rate (70-80%) for recommended cassava varieties. However, the full yield potential of such improved cultivars is still to be achieved. In addition, it has highlighted the potentials of roots and tubers as industrial raw materials (HQCF, starch and chips; as well as cassava pellets for animal feeds) (IFAD, 2010). By expanding root and tuber crop production RTEP increased income and reduce poverty amongst participating farmers and communities. This has been shown by findings reported by various authors

(Ater et al., 2006; Olujide and Leoto, 2010; Obisesan et al., 2013; Olusegun et al, 2015). Crop income of farmers was increased by a range of about ₦39,705 to ₦42,133 respectively and poverty reduced by a range of about 5 to 20%. Poverty incidence and indices of beneficiaries of RTEP decreased and were lower than those of non-participants. Ugwu (2006) reported that in Enugu State, RTEP contributed to rural livelihood development mainly in terms of increased farm household income, farm input provision, extension contact, additional family/farm assets, food security as well as capacity building/skill training and improved storage/preservation methods. According to the project completion digest (IFAD, 2010a), in terms of physical assets, RTEP contributed to constructing/upgrading a total of 354 cassava processing sheds/centres, of which 166 centres were functional as at RTEP completion, established, owned and operated by small-scale programme beneficiaries. In addition, at RTEP completion, a total of 65 cassava processing factories had been established by medium-scale operators. The findings of the study by Achem et al., (2013) showed that RTEP provided more than 73 percent of total cassava processing equipment in the Kwara State. The study further revealed that there was significant increase in income of RTEP compared to Non RTEP participants. RTEP helped create higher level of awareness about the potentials of roots and tubers, especially cassava, for direct consumption. In addition, the contribution of the programme in increasing the national output of roots and tubers between 2000 and 2009 infers more and greater resources to farming families and, consequently, improved living standards (IFAD, 2010a). From the perspective of crop processing and value addition, the implementation of RTEP has successfully demonstrated the bright future for and the high potential of cassava for household consumption.

RTEP enhanced food security by lowering food insecurity incidence and indices of RTEP farmers compared with non-beneficiaries (Obisesan and Omonona, 2013). This reveals that RTEP improved production technology has the potential to improve food security.

Sustainability post funding

Some well to do farmers and processors have started replicating improved processing shed/centres models. Scale expansion in more in the area of cassava production, as over 75% of farming groups have seen the need to cultivate more than the 1-2 ha allocated to them under the RTEP. In addition, the huge human capacities developed/built, the skills imparted, the orientation and perspectives inculcated in root and tuber farmers/producers, processors, are likely to be long lasting, especially in terms of attracting future investments in the subsector and exploring opportunities especially relating to cassava. According to the project completion digest (IFAD, 2010a), the Nigerian small holder farmers, small processors and medium-scale are willing to continue with activities beyond and after the programme period and IFAD support. It is likely that the beneficiaries may further continue their investments in roots and tubers cultivation and processing, long after programme closure. In addition, with the availability of crop varieties whose potential productivity has only been minimally explored, the effort by farmers to enhance production per unit of land is necessarily a continuing agenda even after RTEP. Federal government launched phase 2 of the RTEP in 2010 to consolidate on the successes achieved in phase 1 and address the problem of production growth experienced each year by farmers after harvest. RTEP unit now exists as a unit in the Federal department of Agriculture.

RESEARCH BASED PROGRAMMES FOR ENHANCED PRODCUTION OF ROOT AND TUBER CROPS

There are a growing number of programs of research in Africa on yam, cassava, potato and sweet potato addressing genetic enhancement, seed systems, production, marketing and nutrition impacts. These programmes include Yam Improvement for Income Generation and Food Security in West Africa (YIIFSWA), Next Generation Cassava Breeding Project (NEXTGEN), Alliance for Green Revolution in Africa (AGRA), HARVESTPLUS, Cassava: Adding Value to Africa (C:AVA) amongst others (Table 2). Different approaches to improve the quality of production technologies used by smallholder farmers have been developed. New varieties were developed and distributed to farmers. Farmers were trained to produce quality seed for their own use, for local seed provision and opportunities for small-scale seed enterprises were explored. Partnerships involving both national and international actors were created to expedite access and availability of the improved technologies to African small holders. Some instances will suffice. HarvestPlus, for example leads a global effort to improve nutrition and public health by developing and disseminating staple food crops that are rich in vitamins and minerals. Over 106, 000 farmers received and planted vitamin A cassava stems in four target and 10 expansion states in 2013 alone, according to Dr. Ilona, HarvestPlus Country Manager, Nigeria. The number, he said, will exceed 350, 000 farmers in subsequent years, as more partners engage in vitamin A cassava stem dissemination to vulnerable households. YIIFSWA uses aeroponics to produce yam vines and minitubers. The vines are used to generate single node cuttings which are then planted to produce minitubers and seed yams. Through this process, millions of seed yams can be produced thus addressing a critical bottleneck in yam production which is scarcity of seed yams (EkeOkoro, O.N, personal commun.). The Next Generation Cassava Breeding (NEXTGEN Cassava) project aims to significantly increase the rate of genetic improvement in cassava breeding and unlock the full potential of cassava using Genomic Selection that relies on statistical modeling to predict cassava performance before field-testing, and dramatically accelerates the breeding cycle (http://www.nextgencassava.org/about.html). Cassava weed management project (CWMP) is seeking to find solutions to the labor-intensive weeding usually performed by women and children and to increase cassava productivity for 125,000 Nigerian farm families (http://www.cassavaweed.org/about-us/). This gender mainstreamed project is evaluating the use of portable machines for weeding of cassava farms, trying out new herbicides and cropping systems.

Table 2: Research Based Projects for increasing the production of root and tuber crops in Nigeria

Name of Project	Crop of Interest	Funding Agency	Achievement
Alliance for Green Revolution in Africa (AGRA)	Cassava, Yam, Sweetpotato	B&M Gates, Rockfeller	Varieties of Cassava, Sweetpotato released
Next Generation Cassava Breeding Project (NEXTGEN)	Cassava	B&M Gates	Reduced breeding cycle, Improved flowering in recalcitrant types
Harvestplus	Cassava	CGIAR	Some pro-vitamin A rich varieties released
Cassava: Adding Value in Africa (C:AVA)	Cassava	B&M Gates	Development of value chain for HQCF
Generation Challenge Project (GCP)	Cassava	CGIAR	Marker assisted selection
Ecologically Sustainable Cassava Plant Protection (ESCaPP)	Cassava	UNDP	Rolled back Cassava Mealybug
African Yam	Yam	B&M Gates	Assembling germplasm Breeding yam
YIIFSWA	Yam	B&M Gates	Increased seed yam production
African Cassava Agronomy Initiative (ACAI)	Cassava	B&M Gates	Enhanced Agronomic management of cassava
IFAD CASSAVA	Cassava	IFAD	Cassava stem multiplication
Cassava Weed Management Project (CWMP)	Cassava	B&M Gates	Weed control in Cassava

WAY FORWARD

Future intervention strategies for root and tuber crops expansion can broadly be grouped under the following headings: Intensification, Mechanization, Value addition and product development, Strengthening extension delivery and advocacy, Improvement of rural infrastructure and encouraging the production of minor roots and tubers

Intensification

- Efforts to develop, rapid multiply and disseminate improved varieties should be encouraged and strengthened in order to enhance the availability and diversity of improved planting materials;
- Along with the above, efforts to develop and extend improved agronomic practices for enhanced productivity of root and tuber crops should be encouraged

Mechanization

- Deliberate efforts to support the development of root and tuber crop production and processing prototypes and identification of applicable and useful technologies and incentives for local entrepreneurs to fabricate them. This will reduce drudgery, save labour and improve the efficiency of production and processing, raise the quality and enhance marketability of products. The design of such machines should be gender-sensitive, bearing in mind the cardinal role of women in production and processing

Value addition and Product Development

- New products of root and tuber crops and improved packaging techniques for existing ones should be developed to reduce spoilage, increase shelf-life and widen their spectrum of acceptability. Roots and tubers because of their high moisture content are perishable and upon harvesting have relatively short shelf life. Cassava – the flagship of roots and tubers is particularly notorious in this respect as it hardly stores beyond three days due to post-harvest physiological deterioration and must be processed into more stable products.
- Promotion of industrial uses of root and tubers and diversification of processing options to encourage increased production and enhance rural household income;

Strengthening Extension and advocacy

- Strengthening of extension-farmer linkage with research to facilitate the ongoing spread of cultivars, management practice and processing techniques. This should lead to the mobilization of farmers through emphasis on a participatory development approach, family- or group-based extension and seed multiplication activities involving due recognition of the role of women in production, processing and marketing and assistance that would enable all farmers to take advantage of development programmes as far as possible; adequate and sustained research funding which must be timely released.
- Promoting greater involvement of the private sector and non-governmental organizations in the use of research and technology in root and tuber production, processing and marketing and in the development of infrastructural facilities.

Improvement of rural Infrastructure

- Feeder roads, water and electricity should be provided for our agrarian rural communities to promote root and tuber production, processing and marketing.

Bringing on Minor Root Crops

- We should as a matter of deliberate policy, encourage production and utilization of minor root and tuber crops like Livingstone potato (Rizga), Hausa Potato, Ploynesian Arrowroot, turmeric, etc. These are alternative crops that can contribute to food security.

Acknowledgments

I am grateful to the organizers of this conference for selecting me as a lead speaker and to those whose work I cited in this review.

ECONOMIC STUDIES ON HAULM KILLING IN POTATO PRODUCTION ON THE JOS PLATEAU, NIGERIA

D.M. Lenka, G.L. Daure & A.J. Lang

National Root Crops Research Institute Umudike
Corresponding author: lenkadaniel@yahoo.com

ABSTRACT
This experiment was carried out in 2014 and 2015 rainy season potato production at the experimental field of the Potato Programme of National Root Crops Research Institute. The experimental site is located along Latitude 09^{0} 44'E and Longitude 08^{0} 44'N with an elevation of 1,239.4 m above sea level. The average annual rainfall of the location was 1,289.89 mm. The Soil type is sandy loam with low Nitrogen content. The objective was to study the economics of haulm killing in potato, on treatment combinations of three levels of time of haulm killing, comprising of control HN0, Natural haulm senescence, HN1, Natural haulm senescence at 1 week before natural haulm senescence, HN2, 2 weeks before natural haulm senescence, HN3, 3 weeks before natural haulm senescence and four varieties of potato; Nicola, V1, Bertita, V2, Diamant, V3, and Agria, V. The data collected was analysed using Analysis of Variance Statistics. The study identified, three weeks to natural haulm senescence as the optimum time of haulm killing in seed potato production on the plateau. The responses of varieties to time of haulm killing were significantly different in times of yield and tuber size distribution. ($P<0.001$). The study recommends haulm killing for seed multiplication in potato production on the plateau. The study also suggested that, when the recommended seed size during bulking of potato is reached, the farmer can terminate the bulking of the tuber by killing the haulm. This will reduce cost of production, thereby increasing the profit margin.
Keywords: Economics, Haulom Killing, Potato and Jos Plateau

INTRODUCTION
Haulm killing can be described as the deliberate removal or destruction of the vegetative part of a plant. This will prevent photosynthetic, respiratory, transpiratory and other biological processes taking place in the plant (Tiessen et al., 2002). In literatures, haulm killing is used interchangeably with the words defoliation and de-haulming. Haulm killing is also carried out for the following reasons: to hasten maturity and harvesting (Vinod, et al., 2009), to reduce foliage mass, to obtain suitable tuber size (Virtanen and Seppannen, 2014, Garg and Sarjeet, 1999, Ravichandran and Sarjeet, 2003, Struik and Wiersema, 1999), to strengthen tuber skin before harvesting and to prevent plant pathogens from spreading among foliage and to prevent spreading of soil and seed borne diseases (Kempenaar and Struik, 2007, Miller and Cummings, 2002). There are many known methods of haulm killing (steaming, flaming, electrocutting, vine pulling, Misener and Everett, 1981) but the two methods of haulm killing in potato production that is most popular is the mechanical or chemical methods (Virtanen and Seppanen 2014). In the mechanical haulm killing simple farm implement like the cutlass and machete are used to cut down the vegetative part. This practice is done elsewhere, in small scale production, where the area of land cultivated is small and not large. For mechanical haulm defoliation in large scale production, farm machineries; mower and slasher are used. Chemical haulm killing, is haulm killing method applied in large scale production. It is convenient where the vegetative period of potato crop is long enough. There is paucity of information on haulm killing in literatures, in potato production in Nigeria. Potato farmers have been suffering losses over the years, due to lack of knowledge and application of haulm killing practices, to increase seed supply and manage seed production during outbreak of diseases and pests. In Jos Plateau farmers were not able to manage the damage of over 500 ha of potato crop caused by the potato late blight epidemics in 2014, due to lack of information on haulm killing. The farmers could have terminated the plant vegetative growth thereby reducing the spread of the disease and saving some seed materials. The study therefore, is set out, to determine the following objectives**:** generate information on haulm killing practices and its usefulness in seed potato production, to determine the best time of haulm killing in potato for maximum economic benefits, to compare the costs and returns of haulm killing and harvesting of potato at natural haulm senescence.

METHODOLOGY
The experiment was conducted at the experimental field of the Potato Programme of National Root Crops Research Institute Umudike. The experiment was planted on the 26th May 2014. The experimental site is located along Latitude 09^{0} 44'E and Longitude 08^{0} 44'N with an elevation of 1,239.4 m above sea level. The average annual rainfall of the location was 1,289.89 mm. The Soil type is sandy loam with low Nitrogen content. The experimental design was randomized complete block. The treatment combination was sixteen and replicated three times. The first factor was haulm killing, comprising of three levels with a control HN0 = Natural haulm senescence, HN1 = 1 week prior to natural haulm senescence, HN2 = 2 weeks prior to natural haulm senescence,

HN3 = 3 weeks prior to natural haulm senescence. The second factor comprises of four varieties of potato; Nicola, (V1), Bertita, (V2), Diamant, (V3) and Agria, (V4). The experimental plot size was 4m x 4m and the net plot size was 12m^2. The recommended agronomic practices by National Root Crops Research Institute Umudike for potato production were applied to the treatments before the haulm killing. The haulm killing was done manually with cutlasses. Data was collected on yield and tuber sizes, diseases and pests. The costs and prices of Inputs and outputs from the experiment were also recorded. The data was analysed using Analysis of Variance Statistics (ANOVA) and mean separation was performed using Fischer's least standard deviation (LSD).

RESULTS AND DISCUSSION

Table 1, shows that there significant differences @ P<0.001 in total tuber yield (t/ha) between varieties. The distribution of tuber sizes among varieties was also significantly different between varieties (P<0.001). The table 1, also shows that there is significant differences in haulm killing methods, with the best time of haulm killing of three weeks before natural senescence optimum. In terms of interaction effect of varieties and time of haulm killings on yield and number of tubers, Table 2, showed significant differences in both intra and inter differences in varieties, and also in time of haulm killing. It was found that time of haulm killing positively and significantly influence the distribution of mean tuber number (no/m2), mean tuber yield (t/ha), and also time of haulm killing significantly influence the yield of varieties. Gross margin analysis of main effects of varieties and time of haulm killings, and Gross Margin analysis of Interaction effects of varieties and time of haulm killings on potato table 3 showed that the optimum time of haulm killing in potato is 3 weeks prior to natural haulm senescence. However the Natural haulm senescence remains the best method in terms of costs and return analysis.

CONCLUSION

Haulm killing is a useful farming practice. The optimum time of haulm killing in seed potato production on the plateau is three weeks to full potato maturity. Haulm killing affected varieties cultivated significantly differently. The study also suggested that, when the recommended seed size during bulking of potato is reached, the farmer can terminate the bulking of the tuber by killing the haulm. This will reduce cost of production, thereby increasing the profit margin.

ABSTRACT

Development of early bulking cassava varieties has become important in national cassava breeding programmes in Africa as a result of increasing demand for such cultivars by farmers. F_1 progenies developed from two elite cassava varieties (TMS98/0505 and TMS98/0581) were evaluated for yield, early bulking and traits associated with early bulking. Result shows that at 7MAP, values for yield and other yield related traits in some of the developed F_1 progenies were higher that their parents. Simple correlation statistics shows that fresh root yield and dry root yield significantly and positively correlated with all the yield related traits evaluated. Principle component coefficient showed that root and stem diameter were major contributors in three PCs out of five PCs considered, dry matter content and biomass were present in two PCs while fresh root yield and dry root yield were present in one PC.

Keywords: Breeding, Early bulking, Productivity and Cassava

INTRODUCTION

Cassava (*Manihot esculenta* Crantz) is a staple food for nearly a billion people in 105 countries of the world, especially tropical Africa, South America, and Asia (FAO 2008). It ranks second to sugarcane and is better than both maize and sorghum as an efficient producer of carbohydrate under optimal growing conditions. Annual consumption of the crop is highest in Africa. It is drought tolerant; this attribute makes it the most suitable food crop during periods of erratic rainfall and famine. Bulking in cassava is referred to the swelling or thickening of storage roots as they are filled with excess assimilates after the plants might have satisfied the need for vegetative growth (Okogbenin et al 2013). Early bulking (EB) varieties shorten the growth period from planting to harvesting, thus making cassava to be better fitted into environments with short rainy season and risky biotic stresses thereby increasing its productivity. The need for food production to keep pace with the rapidly expanding human population coupled with marginal rainfall in cassava production areas has made it necessary to develop early bulking and drought tolerant genotypes for Africa. Given the expanding demands for cassava as food, feed and industrial raw materials, genotypes with high yield, early bulking genotypes are highly desired. Objectives are to identify traits significantly associated with early bulking and evaluate and select high yield and early bulking cassava varieties.

MATERIALS AND METHODS

The trial was conducted in National root Crops research Institute (NRCRI) experimental field in Umudike. A total of one hundred and eighty F_1 genotypes developed from two elite genotypes (TMS98/0505 and TMS98/0581) were used for the experiment. The parents were used as check. The experimental design was randomized complete block design (RCBD) of twenty plant stands per plot replicated two times. The progeny and their parents were evaluated at 7 MAP for yield and other yield related traits such fresh root yield, biomass, number of tuberous roots, stem diameter and root diameter. At harvest, roots produced by each plant, as well as the above ground biomass (stem and foliage), were weighed. Net plants were harvested during harvest. Plot yield was converted to fresh root yield (FRY t/h) Harvest index (HI) was measured as the ratio between fresh root yield and total biomass. Percentage dry matter content of the roots was estimated using the specific gravity methodology Approximately 3kg of root were weighed in a hanging scale (W_A). The same sample was weighed with roots sub-merged in water (W_W). Dry matter content was estimated as: %DMC = [158.3 x ($W_A/(W_A-W_W)$ – 142]. Where W_A= weight in air and W_W= weight in water (Jaramillo *et al*., 2005). Dry root yield (DRY) was derived by multiplying FRY with percentage DMC.

RESULTS AND DISCUSSION

The result shows that fresh root yield ranged from 0.67 to 44 t/h while mean value across all the F_1 progenies was 13.87t/h (Table1). The highest fresh root yield was attained by the genotype 097B. The maximum yield for fresh root yield, dry root yield, dry matter content and other yield related traits of the F_1 population were found to be higher than that of their parents (checks) (Tables 2). This means that some of the F_1 progenies performed better than their parents. Fresh root yield and dry root yield positively correlated with all agronomic traits studied (Table

3). Among all the traits significantly correlated with FRY, root weight per plot had the highest correlation (r= 1.00) (Table 3). The positive correlation among the yield and yield related traits shows that they make important contributions towards economic yield (Ojulong 2008). It also indicates that all the yield traits were important by positively correlating with each other. This suggests that these traits (root weight, root number, root diameter, biomass, plant vigour, harvest index and stem diameter) are components triggering early yield as a complex trait. This agrees with the study conducted by Okogbenin and Fregene (2002) to investigate traits associated with early bulking where they found that storage root diameter, plant height, harvest index, number of storage roots and plant vigour were all positively correlated with dry storage root yield. Principle components indicated that the first five principle components explained 93.50% of the total variation (Table 4). The PC1 alone accounted for 47% of the total variation mostly contributed by root weight and fresh root yield. Principle component two accounting for 15.3% of the variation had dry matter content, root diameter and dry root yield as the major contributors. PC3 accounted for 15.2% of the total variation had root diameter, stem diameter and root number as the main contributors while PC4 with total variation of 9% indicated that root diameter, biomass, dry matter content, and stem diameter as the main contributors. PC5 which only accounted for 7% of the variation indicated biomass and stem diameter as the most important. Combining these important traits (FRY, RTWT, RTDIAM, DMC, FRY, DRY and STDIAM) as revealed by PCA will help breeders in the selection stage to shorten the time required to complete a breeding cycle and enhance yield productivity. Root diameter and stem diameter were major contributors in the three PCs out of the five PCs, dry matter content and biomass were present in two PCs while fresh and dry root yield were present in one PC indicating their relative importance to yield. This also indicates that breeders seriously should consider including root diameter and stem diameter in their selection indices when evaluating at advanced selection stages.

CONCLUSION

This research was aimed at identifying high yield, early bulking cassava genotypes as well as traits associated with early bulking in the F_1 progenies. Result showed that at 7 months harvest, yield of 44t/h was attained by the genotype 097B. Significant and positive correlations among the traits identified traits associated with early bulking. It also shows interdependence and importance of these traits influencing fresh root yield. Principle component analysis showed important traits that when put together can be used in selecting high yielding cassava genotypes at selection stage. In conclusion, further studies are required to more accurately determine the optimum time for harvesting and also confirm their earliness in other diverse environments.

ABSTRACT
The general trend in education worldwide is towards improvement of effective learning so as to facilitate good understanding of the subject-matter that will enable the practitioner acquire relevant knowledge/experience in equipping him/her for life. This paper therefore examines the appropriate terminologies used in agronomy or crop protection aspect of crop production to foster universal understanding of crop production, facilitate uniformity of information and elimination of contradiction of terms.
Keywords: Terminologies, Crop Production and Crop Protection

INTRODUCTION
Crop production is the branch of agriculture that deals with the principle of crop husbandry. It involves production and consumption. From these involvements it entails, it has many areas or disciplines like agronomy, crop science, soil science, crop protection, horticulture, forestry and wood technology, post-harvest technology and biology. Also, contemporary disciplines in crop production are sericulture, viticulture, agricultural biotechnology etc. Crop protection on the other hand, is an aspect of crop production that deals with the prevention of crops and stored products from attack by pests, disease causing organisms and weed interference in order to prevent reduction in yield and the value of crop and produce. It entails the study of insect (entomology), fungi (mycology), bacteria (bacteriology), virus (virology), nematodes (nematology) and weeds (weed science). (Durojaye, 2002). Abeke (2010) asserted that, every profession has its own terminology and this describes the operation and content of practice of such given profession. Terminology as the body of specialised words relating to certain field of study or particular field of human endeavour, its understanding and usage is expected to:

I. Ease information passage from resource persons to clients.
II. Fast-track communication with better clarity.
III. Guide against erosion of appropriate use of the right phrase or terminology in both teaching and research.
IV. Facilitate better understanding of the subject-matter.
V. Reflect trend in production, new knowledge and innovations brought about by changes in terminology over the years. (Abeke, 2010)

It is against this background that, this paper attempts to discuss appropriate terminologies used in crop protection with a view to educate the practitioners (such as teachers and students) and would be-farmers for better understanding of the subject matter so that there is uniformity of information and elimination of contradiction of terms.

MATERIALS AND METHODS
The review of the terminologies used in crop protection as well as its benefits was emphasized. This information was obtained from periodicals website and textbooks from libraries.

DISCUSSION
Terminologies used in Crop Protection
Allelopathy: Direct or indirect harmful or beneficial effects of one plant on another through the production of compounds (toxic substance) that escape in the environment.
Active ingredients (ai): Constituent of a preparation or formulation (insecticidal or herbicidal) to which all or part of its effectiveness is attributed or biologically active component of a formulated pesticide.
Adjuvant: Biologically inactive substance that is capable of modifying the physical or physico-chemical properties and hence the effectiveness of a plant projection, preparation or a compound added to a pesticide to increase its efficacy.
Antagonism: A substance's ability to reduce by means of the presence biological activity of aj,lnother substance.
Abscission: Falling off or shedding of leaves (or any other part) due to development of a layer of cells that cuts off the organ. It occurs in a zone where hydrolytic enzymes reduce cell adhesion.
Blight: Rapid discolouration and death of tissue over a large area.
Bacteria: Microscopic organisms which are used in fermentation, putrefaction and are causative agent of diseases in both plants and animals.
Biological control (bio-control): Pest control strategy making use of living natural enemies or competitors and other self-replicating biotic entities.

Canker: Dead area on the stem of plant, surrounded by living cortical tissues.
Chlorosis: Severe yellowing and loss of green colouration due to chlorophyll destruction.
Concentrated emulsion: Commercial preparation in the form of an emulsion which must be diluted at time of use in dispersant liquid.
Contact herbicides: A herbicide which, if applied to the aerial part of the plants to be controlled, causes visible necrosis (scorching). It penetrates the plant tissues to a greater or lesser extent, spread to a limited degree, if at all and is fast-acting.
Control: Suppression, containment and maintaining a population of parasites, pests or weeds at an acceptable rate/level.
Disease: Any disturbance of plant that interferes with its normal structure, function or economic value caused by pathogen.
Diagnosis: The act of discovering or identifying the exact cause of a disease
Drift: Movement or spread of sprayed liquid to areas where it is not intended to fall.
Dosage rate: Recommended rate of a chemical for a particular soil type, pest and crop expressed in mass (kg) or volume (litre) of product per treated hectare.
Defoliating: Removal of shoots and leaves.
Dusts: Pesticides in which active ingredient is formulated into dry, very fine powder for direct application.
Emulsifiable concentrate (ec): Pesticides in which the active ingredient (in the solid phase) is dissolved in an organic solvent which are then diluted in water for application.
Epinasty: Stiff, downward growth or bending of petiole, without flaccidity.
Epiphyte: A plant which grows or is parasitic on another plant.
Etiolate: Pale spindly growth resulting from lack of light.
Exudates: Toxic substance incorporated in a preparation and intended to adjust the concentration of the active ingredients.
Eradication: Application of phytosanitary measures to eliminate a pest from an area.
Facultative parasite: parasite that can exist as saprophyte and they kill their host.
Fumigation: The use of smoke or fumes to destroy insects and other pests. Mainly used in enclosed areas such as grain stores.
Fungus: A group of primitive types of plants including mushrooms, moulds, mildews, rusts and smuts. They are non-green and feed on living or dead organic matter. Many fungi are responsible for diseases of crop plants and are controlled with the use of fungicides.
Flow rate: Is the rate at which the spray liquid is emitted through the nozzle and is expressed in multilitters per second (ml/sec) or liters per minute.
Gall: An overgrowth (swelling) resulting from excessive local proliferation of abnormal cells without tissue differentiation caused by insects, diseases etc.
Granule: Substances presented in the form of particles of which the largest are between 0.150mm and 5mm in diameter.
Gynophores: Plants bearing ova or pistils.
Herbicides: Chemical substances/preparations for controlling weeds synonymous to weed killer.
Herbicides tolerant: Ability of a plant to survive and reproduce after herbicide treatment. Often used interchangeably with herbicides resistant.
Host-plant resistance: Genetically controlled innate or bred phenotypic or physiological property of a plant that enables it to withstand injury from insect feeding and pathogenic infection.
Host-range: Species of plants capable, under natural conditions of sustaining a specific pest.
Hyperplasia: Abnormal cell division that may result in enlargement of plant parts caused by diseases etc.
Hypoplasia: Abnormal cell division, resulting in reduction in the number of cell produced. It may be related to stunting.
Infestation: The presence of insect's pests or organisms in large numbers which often causes damage or disease.
Infection: The act or process of causing damage or disease.
Integrated pest management (IPM): The ecologically based decision support system for managing weeds, plant pathogens and insect pests while minimizing use of agrochemicals. Combines complementary and compatible biological, chemical and cultural control tactics to make pest management economical, environmentally sound and socially acceptable.
Introduction of pest: The entry of a pest, which could result in its establishment.
Leaf spot: A definitely delimited necrotic area that does not expand beyond a given size.
Lesion: a necrotic area (dead cells).
Lodging: Breaking or falling over of stalks of crops due to effects of pests, disease, wind or water erosion and heavy/excessive nitrogenous fertilization which reduce straw strength.
Mixture: Liquid ready for use by spraying, sprinkling or soaking and in which the pesticide to be applied is disposed.

Moulds: Fungi develop and feed on vegetative material, appearing on the surface as a white downy mass of fine fibres. Moulds particularly affect stored products.
Micro-organism: A protozoan, fungus, bacterium, virus or microscopic self-replicating biotic entity.
Necrosis: Burning of leaves causing dry scorched or twisted leaves resulting n death of cells usually due to diseases or unfavourable condition.
Nocturnal: Organisms that is active during night time
Natural enemy: An organism which lives at the expense of another organism and which may helps to limit the population of its host (includes parasitoids, parasites, predators and pathogens).
Non-Selective herbicides: chemical compound that is generally toxic to all plants treated, used to kill a wide range of plant species that usually includes crop species in the treated area.
Occurrence: The presence in an area of a pest officially reported to be indigenous or introduced and or not officially reported to have been eradicated.
Oleaginous plants: Plants which produce oil.
Organism: Biotic entity capable of reproduction or replication, vertebrate or invertebrate animal, plant and micro-organism.
Oviparons: Laying of eggs in which the embryo have not developed
Outbreak: A recently detected pest population or a sudden significant increase of an established past population in an area.
Pest: An injurious, destructive or troublesome plant or animal.
Pesticides: Chemical substances which are used for destroying pests of crops or harvested products.
Persistence: Period for which pesticide remains effective after application.
Predator: A natural enemy that preys and feeds on other animal organisms.
Pheromone: Chemical produced by one member of a species that has a physiological effect on members of the same species. Sex pheromones attract males to females or vice versa. Aggregation pheromones attract box sex.
Plant pathogen: Fungi, bacteria, viruses, nematodes or oomycetes that infect plants and cause injury and or disease.
Parthenogenesis: Production of young ones without mating (fertilization) e.g. Aphids.
Quarantine: Official confinement of plants, plant products or regulated articles for observation and research or for further inspection, testing and or treatment.
Residual herbicide: A herbicide that persists in the soil and injuries or kills germinating weed seedlings for a relatively short period of time after application.
Rot: disintegrated/decay of tissues caused by some organism or naturally and gradually.
Saprophyte: Organism that feed on dead organic matter i.e. dead body of plant. The parasite could be obligate when it cannot live outside the host and do not kill its host but cause diseases, symptoms of which only result in growth reduction.
Selective herbicide/pesticide: A chemical compound that kills only certain species of plants (weeds) or plant pathogens (but leaves certain crops untouched) broad or narrow spectrum, depending on the compound.
Stunting: Smallish size of plant due to reduction in the growth or as a result of underdevelopment.
Symptoms: External evidence of disturbance by disease resulting in change in appearance.
Systemic pesticide: Ability of certain pesticides to spread within the plant.
Susceptibility: An inherent weakness that makes an organism opens to attack.
Total herbicide: A herbicide of varying persistence which is used at the dosages recommended for the application in questioning is capable of destroying or preventing the growth of vegetation on uncultivated land.
Toxins: Chemicals secreted into the plants or which the plant is induced to secrete. Such chemicals have deleterious effect on the host.
Toxicity: A substance's ability to cause by means of penetrating into the organism in one application or via repeated doses, temporary or lasting alterations in one or more functions of that organism.
Transience: Presence of a pest that is not expected to lead to establishment.
Translocated: Term describing a pesticide that is capable of acting after penetrating and spreading within the plant.
Tolerant: The inherent ability of a plant to survive and reproduce after application of herbicides or during infestation by plant pathogens. Many either be inherent (natural) or acquired through genetic manipulation. Often used synonymously with Resistant, this implies that a plant is either immune to or unaffected by a particular biotic or abiotic stresses
Varietal resistance: Resistance of a particular variety to injury caused by herbicides, pathogens or insects. Resistance to the same pest may be expressed at different levels among different varieties of the same species.
Vector: Disease carriers e.g. Aphids as vectors of various virus diseases.
Wettable powder: Powdery product intended o be dispersed in a liquid for application.
Wilting: Loss of turgidity, resulting in flaccidity of leaves and other parts of the plants.
Weed control: The process of reducing weed growth and or infestation to an acceptable level. Often synonymous with weed management.

CONCLUSION

Today farming is a business involving many scientific practices, which has become highly organised, specialised and mechanized. Production, management and marketing problems are becoming more complex and competition between farmers becomes Keener each year.

Therefore the use of appropriate terms is desirable and attainable to foster universal understanding of crop production. However, this should be updated regularly as the lists here are far from being exhaustive.

ABSTRACT
Evaluation of newly introduced herbicides in the open market for weed management in an oil palm plantation was investigated at the Nigerian Institute for Oil palm Research (NIFOR) main station in 2013. The experiment was conducted during the early and late growing season prior to planting of food crops in the experimental area. Newly introduced herbicides with the trade names of Uproot, Delsate, Bush fire and Round-up were tested. Herbicide application was done at the rate of 200ml of the test product per 20 litres of water using a knap sack sprayer and this was done in the morning at the onset of sunshine. Data was collected on the duration of visible herbicide action on the weed species, effectiveness of the herbicide and time it took for re-growth. The preliminary results indicated that the newly introduced herbicides (Uproot, Delsate and Bush fire) had a similar effect as Round-up. However, in terms of duration before weed re-emergence, round-up had more lasting effects while the least was uproot.
Key words: newly, herbicides, market, weed and oil palm

INTRODUCTION
Weed competition has been identified as a major production constrain in crop production in Nigeria (FAO, 2006). Uncontrolled weed growth has been reported to cause yield reduction of 34-55% in maize production, 28-100% in rice production, 40-46% in grain and legume production, 52% in oil palm and fibre crops, 65-91% in root and tuber crops (Akobundu, 1987). It has been observed that for successful crop production, many factors such as quality seeds, proper fertilization and weed control are indispensable. The common weeds of oil palm plantation can be shrubs, trees, regrowth from stumps, climbers, grasses and uncontrolled legume covers. Weed management in oil palm plantations involves provision of weed free zones round the palms, inter and intra row maintenance and the removal of epiphytes, parasitic weeds and other climbers from the palm trunks and crowns. All over the world, more attention is being given to the production and use of herbicides to control weeds. Under the prevailing conditions in Nigerian agricultural sector (inadequate labour, poor cultural practices and the need to conserve energy), the task of weed control without the use of herbicides become very difficult. Nowadays, herbicides are commonly being used to control weeds and new herbicides are being released on a daily basis into the market by the manufacturers without being properly screened for use. Attah *et al*., (2010) reported that continous use of a particular herbicide year-in, year-out on the same piece of land could result in the formation of resistant races in some weed species. Thus observation were corolaborated by Stalow, (2003) who reported that over 30 species of other weed species had become resistant to Triazine in Europe and America. There are likely to be more weed species resistant to the available herbicides as crop production becomes intensified. At the Nigerian Institute for Oil palm Research (NIFOR) the commonly used post emergence herbicide is Touchdown which is a brand of glyphosate. However, at present this herbicide is not readily available and if available usually very expensive, thus many oil palm farmers are resulting to the use of readily available and cheaper brand of glyphosate products such as uproot, delsate, Bush fire e.t.c. There is therefore a need to investigate the efficacy of these newly introduced herbicides in the market in control of weeds in oil palm plantation order to minimize the cost of field maintenance.

MATERIALS AND METHODS
The experiment was conducted at field 23 located at the Nigerian Institute for Oil palm Research (NIFOR) main station in 2013 cropping season. Three newly introduced herbicides were tested along with the conventional herbicide at 200 ml / 20 litres of water. The herbicides tested are Uproot, Delsate, Bush fire and Round up. Spraying was done in the morning at the onset of sunrise. Data was collected on the number of days it took from treatment application to the day visible signs of herbicide action were noticed on the affected weed species. Data was also taken on the herbicide effectiveness and duration of weed control.

RESULTS AND DISCUSSION
The preliminary results obtained from the trial, indicates that the newly introduced herbicides could be used as herbicide in weed management in oil palm plantation. All the tested herbicides showed effective weed control in oil palm plantation. The herbicide's effects on weeds were not noticed until the third day after treatment

application. The effect of the herbicides on the weeds was visible on the third day on areas sprayed with uproot, on the fifth day in areas sprayed with bush fire, while areas sprayed with Delsate and Round up took seven days before any noticeable symptoms were observed (Table 1). It was also observed that total weed control was achieved for a period of 30-37 days before any visible form of re-growth was noticed. All herbicides used acted on broad leaf weeds, sedges and grasses. In terms of effectiveness or rating in order of performance, it was in this order: Round up>Delsate>Bush fire>Uproot. The effectiveness of the tested herbicides in weed control may be attributed to the fact that they all contain glyphosate as their active ingredient, and only differ in terms of their trade name. Uproot contains 360g glyphosate/litre in the form of 450g glyphosate 150 polyamine salt (sl), Bush fire contains 380g glyphosate/litre in the form of 480g/litre soproplylamine salt of soluble liquid (sl), Delsate contains 360g glyphosate/litre in the form of 480g/litre glyphosate isoproplylamine salt as well as Round up. They were all foliarly applied and are systemic non selective post emergence herbicides for the control of annual and perennial weeds weeds which includes grasses, broad leaves, aquatic and woody shrubs. `

Table 1: Time taken for the weeds to react to herbicide application

Herbicide Name	No. of days to action	Total weed control	Duration before Re-growth
Uproot	Three (3)	20 days	30
Delsate	Seven (7)	20 days	35
Bush fire	Five (5)	20 days	33
Round up	Seven (7)	20 days	37

CONCLUSION

The preliminary results of the tested newly introduced herbicides in the market for weed control shows that Delsate, Bush fire and Uproot performed equally well as Round up. Thus they could be used for weed control in Oil palm plantation.

ABSTRACT
Laboratory experiments were conducted to evaluate the toxicological properties of Hevea brasiliensis W. And Carica papaya L. lattices against the maize weevil Sitophilus zeamais (Motschulsky) (Coleoptera: Curculionidae) on stored maize at two concentrations (4 and 6 mls). The experiment consisted of five treatments and four replications in a Completely Randomized Design (CRD). Results revealed significant differences (P < 0.05) on the effect of test plant lattices on the mortality of the insect. The most toxic plant latex was the higher concentration (6%) of H brasiliensis, while the least efficacious was C papaya at 4%. Both H brasiliensis and C papaya lattices significantly suppressed the F1 progeny of S zeamais when compared with the control. The highest percentage progeny (32.46%) emerged in jars treated with 4% latex of C papaya and the least emergence of 14.54% was observed at 6% level of H. brasiliensis latex. Among the trial plant lattices, the highest percentage weight loss of grains was observed on seeds treated with 4% latex of C. papaya, which were however statistically heavier than the untreated control grains. Lattices of the two plants significantly (P < 0.05) provided protection to the grains against damage by the weevil. Percentage grain damage (49.89%) was highest in untreated control jars. The least grain damage (11.97%) was recorded by H. brasiliensis at 6% dosage level. Results of the phytochemical study of the test lattices revealed the presence of the phytochemical constituents at varying degrees. It is therefore, apparent that these phytochemical are likely responsible for the toxicological properties exhibited by these plant lattices. The present study confirms the toxicological activities of plant latex, their effect on S. zeamais and potential future use in biopesticide formulation for safe control on insect pests of stored products in an environment friendly manner.

Keywords: Toxicological Properties, Maize Weevil and Maize Storage

INTRODUCTION

Maize (*Zea mais L.)* is an annual crop belonging to the family poaceae. In many countries, it has almost replaced earlier grown cereals such as sorghum, millet etc (Onwueme and Sinha, 1991). Maize is the world's most widely grown cereal and essentially a food source of millions of the world's poor (Ferris and Graver, 2000). According to Food and Agricultural Organization FAO (2013), 589 million tonnes of maize was produced worldwide in 2000 on 138 million hectares of land. Maize is an important crop of West Africa including Nigeria (Onwueme and Sinha, 1991). *Bonsall (1999) reported* that maize is also a versatile crop that grows across large agro-ecological zones. Maize is one of the main cereal crops of West Africa and one of the most important cereal crops in Nigeria. Nigeria produces 30 million tonnes of maize per year (FAO, 2013). It comes after wheat and rice in terms of world importance (Ferris and Graver, 2000). Maize has been of great importance in providing food for man, feed for livestock and raw materials for agro-based industries. *Maize* is a staple food in many regions of the world particularly in developing countries (FAO and ILO, 1997). Maize is number one feed grain in the world; it is used extensively as the main source of carbohydrate in animal feeds and feed formulation (Wikipedia, 2006). Post-harvest crop management is critical in crop production. This is due to the fact that substantial losses occur during storage of produce in developing countries, a major part of which is due to insect attack. A serious pest of maize in the field and storage is the maize weevil *Sitophilus zeamais* Motsch. The beetle causes characteristic damage to maize by making holes on the grain *that is about 1mm* in size in which the adult female deposit eggs. Maize weevil damage results directly in lost food ready for consumption or lost cash from farmers pocket ready to buy other valuable resources for the family. Damage of grains by *S. zeamais* has resulted to about 5% - 10% losses after 6 months storage period (Nilsa and Perez, 1995). *Cabi (2010)* stated that maize weevils population builds up the longer the maize is kept in store, resulting to weight loss of 30% - 40%. Many control strategies have been adopted for the control of this notorious stored product pest of cereals crops including the use of synthetic pesticides with varying degrees of success. synthetic insecticides are generally preferred due to easy availability and potency, but their indiscriminate use has resulted in the development of pesticides resistance, longer residual persistence in the environment, poison the food chain, generate undesirable effects against humans, toxicity to fish and beneficial organisms. Thus alternatives to synthetic chemicals have been explored in the form of pesticides of natural or plant origin, which have low impact on the environment, exhibit low toxicity to humans and have low costs. Onolemhemhem and Oigiangbe (1991) revealed that various plant materials and plant extracts have been used effectively to control storage pests of cereals, legumes and to a limited extent field pests. Plant latex is a natural plants polymer secreted by highly specialized cells known as laticifers (Hagel *et al*; 2008). Studies have revealed the insecticidal potential of latex – bearing plants. Plant latex show deleterious effects like toxicity, antifeedant, growth and reproduction inhibition on a number of insect species (Carlini and Grossi-de-sa,2002). According to Ogunleye and Omotoso (2011), *Jatropha curcas* offered 100% mortality of adult *S. zeamas* at the rates of 0.3mls and 0.4mls after 24 hours *of application*. The insecticidal activity of *Calotropis procera* have been tested and reported by Vikash (2003). The plant latex of *C. procera* at the rates of 1.5mls and 2.0 mls evoked 100% mortality of adult *Callosobruchus maculatus* after 4 days. Bragay *et al*. (1997) reported that *Hevea brasiliensis* latex protected the seeds of cowpea (*Vigna unguiculata L*) against *C. maculatus.* Latex from few plant families possess phytochemicals, which showed insecticidal activity (Shaalan*et al;* 2005). Thus the import of this study was to determine the efficacy of two latex bearing plants *H. brasilensis* and *C. papaya* and their phytochemicals against the maize weevil *S. zeamais.*

MATERIALS AND METHODS

The experiment was conducted in the Pest Management Technology Laboratory of Federal College of Agriculture, Ishiagu, Ebonyi State, Nigeria. A culture of *S. zeamais* motsch was maintained on a susceptible maize variety TZSR – Y. The insect was reared in a growth chamber (5L) in the laboratory at 28 + 2^{0c}, 70 + 5% relative humidity with a light/dark photoperiod of 12:12 hours. The test crop maize grain was fumigated with phostoxin for 48 hours to obtain an insect free grain. Latex was obtained from the stems of both plants in separate aseptic glass vessels. Lattices were collected by tapping method, in which sharp incisions were made on tree trunks to open the latex vessels. In the bark to collect unconjugated latex in sterile plastic vessels following the method adopted by Buranov and Elmuradov (2010). The lattices were thereafter stored under refrigeration at – 20^{0c} until used. Using an electric balance, 50g maize grain was weighed into each of the kilner jars. With a syringe, lattices derived from para rubber *H. brasiliensis* and *C. papaya* plants were collected at two volumes 4 and 6mls each and dropped into 500mls measuring cylinder. Thereafter, the products (lattices) were homogenized in water through a serial dilution of each of these volumes by pouring 100mls of distilled water into each cylinder of the latex corresponding to 4 and 6% concentrations of the lattices. The 50g uninfested maize grains in kilner jars were steeped in solutions of 4 and 6 mls latex treatment concentrations in 100mls beaker for 30 seconds and latex air-dried for 4 hours. Maize grains immersed in sterile water served as control. Thereafter, each jar was inoculated with 20 two day old adults of *S. zeamais* and later covered with muslin white cloth with perforated lid to ensure ventilation. Treated and untreated jars were arranged in a completely randomized design (CRD) with four replications on laboratory table undisturbed.

Adult mortality of the weevil was assessed at 1, 3 and 7 days after insecticidal treatment. Data obtained was arcsine transformed. After adult mortality assessment, the maize grains were carefully returned to the jars and allowed to stay for 35 days for progeny developments. A count of the emerging adults was taken and square root transformed. At the end of the storage, weight loss of grains was determined by re-weighing the grains left in each experimental jar. The differences in weight between the weight at the commencement of the study and at the end of the experiment constitute loss in weight due to the insect pest activity. Percentage weight loss was calculated by the method of FAO (1985) as:

% weight loss = (UaN – (U +D) x 100 UaN x 1

Where

U = weight of undamaged fraction in the sample

N = total number of grains in the sample

Ua = average weight of undamaged grains

D = weight of damaged fraction in the sample. Grain damage was observed through a random selection of 100 grains from each treatment and a count of the number of grains with adult emergent holes.

Data obtained were subjected to analysis of variance (ANOVA) and significant means were separated using the Least Significant Difference test at 5% level of probability. Thereafter, the phytochemical composition of the plant materials (*H. brasiliensis* and *C. papaya*) studied was analyzed following the method of Oberlease (1973).

RESULTS AND DISCUSSION

Following the statistical analysis of data, results in Table 1 showed that there were no significant differences among the treatments on insect mortality 1 day post – infestation. However, at days 3 and 7 after insect infestation, potencies of the plant derived products different statistically such that by 7, the highest percentage mortality (74.11%) of the weevil occurred in jars treated with the higher dose (6%) of *H. brasiliensis* latex, which was followed by the lower concentration (4%) of *H. brasiliensis*, 87.50% and the higher rate 6% of *C. papaya* with toxicity of 73.75%. the least potent of the trial plant lattices was 4% *C. papaya* with 45.75% mortality, which was however statistically more toxic than the untreated control, which did not record any mortality. The lattices of both *H. brasiliensis* and *C. papaya* significantly suppressed the F1 progeny of *S. zeamais* when compared with the control (Table 2). Among treatments, the most effective in protecting grains against post embryonic development was 6% concentration of *H. brasiliensis* with 14.54% progeny emergence, while the least efficacious was *C. papaya* at 4% (32.46%). Progeny emergence was concentration dependent. The lowest percentage weight loss of the grains was recorded by *H. brasiliensis* latex at 6% (Table 3), which was significantly ($P < 0.05$) different from the 4% concentration of *H. brasiliensis* and the higher rate of *C. papaya* at 6%. The highest percentage weight loss of grains was found on seeds treated with 4% latex of *C. papaya*, which were however statistically heavier than the untreated control grains. Table 4 revealed the effect of the test lattices on grain damage, in which the plant lattices of both *H. brasiliensis* and *C. papaya* significantly provided protection to the grains against *S. zeamais* damage. Percentage grain damage (49.89%) was highest in untreated control jars. The least grain damage (11.97%) was recorded by *H. brasiliensis* at 6% dosage level, which statistically differed with the rest treatments. The result of phytochemical study shown in Table 5 revealed the typical compositions of the plant materials assayed including alkaloids, flavonoids, saponins, tannins, oxalates and phenols but in different proportions. Toxicity of the plant lattices to the weevil was concentration-dependent and increased with duration of exposure. Conversely, progeny emergence decreased with increase in the concentration of the plant lattices. It could be observed that the low progeny emergence largely is the consequence of high adult mortality few days after infestation. This result could be due to the insecticidal properties contained in members of the family Euphorbiceae and other latex bearing plants (Adebowale and Adedire, 2006). Different latex proteins seem to participate in defensive approaches against insects (Konno *et al*; 2004). The result corroborates the findings of Ogunleye and Omotoso (2011) who reported 100% adult mortality of *C. maculates* on cowpea seeds treated with drops of *J. multifida* latex 24 hours after application. Similarly, the plant latex of *C. procera* at the rates of 1.5mls and 2.0mls evoked 100% mortality of adult *C.maculatus* after 4 days (Vikash 2003). Furthermore, it is in agreement with the work of Suleimen *et al;* (2012) who reported zero percent adult emergences of *S. zeamais* when sorghum grains were treated with *J. curcas* latex. *H. brasiliensis* latex protected the seeds of cowpea (*V. unguiculata L.*) against *C. maculatus* damage (Bragay *et al*; 1997). Phytochemical analysis of the trial plant materials showed that the more potent latex derived from *H. brasiliensis* had a high content of flavonoids, phenols and tannins, *and lower proportions of alkaloids, saponins and oxalates*, which could be responsible for the insecticidal properties. Studies performed aimed at understanding the biochemical profile of latex have offered convincing evidence for a defensive role played by the saps (Ramos *et al*, 2009). According to Sabu and Vinod (2009) plant latex is a complex mixture of proteins, alkaloids, starch, sugars, oils, tannins, resins and gums. Latex bearing plant species from few families possess diverse phytochemicals having very high insecticidal activity (Shaalan *et al*, 2005) against many insect pests such as *C. quinquefasciatus* and *Musca domestica* (Morsy *et al;* 2001). Therefore, it is likely that the phytochemicals contained in these plant lattices could be associated with their potencies.

CONCLUSION

The result of this study suggest that test plant lattices obtained from *H. brasiliensis* and *C. papaya* could be used to cause insect toxicity and deter adult emergence of *S. zeamais* on maize in storage. They could also reduce percentage weight losses and grain damage due to insect infestation during storage. These plant materials are readily available, cheap and could be employed as a component of integrated pest management in environment friendly manner. Their phytochemical constituents are likely responsible for their insecticidal properties.

ABSTRACT

A wide range of soil amendments improve soil nutrients which are known to influence the production of plant secondary metabolites. Curcumin is one of the secondary metabolites of turmeric (Curcuma longa Linn) responsible for its multipurpose uses. Turmeric rhizomes were harvested from a split plot experiment in a randomized complete block design (RCBD) at the western farm of National Root Crops Research Institute, Umudike. Where empty palm bunch (EPB) treatments (0 (12 t/ha elephant grass), 4, 8 and 12 t/ha EPB) occupied the main plots, while palm bunch ash (PBA) treatments (0 (60 kg N + 13 kg P + 25 kg K), 4, 8 and 12 t/ha PBA) occupied the sub plots. Composite primary rhizomes were collected from the treatment plots for the analysis of curcumin, dry matter and ash contents (%). Results obtained showed that application of 4 t/ha EPB significantly (P < 0.01) yielded the highest amount of curcumin (7.96%). Highest amount of dry matter (84.09%) was achieved using 8 t/ha EPB. Application of PBA at 8 t/ha significantly (P < 0.01) yielded the highest amount of curcumin (7.24%). Highest amounts of dry matter (84.36%) and ash (9.37%) were produced with 12 t/ha PBA. Significant treatments interaction effect was also observed. Application of 4 t/ha EPB + 8 t/ha PBA yielded significantly (P < 0.05) highest amount of curcumin (9.44%). Significantly optimum amounts of dry matter (85.94%) and ash (10.63%) contents were achieved from rhizome grown with 4 t/ha EPB + 12 t/ha PBA. It was recommended that EPB and PBA are good sources of organic manure and fertilizer for increased curcumin, dry matter and ash yields in turmeric production.

INTRODUCTION

Turmeric (*Curcuma longa* Linn) is a perennial herbaceous plant grown primarily for the rhizome and is regarded as the golden spice. Turmeric spice is the principal ingredient in curry powder. The rhizome has been used extensively in cooking, medicine, cosmetics and fabric dying for more than 2000 years (Ammon and Wahl, 1991). Curcuminoids are the polyphenols responsible for the turmeric yellow colour. Curcumin, the principal curcuminoid of turmeric has potent anti-oxidant (Masuda *et al*., 1993), wound healing (Srimal, 1997), anti-malarial (Nandakumar *et al*., 2006), anti-carcinogenic (Gupta *et al*., 2012) anti-inflammatory properties (Gupta *et al*., 2013). A wide range of soil amendments improve soil nutrients which are known to influence the production of plant secondary metabolites (Morison and Lawlor 1999). Thus, variation in secondary metabolites with respect to different soil amendments will play a critical role in their increasing multipurpose uses and export potentials in the international market. In Nigeria, oil palm is widely grown and is a valuable economic crop (Lua and Gua, 1998). However, palm oil mills produce large amounts of solid wastes consisting of huge amount of lignocellulosic material such as empty palm bunch (EPB) . The uses of EPB in agriculture has not been fully exploited and farmers are becoming aware of the use palm bunch ash (PBA) in cultivation of root and tuber crops because it is rich in potassium, magnesium, phosphorus and calcium (Adjei-Nsia 2012). A study was carried out to analyze the effect of EPB and PBA on curcumin and some nutrient parameters of turmeric.

MATERIALS AND METHODS

Turmeric rhizomes were harvested from a split plot experiment in a randomized complete block design (RCBD) at the western farm of National Root Crops Research Institute, Umudike. Empty palm bunch treatments (0 (12 t/ha elephant grass), 4, 8 and 12 t/ha EPB) occupied the main plots, while PBA (0 (60 kg N + 13 kg P + 25 kg K), 4, 8 and 12 t/ha PBA) occupied the sub plots. Composite primary rhizomes were collected from 16 treatments combination plots for the analysis of curcumin, dry matter and ash contents (%). Standard methods of A.O.A.C. (1990) were used for the determination of dry matter and ash contents. Curcumin content was determined by the method of Thimmaiah (1999). Data generated were subjected to analysis of variance (ANOVA). Significant treatment means were separated using Fischer's least significant difference (FLSD) at 5% probability level.

RESULTS AND DISCUSSION

Table 1 shows the simple effect of EPB and PBA on the curcumin, dry matter and ash contents of turmeric rhizomes. Curcumin content was significantly (P < 0.01) influenced by EPB. Optimum amount (7.96%) was recorded with 4 t/ha EPB. Highest amount of dry matter (84.09%) was obtained from rhizomes grown with 8 t/ha

EPB. This amount differed significantly with those obtained with 0 or 4 t/ha EPB (82.82 and 81.64%, respectively). There was no significant difference in ash content due to EPB. However, ash content ranged from 8.22 – 8.43%. According to Udoetok (2012), EPB is a lignocellulose material that contains 25% lignin, 50% cellulose and 25% hemicellulose in its cell wall and consequently undergoes differential decomposition. High curcumin content in the rhizome of turmeric may have resulted from nutrients released from EPB at different decomposition rates. Effect of PBA on curcumin content and some nutrient parameters are also shown in Table 1. Application of 8 t/ha PBA yielded the highest amount of curcumin (7.24%) which differed significantly with those obtained using other treatments. Lowest amount of curcumin (5.88%) was obtained from rhizomes of 4 t/ha treatment. Hikaru *et al*, (2007) reported potassium (K) and nitrogen (N) to be the key elements in the formation of curcumin. Lim and Zahara (2000) reported that PBA contains over 30% of potassium oxide and is used as fertilizer. Palm bunch ash is 100% organic fertilizer and is used commercially in neutralizing acidic soil effectively (Udoetok, 2012). Sandeep *et al*. (2015) implicated soil N as the precursor for phenlypropanoid pathway which leads to curcumin production in turmeric. They reported a curcumin yield of 1.4 to 5.0% due to variations in environmental and soil nutrient factors, pointing out that high N, P and K contents in the soil inhibit curcumin production. Percentage dry matter increased with increase in PBA. Highest amount of dry matter (84.36%) was obtained using 12 t/ha PBA and the least (81.37%) with NPK fertilizer. High dry matter depicts a good keeping quality on the turmeric flour. The ash content measures the amount of mineral element in a plant. Udoetok (2012) corroborated this when he posited that oil palm bunch ash contains appreciable concentration of anions like nitrate (97.6 mg/kg), phosphate (47.5 mg/kg), chloride (2280.0 mg/kg) high concentration of potassium (139.35 mg/kg), calcium (146.15 mg/kg) and high pH value (10.9). There was a similar increase in ash content as the rate of PBA increased. Application of 12 t/ha PBA recorded the highest ash content (9.37%), while NPK fertilizer recorded the least (6.79%). Effect of EPB and PBA interaction on curcumin yield, dry matter and ash contents of turmeric are as shown in Table 2. Application of 4 t/ha EPB + 8 t/ha PBA yielded significantly ($P < 0.05$) highest amount of curcumin (9.44%). Significantly optimum amounts of dry matter (85.94%) and ash (10.63%) contents were achieved from rhizome grown with 4 t/ha EPB + 12 t/ha PBA. Interaction results obtained showed that application of 12 t/ha PBA to 4 t/ha EPB improved the yield of dry matter and ash content, whereas, the application of 8 t/ha PBA to 4 t/ha EPB resulted in highest yield of curcumin. These increases show the relevance of EPB at 4 t/ha in the curcumin, dry matter and ash contents of turmeric.

CONCLUSION

From the study, it could be concluded that the use of 12 t/ha straw mulch (Nwokocha *et al*., 2009a) and/or 60 kgN + 13 kgP + 25 kgK/ha fertilizer (Nwokocha *et al*., 2009b) for turmeric production did not improve the yield of curcumin, dry matter and ash content of turmeric rhizomes. Application of 4 t/ha EPB as a mulch material improved curcumin yield, while at 8 t/ha, dry matter yield was significantly improved. Application of 8 and 12 t/ha PBA significantly improved curcumin yield and dry matter/ash contents, respectively. This may be attributed to the potassium oxide content of the PBA. The curcumin contents in this report are higher than values reported in other experiments.(Kamal and Yousuf 2012; Sandeep et al., 2015). It could be recommended that EPB and PBA are good sources of organic manure and fertilizer for increased curcumin, dry matter and ash yields in turmeric production, while maintaining cheap and readily available sources of nutrients to the plant.

Table 1: Simple effect of EPB and PBA on curcumin, dry matter and ash contents (%) of turmeric rhizome.

Treatment	Curcumin (%)	Dry matter (%)	Ash (%)
EPB rate (t/ha)			
0 (12 t/ha straw)	6.111	82.82	8.431

INFLUENCE OF SOIL PARENT MATERIAL ON YIELD AND NUTRIENT UPTAKE OF SWEET POTATO: IMPLICATION FOR FOOD SECURITY

E.N. Nwaogu

National Root Crops Research Institute Nyanya Sub-Station, Abuja, Nigeria
Email: eddynwaogu2012@yahoo.com

ABSTRACT

The influence of soil parent material on the root yield and on N, P and K uptake responses of different sweet potato varieties was assessed in a greenhouse study conducted at NRCRI Umudike, Southeast Nigeria. Treatments were soils formed from four soil parent materials (Sandstone, Coastal Plain Sands, Shale and Fresh Water Alluvium) in factorial combinations with three sweet potato varieties (TIS 87/0087, TIS 2532.OP.113 and Ex-Igbariam). Both soil parent material and sweet potato variety significantly influenced root yield and N, P and K uptake responses of sweet potato. Across the three varieties, soils formed on shale parent material gave highest mean root yield response of 18.3 t/ha while the least yield outcome of 12.8 t/ha was recorded on soil formed from sandstone. TIS 87/0087 followed by TIS 2532.OP.113 sweet potato varieties were more adaptable to soils of diverse parent materials than Ex-Igbariam variety.

Keywords: Soil, Parent Material, Yield, Sweetpotato and Food Security

INTRODUCTION

Sweet potato is ranked 3rd most important root crop after cassava and yam in Sub-Saharan Africa (Han and Hozyo, 1998). Sweet potato is reported to possess the highest energy-fixing efficiency; producing up to 20 t/ha in 4 – 5 months (Han, 1977). In some parts of northern Nigeria, the crop plays a vital role as a food security crop because of its resistance to drought. It has tremendous potential to be an efficient and economic source of food energy. Average yield of sweet potato in Nigeria is 3 t/ha (Stathers *et al*., 2013). This yield figure is very low compared to the yields obtainable from other countries of the world. Low soil fertility has been adduced as part of the reasons responsible for low yields of sweet potato in Nigeria as majority of the soils in Nigeria are formed from low nutrient parent material rock types. The character and chemical composition of the parent material plays an important role in determining soil properties, especially during the early stages of development. As soils form, nutrients are being continually removed from and added to the soil with time. The conditions that are present during soil formation ultimately determine how much and what kind of nutrients the soil can naturally supply and hold and this has implications on soil fertility and productivity. For example, if parent materials are low in soluble ions, water moving through the soil removes the bases and substitutes them with hydrogen ions thus making the soil acidic and unsuitable for agriculture. Soils developed over sandstone are low in soluble bases and coarse in texture. Such soils tend to have high rate of leaching and require proper management manipulation to achieve sustainable crop growth and yield. Soils which were weathered from basalt tend to be finely textured, as well as fertile when not highly weathered. In contrast to basalt, granite is coarse-textured rock that generally weathers into coarsely-textured soils. Granite is the parent material of most soils in Nigeria. Parent material affects soil fertility in many ways. First, the type of parent material determines which minerals will predominate in the soil. Secondly, as parent material weathers, nutrients are released into soil solution, which subsequently can be taken up by plants and other organisms or leached from the soil. The implication of such variations in soil parent materials on crop growth and yield is not well understood. The objective of this study therefore, is to assess the influence of soil parent material on the root yield and N, P and K uptake responses of three sweet potato varieties under greenhouse condition.

MATERIALS AND METHODS

The study was conducted in 2012 in the greenhouse of the National Root Crops Research Institute, Umudike in Southeast Nigeria. Selected physico-chemical properties of the soils from different parent materials used for the study are shown in Table 1. Treatment comprised soils formed from four parent materials {Sandstone (SS), Coastal Plain Sands (CPS), Shale (SH) and Fresh Water Alluvium (FWA)} in factorial combinations with three sweet potato varieties (TIS 87/0087, TIS 2532.OP.113 and Ex-Igbariam). The soils were collected with a soil auger. The Soils were collected from Okigwe (Sandstone), Umudike (CPS), Amaeke (Shale) and Owerrinta (Fresh Water Alluvium) all in Abia State, Nigeria. The soils were air-dried, crushed and sieved with a 2 mm sieve mesh. Three (3) kg of the air-dried soil were weighed into a 5 liter plastic bucket. The soil in each bucket was mixed thoroughly and moistened to 70 % field capacity with distilled water. Pre-planting laboratory analyses of the soils to determine their chemical compositions were made using standard methods. The soils were planted up with 3 node-vine cuttings of three sweet potato varieties (TIS 87/0087, TIS 2532.OP.113, and Ex-Igbariam). After 8 weeks of growth, NPK fertilizer was added at a rate equivalent to 400 kg/ha. The fertilizer was solubilized and added into the soil in each bucket in solution form. Data on fresh rhizome yield and on N, P, and K nutrient uptake were collected after 3 months of growth in the greenhouse. Nutrient uptake was measured by multiplying tissue N, P and K concentrations with biomass yield. Data were analyzed using ANOVA and treatment means with significant differences were detected using Least Significant Difference (LSD) at 5 % level of probability.

RESULTS AND DISCUSSION

The physico-chemical properties of the soils of the different parent materials are shown in Table 1. The soils varied in their chemical properties with soil formed from shale parent material having the highest amounts of total N, available P and exchangeable basic cations. Generally, the soils were of low to medium fertility as indicated by their chemical characteristics. The results of this study in Table 2 are indicating that both soil parent material and sweet potato variety are important factors for consideration in designing intervention measures for increased sweet potato productivity in Nigeria as both factors significantly affected the root yield response of the crop. Across the three varieties, soils formed from shale parent material gave highest mean root yield response of 18.3 t/ha while the least yield outcome of 12.8 t/ha was recorded on soil formed from sandstone. The exceptionally very low level (below 2%) of organic matter content and low exchangeable cations of soil formed from sandstone implies that sustainable sweet potato yield is only achievable if large and regulated quantities of organic inputs are regularly applied on them. Variety TIS 87/0087 was superior to TIS 2532.OP.113 and Ex-Igbariam in terms of root yield response. Highest interactive yield result of 21.6 t/ha was recorded when TIS 87/0087 was grown on soil formed from shale while the lowest yield result of 10.3 t/ha was obtained when Ex-Igbariam was grown on soil formed from sandstone. The significantly higher root yield response recorded on soil formed from shale over soils from other parent materials is attributed to increased nutrient N and K uptake characteristics exhibited by shale in this study (Tables 3 and 5). In the agronomy of sweet potato, nitrogen is one of the most important soil nutrients for efficient vegetative growth (Havlin et al., 2004). Apart from being a template for protein synthesis, N is also an integral part of chlorophyll, which is the primary absorber of light energy needed for photosynthesis. Being a short duration crop, adequate supply of N is important for enhanced photosynthetic activities and vigorous vegetative growth of sweet potato crop. Potassium ions are needed for root bulking (Okwuowulu and Asiegbu 2000). The better yield performance of TIS 87/0087 and TIS 2532.OP.113 over Ex-Igbariam variety is assumed to be due to differences in genetic composition. While Ex-Igbariam is a local variety, TIS 87/0087 and TIS 2532.OP.113 are improved varieties with improved traits that make for better adaptation in most soil types in Nigeria.

CONCLUSION

Soil parent material and sweet potato variety are important factors for consideration in designing intervention measures aimed at increasing sweet potato productivity in Nigeria as both factors significantly affect the root yield response of the crop. Soils formed from shale are better in terms of root yield and N and K nutrient uptake response outcome of sweet potato than soils from sandstone, coastal plain sands and fresh water alluvium. TIS 87/0087 followed by TIS 2532.OP.113 sweet potato varieties are more adaptable to soils of diverse parent materials than Ex-Igbariam variety.

Table 1: Selected Physico-chemical Properties of Soils used for the Study

Soil Parent Material	Total N (%)	Av. P (mg/kg)	Exch. K	Exch. Ca	Exch. Mg	Org. M (%)	pH	Texture
			……………..(cmol/kg)……………………..					
Sandstone	0.11	9.0	0.16	1.5	2.1	1.6	5.4	Sandy clay loam
Coastal Plain Sands	0.24	10.6	0.22	3.8	3.3	2.8	6.2	Loamy Sand
Shale	0.26	14.7	0.30	4.8	3.8	2.9	6.6	Clay Loam
Fresh Water Alluvium	0.18	13.2	0.42	2.5	2.8	2.6	5.6	Loamy Sand

Table 2: Effect of Soil Parent Material on the Varietal Root Yield (t/ha) Response of Sweet Potato in South Eastern Nigeria

Parent Material	Sweet Potato Variety			
	TIS 87/0087	TIS 2532.OP.113	Ex-Igbariam	Mean
Sandstone	15.7	12.4	10.3	12.8
Coastal Plain Sands	18.4	16.6	13.1	16.0
Shale	21.6	18.9	14.3	18.3
Fresh Water Alluvium	12.2	13.5	14.7	13.5
Mean	17.0	15.4	13.1	-
