Ginger production in Nigeria started in 1927 and has been on for many years. Ginger has enormous potentials for export, income generation and creation of employment opportunities. As a crop that is well cherished the world over due to its spicy taste and anti-oxidant properties, ginger has found wide application in many pharmaceutical, brewery and food industries. However, despite its numerous potentials, the crop is not popular among most small scale farmers in Nigeria. This review paper is an attempt to highlight the numerous benefits of ginger, its uses and factors responsible for low adoption of the crop among farmers in Nigeria. The underlining objective of this review is to reposition ginger so as to play a leading role in agricultural diversification programme of the Federal Government of Nigeria.
Keywords: Origin, Utilization, Adoption and Ginger

Historical Origin of Ginger

Ginger (*Zingiber officinale Rosc.*) is an herbaceous perennial plant belonging to the family *Zingiberaceae*. It is a tuber crop and is extensively grown across the world for its pungent aromatic under-ground stem or rhizome (Ajibade and Dauda, 2005). The origin of ginger is not well established though it is generally believed to be a native of Asia, where it was first cultivated (Kaduna State Ministry of Agriculture, 2007). It was also cultivated in the tropical regions of America. Ginger was introduced to Europe by Arab traders from India in the first century AD. The Arabs also took the plant from India to East Africa in the thirteenth century while the Portuguese took it to West Africa and other part of the tropics in the sixteen century. Ginger was introduced to Nigeria in 1927 (Kaduna State Ministry of Agriculture, 2007). The spice was known in Germany and France in the ninth century and had become common in trade as pepper by the thirteenth century. The plant is now cultivated in different parts of Nigeria, though the major producing areas include Kaduna, Nassarawa, Sokoto, Zamfara, Akwa Ibom, Oyo, Abia and Lagos states although southern Kaduna still remains the largest producer of fresh ginger in Nigeria (KADP, 2000, KADP, 2004;Bernard, 2008). Ginger grows best in tropical areas that have high rainfall and hot and humid conditions.

Uses of Ginger

Ginger can be used in a variety of ways:

(i) Ginger adds to the flavour of a meal creating a fresh, spicy pungent taste which is now becoming a valued commodity all over the world. It is revered as one of the most important and valued spices of the world.

(ii) Ginger is now used in many different ways and is a complement to many different dishes and flavours. It complements coconut milk curries, lemon grass and gravy.

(iii) It can be used raw, fried, dried, pickled or as a juice and is a favourite in tea and ale.

(iv) Ginger is now grown as a cash crop in Nigeria especially in Southern part of Kaduna State where the crop is mostly grown. Recently ginger has been introduced in a crystallized form creating a type of sweet appropriate for dessert or snack.

Medicinal Value

For over 5000 years ginger has been recognised as the "universal medicine" by the ancient Orientals of China and India. Today ginger remains a component of more than 50% of the traditional herbal remedies and has been used to treat nausea, indigestion, fever and infection and to promote vitality and longevity. The report of Authority Nutrition (2012 – 2016) identified several health disorders and illnesses which ginger can help to remedy. These health disorders include: (a) Flatulence; (b) Nausea; (c) Intestinal infection; (d) Food poisoning; (e) High blood pressure; (f) Chilblains; (g) Fever Clotting; (h) Motion sickness, (i) Morning sickness Cold and Flu; (k) Arthritis pain; (l) Skin cancer; (m) Weight Loss; (n) Thirst; (o) Depression; (p) Gastrointestinal disorders; (q) Bone fragility.

Anti-Oxidant Properties of Ginger

Ginger's anti toxic properties have an anti viral, anti fungal, anti histamine and anti bacterial effect, which is basically the effect of an anti biotic, cold and flu tablet or an aspirin. Ginger has played an important role in Asian medicine as a folk remedy to promote cleansing of the body through perspiration, to calm nausea and to stimulate the appetite. Ancient Indians used ginger root to treat digestive problems. Chinese sailors chewed ginger root to combat seasickness. Chinese women drank ginger tea to alleviate menstrual pain. Ginger contains no fat or sugar and so can be added to foods to heighten flavour without adding calories. Ginger tea brewed from the fresh root has not only a weight loss purpose but has been used for centuries in India and China as an after meal drinks to aid digestion. Ginger's enzymes catalyse protein digestion in the stomach quickly and leave little time for nausea. Ginger also contains moderate amounts of magnesium, calcium, protein, calcium, iron, sodium, potassium and phosphorus. Together they act as a remedy for muscle spasms, depression, hypertension, muscle weakness, convulsions, confusion, personality changes, nausea and gastrointestinal disorders. The high level of potassium in ginger protects the body from bone fragility, paralysis, sterility, muscle weakness, kidney damage and damage to the heart. Ginger also has a high content of antioxidants which means it also has anti-inflammatory properties.

Value-Addition and Alternative Product Development

Ginger can and has been used in many different products. Ginger tea has been used as a carminative and for the treatment of colds at their onset for centuries. It has been used in China as a tonic. The Greeks, after a large meal, wrap bread around a piece of ginger and eat it to ease indigestion. This practice gave rise to the production of ginger bread. In England, ginger was added to beer, forerunner to ginger ale, as a remedy for diarrhea, nausea and vomiting. The Chinese also considered ginger root to be an antidote for shellfish poisoning, explaining why it is found in so many seafood dishes. Ginger is important in many homes because of its pungent flavour. It is a complement to many meals, drinks and desserts. Unfortunately, despite the fact that ginger has a diverse scope for product development and multiplicity of uses, the crop is not very popular among most farmers in Nigeria. Many reasons have been adduced for this unpopularity of the crop among small scale farmers. The following are some of the identified reasons or factors responsible for low adoption of ginger among farmers and hence, low ginger productivity in Nigeria:

Misconception about the adaptability of ginger to different ecologies in Nigeria

Most smallholder farmers are yet to understand that ginger can grow in many ecologies in Nigeria apart from Southern Guinea Savanna. Research efforts by National Root Crops Research Institute, Umudike have shown that ginger grows well even in the rainforest ecology of Nigeria.

Lack of basic information on the agronomic requirement of the crop

There is paucity of information on modern and sustainable ways of growing ginger taking into cognisance differences in soil types, income base of the farmers and community behavioural change dynamics. Information is scanty on ginger cultural management and agronomic requirements (plant population, fertilizer rate, disease management etc) for sustainable yield in Nigeria.

Inadequate information on the marketing channels and market potentials of ginger

There is inadequate information on the value-addition potentials of the crop and available marketing channels for disposing of ginger produce.

Rampant disease and storage problems of the crop

Due to the high moisture content of ginger rhizomes, microbial deterioration of rhizomes is very fast and this poses a very great problem to small scale ginger farmers. In addition, the crop is susceptible to many fungal and bacterial diseases which reduce its nutritional and market values thereby predisposing farmers to great economic loss.

High labour requirement for ginger production

Ginger requires high labour input. Apart from the very close planting distance of 20 cm x 20 cm which calls for high rate of labour to achieve, the compulsory requirement of mulching in ginger production scares away most prospective ginger farmers.

Low Soil Fertility

Most soils in Nigeria are of low to medium fertility classification (Agboola, 1986) and therefore, cannot adequately support sustainable yield of crops without external fertilizer input. Being a high nutrient-demanding tuber crop, ginger requires high level of soil fertility with adequate organic matter content. Meeting the nutrient needs of ginger is a big task especially for the resource poor farmers in Nigeria.

Other factors responsible for low adoption and hence low productivity of ginger crop in Nigeria include: low multiplication ratio, narrow genetic base and low house-hold consumption of the crop due to its spicy nature.

CONCLUSION

Restoring the lost glory of ginger in the light of the above facts would therefore, require a systemic and pragmatic approach and refocusing of our research priority agenda to address the identified gaps. There should be an increased advocacy on the potential economic and health benefits of ginger crop as a way to stimulate interest of farmers in its production. Research studies aimed at identifying sustainable ways of growing ginger without mulch application, intensifying and creating more marketing channels, increasing the multiplication ratio and storage should be embarked upon. Government (Local, State or Federal levels) should fund ginger research and development activities as a way of diversifying Nigerian agriculture and creating employment opportunities.

ABSTRACT
Field trial was conducted during the raining season of 2015 at the National Root Crops Research Institute (NRCRI) Umudike to evaluate 52 breeding lines developed in 2014 with three checks. The experimental design was randomized complete block replicated 3 times. The root yield ranged 5.21 – 16.24 t/ha with an overall mean root yield of 8.44 t/ha for the 52 breeding lines. The top thirteen breeding lines with yields above 10 t/ha were selected. TIS 87/0087 with 16.24 t/ha had the highest root yield. Of the 13 top lines, five were orange-fleshed sweetpotato (OFSP), while out of the 52 breeding lines evaluated, 54% were OFSP. Only 19 of the 52 breeding lines showed symptoms of sweetpotato virus disease (SPVD), while 14 of the susceptible 19 lines had SPVD severity score of above 3, of which score 5 means severe damage.
Keywords: Sweetpotato, Yield evaluation, genotype, virus disease

INTRODUCTION
Sweetpotato is an important food security crop in Nigeria. It is grown in all agro-ecologies of the country. With 3.48 million metric tonnes of production (FAOSTAT, 2015), Nigeria is the highest producer of sweetpotato fresh roots in Africa and the second highest producer in the world after China. While root production has increased ten-folds over the last 25 years, yield has declined progressively to approximately 3.0 tonnes per hectare (Anderson et al. 2012). Some of the production constraints militating against high yield include low genetic ability of the old farmer cultivars, susceptibility of popular farmer cultivars to the sweetpotato virus disease (SPVD), random drought, and insect-pest issues of which Cylas puncticollis is the main problem. Low use of fertilizer and poor field management also contribute to the observed low productivity. Some of these production challenges as well as combating vitamin A deficiency among urban and rural dwellers in Nigeria can be tackled using plant breeding approach. Preliminary yield trial is the first replicated yield evaluation phase in the development of new varieties. It is at this stage that the true yield potential of newly developed genotypes is first determined. Therefore, the objectives of the work are:

- to evaluate the 2014 cycle breeding lines for their root yield, virus disease resistance and root flesh colour attributes, and
- to select the promising lines that will be advanced to advance yield trial stage in 2016.

MATERIALS AND METHODS
Fifty-two newly-bred sweetpotato lines selected from clonal evaluation trial were evaluated using randomised complete block design (RCBD) with three replications in Umudike. Plot size was 9m^2 while plant spacing used was 1m X 0.3m, giving plant density of 33,333/ha. First weeding was carried out at four weeks after planting (WAP) while NPK 15:15:15: at the rate of 400kg/hectare was applied immediately after first weeding. Supplemental rouging was carried out at 8 WAP. Harvesting was done at 4 months after planting. Data collected were:

- Total weight of fresh roots (kg/plot but later converted to tons/ha);
- Incidence of sweetpotato virus disease (SPVD) at 10 WAP per plot;
- Severity of SPVD at 10 WAP per plot on a scale of 1-5 where 1 = no observed symptoms and 5 = severe symptoms on all leaves with reduced leaf size ad stunting;
- Root flesh colour.

RESULTS AND DISCUSSION
Total root yield (t/ha)
The root yield of the 52 lines ranged from 5.21 to 16.24 t/ha, while the combined mean root yield was 8.44 t/ha. Genotype TIS 87/0087, a check material, had the highest yield of 16.23 t/ha. Its yield was not significantly (P>0.05) different from those of lines A 005 (14.19 t/ha), E 016 (13.49 t/ha), D 075 (13.36 t/ha), A 097 (12.72 t/ha), C 081 (12.13 t/ha) and A 097B (11.41 t/ha). Lines A 005, E 016 and D 075 had significantly (P<0.05) higher root yield than the other two checks (UMUSPO/1 - 8.3 t/ha and UMUSPO/3 – 7.43 t/ha). Previous authors

(Afuape et al., 2011; Nwankwo and Afuape, 2013; Yahaya et al., 2015) had reported significant ($P<0.05$) variation in root yield among different genotypes. The observed variation among the lines for root yield provides the chance for selection.

Root flesh colour

There were five orange-fleshed sweetpotato (OFSP) genotypes in the top best 13 lines (Table 1). All the five OFSP lines had fresh root yields of 10/ha and above compared to the two OFSP checks of UMUSPO/1 (8.31 t/ha) and UMUSPO/3 (7.43 t/ha). Figure 1 shows that in total, more than half (54%) of the 52 breeding lines belong to the OFSP class – light orange (22%) and orange (32%). While 26% were white, 18% were yellow and only 2% were purple-fleshed. The development of bio-fortified sweetpotato has been receiving breeding attention of recent at the National Root Crops Research Institute, Umudike Nigeria. So, the more than 50% OFSP in the breeding lines confirms the attention being given to developing new OFSP varieties, while other flesh colours are not totally discarded. Orange flesh is known to be associated with beta-carotene in sweetpotato.

Incidence and severity of sweetpotato virus disease (SPVD)

Figure 2 shows the mean proportion of stands per genotype that expressed SPVD. Only 19 of the 52 genotypes evaluated showed SPVD symptoms (Figure 2). Four breeding lines (A058, Mother's Delight, Mozambique and E054) had most of their stands (100%, 100% 100% and 91% respectively) expressing SPVD symptoms. Breeding line C071 (6%), A060 (7%), D002 (8%) and ZC002 (9%) had the fewest plants showing SPVD symptoms.

Figure 3 shows the severity score of the 19 genotypes showing SPVD symptoms. Fourteen of the 19 genotypes with SPVD symptoms had severity score above 3.0. All the genotypes with >3.0 score will be discarded. The SPVD is the economically most important sweetpotato disease. Yield lose of up to 90% due to SPVD had been reported (Gutiérrez et al., 2003). Breeding for resistance has been identified as the best approach to control the virus (Gibson and Krueuze, 2015).

CONCLUSION

Genotypes with good root yield, low or no virus incidence and severity, as well as possess acceptable flesh colour will be selected for advanced yield trials in 2016. All the seven OFSP lines will be advanced to the next evaluation stage. Their nutritional and processing qualities will also be determined in during the advanced yield trial stage.

Table1: Fresh root yield (t/ha) and flesh colour of top 13 genotypes with above 10t/ha evaluated at PYT stage in Umudike in 2015.

Genotypes	Total root yield (t/ha)	Flesh colour
A 005	14.19	orange
E 016	13.49	Yellow
D 075	13.36	Yellow
A 097	12.72	Light orange
C 081	12.13	white
A 097B	11.41	orange
D 115B	11.06	orange
A 176	11.04	white
I 012	10.88	yellow
A 035	10.55	white
D 077	10.38	white
A 098	10.33	orange
K 003	10.09	yellow
TIS 87/0087 (check)	16.23	white
UMUSPO/1 (check)	8.31	Light orange
UMUSPO/3 (check)	7.43	orange

College of Agriculture, Division of Agricultural Colleges, Ahmadu Bello University Zaria, Nigeria
Kaiyesolomon@gmail.com

ABSTRACT
The field experiment was conducted during the early growing season of 2015 at Kabba College of Agriculture, Ahmadu Bello University on student experimental plot in the Horticultural section to determine the effect of different levels of poultry manure on the growth and yield of Okra (Abelmoscus esculentus). The objectives of the study were to determine the effectiveness of the different levels of poultry manure on the growth and yield of okra, and to identify the optimum rate of poultry manure for the growth of Okra. The experiment consisted of five treatments fitted into Randomized Complete Block Design (RCBD). Each treatment was replicated three times. The treatments were 0g, 5.0 g, 10.0 g, 15.0 g and 20.0 g per plant. The parameters measured were plant height, number of leaves, stem girth, weight of fruit per plant, number of fruit per plant and fruit diameter. All data were subjected to analysis of variance (ANOVA) and mean were separated using New Duncan Multiple Range Test at P<0.05. The results of this experiment showed that 15.0 and 20.0 g of poultry manure per plant had significant effect on the growth and yield of okra.
Keyword: Okra, Abelmoscus esculentus, poultry manure, growth and yield

INTRODUCTION
Okra (Abelmoscus esculentus L.Moenh) belongs to the family Malvaceae. Okra was domesticated in west and central Africa. It is one of the numerous vegetable crops cultivated in Nigeria covering an estimated land are*a of 1-2 million hectares (FMAW*&RD, 1989). The plant is cultivated in tropical, subtropical and temperate regions around the world. The economic importance of okra cannot be overemphasized. Okra contains carbohydrate, protein and vitamins in large quantities. For consumption, young mature fruits are important vegetables that can be boiled, fried or cooked. In Nigeria okra is usually boiled in water, resulting in sliming soups and sauces. The fruit also serves as soup thickeners (Schipper, 2000). Okra is an important vegetable crop which plays important roles in human nutrition. According to (FAOSTAT, 2006), the production of okra in Nigeria depends on the farming capacity of poor peasant farmer who often cannot bear the exorbitant cost of large scale production. The cultural and management practices and the problem of okra production needs to be addressed in order to boost the crop output to meet market demand.

Tropical soils are adversely affected by sub-optimal soil fertility and erosion, causing deterioration of the nutrient status and changes in soil organisms' populations (Economic Commission for Africa, 2001). Use of inorganic fertilizers can improve crop yield and soil pH, total nutrient content and nutrient availability, but its use is limited due to scarcity, high cost, nutrient imbalance and soil acidity. Use of organic manures as a means of maintaining and increasing soil fertility has been advocated (Rodale, 1984; Alasiri and Ogunkeye, 1999; Smil, 2000). Animal manure, when efficiently and effectively used, ensures sustainable crop productivity by immobilizing nutrients that are susceptible to leaching. Nutrient contained in manure are released more slowly and are stored for a longer time in the soil, ensuring longer residual effect, improved root development and higher crop yield (AbouEl Magd et al., 2005). Manures are usually applied at higher rates, relative to inorganic fertilizer. When applied at high rates, they give residual effects on the yield of succeeding crops (Makinde and Ayoola, 2008). Improvements of environment conditions as well as the need to reduce cost of fertilizer use are reasons for advocating use of organic materials (Bayu et al., 2006). Organic manures improve soil fertility by activating soil microbial biomass (Ayuso et al., 1996). Application of manures sustains cropping system through better nutrient recycling (El-Shakweer et al., 1998). Manure provides a source of all necessary macro and micronutrient in available forms, thereby improving the physical and biological properties of the soil (Abou El-Magd et al., 2006). Mixing organic and inorganic fertilizer may be a sound soil fertility management strategy in many countries. Akande et al. (2003) reported that combined use of ground rock phosphate applied together with poultry manure significantly improves growth and yield of okra (Abelmoschus esculentus) L. Moench) compared to application of each material separately.

Justification of the Study

Vegetable crops such as okra play an important role especially in the supply of essential nutrients in the body such as protein, carbohydrate and vitamin C in large quantity. It also serves as a mean of revenue generation to peasant farmers. Increasing the yield of okra in farmers' fields using cost-free nutriet sources is important to enhance farmers' well-being and food security. Organic manure, especially poultry manure are usually available in most communities as waste, constituting environmental nuisance. The current study is therefore undertaken to determine the effectiveness of different levels of poultry manure on the growth and yield of okra, and to identify the optimum rate of poultry manure for the growth of okra.

MATERIALS AND METHOD

The experiment was conducted during the 2015 cropping season at the student's experimental field, Kabba College of Agriculture at the Horticultural Section. Kabba College of Agriculture is located in the Southern Guinea Savannah ecological zone of Nigeria on latitude 07^0 53'N and longitude 06^0 80'E with average rainfall of about 1850mm per annum, temperature of 18-30^0C and altitude of 420 meters above sea level (Kabba College of Agriculture Meteorology Station Field Survey, 2014). The okra seeds used were collected from Kogi state Agricultural Development Program (ADP) office at Aiyetoro Gbede, Ijumu Local Government of Kogi State. The okra variety used was NHAE 47-4.

Experimental Design and Treatment Allocation

The experimental design for this experiment was Randomized Complete Block Design (RCBD). The treatments were five poultry manure rates replicated three times. The poultry manure rates were applied randomly within the experimental plots.

Treatments: Control (0g) per plant stand; 1 t/ha (5g) per plant stand; 2 t/ha (10g) per plant stand; 3 t/ha (15g)per plant stand; and 4 t/ha (20g) per plant stand. The land was cleared manually using cutlass to clear the grasses and shrubs after which the soil was tilled manually using hand hoe. The experiment was conducted on a gross plot of 9m x 8m ($72m^2$) with 1m spacing between the blocks. Each block consisted of five plots, and each plot measured 1m x 2m ($2m^2$) with 1m spacing between plots. Each plot contained eight (8) plants and 4 plants were tagged per plot for data collection. Then the total tested plants were 60 plants. Three to four seeds were sown per hole 2-3cm deep at intra-row spacing of 25cm and inter-row spacing of 60cm. The seedlings were later thinned to two plants per stand. Weed control: Weeds were manually controlled with the use of hoe at two weeks interval. The okra plants were attacked by flea beetles. The insect-pest was controlled using an insecticide called Auesthrin. Harvesting was done manually by hand-picking and the use of sharp knife to detach pods from the stem. This was done at five days interval. There were three pod harvests in all. Harvested pods were gathered per plot and weighed for each harvest time.

Data collection

Other data collected included:

i. Plant height: This was done using a tape rule to measure the length of each of the four tagged plants from the base to the tip of the last leaf in each plot at 3, 4, 5 and 6 weeks after sowing (WAS).
ii. Stem girth: The diameter of the stem was measured using a Vanier calliper at 3, 4, 5 and 6 weeks after sowing (WAS).
iii. Number of leaves: The number of leaves was obtained by counting the leaves of the four tagged plants and the average was recorded.
iv. Diameter of fruit per plant was measure using tape rule at five days interval.
v. Number of fruit per plant: Number of pods per plant at five days interval was counted.
vi. Weight of fruit per plant (fresh weight): pods per plant at each harvest were weighed and recorded.

RESULTS AND DISCUSSION

The effects of the different poultry manure rates on plant height are presented in Table 1. At 3, 4, 5, and 6 weeks after planting, it was observed that there were significant differences in plant height among the different poultry manure rates. Poultry manure rates 15 and 20 g/plant showed significantly higher mean plant height (cm) than other rates, except at 6 WAP where the means of all poultry manure treatments were not statistically different from one another, but were all significantly higher than the control (0g rate).

Table 2 shows the effect of poultry manure at different levels on the number of okra leaves at different stages of growth. While the poultry manure rates had no significant effects on the number of okra leaves at 5 and 6 WAP, the treatments had significant effects on the measured attribute at 4 WAP. At 4 WAP, 20g/plant poultry manure rate had the highest mean number of leaves of nine which was higher ($P<0.05$) than the other rates. The control (0g/plant had the least mean number of leaves of 6. The mean number of leaves at 5 WAP for all the poultry manure treatments were not different, but were all statistically higher than the control.

Effects of poultry manure application at different levels on stem girth (Table 3) showed that stem girth was significantly influenced by the different poultry manure levels at each period of measurement. At 3, 4 and 5 WAP, 15 ad 20 g/plant poultry manure had significant effects on stem girth compared to the other rates. At 6 WAP, 5, 15 and 20 g/plant rates had no significant mean stem girth. However, the range of stem girth at 6WAP was 1.000 – 1.208 cm. The control had the least stem girth across all sampling periods.

The effects of poultry manure treatments on mean weight of fruits (g) per plant, mean number of fruits per plant and diameter of fruits per plant at 8weeks after planting are presented in Table 4. Poultry manure rates of 15 and 20 g/plant had the highest weight per plant of 0.767 and 0.833g respectively. For mean number of fruits per plant, 15 and 20 g/plant with mean number of fruits of 6.167 and 6.433 respectively also had the highest values. Same trend was observed for mean fruit diameter. Rates 15 and 20 g/plant with mean fruit diameter of 3.333 and 3.400 respectively, had the widest fruit diameters. In all the measured attributes, the control had the least values.

CONCLUSION

This trial was conducted in order to study the effect of poultry manure at different rate on the growth and yield of Okra. With the parameters such as plant height, leaf numbers stem girth weight of fruit/fruit/plant fruit with regards to the test crop, poultry manure rate of 15 and 20 g/plant were found to have the best growth parameters and yield components. Based on this preliminary result, 15 g/plant poultry manure can be recommended to farmers that have access to poultry manure for okra production.

Table 1: Effect of different rates of poultry manure on plant height (cm) of okra

Poultry manure treatments	3rd WAP	4th WAP	5th WAP	6th WAP
0g	15.25^{c}	18.17^{c}	21.67^{c}	25.42^{b}
5g	16.35^{bc}	20.17^{b}	24.17^{b}	29.42^{a}

ABSTRACT

Yam (Dioscorea rotundata; family Discoreaceae) is among the most important staple foods in the world, especially in some parts of the tropics and subtropics. In Nigeria, rot is a major factor limiting the storage life of yams, and losses can be very high. Rotted yam tubers were collected from three markets and taken to the Laboratory of Plant Pathology, Federal College of Agriculture, Ishiagu. The fungi were cultured on Potato Dextrose Agar and the effects of the two plant extracts were studied on the fungi at 50% and 70% concentration. The fungi isolated were Aspergillus flavus, Fusarium solani, Sclerotium species and Rhizopus stolonifer. A. flavus (50.00%) had the highest percentage of occurrence while Sclerotium species had the least (7.14%). The efficacy of the extracts differed with the materials, concentrations and with the tested fungus. The variations were due to different active compounds present in these plants. Therefore, the use of Ocimum. gratissimum and azadirachta. indica extracts has a viable prospect as alternative substitutes to synthetic chemical for the control of yam rots.

Key words: Extracts, Fungal, Yam, Rot, Ishiagu

INTRODUCTION

Yam, (Dioscorea rotundata) belongs to the family Discoreaceae. It is a herbaceous annual climbing plant with edible underground tubers (Orkwor et al., 1998). It is among the most important staple foods in the world especially some parts of the tropics and subtropics (Okigbo and Ogbonnaya, 2006). The most cultivated varieties in Nigeria are the D. rotundata (white yam), D. cayenesis (yellow yam) and D. alata (water yam) (Amusa, 1999). Nutritionally, yams are mainly carbohydrate foods. It is one of the most important dietary sources of energy produced in the tropics (Ekefan, 1999). White yam (D.rotundata) is the most important and cultivated variety found in Africa. It is much preferred to other yam varieties and it is believed to constitute about 80% of the total yams produced in Nigeria. It is generally believed that over 50% of the yam tubers produced and harvested in Nigeria are lost in storage. The disease-causing agents not only reduce the quantity of yam produced, but also reduce the quality by making them unappealing to the consumers. There are many microorganisms associated with yam in Nigeria, some of which may include, Rhizopus stolonifer, Geotriclum candidum, Aspergillus flavus, Aspergillus niger, Aspergillus fumigatus, Botryodiplodia theobromae, Fusarium oxysporum, Fusarium solani, Penicillium chrysogenum, Rhizoctonia spp, Penicillium oxacilum, Trichoderma viride and Rhizopus nodosus (Adeniji, 1970; Okigbo and Ikediugwu, 2002; Aidoo, 2007).

Scent leaf, (Ocimum gratissimum) is a tropical aromatic plant which is known to exert high antimicrobial activities, and is widely consumed by man. There is little or no fear of poisoning even at very high concentrations (Adegoke et al., 2002). Ocimum gratissimum leaf has been shown to have several medicinal uses (Ojeifo and Denton, 1993). Its leaves have been reported to exhibit high antifungal activities against Fusarium moniliforme, Aspergillus flavus and Aspergillus fumigatus (Nguefack et al., 2004). Neem (Azadirachta indica) is a common tropical tree widely distributed in Africa and Asia. Its medicinal uses have been known for several centuries. A. Indica contains photochemical compound such as azadirachtin, betasiterol, b-desacetyl, nimbinene and 3-deccacetyl alamine which exhibited antifungal properties (Verma et al., 2006).

Rot is major factor limiting the post – harvest life of yams, and losses can be very high. It is estimated that an average of 25- 50% of yam tubers produced in Nigeria are lost to pests and diseases (FAO, 2005). Losses due to post- harvest rot significantly affect farmers' and traders' income, food security and seed yams stored for planting. This work was carried out to isolate and identify fungal organisms associated with Yam (Dioscorea spp) in Ishiagu; and to determine the effect of Scent (O. gratissimum) and Neem (A. indica) leaf extracts on the growth of the fungal organisms.

MATERIALS AND METHODS

The study was conducted at the Plant Pathology Laboratory of the Federal College of Agriculture, Ishiagu, Ebonyi State, Nigeria. The rotted yam tubers were collected from three different markets within Ishiagu: Ekeh, Mile2 and Ayaragu markets in Ivo Local Government Area of Ebonyi State, Nigeria. The collected yam samples were taken to the Laboratory. Healthy leaves of Scent (O. gratissimum) were obtained from Ekeh market while Neem (A. indica) was obtained from the premises of the College.

Preparation of Potato Dextrose Agar (PDA)

The Potato Dextrose Agar (PDA) was prepared by weighing 39g of PDA powdered into distilled water in a conical flask and made it up to 1.0 litre. The flask was swirled gently and the conical flask was plugged with cotton wool and covered with aluminum foil paper. This was sterilized in an autoclave at 121˚C for 15minutes. The sterilized medium were subsequently allowed to cool to 45˚C and streptomycin at the rate of 10 drops was added and poured aseptically into 9cm diameter Petri dishes, covered and allowed to gel.

Isolation of fungi from infected leaves

Rotted yam samples (2 x 2mm) were cut between the advancing edge of infected and healthy tissues and surface-sterilized (soaked in 1% NaOCl for 1min and rinsed in five changes of sterile distilled water), dried on sterile tissue paper and plated on 0.3ml streptomycin amended PDA medium. Three replicate pieces from each of the rotted yam tuber were incubated at 28-30^{o}C for 3-4 days. Fungal growths associated with the infected tissues were observed and detailed structural features of each isolate were compared with those described in a standard manual of fungi (Barnett and Hunter, 1999).

Determination of percentage occurrence of fungal isolates. To determine the percentage occurrence of the fungal isolates, the occurrence of the fungi organisms was recorded as follows:

$$\%\ occurence\ of\ isolates \quad = \frac{Total\ number\ of\ plates}{Total\ number\ of\ fungal\ occurrence} x100$$

Preparation of Aqueous Extracts of the Leaves

Fresh, clean and fully expanded Scent and Neem leaves were washed thoroughly under running water and surface-sterilized (1% NaOCl for 2 minutes) and rinsed in several changes of sterile distilled water and air dried at room temperature for 2 hours. Two different water extract concentrations were prepared by blending 50g and 70g of leaves each in 100ml of sterile distilled water to produce 50% and 70% extract concentrations respectively.

Effect of the extract on fungal growth

Food poisoning techniques were used to determine the effect of the extract on fungal growth (Okigbo et al., 2009). One milliliter of each extract concentration of extract was dispensed into 9ml of molten PDA to obtain an agar-extract mixture in petri dish. The plates were gently rotated to ensure even dispersion of the extracts. The agar-extract mixture was allowed to solidify and 6mm diameter mycelia disc obtained from the colony edge of 7 day old culture of each test fungi was inoculated into the centre of each petri dish. The control consisted of an inoculated agar plates containing no extracts. There were three (3) replicate plates of extracts agar per isolate and concentration which were incubated at 27^{o}C. Radial growth was measured daily for 7days. Colony diameter was taken as the means along two directions on two pre-drawn perpendicular lines on the reverse side of plates.

Percentage inhibition was calculated according to the method described by Whipps (1987)

$$Percentage\ inhibition \quad = \frac{R1\ -\ R2}{R1R1} x100$$

Where R1 = furthest radial distance of the pathogen in control plates

R2 = Furthest radial distance of the pathogen in extract incorporated plates

Inhibition percentage was determined as a guide in selecting the minimum inhibitory concentration that was effective in controlling yam tuber rot disease caused by fungi.

Statistical design and analysis

The experimental design used was Completely Randomized Design (CRD) with the three (3) replicates. Data collected were subjected to analysis of variance (ANOVA) using Statistical Analysis System (SAS) Version 91, Institute 2002, USA and the treatment means separated using LSD at $p \leq 0.05$.

RESULTS AND DISCUSSION

The result reveals that four fungal organisms were isolated and identified from the rotted yam tubers from the three markets within Ishiagu. They include Aspergillus flavus, Fusarium solani, Sclerotium species and Rhizopus stolonifer. The findings of Liamngee et al (2015) and Okigbo and Ikediugwu, (2002) that A. niger, A. flavus, A. fumigatus, F. solani and Botryodiplodia theobromae were fungi associated with rotted white yam tubers supports the findings of this work. The organisms occurred at a various levels. A. flavus had the highest (50.00%) percentage of occurrence, followed by F. solani (28.57%) while Sclerotium species had the least (7.14%) percentage of occurrence (Fig: 1). Most of these microorganisms usually infect yam tubers in the field and subsequently manifest in storage barn. The presence of anti-fungal active ingredient in the leaves of O. gratissimum and A. indica was demonstrated on the four fungi organisms isolated from rotted yam tuber. This was revealed by their ability to inhibit the growth of the four tested fungi at the two levels of concentration (Tables 1 and 2). This agrees with the findings of Akpa et al (1991) who reported significant inhibitory property of A. indica extract on most fungal pathogens, just as Amuchi, (1999) found the extract of O. gratissimum to reduce the growth of Rhizopus spp. However, the efficacy of the extracts differed with the materials, concentrations and with the tested fungus. The results also buttress the potential of natural plant products in the management of rotted yam disease in storage.

CONCLUSION

Therefore, it is recommended that further study should focus on the pathogenicity of these four fungal organisms on the rotted yam tuber. Also, the use of O. gratissimum and A. indica extracts has a viable prospect as alternative substitute to chemical for the control of yam rots.

ABSTRACT
Castor oil plant (Ricinus communis L.) is one of the most versatile oil crops with high socio-economic values around the world. The crop has been demonstrating its economic potentials by earning notable foreign exchange credits to many countries. However, following the incorporation of castor into national research mandate in Nigeria, poor seedling establishment and low yield have been identified as some of the limitations to its commercial production in the country. Based on this background, 51 local and 48 exotic castor germplasm were surveyed on seed physical characters and evaluated for field seedling establishment at three locations. The collections revealed high divergence in seed colour, seed shape, seed mottle, seed caruncle and seed sizes. Variability observed in 100 seed-weights among the accessions ranged from 8.51g to 65g with average of 26.48g. High significant variability in seedling establishment was observed among the accessions. The highest establishments (87 – 89 %) were recorded in Acc. 002 and Acc.062 across the locations and the least (10 – 17 %) was recorded in Acc.104. Significant genotypic effect and no significant effect of genotype X location were recorded. High broad sense heritability of 88 and 22.51 per cent genetic gain show good expected gain from selection programs.
Keyword: Ricinus communis, Germplasm, Nigeria, Establishment, Characteristics

INTRODUCTION
Castor (Ricinus communis L., 2n = 20) is an oil crop with high economic values (Anjani, 2012). The recent rapid increase in demand of castor seed/oil in local and international markets (Mutlu and Meier, 2010) has aroused the interest of Nigerian farmers to cultivating the crop. Unfortunately, castor is presently receiving little or no active research attention in Nigeria, resulting in lack of improved production technologies for farmers. This has necessitated integrated castor research efforts among Nigerian scientists (Salihu et al., 2014). Therefore, the aim of this research is to survey the NCRI castor germplasm for seed physical characteristics and seedling establishment.

MATERIALS AND METHODS
Seed Physical Characteristics: In 2014, the seeds of all the collections were multiplied and 100 seeds weights were taken from three replicate samples per accession. The seeds were characterized based on the seed shape, seed colour, mottle, caruncle, seed size and seed weight using INDIA Castor Descriptors (2004). The seed colour was determined using Graf Colour Chart (2012).
Seedling Establishment: 99 castor accessions including 51 local and 48 exotic collections were evaluated on experimental fields at three different locations: NCRI Mokwa (Lat. 9º 12'N, Long. 5º 20'E), NCRI Badeggi (Lat. 9°45'N, long. 6°07'E) and Mina (Lat. 9º 36'50"N, Long. 6º 33'25"E) . The treatments were laid out on Alpha Lattice Design with 3 replications. Each plot size was 3m X 1.5m in dimension with inter-row and intra-row of 75cm. Thirty (30) intact seeds, pre-treated for seed-borne diseases, were planted at two seeds per hole in each of the replicate plots, resulting to 90 seeds planted per location and total of 270 seeds across the locations. The planting was done in Mid-June 2015, when rainfall has completely stabilized at the locations. Insecticide (Cypermethrin) was applied at 5, 15, 25 and 35 days after planting to prevent seedling lose due to insect attacks. Seedling establishment was taken (at 40 days after planting) as the number of plant stands expressed in percentage. Descriptive statistics was used to summarize the date. Combined Analysis of Variance was performed across the locations. Genotypic effect, and GXE effect were tested using -2 log-likelihood ratio test procedure of PBtools 1.3. Broad-sense heritability was estimated according to Eckebil et al. (1977). Genetic advance (at 10% selection differential) as described by Johanson et al. (1955) and Genetic gain (%) as genetic advance (GA) expressed in percentage of the population mean were estimated.

RESULTS AND DISCUSSION

Seed physical characters of castor accessions at NCRI, Badeggi

The accessions reveal high divergence in seed colour, seed shape, seed mottle, seed caruncle and seed sizes. Exotic collections comprise of 17 large seeded (diameter > 15mm), 23 medium (diameter, 9mm – 15mm) and 13 small seeded (diameter < 9mm) castor types (Table not included). Variability observed in 100 seed-weight among the accessions ranged from 8.51g to 65g with average 26.48 (Table not included). The result obtained is in conformity with result of 1033 accessions reported by Wang et al., (2010).

Field seedling establishment

High significant variability in seedling establishment was observed among the accessions (Table 2). The highest establishments (87 – 89 %) were recorded in Acc. 002 and Acc.062 across the locations and the least (10 – 17 %) was recorded in Acc.104 (Table 3).

Analysis of variance revealed no effects of blocks and location, and genotype variation has the highest value among the sources of variation (Table 1). Significant genotypic effect and no significant effect of genotype X location were recorded (Table 2). High broad sense heritability of 88.00%, and 22.51 per cent genetic gain show good expected gain from various kinds of selection programs.

Inherent problem of castor seedling establishment caused by poor seed germination is an issue that deserves attention from scientists. Machado et al., (2010) reported seed internal morphology and apparent level of reserved food as two important factors for fast germination and seedling establishment. Low soil temperature is one of the factors that also influence poor germination and seedling establishment in castor.

CONCLUSION

The diversity in seed weight and seedling establishment observed in the germplasm provides good sources of variability upon which selection can be made to generate improved genotypes. Although the results reported here may justify the aim of the research, however there is need for proactive research in seed technology and genetic improvement to enhance the seedling establishment of the present castor cultivars among Nigerian farmers.

ADVANCED YIELD PERFORMANCE OF HYBRID WHITE YAM (DIOSCOREA ROTUNDATA) GENOTYPES FOR EXPORT POTENTIAL AND TOLERANCE TO MAJOR FIELD PESTS AND DISEASES OF YAM

I.I.M. Nwankwo & G.O. Nwaigwe

National Root Crops Research Institute, Umudike PMB 7006, Umuahia, Abia State
nwankwomaxwell@yahoo.com

ABSTRACT
Eleven hybrid white yam genotypes plus three landraces of white yam were evaluated in the Western Experimental Field of National Roots and Crops Research Institute (N.R.C.R.I.), Umudike in 2014 and 2015. The objectives were to select high yielding genotypes with high fresh weight gain for export and tolerant/resistant to field pests and diseases. The experiment was laid out in a randomized complete block design with three replications. Yam setts weighing 40g were sown 45 cm x 100 cm on ridges at 10cm depth, on 20m^2 plots. Data were collected on tuber weight at planting (kg), tuber weight at harvest (kg), mean total tuber yield, tuber size and tuber shape index. Pests and diseases reactions of the tubers were scored using severity rate of 1 to 5. Tuber yield was analyzed using analysis of variance and means separation was done using standard error of difference between means. Tuber shape and tuber surface texture was scored after determining the tuber shape index, while weight gain index was computed by dividing weight at harvest by the initial weight of tuber planted. The result showed that yam genotypes (OKG08/002, GLD08/008, GLD08/0023 and UM08/037) with weight gain index of above 3.0 were selected as yam with export potential. Their mean tuber shape index was 3.44, an indication that they were cylindrical in shape, with a good shape for export. They are equally tolerant to field pests and diseases and could be produced without investing much in pesticides.
Keywords: Export potential, weight gain, pests and diseases, tuber weight and tuber shape index

INTRODUCTION
Yam (Dioscorea spp.) constitutes a primary food source in a number of households in Nigeria particularly amongst populations of rural communities and selected few rich households in urban centres (Cristina et al, 1999). The cultivation of yam is becoming more important because of its great potential as food and for export (FAO, 2009). It is important to develop and select yam tubers with heavy tuber weight for export since yam for export is by weight and not by number as is sold in Nigerian local markets. The crop needs inputs and it has potentially high yields which made it an expensive food (Bovell-Benjamin, 2007). Yams can be processed into food products for people and animals. Research objectives are to increase the yield of yam and area under cultivation so that excess produce will be exported. As a result of this, trials are conducted for careful selection of new varieties which showed greater photosynthetic efficiency, stability and excellent market characteristics (Cristina et al, 1999). Genotypes which also met acceptable breeding and agronomic requirements are selected for release to farmers and consumers. The release of the new varieties that display the characteristics required by subsistence and commercial farmers will be of benefit to farmers.
In Nigeria, the yam crop is grown for its enlarged tuber which can be boiled, baked, fried or processed into chips. The tuber may be boiled or fried for use in soups and salads (James, 1994). Not all fresh tubers with the same length and diameter have the same weight or fresh matter accumulation. Weight gain/fresh matter accumulation in yam depends on varieties. Therefore, newly bred yam varieties need to be tested for weight gain before being advanced to another stage of evaluation. The study was initiated with the objectives to select high yielding genotypes with higher fresh weight gain for export and response to major field pests and diseases of yam.

MATERIALS AND METHODS
Eleven hybrid white yam genotypes plus three landraces of white yam were tested in the Western experimental field of NRCRI, Umudike in 2014 and 2015. The experiment was laid out in a randomized complete block design with three replications. The land was mechanically ploughed, harrowed and ridged at 1m apart. Yam setts weighing 40 g were sown 45cm x 100 cm at a depth of 10 cm. The plot size was 20 m^2. The plots were kept weed-free manually. There was no Fertilizer application. Pre-emergence herbicide (Diuron) was used immediately after planting and complemented with manual weeding at 12 weeks after planting (WAP). Data were collected on tuber weight at planting (kg), tuber weight at harvest (kg), mean total tuber yield, tuber size and tuber shape index. Pests and diseases attack on the tubers were scored using severity rate of 1 to 5. Tuber yield was analyzed using analysis of variance and means separation was done using standard error of difference between means. Tuber shape and tuber surface texture was scored after determining the tuber shape index

(Nwankwo, 2014). Weight gain index was computed by measuring weight at harvest over the initial weight of tuber planted, thus:

$$WG = \frac{\text{Tuber weight at harvest}}{\text{Weight at planting}}$$

RESULTS AND DISCUSSION

Total tuber yield: The result on indicated high significant (P0.01) yield variability among the hybrid white yam genotypes (Table 1). Yield of the genotypes varied from 3.0 t/ha (OKG08/022) to as high as high as 27.8t/ha (UM08/037). However, 19 out of 22 genotypes yielded more than Nwopoko a check variety. In breeding for export potential genotypes, weight gain index is used to determine the efficiency and profitability of yams for export since yams for export are determined by weight and not by number of tubers. Yam tubers that gain more at harvest should be selected for further evaluation. The higher the weight gain index, the higher the tuber yield efficiency and the profitability of yams for export. Therefore, yam genotypes with weight gain index of 3.0 and above were selected for further evaluation as genotypes with advantageous tuber yield potential for export.

Tuber size: Significant variability exists in the tuber length and tuber width of the genotypes. The tuber sizes determine the size of fresh weight of carbohydrate accumulation. The highest length of the tuber from various genotypes ranged from 12.37 to 25.80 cm while the width ranged from 4.15 to 7.34 cm. However the mean tuber shape index of the genotypes was 3.44 cm an indication of cylindrical shape, a good shape for yam with export potential.

Pests and diseases reaction:

Table 2 shows the field reaction of the white yam clones to foliar and tuber pests and diseases. There were very mild reaction of the genotypes to yam mosaic virus diseases (with mean score of 1.16) and very mild infestation of crickets), having a mean score of 1.03. Generally, the result indicated that most of the white yam genotypes were field tolerant to the pests and diseases.

CONCLUSION

Based on the result obtained, yam genotypes with weight gain index > 3.0 were selected as yam with export potential. The genotypes were OK08/006 with yield of 14.2t/ha and weight gain index of 3.09, OKG08/002 with yield of 27.6t/ha and weight gain index of 3.42, GLD08/008 with yield of 19.2t/ha and weight gain index of 3.42, GLD08/023 with yield of 22.4t/ha and weight gain index of 3.17t/ha, UM08/037 with yield of 27.8t/ha and weight gain of 3.39 and UM08/039 with yield of 9.0t/ha with weight gain of 3.46. These genotypes have grand mean tuber length of 18.67cm and width of 5.23cm. Their mean tuber shape index is 3.44 an indication that they were cylindrical in shape, a good shape for exportable yam. They are equally tolerant to field pests and diseases and could be produced without investing much in pesticides.

ABSTRACT

The study evaluated the fresh root yield, dry matter and starch content of nine sweetpotato genotypes in the high rainforest ecology of Southeastern Nigeria. The genotypes were laid out in a randomised complete block design with three replications while the plot size was 9m² (3mx3m) containing 30 plants per plot with plant spacing of 1 m x 0.3m, giving plant density of 33,333 stands per hectare. NPK fertilizer 15:15:15 was applied at the rate of 400kg/ha. Harvesting was done at four months after planting and three medium dominant root samples from each plot were collected, bagged in black polythene, labeled and analyzed in the laboratory. The analysis was for the determination of the dry matter content, starch content and moisture content. Results show that all the sweetpotato genotypes evaluated had high dry matter content (≥ 30%) except UMUSPO/3 (23.05%), SOLO-2 (24.11%) and PYT/12/053 (26.04%). The starch content is generally low. This is an indication that they are good enough for flour production and also for sugar syrup production in the pharmaceutical industry. They are likely to reduce poverty for food insecure generation.

Keywords: Fresh root yield, dry matter, starch content, sweetpotato, genotypes, rainforest

INTRODUCTION

The sweetpotato (Ipomoea batatas [L.] Lam) is an important staple crop in many parts of the tropics. In Nigeria, most of the roots are consumed in various forms. Road-side fries, fried chips and kunnu (non-alcoholic drink) are the few ways the roots are processed. The low industrial processing is often associated with low dry matter and starch contents of the cultivars produced by farmers. Dry matter is one of the most important traits that influence acceptability of sweetpotato varieties for consumption and processing. Processing industries require high dry matter greater than 30% (Rees et al., 2003) and high starch content and quality. Sweet potato is rich in carbohydrates and vitamins (Villareal, 1982) and is a potential in the fight against vitamin A deficiency. Indeed, recent research results indicate increased availability of beta-carotene (Provitamin A) and crude protein for good nutrition and health (Ukom et al., 2009). Sweet potato blends with rice, cowpeas and plantain in Nigeria diets. It may be boiled or steamed, fried or roasted and eaten with sauce. It can be reconstituted into fufu or blended with other carbohydrate flour sources such as wheat (Triticum aestivum) and cassava (Manihot esculenta) for baking bread, biscuits and other confectioneries (Nwankwo et al., 2012). The leaves which are used in cooking soup and stew are rich in protein (27%), starch (8%), sugar (4%) and ash (10%). Smaller roots, peels and leaves constitute excellent food to livestock (Anyaegbunam et al., 2008).

MATERIALS AND METHODS

Nine varieties of sweetpotato with various flesh colours (white/cream, orange and yellow) were evaluated at Umudike, southeastern Nigeria in 2015. The genotypes were laid out in a randomised complete block design with three replications. The plot size was 9m² (3mx3m) containing 30 plants per plot with plant spacing of 1 m x 0.3m, giving plant density of 33,333 stands per hectare. NPK fertilizer 15:15:15 was applied at the rate of 400kg/ha after the first weeding at five weeks after planting. Harvesting was done at four months after planting. At harvest, three medium root samples (which were the dominant root size) from each plot were collected, bagged in black polythene, labeled and sent to the laboratory for immediate analysis. Standard methods of the official methods of analytical chemist (AOAC, 2010) were used for the determination of the dry matter content, starch content and moisture content.

RESULTS AND DISCUSSION

The flesh colour of the fresh root of each of the nine genotypes evaluated in the trial was presented in Table 1. Four of the genotypes were in the orange flesh group (two light orange, one orange and one deep orange). There were four white-fleshed as well as one yellow-fleshed genotype. Flesh colour is an important attribute that is correlated with carotenoid accumulation. Orange-fleshed genotypes usually have high carotenoid content than the yellow-fleshed, which also is higher in carotenoid than the white-fleshed ones.

The dry matter, starch and moisture content of the genotypes are presented in Figure 1. All the sweetpotato genotypes evaluated had high dry matter content (≥ 30%) except UMUSPO/3 (23.05%), SOLO-2 (24.11%) and

PYT/12/053 (26.04%). The starch content is generally low. It ranged between 10.42 and 28.63% with only four genotypes having 20% and above starch content. Usually, root and tuber crops are known to contain high moisture content and that is why the high range of 59.4 – 76.95% is not surprising. Moisture content is known to be one of the root causes of low shelf life of sweetpotato as it creates an atmosphere conducive for rot organisms to develop and multiply.

CONCLUSION

UMUSPO/1,PYT/12/012, PYT/12/121, TIS/87/0087 and Ex-Igbariam have high starch and high dry matter contents. This is an indication that they are good enough for flour production and also for sugar syrup production in the pharmaceutical industry. They are likely to reduce poverty for food insecure generation.

ABSTRACT
In vitro studies on biological control using dual culture method was carried out to assess the antagonistic activities of Trichoderma harzianum as a biocontrol agent of Fusarium oxysporum, the causal agent of dry rot disease of white yam in storage. The antagonist was introduced at three different times (same time with the pathogen, 2days before the inoculation of the pathogen and 2days after the inoculation of the pathogen) with the pathogen on potato dextrose agar. The experiment was conducted in the Advanced Plant Pathology Laboratory of Federal University of Agriculture, Makurdi. The plates were incubated for 192 hours and measurements of mycelia radial growths were done at 24 hours intervals beginning from the third day. Observation on the dual culture plates showed competition for nutrient and space which subsequently starved the pathogen to death. The result of the interactions showed that the highest percentage growth inhibition of mycelia of the pathogen (77.99%) was recorded when T. harzianum was introduced two days before the inoculation of F.oxysporum, followed by introduction of T. harzianum same time with F.oxysporum (45.69%) and the least percentage growth inhibition (13.72%) was observed when the antagonist was introduced two days after inoculation of the pathogen. In all the treatments, T. harzianum was able to significantly ($P \leq 0.05$) inhibits the growth of A.niger at the three different times of introduction of the antagonist and this continued throughout the period of incubation. T. harzianum was observed to be effective in reducing the mycelia growth of F. oxysporum in culture in all the treatments and therefore showed the potential for biological control of the pathogen.
Key Words: In vitro, T. harzianum, biocontrol, F. oxysporum, yam, inhibition

INTRODUCTION
Yam (Discorea spp.) is a major staple food crop in West Africa, where it provides food for over 60 million people (Nweke et al., 1991). FAO (2000) estimated that the World production of yams is around 20 million tons per year. Inspite of the high volume of yam production, rotting of yam in storage continue unabated. Fungi organisms commonly involved in yam rots includes: Aspergillus niger, Botryodiplodia theobromae, Fusarium solani, Fusarium oxysporum Penicillium spp. Rhizopus stolonifer and Mucor spp. (Okoro and Nwankiti, 2004; Aidoo, 2007; and Okigbo et al., 2015). Losses due to post-harvest rot significantly affect farmers' and traders' income, food security and seed yams stored for planting. Okigbo and Ikediugwu (2000) indicated that between 20 and 39.5 % of stored tubers in storage may be lost to rot organisms. The use of synthetic chemicals such as sodium orthiophenylphenate, mancozeb and borax has been found to reduce storage rot in yam (Okigbo, 2005; Aidoo, 2007)). However, biological control is generally favoured as a method of plant disease management (Siameto et al., 2011). This is because it is selective in action, produces no side effect and cost less. Resistance to biological control is rare and biological control agents are self- propagating and self-perpetuating (Okigbo and Ikediugwu, 2000). The aim of this research was to study the antagonistic activities of a bioagent, T. harzianum introduced at different times in vitro to control Fusarium oxysporum, the causal agent of dry rot of yam tubers

MATERIALS AND METHODS
The experiment was conducted at the Advanced Plant Pathology Laboratory, Federal University of Agriculture, Makurdi, Nigeria. T. harzianum used in this study was obtained from yam Pathology Unit of University of Ibadan, Oyo State, Nigeria. Stock cultures of the isolate were maintained on slants of acidified potato dextrose agar (PDA) in McCartney bottles for subsequent studies. Rotten tubers of white yam varieties (Dioscorea rotundata) showing various diseased symptoms of dry rots were obtained from yam farmers from various storage barns in Zaki- Biam, Ukum local government area of Benue State, Nigeria. The rotten yam tubers were packaged in sterile polyethylene bags, taken to the laboratory and protected using wire mesh to prevent rodent attack. Potato Dextrose Agar (PDA) was the medium used. Test fungus for this study was Fusarium oxysporum. It was isolated from naturally infected yam tubers. Small sizes of approximately 2x2mm were cut out with sterile scalpel from yam tubers infected with rot at inter-phase between the healthy and rotten portions of the tubers. The cut tissues were soaked in 5% sodium hypochlorite for 2 minutes for surface sterilization and then rinsed in four

successive changes of sterile distilled water. The infected tissues were later picked onto sterile filter paper using a sterile forceps and then wrapped with filter paper for 2–3 minutes. The dried infected tissues were plated on several prepared sterile plates of acidified potato dextrose agar (PDA) and the plates were incubated at ambient room temperature (30±5°C) for 192 hours. The different fungi that grew from infected tissues were sub-cultured on separate sterile acidified PDA plates and incubated to obtain pure cultures of pathogens. Macroscopic and microscopic examination and morphological characteristics and identification were made and compared with existing authorities (Burgess et al., 2008).

The assay for antagonism was performed on Potato Dextrose Agar (PDA) on Petri dishes by the dual culture method (Evans et al., 2003). Percent Growth Inhibition (PGI) of pathogen was also calculated as described by Korsten and De Jager, (1995).

$$PGI\ (\%) = \frac{R - R_1}{R} \times 100$$

Where,

PGI = Percent Growth Inhibition

R = the distance (measured in mm) from the point of inoculation to the colony margin in control plate,

R_1 = the distance of fungal growth from the point of inoculation to the colony margin in treated plate in the direction of the antagonist. And the width of zone of inhibition (ZI) measured as the smallest distance between the colonies in the dual culture plate if any was determined (Singh and Sharma, 2014).

The experimental design was Completely Randomized Design (CRD) with three replicates. Test of variance was calculated using Analysis of variance (ANOVA) and statistical F-tests were evaluated at $P \leq 0.05$. Differences among treatment means for each measured parameter were further separated using Fisher's least significance difference (LSD) to determine levels of significance.

RESULTS AND DISCUSSION

Fusarium oxysporum was isolated and identified as one of the organisms causing rot of yam tubers in the study area. This result corroborates the findings of Okoro and Nwankiti (2004) that had earlier on identified this organism in rotten yam tubers at different locations in Nigeria. Colony characteristics growth on PDA was rapid. There was white aerial mycelium colour (figure 1). Microscopic examination and morphological characteristics and identification showed that micro and macro conidia were present, macro conidia slightly sickle-celled with apical cell and foot shaped basal cell, chlamydospores are present, single and some in pairs (figure 1).

T. harzianum assessed in this investigation was able to reduced mycelia growth of F. oxysporum when grown in dual culture irrespective of the time of introduction of the antagonist (figure 2). The results of dual culture indicated that T.harzianum significantly ($P \leq 0.05$) inhibited the growth of F. oxysporum at varying degrees across duration of incubation (table 1).The findings revealed that T. harzianum introduced 2days before inoculation of F. oxysporum has the highest mean percentage growth inhibition (77.99%), followed by that introduced same time with the pathogen (45.69%) and the least mean percentage growth inhibition (13.72%) was observed when the antagonist was introduced 2days after inoculation of the pathogen (table 1). The inoculation of the test antagonists two days before the pathogen was done because there are no biocontrol agents that have enough competitive ability to displace an already established pathogen. The time lapse allows adequate increase in cell concentration and subsequent colonization by antagonist before the arrival of the pathogen (Adebola and Amadi, 2010a).

The results of the dual culture showed that T. harzianum inhibited the growth of the target organisms through its ability to grow much faster than the pathogenic fungi thus competing efficiently for space and nutrients. Starvation was the most common cause of death for F. oxysporum, so that competition for limiting nutrients resulted in biological control of the test pathogen. This finding is in agreement with the work of Siameto et al., (2011). Antagonists may also affect growth of pathogen either through antibiosis or mycoparasitism (Saba Banday et al., 2008). It was observed microscopically that the interaction region between F. oxysporum with T. harzianum showed mycelia of T. harzianum grew on the surface of the pathogen and later penetrated the cell walls directly without formation of appresorium structures (figure 3). It also prevented the formation of both micro and macro conidia of the test fungus. The pathogen mycelia then disintegrated suggesting enzyme action (figure 3). This result agreed with the work done by Mokhtar and Aid (2013) who reported the inhibition of the growth and spore formation of F. acuminatum by 66.66% using T. harzianum in vitro. Siameto et al., (2011) demonstrated possible role of chitinolytic and/or glucanases enzymes in bio-control by Trichoderma. They showed that the enzymes function by breaking down the polysaccharides, chitin, and glucans that are responsible for the rigidity of fungal cell walls, thereby destroying cell wall integrity limiting the growth of the pathogen. Microscopic observation also showed that the antagonist, T. harzianum prevented the formation of spores of the test pathogen. It was observed in the study that a clear zone of interaction was formed in all Trichoderma- F. oxysporum interactions except in the interaction between T.harzianum and F. oxysporum; where T. harzianum was introduced 2days before inoculation of F. oxysporum. The zones of inhibition produced might be due to the production of antifungal metabolites by the test antagonist as reported by Adejumo et al. (1999).

CONCLUSION

The study found out the antagonistic potentials of T. harzianum as good biological control agent of yam tuber rot caused by F. oxysporum. The study also revealed that the best time for the introduction of bio-agent is before the arrival of the pathogen. This is because the introduction of the antagonist 2days before in vitro inoculation of F. oxysporum gave the highest inhibition of the mycelia growth of the pathogen.

ABSTRACT
Experiment was conducted at the National Cereals Research Institute (NCRI), Badeggi, , Bida, Niger State, Nigeria with the objective for morphological characterization and classification of groundnut (arachis hypogeael.) cultivars from Northern Nigeria. Eleven (11) cultivars comprising of six (6) release varieties and five (5) accessions were obtained from the Gene Bank of the National Centre for Genetic Resources and Biotechnology (NACGRAB), Moor Plantation, Ibadan, Nigeria while sixteen (16) other accessions were collected in Niger State by the National Cereals Research Institute (NCRI), Badeggi, Nigeria. The Characterization and classification of the groundnut cultivars were carried out using 18 morphological characteristics based on the IBPGR and ICRISAT Descriptor for Groundnuts and with slight modifications. Pod and seed dimensions were determined by measuring a total of 50 pods or seeds randomly from each sample. The length (L), width (W), and thickness (T) of pods or seeds were measured using a micrometre with accuracy of 0.001 mm. The mass of individual sample was measured using an electronic balance (accuracy of 0.001 mg). The result showed that the traits studied were close to the morphological characteristics from the three countries, indicating that similar postharvest equipment used for groundnut processing in America, China and Egypt may be suitable for Nigerian groundnut cultivars. The relatively small percentage of coefficient of variation (1.25 for AMD) and 10.69 for GMD in this study is an indication of uniformity of groundnut seeds obtained from the northern Nigeria. The close CV is also important in equipment design and selection for improvement during groundnut breeding as it gives some minimal difference in their morphology. The study also classified the groundnut cultivars studied into 7 groups using dendrogram with complete linkage and absolute correlation and found them distinctive
Keywords: groundnut, morphological traits, classification, processing

INTRODUCTION
Groundnut (Arachis hypogeae L.) is one of the world's most important sources of edible vegetable oil and protein (Lusas, 1979). There is great diversity among botanical varieties of groundnut (Ferguson et al., 2006). The genus Arachis for instance consist of 40-70 species which all possess unique quality and morphological characteristics. As a result of the acknowledged diversity in botanical materials, there is need for a common interface for information sharing among breeders and other interest groups in genetic resources management and utilization. This has become more intensive even with the establishment of international foundation for exchange of genetic materials (Kotzamanidis et al., 2006).
The need for national data base on the available varieties and accessions that will facilitate exchange and utilization of the data for the improvement of groundnut value chain including processing techniques and technologies in Nigeria led to the study of some important morphological characteristics of groundnut pods and seeds of the Nigerian groundnut cultivars and to identify cultivars belonging to similar groups. Together with agronomic and grade information, data on seed and pod quality are essential requirements for the release of new groundnut cultivars to ensure acceptability by the entire groundnut value chain actors. Seeds and pods physical attributes like all other agricultural materials are needed to adequately design appropriate equipment and systems for planting, harvesting and post-harvest operations such as cleaning, conveying and storage (Asoegwu et al., 2006). Physical characteristics of cheat, such as dimensions, weight, shape and bulk density were used to establish machine design and operating parameters for roller and hammer mills, selecting the optimum gap between rolls and optimum screen opening size for the hammer mill Hauhouot-O'Hara et al., (1999; 2000). While Vaughan et al., (1980) Asoegwu et al. (2006) and Simonyan et al. (2007) reported that separation of agricultural materials from unwanted materials is based on differences in the physical properties between the crop and foreign materials.
The process of cleaning groundnut pods and seed therefore requires that differences in the physical properties of pods and seeds be known. The surface area (SA) of seeds or pods is useful to estimate the rate of heat transfer and in the design of appropriate heating equipment. It is also required for grading and packaging and in sieve separation and grinding operations (Wilhelm et al., 2004; Singh et al., 2004). In this study, twenty seven (27) cultivars of groundnuts cultivated in the northern region of Nigeria were characterized and classified into groups

as a strategy to provide information for breeders on the available germplasms for improvement and also technical information for production and post-production engineers that will facilitate easy design of machines and processes for the processing of groundnut pods and seeds into intermediate and finished value added products.

MATERIALS AND METHODS

Eleven (11) cultivars comprising of six (6) release varieties and five (5) accessions were obtained from the Gene Bank of the National Centre for Genetic Resources and Biotechnology (NACGRAB), Moor Plantation, Ibadan, Nigeria while sixteen (16) other accessions were collected in Niger State by the National Cereals Research Institute (NCRI), Badeggi, Nigeria. All the materials were cultivated during the 2015 cropping season (between May to November, 2015) at the upland research field of NCRI and harvested pods were cleaned manually and stored in a paper bag at room temperature (30±2°C) for about 6 months until required for analysis. Characterization and classification of the groundnut cultivars were carried out using 18 morphological characteristics based on the IBPGR and ICRISAT Descriptor for Groundnuts (1992) as reported by Kotzamanidiset al. (2006) with slight modifications. Pod and seed dimensions were determined by measuring a total of 50 pods or seeds randomly from each sample. The length (L), width (W), and thickness (T) of pods or seeds were measured using a micrometre with accuracy of 0.001 mm. The mass of individual sample was measured using an electronic balance (accuracy of 0.001 mg).

The arithmetic (AMD) and geometric (GMD) mean diameters were calculated from the three axial measurements (L, W and T).

$$AMD = \frac{(L+W+T)}{3} \quad (1)$$

$$GMD = (LWT)^{1/3} \quad (2)$$

The sphericity (S) of each pod and seed were determined by the following equation proposed by Mohsenin, (1970). Sphericity is the ratio of the geometric mean diameter of the three mutually perpendicular dimensions to the longest dimension of a solid triaxial ellipsoid (Cao et al., 2004). The surface area (SA) and volume (V) were determined by equations reported by Jouki and Khazaei (2012)

Statistical analysis

Data generated were subjected to statistical analysis using Minitab 13. The means and standard deviations of all properties were calculated. Means of the experimental data were compared by Duncan's multiple range test (DMRT) at 95% confidence of interval. The correlation coefficients among the properties were calculated.

RESULTS AND DISCUSSION

The results of the descriptive analysis of the morphological characteristics of groundnut pods and seeds are presented in Tables 1 and 2 respectively.The highest pod mass on the average was observed in BDA/ND-2 (2.00g) with BDA/ND-9 having the highest length and length/width ratio. The highest variation coefficients (7.35 and 12.35%) were obtained for pod density and surface area respectively. The low levels of variability of the majority of morphological characteristics are typical of the common groundnut from the natural populations. The pod weight of 0.736-1.995g is within the average mean of 1.06 - 3.60, 1.14 - 3.21 and 0.66 - 3.01g reported for American, Chinese and Egyptian varieties respectively reported by El-Sayed et al.(2001).

The average length, width, length/breadth ration, seed weight, arithmetic and geometric diameter, aspect ratio and density are presented in Table 2. The average length was 13.14g, width 8.16g, and length/width ratio 7.49. The average seed weight was 0.47g, while arithmetic mean diameter and geometric mean diameter were 9.60mm and 9.26mm respectively. Aspect ratio, sphericity and seed density mean were 63.02, 0.74 and 0.14 respectively. The variation coefficients were 2.44, 1.47, 1.05, 4.47, 1.25, 10.69, 2.65, 1.35 and 2.82 respectively for length, width, length/width ratio, seed weight, AMD, GMD, aspect ratio, sphericity and density. According to El-Sayedet al.(2001), Egyptian groundnut variety have the following dimension, length, width, thickness, geometricdiameter and mass 12.60 - 24.85mm, 5.35 -11.25mm,4.40-10.80mm, 7.19-13.77mm, and 0.22-1.17g,respectively. He also reported three varieties of groundnut pod obtained from China, America and Egypt which indicate the following range of geometric diameter 21.05, 20.59, and 20.34mm and 2.21, 2.17 and 2.13g of mass, respectively. The results of this study is close to the morphological characteristics from the three countries, indicating that similar postharvest equipment used for groundnut processing in America, China and Egypt may be suitable for Nigerian groundnut cultivars. The relatively small percentage of coefficient of variation (1.25 for AMD) and 10.69 for GMD in this study is an indication of uniformity of groundnut seeds obtained from the northern Nigeria. The close CV is also important in equipment design and selection for improvement during groundnut breeding as it gives some minimal difference in their morphology.

The groundnut cultivars were classified by considering all the morphological characteristics considered in this study using cluster analysis (Fig. 1).. In this study, we hypothesize that the cluster analysis can be used to classify the groundnut cultivars having similar morphological characteristics into single group. According to Lee et al. (2012), using this approach, characteristics from different cultivars but with similar morphological properties can be assumed as a single commodity for easy identification and selection by breeders and processing industry for specific application purposes. In this study, the groundnut cultivars were classified into 7 groups using dendrogram with complete linkage and absolute correlation. The first group includes SAMNUT21 and SAMNUT23, group 2 (SAMNUT22, SAMNUT25, NGBO1293, BDA/ND-4, BDA/ND-11, BDA/ND-12), group three (SAMNUT24, NGBO187, NGBO1370, BDA/ND-8, BDA/ND-14, BDA/ND-15), group four (SAMNUT26, BDA/ND-6), group five includes NGBO1294, BDA/ND-1, BDA/ND-7, BDA/ND-9, and BDA/ND-16. Cultivars NGBO1369, BDA/ND-2, BDA/ND-3, and BDA/ND-11 were group in cluster 6 and BDA/ND-5 and BDA/ND-10 were in group 7.

CONCLUSION

The result showed that the traits studied were close to the morphological characteristics from the three countries, indicating that similar postharvest equipment used for groundnut processing in America, China and Egypt may be suitable for Nigerian groundnut cultivars. The relatively small percentage of coefficient of variation (1.25 for AMD) and 10.69 for GMD in this study is an indication of uniformity of groundnut seeds obtained from the northern Nigeria. The close CV is also important in equipment design and selection for improvement during groundnut breeding as it gives some minimal difference in their morphology. The study also classified the groundnut cultivars studied into 7 groups using dendrogram with complete linkage and absolute correlation and found them distinctive

ABSTRACT
In order to meet the ever rising global demand for natural rubber cultivation, cultivation of natural rubber seedlings is been extended to green house where extreme climatic conditions like drought and high temperature negatively influence the crop performance. To ensure maximum productivity, identification of drought tolerant clones of Hevea which can cope with water stress and give better crop yield is essential. Ten genotypes of Hevea clones were screen for tolerance to 26 days of drought stress in the green house. The aim was to select tolerant clones for development of new promising genotypes of natural rubber. Rubber seedlings were transplanted (4 seedlings per poly bag filled with top rich soil) from the pre nursery field to the green house at one month old. After subjection to 26 days of drought stress each clone was evaluated for five juvenile characters. Phenotypic, genotypic and environmental variances as well as heritability estimate were obtained through analysis of variance. Results obtained showed that variations existed in the level of drought tolerance among the genotypes. GT1 recorded the highest plant height, number of leaves, percentage plant survival and leaf area followed by Nig 804 and PR107.

Keywords: Hevea brasiliensis, Rubber seedlings, drought stress, juvenile traits.

INTRODUCTION

The Hevea genus belongs to the Euphorbiaceae family and comprises 11 species native to the Amazon region (Pires et al., 2002). Hevea brasiliensis (Willd. ex Adr. de Juss. Muell-Arg.) is the only cultivated species and the main source of natural rubber. The rubber tree is a perennial and deciduous crop with an economics life span of 25-30 years. The plant is quick growing, erect, with a straight trunk and surfaces. It is the tallest species of the genus, Hevea. It is a tropical crop that survives between 15^0N and 10^0S of the equator, where the climax vegetation is lowland tropical forest and where the climate is hot and humid with temperature range of 25-30^0c with a well distributed rainfall of 1800-2000mm per year. The crop does not perform well if there is a long dry season. It also does badly if the climate is excessively humid, as this encourages leaf diseases. Rubber tree can tolerate a wide range of soil conditions from sandy to loamy soils provided the soils are deep, fertile, well drained and slightly acidic with a soil pH of 4-8 or 4-6.

As global demand for natural rubber increases a major challenge for cultivation of rubber plants is their inability to withstand unfavorable environmental conditions in the context of global climate change (Nair et al., 2010). Drought remains one of the ecologically limiting factors among all environmental constraints. Drought is an extended period of dry weather characterized by shortage of water supply to plants (Acquaah, 2007). Drought begins when the readily available soil water in the root zone is exhausted (Taiz and Zeiger, 2006). Drought stress can occur at any stage of the growing process, and cause complete loss of crops or serious damage to yield. In Nigeria, natural rubber production comes mostly from a single popular clone RRIN 800 series and it occupies most of the area under rubber cultivation. Although it is the highest yielding clone in Nigeria, it does not exhibit good drought tolerance capacity. The present study aimed to identify tolerant genotypes for development of new clones of natural rubber.

MATERIALS AND METHODS

Ten genotypes of Hevea clones were screened at the green house of the National Root Crops Research Institute (NRCRI), Umudike, Abia State, for tolerance to 26 days of drought stress using five juvenile characters. The ten seedling clones were five RRIN developed clones (NIG 800 to NIG 804) and five exotic clones (RRIM 600, RRIM 628, GT1, PR107 and PB5/51 from Malaysia. Sprouted seedlings were transplanted from the pre nursery to the poly bags filled with rich top soil at one month old on October 10, 2013 in a Complete Randomized Design (CRD) with three replication. Each poly bag contains 4 seedlings and the seedlings were watered twice daily (morning and evening) to enhance establishment before imposing 26 days of drought on them. Data were collected on the following five juvenile characters: (plant height, number of leaves, plant girth (circumference), percentage plant survival and leaf area) at 26 days of drought stress.

Plant height was measured from the ground level to the tallest leaf using meter rule at 26 days of drought stress. Number of leaves per plant was obtained by counting the number of leaves of each plant after which their mean was calculated and recorded.

Plant girth was obtained by measuring the diameter of the plants using slide calipers to measure the girth of plants.
Percentage plant survival was calculated by counting the number of seedlings that survived over the total number transplanted from field to the poly bags according to (Samarappuli et al., 1996).
Data on leaf area (cm^2) at 26 days of drought was measured and calculated. Leaf Area (cm^2) = L x W x K, where L is leaf length, W is maximum width of the leaf and K is a correction factor of 0.654.
All the data collected were subjected to Analysis of Variance (ANOVA) using the SAS package (SAS, 1998) to determine if variability existed among the genotypes for various traits. Genetic parameters such as variance components (genotypic, phenotypic and error variances) and heritability in the broad sense was calculated according to Allard (1987) as follows:
$Vg = \{MSG\text{-}MSE/r\}$, $Vp = \{MSG/r\}$, $Ve = \{MSE/r\}$
where MSG, MSE, Ve and r are the Mean Squares of genotypes, Mean Squares of error, Environmental variance and number of replication respectively.

RESULTS AND DISCUSSION

The mean effects of drought stress on plant height, number of leaves, percentage plant survival, plant girth and leaf area of rubber seedlings are presented in Table 1. Plant height varied from 21.8cm in RRIM 600 to 34.98cm in GT1. GT1 recorded the highest plant height of 34.98cm followed by NIG 804 with plant height of 33.04cm. RRIM 600 recorded the least plant height of 21.8cm. The genotype RRIM 600 was reported to be drought tolerant in the field by Korieocha et al., (2015) but cannot withstand 26 days of drought in the green house. This may be due to the fact that the taproots penetrated deep inside the soil and absorbed water that helped them to survive up to 40 days of drought while in the green house root penetration was restricted in the poly bags. This is in line with the findings of (Samarappuli et al., 1996) who reported that root growth in relation to density may have had greater effect in the performance of rubber plants in the green house. Young plants are less likely to survive in the soils with inadequate supply of moisture at the surface; this is particularly so during the dry periods. Well developed and more efficient root system would enable the young plant to tap on a larger reservoir of moisture beneath the surface, thereby increasing the soil water and nutrient absorption efficiency of the plant.
Number of leaves varied from 5.33 in RRIM 600 to19.11 in GT1 after 26 days of exposure to drought stress (Table 1). As a result, GT1 had the highest number of leaves 19.11 after 26 days of drought followed by PR107 with 18.53 while RRIM 600 exhibited the least number of leaves (5.33) at 26 days of exposure to drought stress. There were influences of drought on all the genotypes but the effects of drought stress were more pronounced in RRIM 600 and PB5/51.
The percentage plant survival per genotype ranged from 25% in RRIM 600 to 66.6% in GT1 after subjection to 26 days of drought stress (Table 1). Percentage plant survival of the genotypes was generally high after establishment, before exposing them to 26 days drought, except for RRIM 600 that had 50% survival after establishment. Generally, there was much influence of drought stress on the genotypes after 26 days of drought stress but GT1 recorded the highest plant survival rate of 66 6% while RRIM 600 and PB5/51 recorded the least plant survival rate of (25%) followed by NIG 800 and RRIM 628 with 30.67% and 30.33% respectively. Meanwhile GT1 was the only genotype that can tolerate drought periods of 26 days or even more in the green house and field. The remaining genotypes showed little or no drought tolerance in the green house experiment when compared with field experiment as reported by (Korieocha et al., 2015).
The leaf area varied from 84.48cm^2 in RRIM 600 to 513.87cm^2 in GT1 after subjection to 26 days of drought stress. GT1 produced the highest leaf area of 513.87cm^2 at 26 days after exposure to drought stress, followed by PR 107 with 431.01cm^2 and RRIM 600 produced the least leaf area of 84.48cm^2 at 26 days of drought (Table 1). There was variation among the genotypes during the drought stress period but low leaf area was recorded across the ten genotypes especially in RRIM 600. This result indicated that drought had influence on the genotypes. Since there was limited supply of water and the crops were not exposed to direct sun shine, photosynthetic process was inhibited and the leaves did not grow elaborately well. The significant clonal variations for the five juvenile traits will permit selection among the clones for tolerance to drought stress.

In 2013 all the traits had higher phenotypic variances than genotypic and environmental variances. Also, the environmental variances were more than genotypic variances. Consequent upon this, the broad sense heritability ($h^2_{b\ \%}$) estimates were generally low, except for leaf area and plant girth where moderate heritability (h^2_b) estimates were obtained. Percentage plant survival had the highest phenotypic variance (403.55); lower genotypic variance (7.72) compared to high environmental variance (395.83), and had a lower heritability estimate of 0.02. Leaf area had phenotypic variance of 70.64 and genotypic variance estimates of 30.10, and consequently a moderate heritability estimate of 0.43 (Table 2). The lower genotypic variances recorded, compared to environmental and phenotypic variances, suggest greater influence of the non- heritable components over and above heritable (genetic) components on the total phenotype observed. Genetic gain under this scenario will be very slow, and will take considerable time. Similar results of higher environmental (error) variance than genotypic variance for characters were reported by (Adebisi et al., 2001) for soybean and (Adebisi et al., 2001) for kola. Heritability is a measure of observed phenotype that is accounted for by genetic effects.

CONCLUSION

From the result in the green house experiment, it was observed that only GT1 withstood 26 days exposure to drought. The result also showed that rubber seedlings cannot withstand drought stress at nursery stage for a long period especially in the green house. The lower genotypic variances recorded, compared to environmental and phenotypic variances, suggest greater influence of the non- heritable components over and above heritable (genetic) components on the total phenotype observed. These also further explain that selection under this scenario will be very slow and will involve a lot of recurrent selection.

Table 1: Mean effects of 26 day of drought stress on 10 genotypes of rubber seedlings evaluated in the green house.

Genotypes	Plant height (cm)	Number of leaves	Percentage plant survival (%)	Leaf area (cm^2)	Plant girth (cm)

ABSTRACT:
The field experiments were carried out to evaluate the yield and selected morphological traits of twelve (12) hungry rice (D. iburua) accessions in 2014 and 2015 cropping seasons at the National Cereals Research Institute, Badeggi. The experimental design was a Randomized Complete Block Design with three replications,. Traits such as number of tillers, leaf area, plant height, panicle length, number of spikes, length of spikes and grain yield (kg ha^{-1}) were assessed. The analysis of variance showed significant differences among the accessions for all the traits evaluated. The overall mean grain yield of the accessions in the study was 1,883.51kgha^{-1}. Jipel accession produced the highest grain yield of 992.33kgha^{-1}, followed by Nibang accession in 2014. While in 2015, Nashelleng accession out yielded the rest of the accessions, while Jipel and Pelking accession produced the lowest grain yields in both years of the study.
Keywords: Rice, morphological traits, yield evaluation, accessions

INTRODUCTION:
Hungry rice (D. iburua) also known as fonio, findo, fundi, pom, kabuga or acha in different West African countries is a cereal crop in the Savannah Zone of West Africa. It is the oldest indigenous crop with cultivation record dating back to 7000 B.C. (Cruz, 2004). It is relatively unimproved and is characterized by a number of poor traits such as fragile stems, small seed size and weight, photoperiod sensitive, low seed set, low yielding capacity among others. In Nigeria, hungry rice (D. iburua) is produced on 160,000ha with an annual yield of 85,000t and 500 kg ha^{-1} (FAO, 2011). It is a crop that demands low input for its production and can give appreciable yield on poor or marginal soils and will tolerate a wide range of soils such as sandy, loamy, rocky or shallow soils. However, soils with very high clay content are not suitable for the crop (Philip and Itodo, 2006). In Nigeria agricultural productivity per hectare is characterized by low yield, small holdings and rudimentary farming system, which is also attributed to poor soil conditions and insufficient use of resources. Nevertheless, increases in agricultural productivity for availability of food for the populace must involve the cultivation of minor crops such as hungry rice (D. iburua), finger millet (Eleucine coracana L.), and foxtail millet among others that have high nutritional qualities useful to human health.
Hungry rice (D. iburua) can be utilized in similar ways like major cereals such as maize (Zea mays L.), rice (Oryza sativa L.) and sorghum, (Sorghum bicolor) (Dachi, 2014). Hungry rice (D. iburua) contains two important sulphur amino acids (cysteine and methionine) that are lacking in major cereals. These amino acids are useful to human health particularly for people with diet challenges. Also, in the medical field, hungry rice (D. iburua) starch has been compared with maize starch as a binder at various concentrations and was found to be as good as maize starch in the formulation of paracetamol tablets (Musa et al, 2008, Iwuaguwu et al, 2001). Also, the breakthrough in the processing of this crop which has been a setback to its production has enhanced hungry rice (D. iburua) production to meet local and international demand. This might be responsible for the increase in its production in areas where it is grown in recent years. Hungry rice (D. iburua) can be used in the preparation of porridge, local beverages, couscous or ground and mixed with other cereals for consumption (Purseglove, 1975; Hag and Ogbe, 1995; Anon., 1995). The demand for hungry rice (D. iburua) is on the increase as a result of its nutritional qualities, organoleptic properties and health benefits among other uses of the crop (Dachi, 2014). There is need to intensify the production of this crop to satisfy local and international demands, hence further evaluation of these accessions for yield and adaptability to local conditions is way forward to its availability. The revitalization of hungry rice (D. iburua) production will enhance the diversification of the economy and food security in the country. Thus, this study was aimed at evaluating the performance of some promising hungry rice (D. iburua) accessions in the Southern Guinea Savannah of Nigeria

MATERIALS AND METHOD
The experiments were conducted at the National Cereals Research Institute, Badeggi in 2013 (Lat. 9^0 45N' and Long. 6^0 07'E) in Niger State located in the Southern Guinea Savanna ecological zone of Nigeria in 2014 and 2015. The textural class of the soil of the experimental site was sandy loam with pH of 5.78 in water, low in organic carbon (4.40), organic matter (0.57), low in residual phosphorus (12.45kgha^{-1}) and low in residual nitrogen (0.48). The treatments consisted of twelve hungry rice (D. iburua) accessions selected from the germplasm. The experiment was laid out in a Randomized Complete Block Design with three replications. Plot

size was 3.0m x 4.0m. Seeds were sown by drilling at 30cm inter-row spacing and at 30kgha^{-1} seeding rate in the third week of June in all the seasons. At five weeks after sowing, NPK 15:15:15 fertilizer was applied at the rate of 30kg Nha^{-1}, 30 kg ha^{-1} P_20_5 and 30 kg K_20 ha^{-1} in all the plots.

Weeds were removed manually by hand pulling at 4, 8 and 12 week after sowing (WAS). The crops were harvested at maturity using sickles in the fourth week of October in both seasons and threshed by beating with sticks to remove the seeds from the chaff and winnowed to obtain clean seeds. The data collected included number of tillers, leaf area, plant height at harvest, panicle length, number of spikes, length of spikes and grain yield (kg ha^{-1}). The data collected were subjected to analysis of variance and treatment effects were compared using least significant difference (LSD) at 0.05% level where significant.

RESULTS AND DISCUSSION

There were significant differences among the accessions in terms of all the traits studied. This could be due to the genetic variability among the accessions in terms of the character assessed. Similar result was also obtained among evaluated wheat genotypes by Peyman et al, (2014). The range of number of tillers among the accessions studied varied from 5.60 for Pelking accession to 71.87 for Jarab accession in 2014 (Table 1) and from 5.67 for Pelking accession to 16.60 for Jepel accession in 2015 (Table 2). Sunpiya accounted for the highest leaf area of 29.59 in 2014 while in 2015 the highest leaf area of 42.16 was produced by the accession Jipel (Table 2). Suhn and Gotip accessions had the least leaf area of 24.79 and 24.86 respectively. Plant height was observed to differ significantly among the hungry rice (D. iburua) accessions. Suhn and Sunpiya accessions were significantly taller up to 124.71 and 125.14cm respectively, while Nashelleng and Pelking accessions recorded the shortest heights in both years with heights of 113.92 and 107.53cm respectively. The maximum panicle length was produced by Jipel (59.57cm) and Suhn accession (56.83cm) and the minimum was recorded by Sunpiya and Dinat accessions with 51.14 and 49.19cm (Tables 1 and 2).

In both years of experimentation, Nashelleng accession gave the highest number of spikes per plant and pelking accession produced fewer numbers of spikes per plant among all the accessions. Length of spikes per plant was observed to be significantly longer in Napiya and Suhn accessions, while Pelking and Nibang accessions produced the shortest length of spikes (Tables 1 and 2).

Statistical analysis of the data showed that there was significant difference among the 12 hungry rice (D. Iburua) accessions in terms of grain yield. In 2014, Jipel accession produced significantly higher grain yield, followed by Nibang accession (Table 1), while in 2015, Nashelleng accession gave the higher grain yield, followed by Jipel and Sunpiya accessions (Table 2). Generally, the differences observed among the 12 hungry rice (D. iburua) accessions in respect to yield and yield components assessed could be due to their varied genetic compositions and adaptation to the soil and climatic conditions under which the studies were conducted. The yields obtained from these hungry rice (D. iburua) accessions ranged from 550.10 to 1,500.01kgha^{-1}. The implication of the results is that farmers have a wide range of choice to make for high yielding hungry rice (D. iburua) accessions in and around the study area. Breeders can also select for more desirable traits for improvement.

CONCLUSION:

The variability in the accessions can be exploited by plant breeders for further improvement.

ACKNOWLEDGEMENT

The authors are grateful to the management of the National Cereals Research Institute, Badeggi for the permission to execute the experiment.

ABSTRACT
The objective of the study was to to select high yam yielding genotypes with distinctive desirable characteristics that will enhance the tubers' market potential. The materials used for the study were tubers weighing between 10 to 25g half-sibs developed from open pollination of Amola, Obiaoturugo, Hembakwasi and Faketsa in 2014. Each tuber is a genotype and was planted on a plot size of 4x5m² at a planting distance of 100 x 45 cm. Results indicated that tubers from clones with planted tuber weight of less than 25g and 25g that produced tubers weighing above 500 to 1000g indicated high yield potential. The variability in the morphological features of the tubers of the clones was an indication that variability existed in the clones and the genetic variability of the clones could be enhance to add value to their marketability, breeding and farming systems.
Keywords: Yield, Morphology, clone, open pollinated and marketability.

INTRODUCTION
Yam is one of the most popular tuber crops in Nigeria and abroad because of its yield potential and high calorific value. It is mainly cultivated almost in all the tropical countries. It is heterozygous cross-pollinated and vegetative propagated tuber (modified stem) crop in which many of the traits show continuous variation. It is the king of all roots and tuber crops. It contains raw protein in fresh storage roots which ranges from maximum 49 to minimum 2.24 per cent on wet basis (Ezeocha et al., 2015) . The starch content in raw tuber varies from 33-73 per cent on dry basis (Ezeocha et al., 2015). In addition to protein and starch some of the yam varieties such as yellow yam provide 1-12 mg carotene per 100 gm of tuber making the tubers more nutritious (Ezeocha et al., 2015). According to Grafuis (2009) increasing total yield would be made easier by selecting for components because the components are more simply inherited than the total yield itself. Thus studies on correlation enable the breeder to know the mutual relationship between various characters and determine the component characters on which selection can be used for genetic improvement. The objective of this study was to select high yam yielding genotypes with distinctive desirable characteristics that will enhance the tubers' market potential.

MATERIALS AND METHODS
The study was conducted at western experimental field of National Root Crops Research Institute Umudike. The materials used for the study were tubers weighing between 10 to 25g half-sibs developed from open pollination of Amola, Obiaoturugo, Hembakwasi and faketsa in 2014.. The 53 tubers generated as clones were planted in a unreplicated plots. Each tuber is a genotype and was planted on a plot size of 4x5m² at a planting distance of 100 x 45 cm. The following data were collected: number of plants with .tubers weighing less than 25g, The number of plants with tubers weighing between 25 <500g, number of plants with tubers weighing between >500 <1000g, and number of plants with tubers weighing > 1000g. Data was also collected on tuber morphological characteristics such as smooth surface, hairy, spiny, slender and lengthy tubers and round/ rotund shape tubers.

RESULTS AND DISCUSSION
Percentage of Clone plants with various tuber weight: The weight of tubers from various clone plants and morphological features of the open pollinated hybrid clone of white yam genotypes are presented in Table 1. The result on Table 1 indicated the varying weight of the tubers of the clones. The result classified the clones developed from open pollinated seedlings into 4 various weight populations. The result classified 17 clones with tubers weighing less than 25g representing 29.3% as micro-tubers. Twenty-nine clones with tubers weighing between 25 to less than 500g representing 50% as Mini-tubers while 20 clones weighing more than 500g but less than 1000g representing 34.5% as Seed yams. Nine clones produced tubers with weight above 1000g representing 16.0% classified as Ware tubers. The weight of the clones indicated their yield potentials. Tubers from clones with planted tuber weight of less than 25g and 25g that produced tubers weighing above 500 to 1000g indicated high yield potential, these genotypes multiplies both in plant population and in yield when subjected to minisett techniques (Ezulike et al., 2006), while those weighing between 25 to less than 500g may be regarded as medium yielding genotypes while those with weight less than 25g that produced microtubers are low yielding genotypes with low multiplication ratio..
Morphological features of the tubers: The morphological features of the tubers indicated that thirty-nine clones representing 67.2% have smooth surface texture as distinguishing trait, 13 clones representing 22.4% of the

clones evaluated have hairy surface body while 6 clones which was 10.3% of the total clones tested have tubers with spiny surface texture..

Tuber Shape; Also the tuber lengths and width were used to discriminate against the clones. Fourteen clones representing 24.1% have long slender tubers that are prone to damage during harvest while 44 clones representing 75.9% have rounded body shape that may be regarded as rotund. Genotypes with rotund shape could be further developed since they will be amenable to mechanical harvesting and good candidates for rocky soils or areas with hardpan or impediment less than 30cm soil depth.

CONCLUSION

The variability in the morphological features of the tubers of the clones was an indication that variability existed in the clones developed from open pollinated yam seedling population. Tubers from clones with planted tuber weight of less than 25g and 25g that produced tubers weighing above 500 to 1000g indicated high yield potential. The genetic variability of the clones could be utilized in various food forms, breeding, farming systems and to add value to their marketability.

ABSTRACT
Afzelia africana is a multipurpose indigenous leguminous tree of sub-Saharan Africa origin. Nursery trials were conducted to determine effectiveness of pre-sowing soaking of seeds in water, solutions of potassium nitrate (KNO_3) and hydrogen peroxide (H_2O_2) for varying durations as methods of breaking seed dormancy and enhancing germination. Results showed that seeds treated with pre-sowing soaking in H_2O_2 for four hours and 0.1% KNO_3 treatment for three hours had earliest mean day to first germination of 3 days after sowing (DAS) and 5 DAS respectively, as against non-soaked seeds (7.5 DAS) and cool water treatment for 12 hours (7 DAS). Days to 50% germination was markedly reduced to 8 DAS in seeds treated with 0.1% KNO_3 for six hours soaking. Pre-treated seeds in 0.1% KNO_3 solution for 6 hours and in 0.2% KNO_3 solution for 3 hours produced best results of 100% total germination percent by 15 DAS as well as reduced number of days taken to reach total germination. It was concluded therefore that pre-sowing treatment with 0.1% KNO_3 solution for six hours or 0.2% KNO_3 solution for three hours enhances uniform and massive germination of A. africana seeds within earliest possible time of 15 DAS.
Key words: Afzelia africana, germination, propagation, seed dormancy, seed treatment

INTRODUCTION

The African mahogany (Afzelia africana Sm.) is an important multipurpose leguminous tree of sub-Saharan African origin where it is naturally distributed. A. africana belongs to Caesalpinioideae sub-group of the Fabaceae family (Keay, 1989). The species is a large tree, commonly reaching up to 15 m height, but sometimes in more humid localities can grow up to 30 m. Its bole girth spans to 3 m, buttressed and seldom over 16 m long (Burkill, 1994). It is occasionally grown in other tropical countries as ornamental shade tree since the species possesses fragrant white flowers often characterized by purple markings. The tree, as a multipurpose species, holds great potentials in traditional agroforestry systems practice in the humid forest ecological zone of west and central Africa sub-regions. Its habitat is semi-humid savannah, frying forest, Guinea forest and wooded grassland on deep sandy and alluvial soils. Seedlings are sensitive to fine browsing and drought, and therefore need to be protected from these factors until they have fully established (Owonubi and Otegbeye, 2004). A. africana usefulness is versatile. It is known to produce high quality timber, which is termite free but relatively difficult to work. The wood is used for construction, furniture, cooking utensils, canoes and African talking drum, and also for firewood and charcoal. The plant is used in local medicine for general pain relief, digestive problems e.g. constipation and vomiting, and for treating internal bleeding (haemorrhage). Its seeds ('Akparata') are used by the Igbo of southern Nigeria as spices in the preparation of their local soups (Okeke et al., 2009).

Although it is a wide spread species as earlier indicated, it has declined in population. In 1998 it was re-assessed and classified as vulnerable on the IUCN red list of threatened species due to the threat of over exploitation for a number of international market commodity (Owonubi and Otegbeye, 2004; IUCN Red list, 2015). Often times, most of the species produce harvests are from wild stands and protected volunteer stands in farm lands. A. africana is propagated by seed as evidenced by its high natural regeneration capacity; although natural regeneration is not usually abundance because the seeds predation by animal is high. Besides, the species is not fire-resistance and exhibits recalcitrant behaviour in storage. Delayed and irregular germination due to inherent seed dormancy posed serious challenge to the large scale propagation of the species. In the bid to tackle the afore-mentioned constraints, seed pre-sowing treatments have been practiced and recommended in order to achieve high viability of seeds, bring about massive and uniform early germination, as well as improve early seedling vigour and establishment (Alamgir and Hossian, 2008; Asiedu et al., 2012). In this regard, pre-treatment of seeds in solutions of potassium nitrate (KNO_3) and hydrogen peroxide (H_2O_2) were applied to promote dormancy release and increase germination of the seeds. Some gardeners and plant nursery experts choose KNO_3 and H_2O_2 among other options to break seed dormancy and boost seedling vigour, due to its relative affordability and less toxicity in handling in contrast to acid scarification and plant growth regulator gibberellins (Giri and Tamta, 2012; Rouhi et al., 2012]. The present study was conducted to examine the effect of pre-sowing treatment with KNO_3 and H_2O_2 on seed germination parameters (percent, speed and uniformity of germination) of A. africana.

MATERIALS AND METHODS

This experiment was carried out at Tree nursery section in the Department of Horticulture and Landscape Technology, Federal College of Agriculture Ishiagu Ebony State. Coordinates of experimental location showed that the place lies along $05^0 55^0$.096'N latitude; $007^0 33^0$.567'E longitude and elevation of 59m above sea level with average annual rainfall of about 1735.7m and average annual temperature of about 29.4^0C and relative humidity of about 69% during dry season (FCA Agromet, 2015). The experiment was laid out in Completely Randomized Design (CRD) format. There were fifteen treatments replicated three times. The treatments used in this experiment consist of: no soaking (i.e. the control), soaking in cool tap water at ambient room temperature for 6, 12, 24 hours; soaking in 0.1% and 0.2% concentration of potassium nitrate (KNO_3) solutions separately for 3, 6, 12 hours; and soaking in hydrogen peroxide for one to five hours separately. The treated seeds were sown in perforated polyethylene bags (of 40cm x 50cm dimension) filled with sterilized mixture of river sand and saw dust (at ratio 1:1 by volume). Daily germination count was taken every evening for 20 days after sowing (DAS). The following data were generated from the daily germination count for assessment of treatment effects in the experiment: cumulative germination percent across 20 DAS, days to first germination after sowing (DAS), days to fifty percent germination (DAS) and total germination percent at 20 DAS across the various treatments. Data collected were analysed by use of analysis of variance (ANOVA) and cumulative germination frequency, while mean separation was performed, where applicable using least significant difference (LSD) at $p<0.05$.

RESULTS AND DISCUSSION

Daily germination count showed that the pre-sowing treatments had varying impacts on the germination parameters of the Afzelia africana seed. From the cumulative germination percent result, seeds generally commenced germination after 5 DAS, with exception of pre-sowing soaking in hydrogen peroxide for four and five hours that germinated a little earlier (3 DAS), although this exceptional record did not translate into massive germination ultimately (Table 1). Hydrogen peroxide solution might have been used to enhance germination and seedling emergence in certain plants, e.g. wheat (Triticum aestivum) under stress growth conditions (Hung et al., 2005; He et al., 2009), its application in this study seemed to be relatively less effective in releasing seed dormancy, boosting germination and ensuring mass uniform seedling establishment of A. africana. Other treatments that had early germination records at 5 DAS included the seeds soaked in 0.1% KNO_3 for three hours, as well as those soaked in 0.2% KNO_3 for 12 hours and those soaked in hydrogen peroxide for three hours.
Concerning days to fifty percent germination (D50%G), potassium nitrate solutions treated seeds, across the two concentration levels (0.1% and 0.2%) and varying durations of soaking, had the least number of days (9.5 DAS) to attain 50% germination among the different treatments, while seeds pre-soaked in water across the various durations of soaking had most prolonged mean of 13 DAS to 50% germination in relation to other pre-sowing treatments investigated (Table 2). This result agreed with (Akinsoji and Nwana, 2005) as per the ineffectiveness of pre-germination soaking in cool water for enhancing germination in many tree species seeds. Seed dormancy can be overcome by immersing the seed in boiling water and then allowing it to soak for 24 hours as the water cools. This technique, which can be effective in enhancing imbibition and improving germination rates, is not useful for most tree species. Soaking seeds however, in tap water at ambient room temperature is generally ineffective in breaking dormancy (Kattimani et al., 1999; Akinsoji and Nwana, 2005).
Total germination results at 20 DAS showed that most of the seeds in all the treatments had relatively high percent total germination, ranging from 50 to 100% (Table 2). A greater number of seeds pre-soaked in potassium nitrate solutions reached up to 100% germination, with the exception of pre-sowing soaking in 0.1% KNO_3 for 3 hours and 0.2% KNO_3 for 12 hours which gave 93.3% germination at 20 DAS. Comparatively, pre-treated seeds of A. africana in 0.1% KNO_3 solution for 6 and 12 hours and in 0.2% KNO_3 solution for 3 and 6 hours proved to give best results in total germination percent as well as reduced the number of days taken to reach total germination (Table 2). This impressive high germination percent obtained from potassium nitrate treated seeds agreed with similar reports by Giri and Tamta (2012) and Rouhi et al.(2012) who researched on Hedychium spicatum (family: Zingiberaceae) and Tulipa kaufmanniana (family: Liliaceae) respectively.
Akinsoji and Nwana (2005) reported in their work that Albizia lebbeck (family: Fabaceae) seeds pre-treated with sodium nitrate solution at low concentration of 10ppm promoted germination, while higher concentrations suppressed it. In a similar report, Kattimani et al. (1999) showed that pre-sowing seed treatments of Withania somnifera (family: Solanaceae) with nitrates of sodium and potassium at 1.0% concentration for 24 hours were found to significantly increase total germination percent, as well as hasten speed of germination. Moreover, it had been reported that many nitrogen-containing compounds, including NO gas, nitrite (NO_2^-), nitrate (NO_3^-), nitrogen dioxide, ammonium, azide and cyanide enhance dormancy release and subsequent germination in many species, possibly as a means of sensing soil nitrogen availability (Rouhi et al., 2012). Seeds pre-soaked in water for the various durations had recorded between 60% and 85% total germination. Remarkably, an inverse relation

was observed between duration of pre-sowing soaking in water and the germination parameters of day to first germination, day to fifty per cent germination and total germination percent at 20 DAS.

CONCLUSION

Comparison of the total germination percent, mean days to fifty percent germination (i.e. germination speed) and mean days to first germination in relation to the various pre-sowing seed treatments showed very remarkable differences of relevance to seedling multiplication Afzelia africana. A greater number of seeds pre-soaked in potassium nitrate solutions reached up to 100% germination by 20 DAS; however pre-treated seeds of A. africana in 0.1% KNO_3 solution for 6 hours and in 0.2% KNO_3 solution for 3 hours proved to give best results in terms of total germination percent as well as reduced number of days taken to reach total germination of the seed lot. It was therefore concluded from the results that pre-sowing treatment with KNO_3 solutions at the given concentration in either duration of soaking had proved to enhance uniform and massive germination performance of A. africana seeds within earliest possible time of 15 DAS.

STUDIES ON THE INCIDENCE OF MELOIDOGYNE INCOGNITA INFECTION AND YIELD OF SOME VARIETIES OF YAM

J. I. Oluwatayo & N. S. Asen

Department of Crop and Environmental Protection, University of Agriculture, Makurdi
iyeh2010@yahoo.com

ABSTRACT
Field experiment was carried out in the Teaching and Research Farm of College of Agronomy, University of Agriculture, Makurdi to evaluate five rotundata varieties (TDr 95/18531, TDr 96/01168, TDr 96/01799, TDr 96/01395 and TDr 98/01164) for yield and determine their response to the root-knot nematode attack. Results showed that the five rotundata varieties were significantly different in percentage emergence and crop vigour (growth parameters). However, agronomic characteristics (tuber shape, texture, etc) and yield attributes (number of stands at harvest, number of seed and ware tubers/plot, total fresh tuber yield/plot) were not significantly different for the varieties. The mean values for yield parameters showed that TDr 96/01395 gave the highest yield both in ware tubers and total fresh tuber yield while TDr 96/01799 gave the lowest yield. There was variation in the degree of galling which was observed as the symptoms of the root-knot nematode attack on the tubers. It varied from gall to lesions and excessive root branching. The five varieties showed evidence of susceptibility to the root-knot nematode – Meloidogyne spp. Results of these studies showed that, yam plots could be treated before planting, or susceptible yam varieties be treated, or resistant yam varieties planted for adequate protection against Meloidogyne spp.
Keywords: yam varieties, yield, meloidogyne incogmita, infection

INTRODUCTION
Root-knot nematodes, Meloidogyne spp. (Kofoid and white) are important pest of edible yams, Dioscorea spp, wherever they are grown (Bridge, 1982; Nwauzor and Fawole, 1982). If preplant populations of root-knot nematodes are high enough, plant growth and tuber yield are severely affected. Infected tubers are galled and flaky and may develop abnormal rootlets, especially after a period of storage (Jenkins and Birds, 1962). The deformity and consequent unattractive appearance of infected tubers reduce their market value. More important, however, root-knot nematode-infected tubers in storage lose weight rapidly and are highly prone to secondary infection by fungi such as Aspergillus niger van Teigh and Penicillium selerotigenum Yamomoto. This results in a considerable reduction in the edible portion of the tubers or, in severe cases, the total loss of the stored tubers. Infected tubers also contain fewer pharmaceutically useful steroids such as diosgenin. Jenkins and Bird (1962) reported the formation of "stone cells" in infected storage tubers which were composed of a mature female and egg mass enclosed in wound periderm. Root-knot nematodes complete their life cycle in the yam tuber and egg remains viable even after a 3 – 4 month storage period (Nwauzor and Fawole, 1982).
Yam (Dioscorea spp. L) constitutes one of the most important food crops in the tropics and a most important group of staple foods in West Africa (Coursey, 1967). There are between 300 and 600 species of Dioscorea, of which only a few are edible. The four most commonly cultivated are water yam (D. alata L.) yellow yam (D. cayenensis Lam.), Chinese yam (D. esculenta [Lour.] Burk.) and white yam (D. rotundata poir). D. cayenensis and D. rotundata are indigenous to West Africa; D. alata and D. esculenta are native to Asia. D. rotundata is the most important species of yams in Africa, followed by D. cayenensis. Yams are grown as annual crop. The underground stem tuber is the economically important part of the plant and also the planting material. Yams are adapted to fairly high rainfall areas with distinct dry seasons of not more than 5 months. Nematodes damage yam tissues by their feeding activities and also create micro-wounds through which secondary pathogens (fungi and bacteria) can enter and cause complete yam decay during storage (Bridge, 1972). Such post-harvest losses account for a reduction of about 26% in world yam production (Coursey and Booth, 1972). Root-knot nematodes are the most serious nematode pests of numerous food crops in the tropics. It was in recognition of the involvement of the root-knot nematodes in world food production that the international Meloidogyne project was founded in 1976 with the sole objective of establishing the role of root-knot nematodes in food production, and more importantly, finding ways of reducing crop loss due to these pests.
There is currently reduction in the quality and quantity of yam tubers due to attack by the yam nematodes, and in particular the root-knot nematode. In Nigeria, M. incognita is the major specie that attack yams. Losses of more than 80% within a storage period of 16 weeks have been reported. Also, no matter the degree of the infection by the root-knot nematode, market value is lost because the body of the tuber is disfigured. The objective of this study therefore, was to evaluate rotundata varieties for yield and susceptibility to the root-knot nematode (M. spp), with the intent to research into possible control options should these varieties be susceptible.

MATERIALS AND METHODS

Experiments were conducted in the field to investigate the yield and incidence of the root-knot nematode (Meloidogyne incognita). The crops used for the study were TDr 95/18531, TDr 96/01168, TDr 96/01799, TDr 96/01395 and TDr 98/01164.

Infected field served as source of inoculum. M. incognita was extracted from the soil using the modified Baermann funnel extraction method (Whitehead and Hemmings, 1965) of supporting the material to be extracted on a plastic sieve of about 6 to 8cm diameter and 2cm deep. Paper tissues were then place on the sieves and the chopped yam peel or finely crumbled soil samples put in them. The sieves with the materials to be extracted were placed in water in extraction trays. Overnight, the sieves were gently remove and the content of the dishes examined for nematodes. The dishes can be reimmersed in fresh water for further extraction. This is necessary only when extracting from tubers.

Yams in the field were artificially infested using infected soils for which the nematode content had been estimated. The field trial was carried out during the months of May – December, 2015 in the Teaching and Research Farm of the College of Agronomy, University of Agriculture, Makurdi. The trial involved observing of yam varieties for yield and reaction to the root-knot nematode attack. The plot was cleared and ridges and mounds were made ready for planting. The experiment was a Randomized Complete Block Design with the treatments replicated three times.. One seed tuber per stand was planted. Plant population per plot was 20 (60 for 3 replicates). Mean weight of sett was 200g. Plots were hand-weeded to control weeds. NPK fertilizer application was done at the rate of 30g per mounds (300Kg/ha) eight weeks after planting where more than 60% of stands have emerged. Preplanting soil samples from the inocula field were taken and accessed for nematode occurrence and abundance by the modified Baermann technique as described before. Approximately 500 to 550m M. incognita adult and juvenile were sampled per plot. At harvest, matured tubers upon visual, qualitative inspection were rated for severity of disease symptoms (degree of galling) on a 0 – 5 scale according to the method described by Taylor and Sasser (1978).

R.G. Index	% Damage
0 -	No damage (immune)
1 -	0 – 5% (highly resistant)
2 -	6-25% (fairly resistant)
3 -	26 – 50% (fairly susceptible)
4 -	51 – 75% (susceptible)
5 -	76 – 100% (highly susceptible)

Infected tubers were characterized by gallings or swellings on the tubers. At harvest, agronomic and yield parameters – establishment count at 4WAP, 8WAP, crop vigour at 8WAP, 12WAP; number of stands at harvest, number of seed tubers harvested per plot, number of ware tubers harvested per plot, tuber shape, tuber surface texture, thorniness of tuber, yield of ware tubers (above 1kg) in kg/plot, number of rotten tubers per plot and total fresh tuber yield (kg/plot) were recorded. Data obtained from the field were analyzed using Generalized Linear Model procedure and the means were separated by Duncan's Multiple Range Test (DMRT). Analysis of variance (ANOVA) was used to test the hypothesis that there was no difference in yield, visible symptoms of infection and level of infestation by the nematode on the tubers.

RESULTS AND DISCUSSION

The five rotundata varieties showed significant differences in emergence at 4 weeks after planting (4WAP) and 8 weeks after planting (8WAP). TDr 95/18531 variety gave the highest percentage emergence of 67.33 at 4WAP while TDr 96/01168 variety gave the highest percentage emergence of 96.67 at 8WAP. The lowest percentage emergence at 4WAP was produced by TDr 98/01164 with 52.67% while at 8WAP TDr 96/01799 gave the lowest percentage as 76.00% (Table 1). TDr 95/18531 and TDr 96/01395 showed no difference in crop vigour both at 8 WAP and 12 WAP as shown in the Table 1 with vigor indices 3.00a and 5.00a respectively. Vigour score 3 and 5 indicates moderate to high vigor for the two varieties. Yam varieties TDr 96/01168, TDr 96/01799 and TDr 98/01164 had crop vigour 2.00b and 4.00b at 8 and 12 WAP were respectively, indicating low to high vigor (Table 1).

Attributes like tuber shape, tuber surface texture and thorniness of tuber had the same mean values of 1.00 hence, no significant differences were recorded among the varieties (Table 2). The mean score 1.00 for the three attributes suggests that all the yam varieties evaluated had very good shape, good tuber surface and had no thorns. No rotten tubers were observed among the five varieties, which suggests that the varieties might possess some resistance against rot pathogens. The yam varieties had nematode root gall index of 3-4 range. This indicates that all the varieties were either fairly susceptible or susceptible to nematode infestation (Table 2). The disease symptoms observed on the plots were galls and lesions on the tubers, and excessive root branching at varying degrees. The characteristics multiple heavy galls observed all over the tuber of infected varieties conform with the symptoms of Meloidogyne incognita infection.

TDr 95/18531 and TDr 96/01395 had the highest number of stands at harvest of 92.67 and 91.00 respectively. These were significantly higher than the number of stands at harvest of TDr 96/01168 (77.67), TDr 96/01799 (79.33)and TDr 98/01164 (77.67) (Table 3). The five varieties were not significantly different in number of seed and ware tubers/plot and yield of ware tubers/plot. Number of seed tubers/plot however ranged between 22.00 and 30.33, while number of ware tubers/plot and yield of ware tubers/plot also ranged between 9.00 and 14.33, and 15.67 and 25.67, respectively (Table 3). The observed lack of variation among the five rotundata varieties for the three yield components could be as a result of the fact that all the five varieties must have been developed for high yield Breeding for high yield through improving yield components is a primary objective of yam breeders. As for total fresh tuber yield (kg/plot), only TDr 96/01799 with yield of 25.07 kg/plot had significantly lower yield compared to others. The yield of the remaining four varieties ranged between 26.43 and 34.70 kg/plot. The variation in percentage emergence shows that there is great variation in rate of sprouting among cultivars and consequently their potentials differ for seed yam production. This disparity observed agreed with Bridge (1972). The characteristic multiple galls observed in this study agrees with work of Nwauzor and Fawole (1982) who estimated the possibility of 100% crop loss resulting from M. incognita infestation in field situations. In study by Sasser (1977) to evaluate seven varieties of hybrid yams, varietal differences were observed in tuber yields and susceptibility to the root–knot nematode (Meloidogyne spp). In a similar experiment on screening of new yam clones (D. alata and D. rotundata) in nematode prone ecology, significant higher values were observed for meloidogyne spp occurrence on the tubers of D. rotundata than D. alata in every year of experimentation. Meanwhile, no significant difference was observed for the occurrence of S. bradys in both groups of yam.

CONCLUSION

Result of this trial shows that more yam varieties especially D. rotundata are joining the class of "nematode susceptible". It is therefore necessary to speed up research in control strategies or management to guard against yield and quality loss.

ABSTRACT
A study to assess the performance of S_1 progenies of five African cassava varieties (TMS 30572, TME 419, TMS 98/0505, TMS 01/1371 and TMS 98/0002) for agronomic traits was conducted in seedling evaluation and clonal evaluation trial stages. The average ID obtained in both stages indicated that harvest index, dry matter content and vigour were not severely affected in performance. The average trait value for plant height in the S_1 was not reduced implying no inbreeding depression for this trait. The effects of ID were highest in fresh root yield and fresh foliage yield which are relatively much more complex traits than others. Reduced heterozygosity associated with selfing (S_1) appeared to have strong effects on both traits thus underscoring the relative importance of non-additive genetic effects in their inheritance. For each trait, results identified individual S_1 genotypes that substantially outperformed the non-inbred parents likely representing transgressive segregants for favorable allele combinations. This was observed mainly for plant height, dry matter content and vigour where ID values were lower. These genotypes were therefore used further to generate an S_2 population.
Keywords: Inbreeding depression, conal stages, selfed cassava, traits

INTRODUCTION
Cassava (Manihot esculenta Crantz) is among the most important sources of energy in the diet of most tropical countries of the world. It is also becoming an important source of raw material for different industries. Therefore, it is vital to develop information about the genetic structure and the inheritance of relevant traits. Inbreeding is the reproduction from the mating of two genetically related parents, which can increase the chances of offspring being affected by recessive or deleterious traits. This generally leads to a decreased fitness of a population, which is called inbreeding depression. Cassava, as a typical cross-pollinated species, shows severe inbreeding depression (Rojas et al., 2009). Nonetheless, it is encouraging to observe that interest in cassava inbreeding is beginning to gain momentum (Ceballos et al., 2004, 2007; Rojas et al., 2009). Certainly, it would be prudent in cassava to tap into the benefits of inbreeding as witnessed in maize. Inbreeding provides an opportunity to exploit both additive and non-additive effects (Rojas et al., 2009). It is envisaged that inbreeding in cassava will provide several advantages including: reduction of genetic load which limits attainment of sustainable genetic progress, increased probability of increasing the expression of useful recessive traits, facilitation of the implementation of mutation breeding and allows implementation of backcross scheme (Ceballos et al., 2004). We report results obtained from quantifying inbreeding depression in cassava.

MATERIALS AND METHODS
Seed production
Five of the African cassava varieties (TMS 30572, TME 419, TMS 98/0505, TMS 01/1371 and TMS 98/0002) were obtained from the germplasm of International Institute of Tropical Agriculture, (IITA) Ibadan. These five african cassava varieties were used as progenitors (S_o) to generate S_1 progenies

Establishment of the seedling evaluation trial
After two months in the nursery, S_1 seedlings were transplanted to a well-prepared field where they were grown and evaluated. Harvesting was done at 12 months after planting, after which they were cloned to generate at least 10 stem cuttings per seedling for clonal evaluation trial.

Establishment of the clonal evaluation trial
In the clonal evaluation trial, each S_1 genotype was represented by ten plants, which were established in the field for evaluation. All progeny belonging to the same family, together with the parents, were established in the same block. Each row represented a clone and spacing within rows was 1 m, with between row spacing of 1.5 m to minimise inter-plot interference. The parental clones served as checks or controls. Evaluation was conducted in a single location, using augmented experimental design (AED) Federer (1956).

Data collections
During the growth period, the plants were evaluated for vigour at 1, 3, 6, 9 and 12 Months After Planting (MAP). Vigour was scored based on the scale of 1-5; where 1= very weak (plants somewhat stunted with very thin stems), 2= weak (thin stem), 3= intermediate (moderately growing), 4 = vigorous (fast growing and no bending), 5= extra vigourous (very fast growing, strong and no bending) (IITA, 1990).

At harvest (12 months after planting), plant height (cm) was measured from the soil level to the highest apical point of the plant at harvest time; eight innermost plants per clone were uprooted and used for phenotypic assessments. Roots were separated from the vegetative harvestable biomass (leaves, stems and original planting stake) and independently weighed with a weighing balance. Fresh root yield and fresh foliage yield (kg $plant^{-1}$) were computed. Harvest index (root biomass as proportion of total biomass) was computed for each clone following the procedure outlined by Kawano (1990). Estimation of Dry Matter Content (DMC) (measured as a percentage) in the root samples, were determined by the specific gravity method as suggested by Kawano et al., (1987).

$$Specific\ gravity = \frac{Weight\ in\ air}{Weight\ in\ air - Weight\ in\ water}$$

$$DMC = 158.3\ specific\ gravity - 142.0 \text{ (IITA, 1990)}$$

Inbreeding depression (ID) was estimated for plant height, vigour, fresh root yield, fresh foliage yield, harvest index and dry matter content as a percentage of the S_1 average. The ID was obtained following the equation suggested by (Rojas et al., 2009)

$$ID = \frac{S_0\ mean - S_1\ mean}{S_0\ mean} \times 100$$

Inbreeding depression was also measured at the family level. Therefore, the lower the ID value, the lower the depression, which implies that the performance of the S_1 progenies is close to that of the S_0 progenitor.

RESULTS AND DISCUSSION

Phenotypic measurements for key breeding traits were made at the seedling and clonal evaluation trial stages. Results of phenotypic assessment of the families revealed some superior S_1 clones which were found to substantially outperform their S_0 progenitors. This was particularly observed for the following traits: plant height, dry matter content (DMC) and vigour. The result indicates that breeders can explore inbreeding for these traits at early stages of the selfing cycle in the breeding scheme. By implication it shows that genetic progress can be achieved through inbreeding for these traits. The results demonstrated that inbreeding can be strategically explored in breeding to increase genetic gain and identify recessive traits.

Considerable variations in ID were observed among S_1 progenies for morphological/ architectural traits with highest ID ranging from 0.56% in plant height to 46.47% for vigor. Agronomic traits result revealed high ID with for fresh root yield being the highest (53.05%) (Table 1). ID observed for other agronomic traits were 38% for fresh foliage yield and 22% for harvest index (Table 1). The effects of ID tended to be relatively higher for the much more complex traits given their polygenic character. Reduced heterozygousity associated with selfing (S_1) appeared to have strong effects on fresh root yield and foliage yield thus underscoring the relative importance of non-additive genetic effects in their inheritance. Some transgressive segregants were observed in the population at S_1. This was observed mainly for plant height, dry matter content and vigour where ID values were lower.

Generally, inbreeding depression was higher in seedling nursery compared to the clonal evaluation trial (CET) stage for fresh root yield, fresh foliage yield, harvest index and dry matter content. In the seedling stage, cassava is raised from seeds while stem cuttings were used as planting materials at the CET. Seeds typically produce plants with fewer and smaller tubers than those raised from the stem cuttings (clonal stage) (Department of Agriculture, Forestry and Fisheries, 2010) (Table 1).

CONCLUSION

Inbreeding was not severe in the S_1 for morphological and architectural traits. The occurrence of some transgressive segregants in the population for key strategic traits of the crop is indicative of favorable allele combinations at S_1. The results therefore demonstrate that inbreeding can be strategically explored in breeding for these traits to increase genetic gain and possibly identify recessive traits. Inbreeding depression for plant height in this study was much lower than for fresh root yield. For cassava, fresh root yield involve many genes, it is the result of the activity of the whole genome while plant height is a characteristic controlled by fewer genes.

Table 1: Inbreeding Depression values (ID), as a percentage of the performance from the S_0 generation measured in five S_1 Cassava Families based on the yield data from two stages

ABSTRACT

Field experiment was conducted at the Teaching and Research Farm of Adamawa State College of Agriculture Ganye, to evaluate the growth and yield performance of sweet corn under different weeding regimes during the 2012 and 2013 raining seasons. The weeding regime consisted of one weeding at 3 weeks after sowing (WAS) only, two weedings at 3 and 6 WAS, three weedings at 3, 6 and 9 WAS and unweeded check as control. The experiment was fitted in a randomized complete block design (RCBD) and replicated four times. Results indicated that weed dry weight, plant height, leaf area and number of leaves per plant were not significantly influenced at sampling period of 3 WAS in both seasons. At 6 and 9 WAS however, increased weeding regime from control significantly reduced weed dry weight and increased plant height, leaf area and number of leaves per plant in both seasons. Similarly, number of days to 50% tasseling and silking reduced significantly with increased weeding regime in both years, but increased number of grains per cob and 1000-grain weight in both seasons and the combined analysis. Increasing weeding regime to three in 2012 season significantly increased grain yield of 1562kgha^{-1}. In the 2013 season and the combined analyses however, two weedings at 3 and 6 WAS produced grain yield of 1439.0kgha^{-1} in 2013 and 1464.0kgha^{-1} in the combined analysis respectively, which out-yielded other treatments except three weeding regime and could therefore be the recommended weeding regime from this study.

Keywords: weeding regime, growth, yield, sweet corn, Ganye.

INTRODUCTION

Maize (*Zea Mays L.*), also known as corn belongs to Poaceae family and ranks third after wheat and rice in world production and popularity (Dugje et al, 2010). Maize production is also generally gaining popularity in Nigeria as its cultivation transforms from mere subsistence to commercial. However, sweet corn (spp. saccharata) is mostly produced for fresh consumption with its sweet, tender and immature pericarp (Hardenbug et al., 1986).

Weeds by their nature are plants, naturally adapted to certain local environment which tends to interfere with crop performances through competition for space, nutrient, water and light in order to thrive at the expenses of our defined edible crops (Zeenshan, 2003). It has been reported that small, slow growing plants (seedlings) are more likely to suffer from weed interference than the larger and more vigorous ones, thus early weed-crop competition tend to have more adverse effect on crop growth and yield (Akobundu, 1987). Lambart and Anaso (1980) also reported that weed infestation reduce maize nutrient quality by about 63-84%.

Although the consequences of weed-crop field competition has always been reported and documented, the approach that integrates weed frequency and critical stage of crop development together to achieve optimum crop performance is still poorly understood in most weeding schedule, thus the need to undertake this experiment.

MATERIALS AND METHODS

The experiment was conducted during 2012 and 2013 rainy seasons at the Teaching and Research Farm of the Department of Agricultural Technology, Adamawa State College of Agriculture, Ganye. This study area forms part of northern Guinea Savanna agro ecological zone in Nigeria, with soil textural classes of clay-loam in both seasons and total annual rainfall of 877.3 mm and 1363.3 mm during 2012 and 2013 cropping seasons respectively.

The treatments consisted of four weeding regimes (3 WAS, 3 and 6 WAS, 3, 6 and 9 WAS and unweeded check), arranged in a randomized compete block design (RCBD) and replicated four times. Two to three seeds from locally sourced variety of sweet corn ("Bataji") were hand-sown on 2nd and 4th June, 2012 and 2013 rainy seasons respectively at the spacing of 75cm x 25cm on well prepared seed beds measuring 4.0x4.0m each over-seeded holes were later thinned to two per hole at first weeding.

Data on weed dry weight, plant height, leaf of area and number of leaves per plant respectively were taken at 3, 6 and 9 WAS before weeding schedules, and days to 50% tasseling and silking were taken when 50% of plant population in each plot attained tasseling and silking. However, number of grains per cob, 1000-grain weight and grain yield per hectare were evaluated at harvest. Data was subjected to statistical analysis of variance (ANOVA) to determine the level of significance between treatment means as described by Little and Hills

(1978), and the difference between treatment means were evaluated using Duncan's multiple Range Test Duncan, 1955).

RESULTS AND DISCUSSION

Results from the experiment generally indicated that weed dry weight, plant height, leaf of area and number of leaves per plant were not all significantly influenced at 3 WAS in both seasons. From Table 1 however, weed dry weight was higher at unweeded check (control), which reduced significantly with increased weeding regime from control experiment in both seasons, as plant heights increased with increasing weeding regimes at 6 and 9 WAS in both years.

Table 2 indicated similar increase in leaf area and number of leaves per plant respectively, as weeding regime increased to three (3, 6 and 9 WAS). However, difference in number of leaves per plant among all weeding regimes were not statistically significant in both seasons except at 9 WAS in 2012 season. Similarly difference in leaf area per plant among second weeding (3 and 6 WAS) and third weeding were not significant during the sampling of 6 WAS in 2012 season.

Table 3 however, indicated significant reduction in number of days to 50% tasseling and silking as weeding regime increased in both seasons. In days to 50% silking, all weeding regime except the unweeded check (control) recorded statistically similar reduction in both seasons. Number of grains per cob however increased as weeding regime increased to two, after which there was no significant increased in both seasons and the combined analysis (Table 3).

Results from Table 4 also indicated that at three weeding regime of 3, 6 and 9 WAS, 1000-grain weight was highest and out-weighed other weeding regimes and control experiment in 2012. Same trend was observed in the combined analysis. Similarly, three weeding regime treatment produced statistically higher yield per hectare which out-yielded all other treatments and control experiments in 2012 season. In 2013 season and combined analyses however, two weeding regime 3 and 6 WAS produced statistically similarly grain yield per hectare with three weeding regime of 3, 6 and 9 WAS, which out-yielded one weeding regime at 3 WAS only and the unweeded check.

However, improved performance of growth parameters at later sampling periods of 6 and 9 WAS was due to increased weed-free condition which conserved more soil moisture, nutrients and oxygen for crop use and increased photosynthesis ability. Similarly, increased performance of yield and yield parameters and early 50% tasseling and silking were all attributed to reduced weed interference (Zeenshan, 2003), through increased weeding schedule.

It is also more likely that the most critical phase for growth and physiological development that will improve yield performance in maize coincided with weed free condition, provided by two weeding scheduled at 3 and 6 WAS only in this experiment. Thus 1000-grain weight, number of seeds per cob and grain yield per hectare improved significantly as reported by Mahdi et al, (2010) and Mustapha and Bayo (2010).

CONCLUSION

Weeding regime has significant influence on many important agronomic attributes of sweet maize. While increasing weeding regime significantly reduced weed dry weight, 2-3 weeding regimes significantly increased grain yield. Weeding sweet maize field 2- times will be a good recommended practice for sweet maize production provided labour cost is low.

EFFECT OF COLCHICINES ON FLOWERING, FRUITING AND BOTANICAL SEED PRODUCTION IN CASSAVA

N.J. Amanze & O.N. Eke-Okoro

National Root Crops Research Institute Umudike P.M.B. 7006 Abia State, Nigeria.
amanzengozi@gmail.com

ABSTRACT
Five high yielding cassava varieties with good agronomic and disease resistance characters were induced to improve their productivity using colchicine. The experimental materials were evaluated under both green house and field situations in a randomized complete block design replicated three times. Data collected were statistically analyzed. The results from the field showed that cassava varieties treated with colchicines at Level 4 significantly affected most of the physiological characters such as the leaf area index, number of seeds and the girth. While Level 2 of the treatment gave the highest number of leaves, other parameters were not significantly affected. Cassava mosaic disease the most common and yielding reducing disease was not affected by the treatment

Keyword: induction, mutagen, potentials, botanical seeds

INTRODUCTION
Cassava has a great potential of becoming a sustainable food, industrial and a renewable sources of energy crop in SSA Scott et al (2000) and Cock 1985. Most of these potential are locked up and remained untapped as a result of irregular, low flowering and low seed production habit, common in root and tuber crops. Large population size of botanical seeds is required to increase the variables in cassava to harness the great potentials or development the key traits of impotence Olusami et al., (2014). To be able to generate wide range of variables for diverse uses and usefulness in cassava, there is need to overcome the bottle neck of conventional breeding and create room for the development of those traits that naturally do not exist or have been lost through genetic erosion Ceballo (2004), Kasky (2013). Some researchers have used growth hormones such as gibbrellic acid and colchicine to induce flowering in Dioscoerea and aroids Amanze et al., (2010) and Mbanaso et al., 2006) For this reason an initiatives was undertaken to investigate the use of the hormone colchine to manipulate the morphology, flowering and seed production of cassava to develop large population size of botanical seeds as to create large gene diversities needed for diverse purposes.

MATERIAL AND METHODOLOGY
The experiment was conducted in May during the 2013 growing season at National Root Crops Research Institute (NRCRI), Umudike research farm, which lies within the humid rainforest agro-ecology of Nigeria (Njoku et al., 2015). Five high yielding cassava varieties with good agronomic and disease resistance characters: TMS98/0505, TMS94/4479, TMS98/1632, TMS92/0057, TMS98/0581 were treated with manipulating hormone-"colchicines" at two levels: 2%, 4% and0% as control at 100/50cl ppm (parts per million) and established in the field to maturity. Twenty pieces of stem cuttings of about 25cm each of the cassava varieties were cut from the mature plants raised from the treated materials and planted in a well harrowed and ridged field in a 4x5 randomized block design, at a spacing of 1m x1m intra and inter-row replicated three times. Post and pre- mergence herbicides were applied immediately after planting and all the other agronomic practices were applied. Data were collected on the physiological parameters such as: number of leaves, number of branches, plant height and girth, number of plants flowered and no of seed produced, weight and tuber yield.

RESULTS AND DISCUSSION
Table 1 Shows that the concentration of hormone affected the physiological parameters of the cassava varieties treated. Level 4 of the treatment significantly affected the leaf area index, number of seeds and the stem girth. While Level 2 of the treatment gave the highest number of leaves, other parameters were not significantly affected. This result is in agreement with Hahn et al., 1991.It also simply implies that the hormone really induced seed production components well as seed yield.

Table 2 shows that concentration of hormone applied did not significantly affect the cassava mosaic disease of the parent materials. This is a positive result showing that the hormone does not have adverse effect on the materials. However it increased CBB and CAD at ($P<0.05$) but they are not serious cassava disease.

Table 3 shows the effect of variety on the seed yield components and yield of botanical seed. LAI, No of leaves and no of branches produced are significantly effect by varieties. Variety 47791 and 1632 had higher leaf area than the other varieties. Variety 4779 also had the highest number of leaves, followed by variety 0581, but 0505 had the highest number of branches, number of seeds and heaver seed weight than the other varieties, in contrast to positive correction of high root yield with high photosynthetic area as reported by Okeke (1981) and others. This result is in conformity with the ability of cassava cultivars to flower and set seed is variety specific but has been reduced (Jennings, 1962).While the application of mutagens will trigger and enhance it.

CONCLUSION

Though variety is a key factor in flowering and seed production, application of colchicine mutagen enhanced yield component of cassava, enhance seed production of flowering and triggered seed production in dormant ones.

ismailaabubakar44@gmail.com

ABSTRACT
Thirteen sesame genotypes were evaluated under rain fed conditions in 2013 and 2014 at the research fields of the National Cereals Research Institute located at Badeggi, Mokwa and Yandev stations to identify high yielding and stable genotypes. Randomized complete block designs with three replications were used in each location. Results obtained suggest that high yielding genotypes were less stable across all the environments Highly insensitive (stable) genotype GEN10 and GEN8 gave the lowest grain yield compared to GEN1, GEN4 and GEN12 that had higher grain yield but highly sensitive to the environment (less stable). The partitioning of GGE through GGE biplot analysis showed that PCA 1 and PCA 2 accounted for 86.0% and 7.3% of GGE sum of squares respectively for grain yield, explaining a total of 93.3% variation. The GGE biplot revealed the best genotypes under different environments and accurately identified genotype G1 as the best genotype with respect to site E1, E2, E4, and E5 while genotype G4 was revealed as the best for site E3 and E6. Genotype G1 gave the highest average yield (largest PCA 1 scores), but was unstable over the environments.
Keywords: G x E, Sesame, grain yield, stability,

INTRODUCTION

Sesame (Sesamum indicum L.), a member of the order Tubiflorae, family Pedaliaceae is perhaps the oldest oil seed known and used by human beings (Weiss, 1983). It is an important annual crop in the tropics and warm subtropics, where it is usually grown in small plots (Bedigian and Harlan, 1986). Sesame is an erect herbaceous annual plant that has two growth characteristics indeterminate and determinate, with the plant height of up to two meters. Most varieties show an indeterminate growth habit, which is showing as a continuous production of new leaves, flowers and capsules as long as the environment remains suitable for growth (Carlson et al.2008). The crop originated from tropical Africa and was taken at an early stage to India where it was domesticated and became a crop of the New World (Ashri, 1995). The crop is grown in both tropical and sub-tropical regions of Africa, Asia and Latin America. In Nigeria, sesame crop is widely cultivated in northern and central Nigeria between latitudes 7 – 14°N and an annual rainfall of about 1000 – 1500 mm (Iwo, et al., 2005). It is cultivated mainly for its seeds that contain approximately 50% oil and 25% protein. It has been regarded as a crop of insignificant importance compared to other oil seed crops like groundnut and soybeans probably due to its lower yield in Nigeria.

Breeding programmes are intended to develop new varieties with superior agronomic performance compared to those in current production by farmers. Prior to release of the new varieties, they are evaluated in yield trials at several locations for two or more seasons in multi-environmental trials (METs). The varietal trials provide important information that enables identification and recommendation of superior crop cultivars for commercial purposes, (Yan and Tinker, 2006). Assessing any genotype performance without including its interaction with the environment is incomplete and limits the accuracy of measured parameter estimates. Studies of the causal factors of the Genotype x Environment (G x E) effect and quantifying unexplained variation are of prime importance for selection and recommendation of environmentally stable varieties [Signor et al., 2001]. A significant G x E interaction for a quantitative trial such as grain yield can seriously limit progress in selection. The study of the G x E interaction may assist understanding of stability concept. Therefore, the objective of this study is to determine the yield stability of promising genotypes, and identify high yielding genotypes.

MATERIALS AND METHOD

Thirteen sesame genotypes were evaluated under rain fed conditions in 2013 and 2014 at the research fields of the National Cereals Research Institute located at Badeggi, Mokwa and Yandev stations. Field were plough, harrowed and row marked out into 13 plots each measuring 3 m x 5 m in a randomized complete block design (RCBD) with three replications in each location. Sowing of sesame seeds were done by hand-drilling after mixing with soil from the field site to ensure even distribution of the seeds within the plot. Each genotype was sowed in a seven-row of 0.5 m inter row spacing, five plants were tagged in the middle rows and data were collected from the five middle rows to avoid border effect. Recommended crop management practices were followed to raise the crop at all sites. Plots were kept weed, pest and disease free until harvest. Grain yield data were recorded.

RESULTS AND DISCUSSION

Table 1, shows genotypes sensitivity to environments using Finlay and Wilkinson regression analysis (1963) which revealed a high positive linear relationship between the regression coefficient and the average yield of the genotypes, indicating that high yielding genotypes were less stable across all the environments' highly insensitive (stable) genotype GEN10 and GEN8 gave the lowest grain yield compared to GEN1, GEN4 and GEN12 that had higher grain yield but highly sensitive to the environment (less stable). GEN1 recorded the highest mean grain yield of 811.1kg/ha, followed by GEN4 with 786.6 kg/ha while GEN10 recorded the lowest value of 310.4 kg/ha. High variability observed among genotypes as indicated by the range of their mean performance, indicated the presence of sufficient genetic variability for grain yield, with GEN1 having the highest grain yield across the locations while GEN10 recorded the least yield. This result was inconformity with the results reported by Osman, et al. (1974), Parameshwarappa, et al. (2009).

The analysis of stability and Superiority were performed for grain yield based on the Finlay and Wilkinson (1963) stability Model Table 2. Stability of the genotypes on grain yield across the six environments revealed that GEN8 gave a stable yield across locations (Static stability) followed by GEN10 and all other genotypes were less stable across environment (dynamic stability) Genotype GEN1 gave the lowest stability value. This result is in conformity with the finding of Vijendra (2007) that stability evaluated by static concept, is associated with poor yield. He further reveals that a stable genotype is supposed to possess unchanging performance regardless of any variation in the environmental condition. The superiority values of genotypes on grain yield showed that GEN4 and GEN1 had the superiority value of 3848 and 6398 respectively and are more superior in contrast to G8 and G10 that recorded the highest superiority values of 162743 and 165674 respectively having the least mean grain yield. Lin and Binns (1994) proposed a model called superiority analysis, and made known that highest yielding genotypes can be compared with the other entries in a location by using a superiority statistic called **Pi,** that the smaller the Pi value of a cultivar the better adapted. However since Pi is to be measured over all locations it represents superiority in respect of general adaptability and therefore a cultivar that has a large Pi value (poor in general adaptability) may be good in a specific region.

The partitioning of GGE through GGE biplot analysis showed that PCA 1 and PCA 2 accounted for 86.0% and 7.3% of GGE sum of squares respectively for grain yield, explaining a total of 93.3% variation as shown in Figure 1. The GGE biplot revealed the best genotypes under different environments and accurately identified genotype G1 as the best genotype with respect to site E1, E2, E4, and E5 while genotype G4 was revealed as the best for site E3 and E6. Genotype G1 gave the highest average yield (largest PCA 1 scores), but was unstable over the environments, due to its high absolute PCA 2 scores. In contrast, G8 yielded poorly in all environments, as indicated by its small PCA 1 scores (low yielding) and relatively small PCA 2 scores (relatively stable).

The partitioning of GGE through GGE biplot analysis showed that PCA 1 and PCA 2 accounted for 86.0% and 7.3% of GGE sum of squares respectively for grain yield, explaining a total of 93.3% variation as shown in Figure 1. The GGE biplot revealed the best genotypes under different environments and accurately identified genotype G1 as the best genotype with respect to site E1, E2, E4, and E5 while genotype G4 was revealed as the best for site E3 and E6. Genotype G1 gave the highest average yield (largest PCA 1 scores), but was unstable over the environments, due to its high absolute PCA 2 scores. In contrast, G8 yielded poorly in all environments, as indicated by its small PCA 1 scores (low yielding) and relatively small PCA 2 scores (relatively stable). Generally, genotypes show wide fluctuations in their yielding abilities when grown over varied environments or agro-climatic zones (Fan et al., 2007). Based on GGE biplot analysis, in assessing an 'ideal' environment and genotypes, a polygon is first drawn on genotypes that are located away from the biplot origin so that all other genotypes are contained in the polygon. Perpendicular lines are then drawn, starting from the biplot origin, to each side of the polygon (Figure 1). These perpendicular lines divide the biplot into sectors, and the wining genotype for each sector is the one located on the respective vertex. This revealed that GEN1 was the winning genotype in E2, E1, E4, E5 and GEN4 in E6 and E3 were the winners in the rest of the environments. This indicates that sesame genotypes responded to G × E interaction over the environments differently and to varying seasons. The GGE biplot enabled visual comparison of the locations and genotypes studied and their inter-relationship.

CONCLUSION

G X E interactions is significant to plant breeders in the identification and selection of promising genotypes that perform better in terms of yield potential to specific environmental situations or specific locations. The stability analysis provides meaningful information regarding stability and consistency of sesame performance across different environments.

ABSTRACT
Human welfare, health and safety are the principal component of sustainability as the social and economic welfare of farm workers and their community greatly depends upon it. Organic farming is a system of employing agricultural practices that avoid the use of synthetic chemicals in favour of naturally occurring fertilizers and pesticides. It involves a number of activities ranging from acquisition of suitable land, land preparation, right varieties of seeds, pre-planting and post planting operations. The adoption of organic farming increases soil fertility, balance insect populations and at the same time reduce environmental pollution of air, soil and water. The world agriculture is faced with three challenges of improve food security, rural livelihood income and the protection of natural resources. Organic horticultural food crops produced through practices that achieve an optimal balance between economic, social and environmental goals were reviewed. They provide adequate household income, food security and safety to producers while the farmers must adhere to safe working procedures with acceptable working inputs.
Keywords: Organic foods, horticulture, crop production, health

INTRODUCTION

Agricultural productions involve a number of activities which include among others, acquisition of suitable lands for each crops, tilling, use of right varieties of seeds, spectrum of other agronomic practices such as weeding, pest control & management, fertilizer applications, storage and marketing down to the final consumers. These processes are applicable to both crops and livestock with the aim of achieving an effective food security system in the society (Okunade, 2014). Until recently, increase food production had generally been achieved by extending crop land, but population pressure increased competition between crop and livestock farming and declining soil fertility, thus forcing farmers to ramp up investments in pesticides. For food crop production to succeed, certain inputs must be put in place such as fertilizers, (to increase output) pesticides (to control various forms of pests and pathogens) and good agronomical practices. The inputs are obtained from two major sources namely the living matters and the non- living matters otherwise referred to as organic and inorganic materials. The inorganic materials (synthetic) which has been adjudged to be very good and effective has been subjected to abuse by most illiterate poor resource farmers in Nigeria and other developing countries of the world occasioned by the dramatic results achieved in food production. And this has results into loss of life which had given room for total ban or severely restricted use in most countries of the world.

Nigeria is rated as one of the leading producers of tropical horticultural fruits and vegetables in the world, but it is not a major horticultural fresh produce exporting country due largely to poor quality produce, codes and procedures to eliminate fruits that can lead to food borne illnesses resulting from crop contaminated with pathogenic microorganisms, chemical poisons arising from poor handling practices at various stages of production.

It is against this background that organic food production with safe, cheaper, readily available , effective and short life span of degradable and easy to apply inputs are suggested in our farming systems.

Objectives

This work is set out to:

1. review the concept of Good Agricultural Practices (GAP) that has evolved in the context of a rapidly expanding food economy based on food production & security, food safety and quality,
2. raise awareness and upgrade the technical knowledge of fresh horticultural produce and enlighten farmers on the growing concern driven by spread of microbiological hazards and chemical food Contaminants,
3. ensure production of high quality fresh horticulture products for local and international market with the goal of improving rural living standards, increase income and minimize health risks from farm to fork as well as sustainable food safety.

METHODOLOGY

The work is a general review of the state of technical knowledge of fresh horticultural produce and strategy set out in the process for organic food safety and quality, voluntary standards on organic agriculture and sustainability assessment scheme. From the production perspective, farmers inherently apply practices that aim to achieve economic viability while conserving their own natural resource base and maintaining their cultural values. On the demand perspective, consumers can have concern both about the safety and quality of the agricultural products and also the process – including good agricultural practices that are used to produce them. Because GAP is currently being driven by demand – side sectors, with a number of possible implications that must be address for further development and application of GAP approach.

DISCUSSION

The concept of good agricultural practices (GAP)

Since the 1990s, due to frequent outbreaks of animal and plant epidemic diseases and Genetically Modified (GMO) products abuse, the European countries have formulated various agricultural safety management standards to prevent the safety threats of agricultural products. In 1997, the Euro-Retailer Produce Working Group began drafting Good Agricultural Practice (EUREPGAP) which composed of Hazard Analysis and Critical Control Point (HACCP) and Good Agricultural Practices (GAP) specifying the safety management regulations for all aspects in agricultural cultivation, processing and retail supply chain.

With the globalization of economy and product purchasing, a growing number of countries over the world have adopted EUREPGAP by equation or by equivalent, to specify the safety management of domestic agricultural cultivation, processing, marketing and export. EUREPGAP changed its name to GLOBALG.A.P.at the end of 2007 in accordance with its implementation (FAO, GAP WEBSITE).

Broadly defined, a GAP approach aims at applying available knowledge to addressing environmental, economic and social sustainability dimensions for on-farm production and post-production processes, resulting in safe and quality food and non-food agricultural products. Based on generic sustainability principles, it aims at supporting locally developed optimal practices for a given production system based on a desired outcome, taking into account market demands and farmers constraints and incentives to apply practices (FAO, 2003).

World agriculture in the twenty-first century is faced with three main challenges: 1) to improve food security, rural livelihoods and income; 2) to satisfy the increasing and diversified demands for safe food and other products; and, 3) to conserve and protect natural resources, an approach that improves environmental, economic and social sustainability of on-farm production and results in safe and quality food and non-food agricultural products. A GAP approach can contribute concretely to implementing sustainable agriculture and rural development while addressing the demand-side priorities of consumers and retailers, the supply-side priorities of producers and labourers, and those institutions and services that are bridging supply and demand. The development of a GAP approach by FAO emerges against an expanding backdrop of codes, standards and schemes relating to agricultural practices and products. It is also formally recognized in international regulatory framework and associated codes of practice to minimize or prevent the contamination of foods.

Awareness and upgrade of the technical knowledge of organic fresh horticultural produce

In the production of organic horticultural food crops, a number of activities are involved ranging from the acquisition of suitable land, land preparation, right varieties of seeds, pre-planting and post planting operations. Organic farming which is a system of employing agricultural practices that avoid the use of synthetic chemicals in favour of naturally occurring fertilizers and pesticides is adopted for increased soil fertility, balance insect populations and also reduced environmental pollution. The organic farming approach is the systematic sustainable agriculture where by manure from animals are used to fertilize horticulture farms that will in turn serve as sources of animal feeds.

The concern in organic farming was passed into law in some countries like America, where it is known as National Organic Program (NOP) with the essential component of the prohibition on Genetically Modified Organisms (ingredient) and irradiation to decontaminated food products, the prohibition of sewage sludge as fertilizers in the production of horticultural food crops that will be marketed. Among other things, organic products in USA must contain at least 95% organic ingredients while those products with minimum of 75% organic ingredients are referred to as 'made with organic ingredients' (Okunade, 2014).

The application of fertilizer in organic farming is absolutely necessary since it is the addition of substances used for enriching soil in order to promote plant growth. Organic fertilizers are therefore obtained from plants, animals, mineral products and also from processed house waste. The use of manure and guano (dried excrement usually of sea birds, and animals) containing nitrogen are some examples of organic fertilizers used in some horticultural food crop production. Others are bones, wood ash, and leguminous crops. Advantages of the use of organic fertilizers in horticulture crops are; enhances the life span, slowly absorbed by the crops but over a long time for lasting action and also improves soil texture and erosion prevention. Other merits of organic fertilizers are that they are readily available and cheap with no adverse effect on non-target organisms. In the production

of organic horticultural food crops, single organic fertilizer could contain the entire nutrient required for a growth cycle of the crops.
The need to embark on the use of organic pesticides in horticultural food crops arises due to the perceived problems possessed by synthetic pesticides in the developing nations of the world, such as being very costly, application abuse and misuse, high mammalian toxicity, development of resistance, residual effects and drift to non- targeted areas.

Production of High Quality Fresh Horticulture Products (organic) for Improving Rural Living Standards, Increase Income and Minimize Health Risks
Organic horticultural food crops are highly nutritious, free from Genetically Modified Organisms (GMO) and are free from the dangers of withholding period (time between pesticides application and when consumption ought to take place).The selection of suitable varieties before land clearing and preparation will minimize the attraction of pest and weed infestations, while ensuring that all rodent holes are completely blocked with stone and trashes around the farm areas. In the production of high quality fresh horticulture products (organic), adequate supply of water on the crop land should be advocated since little water may cause plant stress, loss of plant vigour that could attract pests on the farm. Adequate soil nutrient encourages plant ability in fighting pest invasion and timely harvest of matured / ripped produce will increase food availability.
In an area that is endemic to pests' infestation, the use of crop rotation and resistance varieties followed by intercropping practicing with a view to interrupt the movement of disease causing organisms within the farm site. This is visible by establishing trap crops (plants that are more attractive to a particular pest than the target crop) and plant attractant (plants that serve as feed or shelter to beneficial insects. This is recommended since many insects and fungi feed on one type of crop and also the planting of crops that beneficial insects like ladybugs and lacewings. These insects will naturally feed on other insects that could be harmful to the crop.
Good Agricultural Practices are used to prevent pest and disease problems as they encourage good health and crop resistance to pests. This is achievable by growing crops in appropriate climate, in appropriate season and constant good sanitation in production. The very moment pest and disease incidence tends towards Economic Injury Level (EIL) of 5% damage, intervention measures such as the utilization of other living organisms predators, parasitoids or pathogens of the pest to control pest population. This is done by either direct introduction of the organisms into the ecosystem or indirectly by altering conditions in the affected areas and it is very effective because the development of resistance by pest is rare. Cultural intervention is achieved by making crop environment unsuitable for pests to the extent of avoidance or displacing the crop plant in time or space thus making it not available for pests during the period of need.
The tropical horticultural crop sector in addition to providing nutrient for health could be a new source of generating income, employment, and savings on foreign exchange. Therefore, every effort towards efficiency of production, stemming post-harvest losses and use of organic materials with enhancement of extension services delivery will position organic food crop production in the right directions of high nutrition and good health. Nigeria's tropical climate can support the production of various types of indigenous, exotic and tropical crops, but land and access road constraints with high cost of improved planting materials as well as lack of skilled manpower in harnessing the potentials of our food crops are impediments.
Nikki, (2012) reported that horticultural food crops boast a long list of healing powers and pack powerful nutritional punch for a relatively low calorie, and are also packed with substances that help in fighting inflammation and cancer. This report had shown that most horticultural food crops inhibit the growth of tumors and even cause cancer cells to die without damaging healthy cells. As a result of the unique blend of phyto-nutrients, vitamins and minerals found in horticultural crops, they help to protect against heart diseases, stroke, cancer and respiratory diseases. Most ailments caused by the intake of un-natural foods can be successfully treated with some horticultural fruits, vegetables and spices and as such not only a good food but also good medicine. Natural health benefits of organic products of horticultural crops ranges from hydrating effects to alkalizing mineralizing, laxative and tonic actions (Dazzle, 2012).

CONCLUSION
The adoption of Global Good Agricultural Practices (GAP) and management of organic farm products in horticultural food crops is of immense importance in areas of food safety, cost effectiveness and improved nutrition. Organic food products and production is a new area that is gradually being recognized world – wide and should be actively considered by both private and public organization for better awareness. It remains a major step towards the attainment of food security in the developed, developing and under – developed countries of the world.

ABSTRACT
A baseline survey was carryout to assess the experience in years of sorghum production, cropping system, hectarages cultivated and identifying most important weed species infesting sorghum in Taraba state. The study aimed at gathering information on the production status of sorghum in the state. A questionnaire was administered to 300 farmers in their local language spread across 5 wards each from 5 Local Government Area (LGA) (Wukari, Takum, Donga, Ussa and Ibi), major sorghum producing area of the State. The surveyed shows that most of the farmers cultivate between 2-3 ha of sorghum more than ten years ago. The cropping system has been intercrop mostly with maize and to a lesser extends with groundnut and millet. Very few of the farmers cultivate sorghum sole. Also 60% of the farmers interviewed identified striga hermontheca to be the most important weed in sorghum. In conclusion, more research effort to finding solution to the challenge of striga hermontheca in sorghum is strongly advocated in this part of the country. This will encourage the farmers to cultivate more hectarages of sorghum considering many years of experience they have in producing the crop. Also there is need to sensitise the farmers on the practice of sorghum-legumes intercrop, instead of the usual cereal-cereal intercrop system, to increase sorghum production for food security in Nigeria.
Key word: Experience, Hectarage, Intercrop, Weed and Sorghum

INTRODUCTION
Sorghum (Sorghum bicolor (L) Moench) is the fifth, fourth and third major cereal in terms of production and acreage in the World, India and Nigeria respectively (ICRISAT, World sorghum). It is a staple food in the drier part of Africa, china and India (Zalkuwi et al., 2013). In Africa, Nigeria and Sudan contribute nearly half of the sorghum production (Robert et al., 2013). Sorghum is used as human food, where it is a staple food for millions of people; as animal feed and industrial raw material (Agrama et al., 2003; Mamoudou et al., 2006). Industrially, the grain is used to manufacture wax, starch, syrup, alcohol, dextrose agar, edible oils and gluten feed (Mamoudou et al., 2006, Rainford, 2005). As food, the grain is used in making fermented and non fermented porridge. The grain has high levels of iron (>70 ppm) and zinc (> 50 ppm), hence may be used to reduce micronutrient malnutrition. There is high demand for sorghum mainly in brewing industry in Nigeria, yet the amount produced by farmers is too low to satisfy the market demand. One of the major constraints in sorghum production in Nigeria is the challenge of Striga hermontheca which have decreased the overall production of the crop in the country.
Understanding the years of experience of farmer, amount of hectarages cultivated, cropping systems as well as identifying the most challenging weed species in sorghum could be important in improving sorghum production in Taraba state Nigeria. Therefore, the study aimed at gathering information on the production status of the sorghum in Taraba state.

METHODOLOGY
Description of study area
Taraba State is located at the north eastern part of Nigeria. It lies between latitude 6° 30' and 8° 30' north of the equator and between longitude 9° 00' and 12° 00'east of the Greenwich meridian. The state shares boundaries with Bauchi and Gombe states in the north, Adamawa state in the east, and the Cameroon Republic in the south. The state is bounded along its western side by Plateau, Nassarawa and Benue states. The state has a land area of 60,291km^2. It is divided into sixteen Local Government Areas (LGAs) and three senatorial districts (Taraba north, central and south). Major cereals produced in the state include maize, rice, sorghum and millet.
Data Collection
Focus group discussions were held with average of 12 farmer groups per five wards each from five LGAs (Wukari, Takum, Donga, Ussa and Ibi), predominantly a sorghum producing areas in the state. The discussion helped to determine the years of farmers experience in sorghum production, hectarages cultivated, major cropping system, important weeds spp. A semi-structured questionnaire was administered to 300 farmers in their local language spread across the wards to supplement findings from the group discussions. The data were summarised into averages and percentages.

RESULTS AND DISCUSSION

Table 1 highlights the years of farmers experience in sorghum production. Among the farmers interviewed in the wards of Wukari LGA, 45% have been cultivating sorghum over 10 years ago, 29% between 7- 9 years, 22% between 4-6 years and 4% between 1-3 years. In Takum LGA, 51% of the farmers have been cultivating sorghum more than 10 years ago, 33% between 7-9 years, 11% between 4-6years and only 5% have been cultivating sorghum for 1-3 years. At Donga LGA, among the farmers interviewed, 46% have been cultivating sorghum, 32% between 7-9 years, 16% between 4-9 years and 6% between 1-3 years. In Ussa LGA, 40 % of the farmers have been cultivating sorghum, 32% between 7-9 years, 16% between 4-6 years and 12% between 1-3 years. Also in Ibi LGA area of the State, 36% of the farmers have been cultivating sorghum for more than 10 years, 33% between 7-9 years, 17% between 4-6 years and 14% between 1-3 years. This implies that farmers in Taraba State have been cultivating sorghum many years ago. This support Oruonye (2014) who reported sorghum among major cereals produced in Taraba state.

Table 2 below presents the hectarages of sorghum cultivated in Taraba state. 60% of the respondents cultivate up to 1-2 ha of sorghum, 35% uses between 3-5 ha, 3% uses between 6-9 ha and only 2% more than 10 ha. In Takum, 65% of the farmers have been cultivating 1-2 ha of sorghum, 32% uses between 3-5 ha, 2% produced between 6-9 ha and only 1% cultivate more than 10 ha of sorghum. Among the farmers interviewed at Donga LGA, 68% have been cultivating sorghum at 1-2 ha, 30% uses between 3-5 ha, 2% uses between 6-9 ha and none cultivate sorghum beyond 10ha. In Ussa LGA, 50 % of the farmers cultivate sorghum about 1-2ha, 43% cultivate between 3-5ha, 5% cultivate between 6-9ha and 2% cultivate between above 10 ha. Also in Ibi LGA, 48% of the farmers cultivate 1-2 ha of sorghum, 38% cultivate between 3-5 ha, 14% cultivate between 6-9 ha of sorghum and none cultivate more than 10ha of sorghum. This means that most the farmers in this part of the country cultivate sorghum majorly within 1-2 ha of land.

Table 3 presents sorghum cropping system in Taraba state. Among the farmers interviewed in Wukari LGA of the State, 45% of the sorghum farmers intercrop with maize. 43% intercrop sorghum with groundnut. 8% intercrop sorghum with millet, 2% grow sorghum sole. In Takum, 32% of the farmers intercrop sorghum with maize. 27% of the farmers intercrop sorghum with millet and 22% intercrop with groundnut. 19% cultivate sorghum sole. In Donga, 35% practiced sorghum/millet intercrop, 30% intercrop maize with sorghum and 22% intercrop groundnut with sorghum. 13% cultivate sorghum sole. In Ussa, 35% practiced sorghum/maize intercrop, 25% intercrop sorghum with millet and 23% intercrop sorghum with groundnut. 17% cultivate sorghum sole. In Ibi, 45% intercrop sorghum with maize, 32% intercrop sorghum with millet, 15% practiced sorghum/millet and 8% cultivate sorghum sole. This implies that most farmers in Taraba State rarely cultivate sorghum sole but intercrop sorghum with other crop particularly maize, groundnut and millet . This agrees with Olukosi et al. (1991) who reported that mixed farming and mixed cropping had been traditionally practiced and were still very common in Nigeria.

Table 4 shows the important weed species infesting sorghum field during production in Taraba state. Among farmers interviewed, 60% perceived that Striga hermontheca dominated sorghum fields. This was followed by 23% Rottboellia cochinchinensis, 6% Imperata cylindrica, 5% Digitaria horizontalis, 4% Commelina benghalensis and 2% Pennisetum pedicellatum. This shows that, farmers in the state are face with the challenge of parasitic striga spp infestation during sorghum production followed by Rottboellia cochinchinensis. This agreed with Ejeta and Gressel (2007) who reported that Striga has long been recognized as the greatest biological constraint to maize, sorghum, pearl millet (Pennisetum glaucum), upland rice, and cowpeas (Vigna unguiculata) production in Africa savanna.

CONCLUSION

More research effort to finding solution to the challenge of parasitic striga in sorghum is strongly advocated in this part of the country as this will encourage the farmers to cultivate more hectarages of sorghum since they have many years of experienced in the production of the crop. Also farmers need sensitising on the practice of sorghum-legumes intercrop, instead of the cereal-cereal intercrop system, to increase sorghum production for food security in Nigeria.

Table 1: Farmers Experience in Sorghum Production in Taraba State, 2015

	Local Government Areas				
Years	Wukari	Takum	Donga	Ussa	Ibi
1-3	4.0	5.0	6.0	12.0	14.0
4-6	22.0	11.0	16.0	16.0	17.0

FARMERS' PERCEPTION OF LEAF SPOTS AND CONTROL PRACTICES IN RAINFED GROUNDNUT CROPPING SYSTEMS IN TARABA, NIGERIA

B.A. Tunwari, M. Gani & C.P. Shinggu

Department of Crop Production and Protection, Federal University Wukari, Katsina - Ala Road, P.M.B. 1020, Wukari, Taraba State, Nigeria. **E-mail address: adamubilkoya@gmail.com; atunwari@fuwukari.edu.ng**

ABSTRACT
Groundnut (Arachis hypogaea L.) is one of the most important oil seed crop in Nigeria. It contains 48-50% oil, 26-28% protein and 11-27 % carbohydrate, minerals and vitamin. Groundnut pod yields from farmers' field are low, averaging about 800 kg ha-1, less than one-third the potential yield of 3000 kg ha-1. Early and late leaf spots, caused respectively by Cercospora arachidicola and Phaeoisariopsis personata, are the most common and serious diseases of groundnut, worldwide with over 50% yield loss. There had not been preliminary information on status of groundnut production in Taraba State. Questionnaires were administered among farmers in a participatory manner. Data were collected on cropping systems, cultural practices, yield levels, constraints to production and utilization. Responses obtained from farmers were analyzed using non-parametric or descriptive statistics. The data was summarized into averages, percentages or ranges. Results identified major production practices, importance and constraints to groundnut production in Taraba State. The second experiment was to determine the extent of leaf spots by random sampling of four farmers' fields per each of the 5 wards in each Local Governments of namely Wukari, Takum, Donga, Ussa and Ibi surveyed. The result revealed that early leaf spot disease was prevalent in all the areas surveyed, and percentage leaf area damaged, infection frequency, lesion diameter and sporulation index were more in Takum and Ussa than other locations. The findings provide important guides to formulate good farmer consumer oriented researches that will help to address these constraints and to improve the livelihoods of farmers in their rural communities.

Key word: Survey, farmers' perception, leaf spots, groundnut, cropping systems

INTRODUCTION
Groundnut (Arachis hypogaea L.) is the 6th most important oil seed crop in the world. It contains 48-50% oil, 26-28% protein and 11-27 % carbohydrate, minerals and vitamin (Mukhtar, 2009). Nigeria was the third highest producer of groundnut in the world after China and India. In Nigeria, the crop is presently grown throughout the country with the exception of the riverine and swampy areas. Groundnut is either cultivated sole or in mixtures with other crops like maize, sorghum, millet or cassava. Fifty five percent of the groundnuts produced in Nigeria are in mixtures (Anonymous, 2004)). In Nigeria, the leading producing states include Niger, Kano, Jigawa, Zamfara, Kebbi, Sokoto, Katsina, Kaduna, Adamawa, Yobe, Borno, Taraba, Plateau, Nasarawa, Bauchi, and Gombe States (NAERL, 2011). Groundnut pod yields from farmers' field are low, averaging about 800 kg ha-1, less than one-third the potential yield of 3000 kg ha-1. This is due to several factors, including low access to high yielding cultivars for a particular ecology, poor soil fertility, unreliable rains with recurrent droughts, inappropriate crop management practices, pests and diseases (Ahmed et al., 2010). In Nigeria leaf spots and rosette virus are the most serious damaging diseases of groundnut (Muhammad and Bdliya, 2011). Early and late leaf spots, caused respectively by Cercospora arachidicola and Phaeoisariopsis personata (until recently known as Cercosporidium personaiurn), are the most common and serious diseases of groundnut, worldwide. Singly or together they can cause losses in pod yield of over 50%**;** in areas where rust disease is also present a combined attack of foliar diseases can cause yield losses in excess of 70% (Macdonald, et al., 1985).
There had not been documented evidence of preliminary information on status of groundnut production in Taraba State. This paper reports the results of a study on farmers' perception of field pests, weeds and pest control practices. It further helped to determine incidence and distribution of leaf spots in Wukari, Takum, Donga, Ussa and Ibi LGAs of Taraba State, Nigeria.

MATERIALS AND METHODS
Taraba State is located at the north eastern part of Nigeria. It lies between latitude 6˚ 30' and 8˚ 30' north of the equator and between longitude 9˚ 00' and 12˚ 00 ' east of the Greenwich meridian. The state shares boundaries with Bauchi and Gombe states in the north, Adamawa state in the east, and the Cameroon Republic in the south. The state is bounded along its western side by Plateau, Nassarawa and Benue states. The state has a land area of 60,291km2 with a population of 2006. Taraba State is regarded as Nature's Gift to the Nation because of its abundant natural resource endowment. The state is blessed with climate and vegetation types that cut across the country, ranging from a more humid climate and forest vegetation in the south to a more seasonal wet and dry climate and savanna vegetation in the north.

This study carried out in 2015 involved interviewing a total of three hundred farmers in five wards each in five local government areas namely Wukari (Babtaji, Tsukundi, Jibu, Avyi, Rafinkada), Takum [Manya, Dutse Gawhetun, Tikari, Chanchanji), Donga (Gayama, Mararraba, Nyita, Kumbo, Asibiti), Ussa (Jenuwagida, Lumbu, Kpakya, Tutuwa in Kwesati LIssam I, Lissam II) and Ibi (Rimi uku I, Nwonyo I, Sarkinkudu, Rimiuku II, Nwonyo II). To minimize bias, the questions were interactive and open – ended, rather than asking the farmer to select an answer among fixed choices. The survey was conducted with twelve individual farmers per ward. After covering basic information on education, farming experience, farmers' age, type of crop grown and cropping systems, the questions focused on crop constraints, pests, weeds and pest control methods. The interview was concluded in each ward with random sampling of four farmers' fields to determine the prevalent of early and late leaf spots. The five wards in each local government served as replicates; while the five local governments are the treatments. Data on prevalent of leaf spots were collected on the following: a) Infection frequency - final number of lesions per cm2 of leaf obtained by counting lesions on each leaflets of five randomly selected main stems and finding average per leaflet. Leaf area was estimated using a leaf area meter. b) Percentage leaf area damage**.** It was estimated for each leaf on the five randomly selected main stems and averaging per main stem in comparison to the diagram depicting the known percentage of the area affected and a scale of 1 to 9 (Subrahmanyam et al., 1995). c) Lesion diameter. The diameters of 10 randomly selected lesions were measured on the leaves of the main stem using millimeter scale. d) Sporulation. Five leaflets were taken from each main stem and incubated on moist filter paper in petri dishes at 25°C under continuous illumination in a plant growth chamber for 5 days. On the 6th day, the lesions were examined under a stereoscopic-microscope (x70) to score the degree of sporulation on a 5-point scale.as follows: Rating description (5-point scale). 1 = No sporulation; 2 = Very few spores; 3 = Moderate sporulation; 4 = More sporulation than score 3; 5 = Extensive sporulation. Responses obtained from farmers were analyzed using non-parametric or descriptive statistics. The data were summarized into averages, percentages or ranges. The data obtained from leaf spots disease prevalence were subjected to analysis of variance (ANOVA) for RCBD using the generalized linear model (GLM) procedure of SAS Version 9 (SAS, 2005).

RESULTS AND DISCUSSION

Farmers listed a total of 17 production constraints of which 7 were insects, 3 diseases, 2 weeds (non-parasitic category), 1 birds, 5 abiotic constraints such as drought or low soil fertility (Table 1). Leaf spots were reported as the most important diseases (55 – 92 %) across the 5 local governments (LG) follow by Rosette virus disease, while the least was Rust disease. This confirms report by Muhammad and Bdliya (2011) that leaf spots and rosette virus were the most serious damaging diseases of groundnut in Nigeria. It was further revealed that termites and aphids were considered very prominent in all the LGs visited. Dominant weed species in most groundnut farms as reported by most farmers was itch weed or Rotboellia (Table 1). The results on production practices showed that farmers employed a range of practices in groundnut production namely: early planting, use of improved varieties, intercropping, pesticide application, use of herbicides, crop rotation, burning of crop residues, fallowing among others (Table 2). Among the recommended management practices, early sowing was the management common and was being practiced by 89 % of the farmers. Pesticide application and fertilizer application were the least employed with 5.7 % and 9.8 % of farmers interviewed implementing them respectively. 46 % of the farmers practiced crop rotation, while 31.4 % reported that they adopt fallows for exhausted fields. Also 8.3 % burned crop debris after harvest. 58 % farmers weeded their farms twice during the growing season, while 39 % weeded only once during the season. Control of leaf spot diseases in Nigeria has depended on some cultural practices and on multiple applications of fungicides, though fungicidal treatment was not reported by farmers as one of the management practices. Effective and long-term control of leaf spot disease can be achieved by applying recommended fungicides at the recommended time intervals. Combination of several control strategies is recommended (Kucharek, 2004). Reduction of initial inoculum is achieved through cultural measures such as crop rotation, removal of volunteer plants, and burial of groundnut residue (Shokes and Culbreath 1997). In addition, low to moderate resistance is present in some released cultivars and much effort has been directed at developing cultivars with high levels of leaf spot resistance.

There were no statistically significant differences in percentage leaf area damaged, infection frequency, lesion diameter and sporulation index across the surveyed locations (Table 3). The result revealed that early leaf spot disease was prevalent in all the areas surveyed. This was supported by the works that both early and late leaf spots diseases are widely distributed and occur in epidemic proportions in all groundnut growing regions of the world (Nutsugah et al., 2007). It was further noted that percentage leaf area damaged, infection frequency, lesion diameter and sporulation index were more in Takum and Ussa with scores of 18.5, 2.6, 2.5, and 4.7 respectively than other locations. Leaf spot can increase rapidly under favorable conditions as several secondary cycles may occur per season. The first appearance of leaf spot and its continuous progress throughout the growing season are heavily dependent upon weather conditions. Environmental conditions required for both types of leaf spot are warm temperatures and long periods of high humidity or leaf wetness. When adequate moisture is present, leaf spot infections may occur in a relatively short period when temperatures are warm (Butler, 1990).

CONCLUSION

In conclusion, results of this survey identified production practices, production constraints, farmers' preferences and important reasons for growing groundnut. The result also revealed that early leaf spot disease was prevalent in all the areas surveyed. The results are important guides to formulate good farmer consumer oriented researches that are geared towards addressing some of these constraints and findings to improve the livelihoods of farmers in their rural communities.

ABSTRACT
Cowpea is an important grain legume. Production of cowpea has reduced in Taraba State due to constraints such as insect pests, diseases, Alectra infestation and lack of improved varieties. Generally, lack of knowledge of good agronomic practices worsens the limitations to cowpea production. In order to ascertain the extent of these problems and determine the needs of farmers, a baseline survey was conducted among cowpea production wards in Wukari Local Government Area of the state in 2015 cropping season. Questionnaires were administered among 125 farmers in 10 wards of the LGA. Data were collected on cropping systems, hectarages, pests constraints to production and utilization. Responses obtained from farmers were analysed using non-parametric or descriptive statistics. The data was summarised into averages, percentages or ranges. Results identified mostly 1-2 hectarages cultivated and sole cropping and a few of maize, sorghum intercrop. Insect pests, diseases and Alectra infestation were identified as major constraints to production. The results obtained will be useful in drawing a pathway for improve cowpea production in the state
Key words: Cowpea, cropping system, hectarage, constraints

INTRODUCTION
Cowpea {Vigna unguiculata (L.) Walp}, is an important grain legume. It is consumed by relatively rural and periurban people of less developed countries. Rural families derive food protein (Bressani, 1985), animal feed (Tarawali et al., 1997; Singh, 1999) and cash from the production of this crop (Quin, 1997). In addition, the crop fixes 80% nitrogen for its growth demand from the atmosphere (Asiwe et al., 2009), thereby reducing nitrogen fertilizer demand and cost for the crop. It is also an important companion crop in most cereal-legume cropping systems because of the benefit from the residual nitrogen originating from the decay of its leaf litter, roots and root nodules (Okereke et al., 2006).
Production of cowpea has reduced in Taraba State due to constraints such as insect pests, diseases, Alectra infestation, and lack of improved varieties. Generally, lack of knowledge of good agronomic practices worsens the limitations to cowpea production. In order to ascertain the extent of these problems and determine the needs of farmers, a baseline survey was conducted among cowpea production wards in Wukari Local Government Area of the state in 2015 cropping season.

METHODOLOGY
Wukari is one of the LG of Taraba State with the largest population created in 1977. It is located at the Southern senatorial districts of the State. It lies between latitude 7° 50' N and 8° 30' N and between longitude 9° 68'E and 9° 89' E. A focus groups discussion was held with average of 1 farmer groups per five wards each from five wards in Wukari. The discussion helped to determine the major cropping system, hectarages cultivated, pests constraints to cowpea production and utilization. A semi-structured questionnaire was administered to 125 farmers in their local language spread across the wards to supplement findings from the group discussions. The data collected was computed based on percentages.

RESULTS AND DISCUSSION
Table 1 presents cowpea cropping system in Wukari L G area of Taraba State. Among the farmers interviewed, 45% intercrop cowpea with maize, 32% intercrop with sorghum, 23% practiced sole cowpea production. None of the farmers practiced cowpea/millet intercrop. The results on cropping systems suggest that intercropping were predominant and that cowpea is intercropped with maize and sorghum. This practice of intercropping cowpea with cereals is in conformity with those practices in other parts of sub Saharan Africa. This explains the importance of cowpea as a companion crop in cereal-legume cropping systems which are common practices adopted by farmers in sub Saharan Africa to avert risk, crop failure and distribution of farm labour (Singh et al., 1997; IITA, 1998; Olufajo and Singh, 2002). This also points to the need to develop varieties suitable for intercrop systems as well as crop livestock integration.
Table 2 below presents the hectarages of cowpea cultivated in Wukari area of Taraba state. 50% cultivate up to 1-2 ha of cowpea, 45% uses between 3-5 ha, 3% uses between 6-9 years and only 2% more than 10 ha. Acreage cultivated per farmer was small because grain yield was also very low. In West Africa, hectarages of cowpea are small with low grain yields (Van Ek et al., 1997; Singh et al., 1997). Farmers are likely to cultivate more land if crop yield is made higher through the introduction of improved varieties as well as cultural practices (Singh and Ajeigbe, 2001, 2002). The results suggest that

cowpea production is still at subsistence level and needs a lot of improvement in terms of yield and constraints to its production.

Table 3 present major and important insect pests, diseases and weeds infesting cowpea in Wukari LGA of Taraba state. They are aphids, thrips, pod-sucking bugs and cowpea weevil (bruchids). Among the diseases (fungal, bacterial and viral), virus diseases ranked first as the most common disease attacking cowpea in both provinces (Table 3). Grasses were the most common weeds (Table 3) than the broad leaves. However, only a few respondents mentioned Striga and Alectra as important weeds in their cowpea fields. The survey revealed that insect pests, diseases (virus), common and parasitic weeds pose major constraints to cowpea production in the LG. Development of Striga/Alectra resistant varieties, use of zero tillage in conjunction with suitable herbicide application would reduce the problems posed by weeds. These findings confirm the report of (Mathews, 2005; Asiwe, 2007, 2009) that insects especially aphids and viral diseases constitute a major constraint to cowpea production. These indicate the need to breed cowpea varieties resistant to these important insect pests, drought and diseases in order to increase yield and sustain cowpea productivity. The results also confirm the reports of previous workers on the importance of these biotic factors to cowpea production (Emechebe and Soyinka, 1985; Jackai and Daoust, 1986; Singh et al., 1990; Singh et al., 1992; Asiwe et al., 2005).

CONCLUSION

In conclusion, results of this survey identified production practices, production constraints, farmers' preferences and important reasons for growing cowpea. The results are important guides to formulate good farmer consumer oriented breeding objectives. The information will be helpful to breeders and agronomists starting a new cowpea improvement programmes. Some of the breeding objectives and on-going activities in the cowpea breeding programme at ARC-Grain Crops Institute, Potchefstroom, were formulated based on the results of this survey, and are already addressing some of these constraints and findings to improve the livelihoods of farmers in their rural communities.

chinweizu93@gmail.com

ABSTRACT

The field experiment was conducted at the Teaching and Research farm of Federal University of Technology Owerri located at latitude 5^0, 27' N and longitude 7^0, 02' E, 89% relative humidity and annual rainfall of 2300-2700mm during the 2011 cropping season. The objective of this experiment was to evaluate the effect of organic mulch types on the productivity of groundnut/maize in Owerri Southeastern Nigeria. The experiment was laid out using the Randomized Complete Block Design with five treatments and four replications. The treatments were: 31.25 ton/ha of multiple species of weeds; 31.25 ton/ha of sawdust; 31.25 ton/ha of wood shavings; 31.25 ton/ha of palm bunch refuse and 0 ton/ha that is no mulch as control. Data on various growth and yield parameters were collected and were subjected to analysis of variance (ANOVA). Means were separated using Duncan multiple range test. Results indicated that palm bunch refuse and multiple species of weed gave the highest yield for groundnut and maize. Also, palm bunch refuse and wood shaving proved most effective in reducing weed density during the experiment. In general, the observations showed that the application of organic mulch as a soil cover was effective in improving maize and groundnut crop yield, reducing weed incidence and improving soil chemical properties.

Keywords: Intercrop, palm bunch refuse, Arachis hypogea, Zea mays, soil fertility

INTRODUCTION

Declining soil fertility due to heavy rains, run-offs and leaching is a major problem facing agriculture in the tropics. In an effort to tackle this menace, it is generally necessary to adopt agronomic practices which conserve soil and water. Run-off is naturally reduced by protecting the soil with cover crops or other vegetation or with mulch, which breaks the impact of raindrops and slows down the movement of water over soil surface (Webster, 1985). Organic mulching of fields help to maintain healthy landscape of plants and soil fertility by enhancing soil nutrients and organic matter content. It also promotes increased soil micro and macro organism's activities, soil aeration and water infiltration.

Groundnut (Arachis hypogea) is one of the widely cultivated and produced legumes in Nigeria. It is cultivated for its fruits which are seeds or kernels in shell (Robbelen, et al, 1984). The seeds are widely eaten in different forms, as they can be eaten raw, roasted, sweetened or boiled with salt (Woodroof, 1984). It has high nutritional value, rich in proteins, vitamins, calcium, iron, magnesium, zinc, carbohydrate, and fat (Robinson, 1984). Groundnut is also of value as a rotational crop, being a legume with root noodles; it can synthesize atmospheric nitrogen and therefore improve soil fertility (Lanrinde, 1999). Maize (Zea mays) is a cereal crop cultivated in all parts of Nigeria. The grains are rich in vitamins A, C, and E, carbohydrates and essential minerals and contain 9% protein. They are also rich in dietary fibre and calories which are a good source of energy (Oladipo et al, 1993). Maize is also processed into pap which is part of breakfast for many families in Nigeria and can be used in the production of livestock feed (Obi, 1991).

Groundnut/Maize intercrop is important in Nigeria's agricultural system. It is therefore important to examine the effect of different organic mulches on the productivity of groundnut/maize intercrop in Southeastern Nigeria, to ensure optimum growth and yield of these crops. The objectives of this research were to: assess the field response of groundnut/maize to the different organic mulch treatments; evaluate the efficacy of the different mulches on weed control in groundnut/maize intercrop; and determine the residual soil fertility in groundnut/maize plots with different organic mulch treatments.

MATERIALS AND METHODS

The field experiment was conducted at the Research farm of the School of Agriculture and Agricultural Technology, Federal University of Technology Owerri, Imo State between March and August 2011. The farm is situated at latitude 5^0, 27' N and longitude 7^0, 02' E, in Southeastern Nigeria about 56.6m above sea level with annual rainfall, temperature and relative humidity ranging from about 2300-2700mm, 21-32 ^{0}C, and 89% respectively (Ibeawuchi, 2004). The area was manual prepared and plots made into beds each measuring 1.2x4m. The experiment was laid out using the randomized complete block design (RCBD) with 5 treatments and 4 replications. The treatments used were: Palm bunch refuse (PBR); Sawdust (SD); Multiple species of weeds (MSW) got from the packed trash after clearing; Wood shavings (WS) and Bare soil as control (C). The groundnut cultivar used was the erect, alternately branching type, whereas the maize was the variety 096EP6 NARZO-18(FARZ-23) with yellow grains. Groundnut was planted at a spacing of 50cmx50cm, whereas maize was planted at a spacing of 100cmx100cm. The various organic mulch treatments were applied on the plots immediately after planting at the rate of 15kg per plot (31.25ton/ha). Chemical analysis of organic mulches and Soil physiochemical analysis before and after the experiment were carried out.

The following growth and yield parameters were measured: plant height and number of leaves at 2, 5, and 8 weeks after planting (WAP); total fresh fruit (cobs and pods) weight at harvest and weed weight.

The data from the experiment were subjected to analysis of variance and differences between means were separated using Duncan multiple range test as described by Obi, (2002).

RESULTS AND DISCUSSION

The chemical and physical analysis of the soil prior to planting shows that the soil is slightly acidic (5.61 in H_2O and 4.62 in KCl). The organic matter content is also low (6.45%), with low nitrogen content (0.32%) and low cation exchange capacity (5.05 cmol.kg). This confirms reports that soils in southeastern Nigeria are characterized by low pH, low organic matter content and low exchangeable cation (Ohiri, 1992).

The post-harvest soil analysis from table 2 shows that there was increase in the nutrient contents of the soil. The total available phosphorus concentration of the soil was increased from 7.36 ppm to 8.35 ppm in soil with MSW treatment. This is in line with the data of Saroa and Lal, (2004) which showed that organic mulching increased total phosphorus concentration in the soil after 4 years of mulching from 601-658 mg/kg. Sinkerviciene et al, (2009) also confirms that grass mulch had the most influence on increased available phosphorus in the soil. From tables 1 and 2 it is evident that soil had higher amount of organic matter than all different mulches non-the-less, organic matter content of the soil increased after the experiment (Table 2).

The response of plant heights of groundnut and maize to organic mulches is presented in tables 3. For groundnut at 2 and 5 WAP, plants mulched with PBR and MSW were significantly taller ($p \leq 0.05$) than those that received other treatments but at 8WAP these differences were no longer evident. The response of maize plant height to organic mulches was inconsistent. This is in agreement with the report by Singh et al, (2007).

Different organic mulch treatments did increase number of leaves of maize compared to the control at most sampling periods (Table 4). The effect of the different organic mulches on weed weight is highlighted by table 5. Visually, the plots with MSW treatments had the highest occurrence of weeds. This could be because of the germination of weed seeds in those plots. This partially varies from the work of Sinkerviciene et al, (2009) which noted that the influence of grass mulch significantly decreased weed number compared to that of unmulched plots. They however observed that in 2008, weed density in plots mulched with grass was higher than in plots mulched with straw, peat and sawdust due to rapid emergence of Poa annua in the second part of summer when grass mulch has been infected with seeds of Poa annua.

The effect of different organic mulches on fresh weight of maize and groundnut at harvest is presented in table 5. In both crops, treatments with PBR and MSW gave the highest yield. This is because they have the highest nutrient contents

CONCLUSION

Results obtained from this study indicated that multiple species of weeds (MSW) and palm bunch refuse (PBR) applied at the rate of 1.25 ton/ha significantly improved yield of maize and groundnut compared to other organic mulch treatments assessed. The residual soil nutrient was also maintained and sustained with the mulch treatment.

ABSTRACT
Flours and starches were processed from three cassava varieties namely TMS 98/0505, TMS 419 and NR 8082. The flours and starches were fermented employing Termamyl Type L Novoenzyme (an alpha amylase), glucoamylase from A.niger and dried form of Saccharomyces yeast .The flours and starches were analysed for moisture/dry matter, fibre, amylose and amylopectin contents. Slurries obtained were analysed for glucose contents, pH, total titratable acidity (TTA) and temperature during 72hrs of fermentation. The ethanol yield of the flours and starches were determined. Significant differences (P<0.05) were found among the cassava flours/starches with respect to moisture/dry matter, fibre, amylose and amylopectin contents. The ethanol yield of the flours and starches tended to be dependent on their amylose contents. Correlation between amylose and ethanol yield were 96.20% (flour) and 86.39% (starch). The yields of ethanol from filtrates of slurries obtained from fermented cassava starch samples were higher than that of the flour samples. Ethanol yields from starch of TMS 98/0505, TMS 419 and NR 8082 were 20.49%, 18.98% and 18.21%, respectively. Those of flour samples were 14.01%, 14.04% and 12.56%, respectively. The glucose contents and the pH of the fermenting slurries of the flours and starches decreased as fermentation progressed, whereas their TTA and temperatures generally increased. Ethanol yields from starch of TMS 98/0505 were the highest when compared with the other varieties used. The study recommends the use of starch from cassava variety TMS 98/0505 as raw material in ethanol production.

Keywords: cassava, flour, starch, fermentation, ethanol yield.

INTRODUCTION
The markets for domestic and industrial starches are expanding and cassava (Manihot Esculenta Crantz) is mostly satisfied as one of the crops. Cassava is particularly important as a source of starch in tropical and sub-tropical regions.

Starch and flour, the main plant carbohydrates are the most important plant derivatives used by man. They have unlimited importance in industry and food and can be modified to suit various applications using in-expensive methods making them ideal for a number of purposes (Nadir et al., 2009). Starch consists of two polysaccharides, the linear molecule, amylose and a highly branched molecule, amylopectin.

Termamyl, an α-amylase isolated from Bacillus licheniformis, a soil bacterium. This enzyme hydrolyses 1, 4-α-glucosidic linkages in starch and possesses a high degree of heat stability. It is used for the continuous liquefaction of starch at temperatures of up to 105-110ºC, breaking them rapidly to dextrins and oligosaccharides. Amyloglucosidase (AMG), an exo-1, 4-α-Dglucosidase (glucoamylase) was obtained from a selected strain of the fungus, Aspergillus niger. This enzyme hydrolyses 1, 4- and 1, 6-α-glucosidic linkages in liquefied starch in stepwise manner from the non-reducing end of the substrate molecules (Alais and Linden, 1999).

Bio-ethanol is a strategic raw material with wide range of applications in food, pharmaceutical, cosmetic, and petrochemical industry (Baras et al., 2002). Also, it has been used as a modern biofuel, applied directly as a gasoline improver or gasoline substituent (Demirbas, 2006), or in the form of ETBE (ethyl tertiary buthyl ether), to substitute for currently added synthetically-produced octane enhancers (Rosenberger, 2005), and in ethanol-diesel blends with particular purpose to reduce the emissions of exhaust gasses (Hansen et al., 2005). Works have been carried out by comparing the yields of ethanol obtained from starches and flours of sweetpotato varieties (Etudaiye et al., 2012). There is dearth of information on the comparative evaluation of ethanol produced from cassava starch and cassava flour. The objective of this work is to evaluate the quality of ethanol produced from starches and flours of different cassava varieties.

MATERIALS AND METHODS
Fresh roots of three (3) cassava varieties TMS 98/0505, TMS 419 and NR 8082 were harvested at about 11 months old from field trial of cassava Programme, National Root Crops Research Institute, Umudike. The Cassava Mosaic Disease (CMD) resistant varieties (TMS 98/0505 and TMS 419) were developed for food, feed and industrial use (Dixon et al., 2005). Termamyl Type L Novoenzyme AYN02215 (an alpha amylase), glucoamylase from A.niger and dried form of Saccharomyces yeast(BP1422-500,Fischer Scientific,Pittburgh,PA) were obtained from the International Center for Tropical Agriculture (CIAT), Palmira, Colombia.

Processing of fresh cassava roots to starch and flour

Cassava starch and flours were produced using the recommended standard methods described by the International Institute of tropical Agriculture (IITA, 2005). The starch constituted 100% particles that passed through a 425 µm sieve.

Determination of moisture and dry matter contents

Moisture and dry matter contents of flour and starch samples were determined by the AOAC methods (1996)

Determination of pH and Titratable Acidity (TTA)

At constant weight (90g) of the fermenting mash, each sample of flour and starch from each variety was analysed for pH, titratable acidity (TTA) and mash temperature. pH and TTA of the fermenting cassava mash were determined by the AOAC methods (1996).

Determination of mash/slurry temperature

Temperature of fermented slurries of starch and flour samples was determined using a calibrated thermometer.

Determination of amylose and amylopectin

Amylose and amylopectin of the flour and starch samples were determined following the colorimetric standard procedure of Sanchez et al., 2009.

Statistical analysis

Data obtained were subjected to statistical analysis with the aid of Statistical Analytical System (SAS) software, version 8, 2009. Analysis of variance (ANOVA) was done. Mean separation by Fischer LSD to determine significant difference (p at 0.05) was carried out.

RESULTS AND DISCUSSION

Table 1 shows values of some biochemical contents of flours from cassava varieties for ethanol production. Moisture contents (MC) were low and ranged from 8.77- 9.60%. Dry matter contents (DM) were high and ranged from 90.40-91.27%. Fibre ranged from 1.06-1.12%. Amylose contents were in appreciable levels and ranged from 17.93-18.74%. There was a significant difference ($p < 0.05$) in the parameters determined. Table 2 shows values of some biochemical contents of starches from cassava varieties for ethanol production. MC were low and ranged from 5.76- 6.18%. DM contents were high and ranged from 93.82-94.24%. Fibre ranged from 0.25-0.30%. Amylose contents were in appreciable levels and ranged from 19.82-20.28%. There was a significant difference ($p < 0.05$) in the parameters determined. Table 3 shows ethanol yields of flours and starches from cassava varieties after 72hrs fermentation. Ethanol yield was highest from the flour of Cassava variety TME 419 (140.4g/L) and highest in the starch of cassava variety TMS 98/0505(204.9g/L). There was no significant difference ($p > 0.05$) in the ethanol yields from flours of cassava varieties TME 419 and TMS 98/0505. There was a significant difference ($p < 0.05$) in the ethanol yields from starches of three cassava varieties used. Table 4 and 5 show some changes in the physic-chemical parameters during 72 hours fermentation of cassava flour and starch slurries, respectively. Glucose, pH and temperature of the slurries decreased as fermentation progressed while the TTA and temperatures decreased. Values of pH and TTA were similar to the previous values reported by Ajibola et al, 2012. Tables 6 and 7 show a positive correlation between amylose and ethanol yields from flour and starch samples. High amylose content gives rise to high ethanol yields and this can be used as a practical approach in determining the production potential and marketability of ethanol. This is in line with previous report of Etudaiye et al., 2012.

CONCLUSION

The study revealed that flours and starches produced from the cassava varieties used are suitable for ethanol production. They were found to have good qualities in terms of high dry matter and high amylose contents. However, cassava variety TMS 98/0505 stands out as it starch has shown very high potential for ethanol production.

Table 1: Biochemical properties of flours from cassava varieties used for ethanol production

ABSTRACT
The effect of cassava processing effluent on the growth performance of Abelmoscus esculentus L. Moench was studied at the University of Port Harcourt Botanical Garden. Experimental treatments were obtained by mixing thoroughly 3kg of loam- sandy soil with 0, 25, 50, 75 and 100% of cassava processing effluent. 0% (unpolluted soil) was used as control. One seed was maintained in a polybag containing the various levels of cassava processing effluent with garden soil. Each level of treatment was replicated three times and maintained for 7 weeks, significant (P=0.05) reduction in the leaf number, fresh weight, dry weight, moisture content, plant height, root length were recorded from cassava processing effluent treated soils. Increase in the concentration of the effluent at 100% level of pollution did not support any growth of Abelmoschus esculentus. This study therefore, shows that cassava effluent is injurious to the growth of Abelmoscus esculentus.
Keywords: Cassava processing effluent, Growth performance, Abelmoscus esculentus.

INTRODUCTION
In Nigeria cassava (Manihot esculenta Crantz) is regarded as a staple food crop due to its rich carbohydrate content (Idem and Showemimo, 2006). However the processing of cassava into usable products generates a lot of liquid waste. These waste product generated from the processing activities get disposed on land and have been shown to constitute negative impacts on soil and plant growth (Kapanen and Itavaara, 2001). Fresh cassava roots contain 60-70% water which make them to deteriorate within 2-4 days after harvest. They also contain Cyanogenic glucosides (Linamarin and Lotaustralin) and endogenous enzyme linamarase, when the enzyme comes in contact with the cyanogenic glucosides, a poisonous substance, hydrogen cyanide (HCN) is released. Processing of cassava root after harvest is therefore very necessary to reduce the risk of cyanide poisoning during their consumption. However, the waste water generated in the process still contains considerable quantity of Cyanogenic glucoside, which has been known to suppress plant growth (Kapanen and Itavaara, 2001). Incidents of deleterious impacts of liquid wastes discharged into the environment are prevalent and thus require serious consideration. The anticipated directional upset of the ecosystem balance may now become emergent or alter the growth and physiological processes in plants as a result of the negative impact of toxic liquid waste (Conley and Olenik, 1992).
It is on this basis that this research is conducted in order to evaluate the effects of waste water generated from cassava processing mills on the growth and nutrient contents of Okro (Abelmoschus esculentus L. Moench).

MATERIALS AND METHOD
The mature seeds of Abelmoschus esculentus were collected from Akwa Ibom State, Agricultural Development Project (AKADEP). Loam - sandy soil was obtained from the University of Port Harcourt Botanical Garden. Waste water cassava processing effluent was obtained from cassava processing mill in Ini Local Government Area. The effluent was analyzed for physico-chemical properties (A.O.A.C, 1984).
Three kilogram (3kg) of the loam-sandy soil was weighed using a triangular weighing balance. The treatment were obtained by mixing thoroughly 3kg of loam-sandy soil with 0, 25, 50, 75 and 100% of cassava processing effluent, samples with or without cassava processing effluent were placed in perforated polybags. The seeds were sterilized with approximately 0.01% mercuric chloride Solution for 30 seconds, thoroughly washed several times with sterile distilled water and air dried (Esenowo and Umoh, 1996). During this treatment floating seeds or those that had bubbles were discarded and the good once were used for the research. Three seeds of were sown directly in each perforated polythene bag containing the various levels of cassava effluent and after germination it was thinned down to one seedling per bag. Each level of treatment was replicated three times using Randomized Complete Block Design. The experimental work was maintained under light condition. The plant watered as need arose and allowed to grow' for 7 weeks in order to determine the growth and yield performance.
Growth parameters were measured and recorded at the end of the studies (7weeks). The plant height (cm), root length (cm), leaf number, shoot/root ratio, fresh weight (g), dry weight (g), moisture contents were determined and recorded.

Data generated from this study were subjected to analysis of variance (ANOVA) according to the method of Obi (2000).

RESULTS AND DISCUSSION

The physico-chemical properties of the cassava processing effluent showed that the effluent was acidic with a pH of 4.50. The proportions of calcium, sodium, magnesium, potassium, lead and iron were high, while the copper and manganese contents were low. The cyanide contents (0.61 MgL^{-1}) and the total dissolve solids content (9, 600 MgL^{-1}) of the effluent were high (Table 1). The effluent used in this study is characterized by an acidic pH, and a biological oxygen demand level that is within the permissible level of 30-70ppm for river discharge (Olorunfemi et al., 2007).

There were significant (P=0.05) reductions in plant height of Abelmoschus esculcntus with increase in the concentration of cassava effluent (Fig.1).100% concentration of cassava effluent treatment did not support the growth of Abelmoschus esculentus (0.00). The leaf number of Abelmoschus esculentus was significantly reduced with increase in the concentration of cassava effluent.Values recorded in cassava effluent treatment were comparatively lower than the control as shown in Fig.1. The root length of Abelmoschus esculentus was significantly (P=0.05) reduced with increase in the concentration of cassava effluent as shown in Fig.1. Similarly, the shoot/root ratio decreased with increased in the concentration of cassava effluent.

In this study, cassava processing exhibit deteriorative effect on the growth parameters of Abelmoschus esculentus. This result agrees with the work of Olorunfemi et al., (2007) who reported that cassava processing effluent posed an inhibitory effect on the germination of some cereal crops. There was significant (P=0.05) reduction in fresh weight of Abelmoschus esculentus with increase in the concentration of cassava effluent .The dry weight of Abelmoschus esculentus decreased with increase in the concentration of cassava effluent. There were slight increase in moisture content ot Abelmoschus esculentus at 25% concentration above the control treatment. In addition the moisture content of Abelmoschus esculcntus increased at 50% and 75% concentrations of effluent above those of the control (Fig.2). The overall decrease in the growth of Abelmoschus esculentus in cassava processing effluent agrees with the work of Ogboghodo et al., (2003). This shows that nutrient unavailability is one the factors that limit growth of crops in acidic medium (Bannister, 1980). In this study the characteristics of the cassava effluent showed the presence of some heavy metals as well as cyanide content. These physico-chemical properties are consistent with the work of Onwueme and Sinha, (1991). Thus, the presence of heavy metals in the cassava effluent together with cyanide contents could have contributed significantly to the reduced growth of Abelmoscus esculentus.

CONCLUSION

This study showed that cassava processing effluent inhibited the growth of Abelmoscus esculentus.The growth parameters such as plant height, leaf number, root length, shoot/root ratio, fresh weight, dry weight and moisture content of the crop were negatively affected by cassava processing effluent. Therefore, this study suggests that cassava processing effluent should be disposed off properly to avoid contamination of the environment.

ABSTRACT
The experiment was carried out in the demonstration farm of Imo State Polytechnic Umuagwo. The experimental land was divided into three (3) blocks each containing four (4) beds to give a total of 12 beds. Each bed sizes was 1mx2m and with 0.5m gap between beds. The blocks were spaced 1m apart to ease movement during cultural operations. A bed contained 2 plants. The treatments involved four (4) different rates of poultry manure application. (i) 0 ton/ha (ii) 5 tons/ha (iii) 10 tons/ha (iv) 15 tons/ha. The treatments were assigned into the plots in a randomized complete block design (RCBD) with three (3) replications. Seed was sown per hole at a spacing of 1mx1m. Data were collected at 2 weeks after planting and at 2 weeks intervals thereafter. The data collected during the experiment included the following parameters; vine length, stem girth, number of branches, and number of leaves and finally grain yield after harvest. Analysis of variance (ANOVA) and Fisher's least significant differences (FLSD) at $p \leq 5\%$ was undertaken on the data collected. The results of the study showed that 10 tons/ha level of poultry manure application was effective in increasing growth parameters and yield of fluted pumpkin.
Keywords: Poultry manure, performance, fluted pumpkin
.

INTRODUCTION

Telfairia occidentals is a tropical vine grown in West Africa as a leaf vegetable and for edible seeds. Common names for the plant include fluted gourd, Fluted pumpkin and Ugu. It is a palatable leafy vegetable in Eastern Nigeria. Telfairia occidental is a member of the Curcurbitaceae family and is indigenous to Southern Nigeria. The seeds are high in protein and fat, and can therefore contribute to a well-balanced diet. The plant is dominantly used by the Igbo tribe, who continue to cultivate the gourd for food source and traditional medicines (Ali, 2005). Fluted pumpkin produces a lot of biomass and its nutrient requirements are generally considered to be high.

Poultry manure is abundantly available in many parts of Nigeria, wasting and sometimes constituting nuisance where it is generated as a by-product of poultry farms-it has been established that poultry manure (pm), contains sizeable levels of nitrogen and that 60-80% of its nitrogen is organic form, while the remaining 20-40% is an inorganic fractions and that approximately 50% of the organic is mineralizeable within 90 days under laboratory conditions. Organic fertilizers including farmyard manure, sheep manure and poultry manure may be used for the crop production as a substitute of the chemical fertilizers becomes the importance of the organic manure cannot be overlooked. Worldwide, there is growing in test in the use of organic manure due to depletion in the soil fertility. Organic manure (OM) improves soil structure, water, air and nutrient retention in the soil, buffers soil chemical imbalances, supports living organisms (I.F.A.S, 2005). Poultry manure is an excellent organic fertilizer, as it contains high nitrogen, phosphorus, potassium and other essential nutrients in contrast to chemical fertilizer, it adds organic matter to soil which improves soil structure, nutrient retention, aeration, soil moisture holding capacity and water infiltration (Deksissa et al., 2008). It was also indicated that poultry manure more readily supplies to plants than other organic manure sources (Garg and Bahla, 2008).

In agriculture, the main reasons for applying PM include the organic amendment of the soil and the provision of nutrients to crops (Warren et al, 2006). Poultry manure is an excellent organic fertilizer as it contains high nitrogen, phosphorus, potassium and other essential nutrients. In contrast to chemical fertilizer, it adds organic matter to soil which improves soil structures, nutrient retention, aeration, soil moisture holding capacity and water infiltration (Deksissa et al, 2008).

The objective of this study was to evaluate the effect of different rate of poultry droppings on the performance of Fluted pumpkin in the research farm of Imo State Polytechnic Umuagwo.

MATERIALS AND METHODS

The experiment was carried out in research farm of Imo State Polytechnic Umuagwo in Ohaji-Egbema Local Government Area of Imo State, Southeastern Nigeria. The experimental site lies between latitude $5^{0}17'$N, and longitude of $7^{o}54$E. It lies within the low lying geomorphology of South Eastern Nigeria (Orajaka et al., 1978).

Palm trees and cassava are the predominant tree and plant respectively in the area. The rainfall pattern is bimodal between April and October. The town is in wet humid equatorial rainforest zone with 2250-2500mm of annual rainfall, annual relative humidity of 88% with mean temperature of 27°C and the soil type is sandy loam.

The conventional tillage operations which include land clearing and preparation of beds were carried out to conserve the soil and its nutrients. The land was cleared and beds were constructed. The experimental land was divided into three (3) blocks each containing four (4) beds to give a total of 12 beds. Each bed size was 1mx2m and with 0.5m gap between beds. The blocks were spaced 1m apart to ease movement during cultural operations. A bed contained 2 plants. The treatments involved four (4) different rates of poultry manure application: T_0 – 0 ton/ha, T_1 - 5 tons/ha, T_2 – 10 tons/ha, T_3 – 15 tons/ha. The treatments were assigned into the plots in a randomized complete block design (RCBD) with three (3) replications.

Fluted pumpkin (Telfairia Occidentalis) seeds were extracted from pods which were obtained from the Agronomy Department, Michael Okpara University of Agriculture Umudike, Umuahia Abia State. They were air dried for 24 hours before planting. Thereafter the beds were irrigated to improve soil moisture content, seed germination and seedling emergence. Planting was done early in July, 2014. Two seeds were sown per hole at a spacing of 1mx1m and later thinned down to one seedling per stand at four weeks after sowing (WAS). Application of fertilizer treatments were done according to the rate allocated to each plots by band placement. Watering of seedling was done every morning at two days interval only when there is no rainfall for two (2) days to avoid wilting and to improve the growth and development. Weeds were controlled twice manually by hoe at 4 and 8 weeks after sowing.

Data were collected 2 weeks after planting and at 2 weeks intervals thereafter. The data collected during the experiment included the following parameter; vine length, stem girth, number of branches, leaf area, number of leaves and finally grains yield after harvest, number of flowers when flowering starts. At pod maturity (at 10 weeks after planting), the pod yield and the yield components collected included number of pod per plant, fruit weight (kg) per plant; number of seeds per pod.

Analysis of variance (ANOVA) was undertaken on the data collected so as to determine if there were any significant differences.

RESULTS AND DISCUSSION

The results of the treatment on growth parameters are presented in tables 1, 2, 3, 4 and 5. Stem girth increased significantly with organic manure application beginning from 2 WAP (Table 1). The increase appears to peak at 10 tons as application of 15 tons did not lead to any further increase in stem girth. Number of leaves of fluted pumpkin increased with application of 5-15 tons of manure beginning from 6 WAP. Application of 15 tons/ha was not better than 10 tons/ha in terms of number of leaves produced (Table 2). Number of branches was similar in all treatments at 2-4 WAP but increased with the application of 10-15 tons of manure per hectare beginning from 6-10 WAP. Again plants that received 15 tons of manure did not produce more branches than those that received 15 tons (Table 3). Vine length followed a trend similar to that of stem girth and number of leaves (Table 4). Average yield increased significantly ($p \leq 0.05$) with poultry manure application up to 10 tons. Thereafter further addition did not increase yield (Table 5).

The result of the study showed that fluted pumpkin growth and yield parameters were improve by the application of 5,10,15 ton/ha of poultry manure. This experiment showed an increase in growth parameter and yield when compared with the control treatment. The mean values of vine length, number of leaves, stem girth; number of branches and yield were positively correlated with different levels of poultry manure application. Plants that received 10tons/ha of poultry manure gave the tallest vine length, highest number of stem girth, number of leaves and branches when compared with other treatments. Application of 15tons/ha of poultry manure has a significant different with T_0 and T_1 and no significant difference where observed when compared with T_2. This result was in line with work done by (Ewulo, 2005) which reported that application of different levels of poultry manure increase the growth parameters and yield of fluted pumpkin.

CONCLUSION

The results showed that the effect of different levels of poultry manure application on fluted pumpkin yield was significant ($p \leq 0.05$). Application of 10 tons/ha level of poultry manure obtained higher yield when compared with other treatments. The data presented in tables illustrated the positive effect of different levels of poultry manure application. The growth parameter and yield were significantly increased by the application of 5, 10 and 15 tons/ha levels of poultry manure when compare to the plot with no application of poultry manure, which showed a reduction in yield.

ABSTRACT
The study was carried out in the Teaching and Research Farm of Ibrahim Badamasi Babangida University, Lapai, Niger State during 2014 and 2015 cropping season to evaluate the performance of three maize varieties in terms of Stand density in Lapai. It was a factorial experiment carried out in a Randomized Complete Block Design (RCBD) with three replicates. Three maize varieties (SAMMAZ 16 and 17 and a Local (Kabako)as check) were evaluated under two different plant stand density (1 and 2 maize stand per hill) for such growth characters as plant height, number of leaves, leaf area and days to 50% flowering at 10 weeks after sowing (WAS) and dry cob weight and grain yield. The results obtained indicate that maize varieties responded significantly in combination with plant height and number of leaves at 10 WAS such that the local variety produced the tallest plant with increasing number of leaves in 2014 and 2015 respectively. Yield and yield components were also not significant in this study. It is recommended that with adequate application of all agronomic practices being observed, SAMMAZ 16 and 17 with Local (kabako) maize varieties will always give higher grain yield in the study area.
Keywords: Variety, Stand Density, Growth, Maize, Yield Components

INTRODUCTION

Maize (Zea mays L.) is an established and most important crop grown among all cereals in Nigeria. World production of maize stood at 872.8 million metric tons in 2012 and 9.4 million metric tons which represent 1.1% of the world total production in 2012 (FAO, 2014). Maize is a multipurpose crop which provides feed for poultry and livestock fodder (Undie et al., 2012). It also serves as source of human consumption such as roasted, baked, fried, pounded or fermented (Agbato, 2003). 100 million hectares of land had been put into maize production in developing countries with almost 70% of the production coming from low and lower middle income countries (FAOSTAT, 2010)

Most importantly, It is a known fact that the yield potential of a crop is depend on its genetic makeup as well as the environment in which it is grown. The genetic potential however, can be exploited to the maximum by providing favorable growth environments (Asghar et al., 2010). Successful Maize production requires an understanding of various management practices as well as environmental conditions that affect crop performance (Eskert, 1995).

The spread of maize can also be attributed to its adaptability to a wide range of soils and climatic conditions. It is therefore most appropriately to select cultural practices such as cultivars, sowing dates and planting densities that have been shown to affect Maize yield potential and stability (Norwood, 2001) and therefore Cultivar selection should be based on adaptation to growing environments coupled with good return.

Against this background, the broad objective of this study, therefore, was to identify variety of maize most suited or adapted to Lapai area and the appropriate stand density for growth and yield of these varieties.

MATERIALS AND METHODS

Experimental site

The study was conducted in Lapai in the 2014 and 2015 cropping season at the Teaching and Research Farm of Ibrahim Badamasi Babangida University, Lapai, Niger State. Lapai lies between Latitude 9^0 2'N and Longitude 6^0 34'E. The soil pH of the experimental site is 5.46 (Garba et al. 2015). The seeds of maize which are tagged SAMMAZ 16 and 17 were sourced from the Institute of Agricultural Research (IAR) Ahmadu Bello University, Zaria. SAMMAZ 16 is a Striga resistant maize variety while SAMMAZ 17 is a tolerant maize variety. The Local variety (Kabako) is the farmers maize variety and it is collected from Lapai market in Niger State.

Experimental Design

The 2 years field experiment consisted of factorial combination of 3 maize varieties (SAMMAZ 16 and 17 and Local (Kabako) maize varieties) and plant stand density (1 and 2 seed per hill). The experiment is laid out in a Randomized Complete Block Design with 6 treatments replicated 3 times. Each plot contained 4 ridges at 2m

×3m (6m^2) and 75cm inter-row spacing. Five maize plants were sampled for data collections from each net plot. Plots were manually weeded at 3 and 6 weeks after sowing (WAS). Side placement of half-dose of NPK 15:15:15 fertilizer was applied at the rate of 120 kg/ha and second –half dose was applied at 6 WAS. The parameters assessed include stand count, plant height, number of leaves, days to 50% flowering and silking, leave area, dry cob weight, 100 grain weight and grain yield. At harvest, the cobs were removed, dehusked and dried. It was later weighed, threshed and winnowed to obtained clean grains and weighed again. Data collected were subjected to analysis of variance (ANOVA) using statistical analysis software (SAS, 2002) and Duncan's multiple range test (DMRT) was used to separate treatment means at 5% levels of probability.

RESULTS AND DISCUSSION

Table 1 shows the response of maize varieties and stand density of stand counts, plant height, number of leaves at 10 weeks after sowing (WAS) and days to 50% flowering during the 2014 and 2015 cropping season in Lapai. The Statistical Analysis revealed that maize stand count and days to 50% flowering were not significant in both years, but significant difference was revealed in both years in combination with plant height and number of leaves such that SAMMAZ 17 produce similar taller plant height with the Local variety (Kabako) in 2014 which is similar with Local variety in 2015, each with an increasing number of leaves. However, SAMMAZ 16 recorded the shortest plant height in this study Increase in plant height with an increasing of number of leaves of the Local variety could be as a result of adaptation of the Local variety to its environment. Similar results were obtained from the same location under Striga infestation where the Local variety recorded taller plants height with increasing number of leaves at 9 WAS as against an improved maize variety (Garba et al., 2015). It was also reported that Local maize varieties are taller than the improved varieties (Raemaekers, 2001). The interaction effects of the treatments were not significant on all parameters (Table 1).

The effect of Maize Varieties and Stand Density on dry cob weight and grain yield at Lapai during the 2014 and 2015 cropping season is presented in Table 2. It was observed from the results obtained in this study that increasing stand density from one to two plants per stand did not significantly affect dry cob weight and grain yield in 2014 and 2015 respectively. However the result shows that maize varieties does not differed significantly with stand density in both years. The results could be attributed to a uniform application of all agronomic or cultural practices to all treatments from planting to harvest and that must have been optimum for similar higher yield of the varieties tested. There was an interaction between variety and stand density on dry cob weight in both years and grain yield in 2015. This reveals that all maize varieties produced similar highest dry cob weight in both years and grain yield in 2015 at all levels of stand density.

CONCLUSION

Based on the result obtained from the study In terms of grain yield of all the varieties tested, , it can be concluded that all the varieties can be adopted by maize growers with adequate agronomic or cultural practices for greater grain yield.

ABSTRACT
A field experiment was conducted 2014 cropping season at the Federal College of Agricultural Produce Technology Research Farm, Barkum, Bunkure Local Government Area of Kano State in the northern Guinea savanna ecological zone of Nigeria to assess the effects of seedling age at transplanting on growth and yield parameters of vegetable amaranth (Amaranthus caudatus L.). The treatments consisted of combinations of three transplant ages (2, 3 and 4 weeks after sowing) laid out in a randomized complete block design and replicated three times. Based from the results shown, seedlings transplanted at 4 weeks of age were significant taller with shoot fresh weight than 2-weeks old seedlings at the initial growth stage. Transplant age had no effect on these growth parameters such as plant height, number of leaves and branches per plant and are were significantly (P=0.05) at later stage. All the other growth parameters were not affected by transplant age. Also shown that in the results, transplanting age of between two and three weeks after emergence, which roughly corresponded with three to four weeks old seedlings would benefit the farmers most when transplanted with an optimum yield.

INTRODUCTION
Amaranth (Amaranthus cruentus) is a dual purpose crop with edible leaves and seeds (Olufolaji and Dimakin, 1988). Apart from its uses as a vegetable, it has also been used as an effective alternative to drug therapy in people with hypertension and cardiovascular disease (CVD) (Martiorosyan and Miroshnichen, 2007). The demand for this crop as vegetable has increased, especially in the urban centre where people are not involved in primary production (Schippers, 2000). Grubben and Van Slotten, (1981) reported that vegetable amaranth is grown primarily for its tender stems and succulent leaves. Its succulent tender stem and young leaves are used in preparing soup and stew; young shoots are sometimes dried for future use as a forage crop for feeding livestock. This has made the vegetable to become an important commodity in our market and production an important economic activity for the rural women (Law- ogbomo et al., 2009). The yield per hectare of this crop is low (7.60 t ha-1) when compared to that of United States (77.27 t ha-1) and world average (14.27 t ha-1) (FAO, 2007). For commercial production, optimum performance of the crop must be desirable through changes in cultural practices (Sterrett and Savage, 1989). Anon, (1984) pointed out that leaf protein concentrate can be extracted from amaranth and used for feeding young children and person's requiring high protein, vitamin A and Iron. Amaranth has also been found to contain high levels of nutritionally critical amino acids, lysine and methionine (Koch et al.,1985). Originally, the bulk of vegetables consumed in Nigeria were supplied by subsistence farmers. Vegetable supply to areas of high demand has remained low and seasonal as the subsistence farmers continue to rely on natural rainfall. Today, high demand for vegetables in the cities and towns has stimulated the growth of market gardening along perennial rivers and streams (Akparobi, 2009). Advantages of using transplant as reported by Vantine and Verlinden (2003) was that seeds are not wasted because seeds growing in a Greenhouse or secured place have a higher germination rate than those growing in the field where various environmental factors can lead to low survival rates. Also when transplants are planted in the field, they are likely to be more uniform since they start off in the field at the same growing stage. Harvesting times are reduced because the plants will likely ripen at the same time. Another merit of transplant was that the harvesting season is longer because transplants yield earlier harvests which are good news for growers who wish to grow warm-season crops. Equally plants get a "head start" in the greenhouse/ secured garden when it is too cold to plant outside in temperate area as they will be ready to plant when the weather is ideal, and the crop will be ready to sell or eat earlier than usual. Orzolek (2009) highlighted that all vegetable transplants have an ideal age/size which enables them to continue active growth in the field after transplanting and be somewhat resistant to environmental stress. In the same vein, younger plants than 6 weeks are not as resistant to desiccation from wind, low temperatures (below 45°F) and soil moisture deficits. On the other hand, older plants (greater than 10 weeks) have a relatively large vegetative mass that has initiated flowers and may be heading into the reproductive phase of growth; hence the plants will produce fruit, but only a fraction of their full potential. Khairul alum et al.,(2010) reported that growers tend to manipulate sowing time in order to obtain better growth and higher quality yield as the time of sowing is also adjusted so as to synchronize with time of harvest and market demand. This study

was therefore conducted to evaluate the effect of seedling age at transplanting on growth and yield parameters of vegetable amaranth (Amaranthus caudatus L.).

MATERIALS AND METHODS

A field experiment was conducted during the months of July to September, 2014 at the research farm Federal College of Agricultural Produce Technology Research Farm, Barkum, Bunkure Local Government Area of Kano State (11^0 39' 0^0 N, 8^0 39' 0 E). The study area has dominant features of the dry savanna of Nigeria with two main seasons: the wet and the dry season. The wet season usually starts from July and ends in October with an annual rainfall varying from 200mm in the north to 650mm per annum with an annual average temperature of 29 ^{0}C to 42 ^{0}C (KNARDA, 2009). The treatments consisted of combinations of three transplant ages (2, 3, and 4 weeks after sowing) laid out in a randomized complete block design and replicated three. The gross plot size was 3.0m x1.8m.(LxB respectively). Seed of amaranth (Large Green Amaranth) cultivar from National Institute of Horticultural Research Station (NIHORT) Bagauda Substation was collected and sown at a college farm nursery site on 4 July, 11 July and 18 July, 2014 for the two, three and four weeks old seedlings ,respectively. The experimental site was ploughed, harrowed and ridged with tractor, thereafter; the plots were laid out and flattened into raised beds. The plots were marked out and a 1.5m border separated each plot from the other plot. The two, three and four weeks old seedlings were transplanted in the evening into moist seed beds of a dimension of 5.4m^2 on 25 July, 2014 at an inter row spacing of 30cm and intra row spacing of 10cm giving a population of 40 plants/plot. The field was weeded manually with hoe in the morning before transplanting the seedlings in the evening on the 25 July, 2014; another hoe weeding was done at three weeks after transplanting (WAT). The established seedlings in each plot were counted and recorded on 31 July, 2014. The parameters measured were plant height, shoot fresh weight, shoot dry weight and usable yield. The data collected were subjected to analysis of variance using SAS system (SAS, 1991). Significant means were compared using Duncan's Multiple Range Test (DMRT) (Duncan, 1955).

RESULTS AND DISCUSSION

At 10 DAT (days after transplanting), results show that there is no significant differences in the production of taller plants between 2 and 3 and 4 weeks transplant age at the sampling period of 10, 20, 30 and 40 DAT. The numbers of leaves per plant were significantly higher at each sampling periods of 10, 20, 30 and 40 DAT of 2, 3 and 4 weeks old transplant. As shown in table 3, there is no significant difference observed at the sampling period in the amount of branches produced by the plant at sampling period between 2, 3 and 4 weeks old transplant. The usable yield produce by the plant at the sampling periods of 10, 20, 30 and 40 DAT were statistically at par with the usable yield produce by the amaranth of 2,3, and 4 weeks old transplant.

CONCLUSION

Based from the study on the effect of seedling age at transplanting on growth and yield parameters of vegetable amaranth (Amaranthus caudatus L.) in Northern Guinea Savanna Ecological Zone of Nigeria, it shows that there is no significant differences in transplanting age between 2, 3, and 4 weeks old transplant in terms of plant height, number of leaves, number of branches and usable yield parameter. This correspond with the work of Mulundana et al.,(2009) who transplanted vegetable amaranth at one, two, three and four weeks after emergence found that the best transplanting age was between two and three weeks after emergence. Vavrina, (1990) reported that, the effect of transplant age on yield remains an issue of major interest to growers of horticultural crops because when transplants are too old, growth and yield are adversely affected as transplanting age depends on the crop, environment and cultural conditions. The conflicting results on literatures on transplant age may likely be due to the differences in environmental and cultural conditions that the plants were subjected to (Vavrina, 1991).

GENOTYPE X ENVIRONMENT ANALYSIS OF YIELD OF SOME SUGARCANE VARIETIES IN NIGERIA

M.N. Ishaq, B.O. Ehirim, A.C. Wada & S. Agboire

National Cereals Research Institute Badeggi, P.M.B, 08. Bida. Niger State
bernard.ehirim@gmail.com

ABSTRACT
Twenty five sugarcane varieties were planted in two locations with different ecologies for two years. In each location, the trial was planted using randomised complete blocks with three replications. Data on yield and yield components were collected in all the locations although only cane yield data was used for the G X E analysis. Significant differences were observed for yield and yield components in all the locations although there was better performance for cane yield in Badeggi than Edozhigi (hydromorphic soil) location. Significant G X E interaction was observed for yield with environments contributing more to the variation. AMMI biplot shows that genotypes BD2002-037 and IMO-001 have high and stable yield while genotypes BD2002-36, BD2007-43, KNB9180 and Co957 appear to be high yielding but relatively unstable. The best environment with highest yield was Badeggi14. Due to differences displayed in the analysis, care must be taken in selecting the best variety for different environment considering high yield and stability of the genotype across the environment.

INTRODUCTION

Sugarcane (Saccharum hybrids L.) is the major raw material from which refined sugar is manufactured and is a source of revenue for many resource-limited sugarcane growers in the Nigeria(Agboire et al,1999). Sugarcane is an important industrial and cash crop in Nigeria. Besides sugar production, sugarcane produces numerous valuable byproducts like alcohol used by pharmaceutical industry, ethanol used as a fuel, bagasse used for paper and chip board manufacturing and also for burning sugar mills furnaces, and press mud used as a rich source of organic matter and nutrients for crop production.
Although sugarcane occupies an important place in cropping pattern of Nigeria and brings large dividends to growers, but its yield and production has become stagnant for the last two decades. Main reason for lower cane yield is lack of high yielding varieties in the country. Most of exotic varieties imported by the sugar companies have dwindling cane and sugar yield and cannot meet up the cane and sugar yield desired by the companies (Olaoye1999).
Productivity of a good sugarcane variety in favourable environments is however important although this does not indicate its adaptability and stability, whereas performance of a genotype in diverse environments is somehow a true evaluation practice of its inherent potential. The use of genotype-environment (GE) interaction in the relative performance of genotypes represents the change due to environmental variations (Gauch, 1992). A method that has been used in studies of GE and its interaction is AMMI (Additive Main Effects and Multiplicative Interaction analysis). This method can contribute both to the identification of widely adapted genotypes with high yields (Gauch and Zobel 1988).
The purpose of this study was to evaluate the stability and adaptability of some exotic, local and hybrid sugarcane germplasm in different ecological zones of Nigeria by the AMMI method and GGE biplot, with a view to determine the effect of GxE interaction on cane yield of the sugarcane genotypes.

MATERIALS AND METHODS

Twenty-five sugarcane varieties (thirteen exotic, ten hybrids bred in the institute and two varieties are local) were evaluated for two years at two locations. The first year was the plant crop while the second was first ratoon. One of locations (Badeggi) is upland while the second location (Edozhigi) is semi-hydromorphic (fadama). The experiment was planted using randomized complete block design with three replications. The plots size was 5m x 6m, spaced 1.50 m apart. Ten (10) cane sett were planted per row and were evenly distributed along the rows of each plot. All the agronomic and cultural practices of sugarcane production were followed as per the recommendation of NCRI. Data was obtained on the following parameters: germination and establishment percent count; stalk length, girth and weight; number of stalks per stool; number of millable stalks per plot, brix % (sugar yield) and cane yield per plot.
Analysis of variance procedure was adopted to test the significance of location, genotype, and first order interactions assuming the location effects as random and genotype effect as fixed. To determine the effect of genotype X environment interaction on cane yield, the data were further subjected to Additive Main and Multiplicative Interaction (AMMI) analysis. GGE-biplot methodology, which is composed of 2 concepts, the biplot concept (Gabriel, 1971) and the GGE concept (Yan et al., 2000) was used to visually analyze the data.

This methodology uses a biplot to show the factors (G and GE) that are important in genotype evaluation and that are also the source of variation in GEI analysis. In the current study, genotype-focused scaling was used in visualizing for genotypic comparison, with environment-focused scaling for environmental comparison. The entire statistical analysis was conducted using the Integrated Breeding Platform Breeding Management System version 3.0.8

RESULTS AND DISCUSSION

Significant differences were observed for all traits in Badeggi location during the plant crop (2013) except stalk girth, number of stalks per stool and brix percent (Table 1). This shows the diversity in the population under study. Similar observations were made by Olaoye and Ishaq (2009) when they studied different populations of sugarcane from different geographical locations. Highly significant differences were observed for cane yield per plot which is the trait of paramount importance in GXE analysis. Significant differences were observed at Edozhigi location during plant crop (2013) for all traits except stalk girth and brix percent (Table 2). The varieties generally performed better at Badeggi than Edozhigi during the plant crop. This is probably due to the soil types in the locations. Edozhigi soil is hydromorphic and suitable for rice and chewing sugarcane production. Most of the sugarcane varieties evaluated were industrial canes cultivated on upland.

The ratoon crop presented a different picture in terms of performance of the varieties. Table 3 shows the first ratoon performance of the varieties at Badeggi location. Significant differences were observed for all the traits except internodes length per plot. The ratoon yield is however much lower than was observed in the plant crop. This shows that most of the sugarcane varieties studied have poor ratoonability and may not be suitable for long term cultivation. Similar trend was observed in the ratoon crop of Edozhigi (Table 4). In Edozhigi location significant differences were observed for all the traits except stalk girth. Although there was significant difference in yield in the four environments (Badeggi 2013, Badeggi 2014, Edozhigi 2013 and Edozhigi 2014), there was better performance among varieties in Badeggi location than Edozhigi.

Highly significant Genotype X Environment Interaction (GEI) was observed in the regression analysis (Table 5). Genotypic differences were also significant which shows the wide differences in the varieties as well as response of the varieties to the environments. Identifying high yielding and stable genotypes is easier when such significant differences are observed (Eberhart and Russell 1966; Ishaq et al 2015). Table 6 shows the mean values for yield and regression coefficient (b), for 25 varieties of sugarcane over four environments. Genotypic sensitivity which shows the changes in the environmental quality is shown by the slope (b value).

According to Eberhart and Russell (1966), an ideal cultivar would have both a high average performance over a wide range of environments plus stability. The existence of genotype x environment interaction (GEI) raised the need to identify high yielding and stable genotypes. Genotypic sensitivity is indicated by b value which shows changes in the environmental quality; where values of $b > 1$ mean genotypes with a higher than average sensitivity ($b=1$), and such genotypes are less stable; while $b < 1$ means genotypes that are less sensitive and more stable. Six genotypes (B991114, BBZ921104, BD 2002-04, BD2002-037, IMO-001 and KNB9218) had more than average mean performance (67.11t/ha) and b value more than 1 hence they are above average sensitivity (i.e. below average stability or less stable). Seven genotypes (BD2002-36, BD2007-43, BD2007-45, Co957, DB75159, ENU-001 and KNB9180) had more than average mean performance and b value less than 1 hence they are below average sensitivity (i.e. above average stability or more stable).

Although IMO-001(78.72t/ha) does better than KNB9218 (70.16t/ha) in the average performance, KNB9218 is superior to IMO-001 in the high-quality environments. This is because KNB9218 has a better ability to exploit improved environmental conditions, which is reflected in the higher genotypic sensitivity of the former ($b_{KNB9218} = 1.5196 > b_{IMO\text{-}001} = 1.1090$). However both genotypes has potential to respond to increase in environmental quality in a predictable way (dynamic stability). High yielding genotypes like BD991114, BBZ921101, BD2002-37, BD2007-43, ENU-001, IMO-001 and KNB9218 had high static stability (1.e. ability to give same performance across environments).

The AMMI Analysis of variance shows the environmental variance was significant and higher than both the genotype and GEI variance. The genotype variance was however higher than the GEI variance (Table 7). The result showed that the environment main effect (E) was the most important source of variation, due to its large contribution to the total sum of squares for yield. The large sum of squares for environments indicated that the environments were diverse, with differences among environmental means causing high variation in cane yield. This might probably be due to differences in growing season rainfall and type of soil in the environments. Variation due to genotype was larger than that due to GEI, meaning that differences among genotypes vary across environments.

Similar observations were obtained by Admassu et al (2008) and Ishaq et al 2015 in their studies. The presence of GEI was demonstrated by the AMMI model, when the interaction was partitioned among the first two Interaction Principal Component Axis (IPCA) as they were significant. The IPCA1 explained 73.32% of the interaction while IPCA2 explained 19.09%. They cumulatively captured 92.41% of the total GEI. This implied that the interaction of the 25 sugarcane with four environments was predicted by the first two principal components of genotypes and environments, which is in agreement with Guach and Zobel (1996).

The biplot of the best genotypes in each of the environments for cane yield is presented in Figure 1. The polygon view of the GGE-biplot explicitly displays 'which-won-where' i.e. (best genotype in each environment) and it is a summary of the GEI pattern of a multi-environment yield trial data. The polygon is formed by connecting the genotypes that are further away from the biplot origin such that all other genotypes are contained within the polygon. To each side of the polygon, a perpendicular line, starting from the origin is drawn and extended beyond the polygon so that the biplot is divided into several sectors, and the different environment were separated into different sectors. The genotype at the vertices of each sector is the best performer at environments included in that sector. In this study there were four sectors only and three mega environments identified. Edozhigi13 and Edozhigi14 formed one environment while Badeggi13 and Badeggi14 formed separate mega environments. BBZ921101won or was the best genotype in Badeggi13 while BD2007-43 won in Edozhigi13 and Edozhigi14 mega environments. Badeggi14 mega-environment fell in the four sector close to the pivot point on the perpendicular line and varieties mostly in this mega environment have high yield and are also stable. This environment also had the highest mean yield across other environments. Genotypes at the vertices of the polygon and do not fall in any mega environment are not the highest yielding genotypes at any environment. However, genotypes within the polygon, particularly those located near the plot origin, were less responsive than the vertex genotypes.

CONLUSION

Selection of suitable genotypes in a multiple environment trial is sometimes difficult due to complication in the environment and the genotype response. The occurrence of the genotype X environment interaction further complicates the selection of superior genotypes. The presence of the G X E interaction confirms particular genotypes being superior in particular environments. In this study, BD2002-37 and IMO-001 were high yielding and stable while BD2002-36, BD2007-43, KNB9180 and Co 957 were high yielding but unstable. The best environment was Badeggi14

Environmental factors are complex and similarities in environments can be deceptive and non-repeatable. For instance, two environmental conditions may be similarly poor, one due to poor soil fertility and the other due to rainfall shortage. Also, same genotype may express different phenotypes in different environments

COMPARATIVE ANALYSIS OF INTEGRATED NUTRIENT MANAGEMENT PRACTICES FOR PRODUCTION OF DIOSCOREA DUMETORUM IN SOUTH EAST AGRO-ECOLOGICAL ZONE, NIGERIA

M. C. Ogbonna & I .N. Onyekwere

National Root Crops Research Institute, (NRCRI), Umudike, P.M.B 7006, Umuahia, Abia State Nigeria.
ogbonnamarcel@gmail.com

ABSTRACT
The study was carried out in 2009 and 2010 cropping seasons at research field of NRCRI, Umudike. The test crop was Dioscorea dumetorum due to decrease in the growth and yield of the crop. It was tested with different soil nutrient management practices. Soil nutrient management practice comprised three levels of NPK 15:15:15 fertilizer such as 0, 300, and 600 kg/ha and three levels of poultry manure (0, 2 and 4) t/ha. The fields were allowed to undergo fallow for two years and then post-harvest soil and poultry manure analysis was carried out. All the stages of land preparation were done mechanically with tractor. The ridges were laid out in plot size of 4mx5m in a randomized complete Block Design replicated three times. Planting was done on ridges with a planting distance of 1mx1m. The tuber weight planted was 5.00kg per plot in 2009 and 5.5kg per plot in 2010. Treatments were applied 8 weeks after planting and the yam specie was harvested 7 months after planting for 2009 and 8 months after planting for 2010. Each treatment represents a technology and data were collected on each activity carried out using cost-route approach. Data collected were subjected to gross margin analysis to compare the technologies with the traditional method. Results show that 300kg/ha of NPK 15:15:15 plus 4t/ha of poultry manure had the highest comparative advantage over the other techniques including the traditional system as the gross margin was ₦16, 447.58/ha and therefore was recommended to resource limited farmers.
Keywords: Dioscorea dumetorum, **Soil nutrient management, Gross Margin, Nigeria**

INTRODUCTION
The yam specie - Dioscorea dumetorum occupies very important position among farming families in Africa because of its carotenoid content and good source of food for diabetics. In Nigeria, the yam specie is popularly grown by subsistence farmers in Abia, Akwa Ibom, Anambra, Edo, Delta, Rivers, Cross River, Ebonyi, Enugu, Kogi States and some states in Western part of the country among other states in Nigeria. The crop is mostly cultivated by women farmers who intercrop the crop with equsi-melon, cassava, okra, pumpkin, cowpea, maize etc. after the land has been allowed to fallow for not less two years. It is a trifoliate yam, the only species with compound leaves. The stems of the crop are strong and thorny, coiling from right to left (Janssens, 2001). The crop is noted for its medicinal value as it plays a significant role in the diets of the farming communities of these states. It is a hunger saving crop often harvested in piece meal. Dioscorea Dumetorum is usually consumed when there is nothing left of other yam species or probably when other yams have been tied up in the barn. The crop is superior nutritionally to other yam species commonly consumed as it has high protein, minerals and vitamin A contents. It has crude protein content of 11.07%, fibre content of 2.06% and total carotenoid content of 217.73ug/100g, but it has low carbohydrate compare to other yam varieties. This makes it a good source of food remedy for diabetics as revealed by research (Ezeocha et al., 2010).
Despite the medicinal value of the crop, it rate of production has been on decrease recently probably due to poor soil fertility management and total neglect of the crop in area of detailed research. The farmlands are no longer allowed to go into fallow due to high demand for other uses. The crop however, can be included among the neglected yam species in Nigeria. A multidisciplinary research to expose the potentials of the crop is therefore necessary. First, the study considered soil management innovations sustainable enough to improve the present yield of the crop. This was done by integrating nutrient management on soil which included inorganic and organic fertilizers options. The study looked at the effect of the different options on the yield of the crop in relation to the traditional method as well as it costs/benefits. The best innovation(s) were selected appropriate for dissemination to producers and adoption. The study used the concept of farm gross margin to select the best innovations. Farm gross margins provide a simple method for comparing the performance of enterprises or technologies that have similar requirements for capital and labour (The State of Victoria, 2016). A gross margin refers to the total income derived from an enterprise less the variable costs incurred in the enterprise. The use of gross margins became widespread in the UK from about 1960, when it was first popularized amongst farm management advisers for analysis and planning purposes (Barnard and Nix, 1979; Firth, 2002). They are not a

measure of farm profit as they do not include capital (land, buildings, machinery, irrigation equipment etc.) or fixed costs (building and machinery depreciation, administration, insurance, rates, taxes etc.). However, they do provide a useful tool in terms of farm management, budgeting and estimating the likely returns or losses of a particular crop. Therefore, the objective of the research was to compare the performance (costs/benefits) of different technologies of the integrated nutrient management on soil for the production of trifoliate yam specie.

METHODOLOGY

The experiment was conducted in 2009 and 2010 cropping seasons at research field of NRCRI, Umudike. The test crop was Dioscorea dumetorum. Soil nutrient management practices comprised three levels of NPK 15:15:15 fertilizer such as 0, 300, and 600 kg/ha and three levels of poultry manure (0, 2 and 4) t/ha. The fields were allowed to undergo fallow for two years and then post-harvest soil and poultry manure analysis was carried out. All the stages of land preparation were done mechanically with tractor. The ridges were laid out in plot size of 4mx5m in a randomized complete Block Design replicated three times. Planting was done on ridges with a planting distance of 1mx1m. The tuber weight planted per stand was 250g totaling 5.00kg per plot in 2009 and 275g per stand summing up to 5.5kg per plot in 2010. Treatments were applied 8 weeks after planting and the yam specie was harvested 7 months after planting for 2009 and 8 months after planting for 2010. Manual weeding was performed 8 and 16 weeks after planting. Each treatment represents an enterprise/technology and data were collected on each activity carried out using cost-route approach. The data collected were on input cost such as planting materials (seed yams), inorganic and organic fertilizers, hiring of tractor, all the various labour activities performed such as planting, fertilizer application, weeding, harvesting and carting. Price of the tubers harvested. Data were subjected to gross margin analysis per hectare for the different technologies. The Gross Margin Method is expressed as;
Gross Margin (GM) = GR- VC.
Where GM = Gross Margin or Net Return,
GR = Gross Revenue and
VC = Variable Cost (Farris et al., 2010; Mbanasor, et al., 2014; Paul and Katherine, 2010; The State of Victoria, 2016).

RESULTS AND DISCUSSION

Comparison of improved soil amendment practices and traditional system

The result of the soil fertility management practices and the traditional system is presented in Table 1. The application of 300kg/ha of NPK 15:15:15 plus 4t/ha of poultry manure had the highest comparative advantage over the other techniques and the conventional system as the gross margin was ₦16, 447.58/ha. This means that the technique could be recommended to producers to promote the yield and growth of the yam specie. The next technique with the second highest gross margin was 600kg/ha of NPK 15:15:15 plus 4t/ha of poultry manure, as the gross margin was ₦15, 306.14. This means that the technique could be selected as alternative to the first innovation. However, there is a set back to the choice of the alternative because it has the highest total variable cost of ₦363, 836.60. Here the concept of cost minimization takes precedent in the selection of this technique. Comparing the two innovations that show promises, first innovation is of a better choice to the second because of costs. Although 600kg/ha of NPK 15:15:15 plus 4t/ha of poultry manure was profitable, it can only be recommended for commercial farmers and not to resource limited farmers. The third technique (300kg NPK + 2t poultry manure) show little promise with gross margin of ₦9, 214.16. This means that the technique could be selected as the best alternative to the first innovation as it has a much lower costs of production and reasonable yield. The three innovations of soil fertility management practices were far better than the traditional system in terms of tuber yield, gross return and gross margin. Thus, the first innovation with the highest gross margin should be recommended to resource limited farmers.

CONCLUSION

From the result, it could be concluded that NPK 15:15:15 alone could not be used for Dioscorea dumetorum production. However the application of 300kg NPK 15:15:15 had the highest comparative advantage over the other treatments and had a reasonable contribution to soils quality amendment. Therefore this treatment is recommended for the production of Dioscorea dumetorum. The second technique with the highest gross margin will not be totally discarded but could be recommended to commercial producers who can afford the cost involved. The third technique could serve as alternative to the first technique and could be recommended to resource limited farmers. However, we should note that the use of gross margin analysis in the selection of the techniques does not measure profit as it did not include fixed costs inputs and therefore appropriate model based on it concept.

Table 1: Comparison of Soil Fertility Management Techniques and Traditional Method using Gross Margin (₦/ha)

Techniques	Mean Yield (t/ha)	Gross Return (₦/ha)	Total Variable cost (₦/ha)	Gross Margin (₦/ha)
0kg NPK+ 0t Poultry	18.05	257,857.07	288,020.60	-30,163.53

ABSTRACT
The study is a systematic inquiry in the comparative evaluation of palm bunch residues, poultry manure and inorganic fertilizer for sustainable production of yam in southern Nigeria. The intention is to maintain the soil fertility and keep the ecosystem of the soil stable. It becomes important as to manipulate the erosion of the ecosystem in such away as to maintain soil fertility and productivity. The basic idea is to achieve physical and chemical, stability as to enhance a high level of production. The intention is to determine the level of availability of the plant nutrients to total output of the yam spp. by laying emphasis on the soil acidic level. Different combinations include; NPK fertilizer, palm bunch residues, poultry manure, NPK/Palm bunch, NPK/Poultry manure, and NPK/Palm bunch/Poultry manure residues. The application of the organic manure was based on existing rate, NPK 15:15:, 400kg/ha is equal to equivalent of nitrogen. Comparatively the combination showed that in 2014 on single dosage palm bunch gave 10.40kg/ha, followed by poultry manure with a yield weight of 8.87kg and lastly with NPK which gave 6.69kg/ha. In the compositions, NPK/palm bunch resulted with the highest yield of 8.73kg/ha, while NPK/Poultry manure gave 8.65kg/ha while the 3 combination gave 6.63kg/ha. In 2015, palm bunch gave 10.94kg/ha, followed by NPK with a mean weight of 5.72kg/ha and poultry manure with 5.34kg/ha. Under the combinations, NPK/Palm bunch resulted with the highest mean weight of 12.49kg/ha, followed by NPK/Poultry manure gave 5.64kg/ha and lastly the NPK/PB/PM gave the mean weight of 5.63kg/ha.
Keywords: Inorganic fertilizer, poultry manure, palm bunch, residues

INTRODUCTION

Soil degradation is associated with low CEC (cation exchange capacity) mineralization and leaching which causes the soil to be acidic, but research has shown that the life wire of our soil is the organic matter. (Shiyam, Y.O, Oko, B.F.D., Obiefuna, Y.C. and Ofoh, M.C. (2010) indicated that the optimum fertilizer rate for high yield was 20 tonnes of sawdust plus 150kg NPK/ha. The adoption of this combination would enhance productivity of the intercrop mixture. Indiscriminate burning of the farm land leads to volatility that loss of nutrient. Grazing of land, the abuse associated with use of fertilizer, chelation (immobility of P), road construction, harvesting and deforestation are limitation to soil out –put. Mulch is any material placed on the surface of the soil to cool the soil and thereby prevent excessive loss of water through evaporation. (Ogbonna, P.E. and Nweze, N.J. (2012) confirmed that high levels of some nutrients elements have been reported to inhibit the availability of others especially micro nutrient elements. Mulch performs some other subsidiary functions. Cover crops are crop which are grown to be plough under into the soil to improve the soil fertility. Legumes may be defined as a plant of the family leguminaceae e.g. Field bean, field peas, cowpea, groundnut and soya beans. (Ojeniyi, S.O., Amusan, O.A. and Adekiya, A.O.(2013) revealed that application of poultry manure significantly improved soil structure and soil moisture content as well as the uptake of N.P.K Ca and mg by cocoyam. Mulch is needed to mulch crops after planting in other to protect it from excessive heat or desiccation. This operation is particularly important if planting is done during dry season, this time soil temperature is very high. Care should be taken to avoid mulch material that contains weed seeds and vegetable propagated plant parts. After planting on beds or ridges, they are mulched with green leaves dry grass, farm yard manure or compost to prevent the beds from drying and to prevent weed growth and break the force of rains biting on the beds surface. Up to tons per hectare of green leaves mulch may be used. Green leaves provide organic matter to the soil and reduce carbon to nitrogen ratio to the soil. (Uwah, O.F., Udoh , A.U and Iwo, G.A (2011) revealed that the adoption of the combination of 15t/ha PM and 80kg k/ha could optimize yield in this agroecology for cocoyam production. This will help to overcome poor drainage due to closure of pore space. Critical appraisal of organic manure include; organic manure enrich the soil with organic matter. They supply minor and trace elements. They contain plant growth regulatory substances similar to hormones and vitamins in the animal body. They are simpler to prepare and in expressive in terms of cash out lay. They are profitable way of disposing refuse so that the farmers holding and farm shade are left clean. In chemical fertilizer lesser labour is involved in applying a mixture than in applying each of the components separately. The chemical fertilizer mixture tends themselves more early to granulation and granules are comparatively from small dust like particles they can loss early and carried by wind. They retard the reaction of the fertilizer within the soil so that nutrient release is not wastefully too fast. There is room for correcting residual acidity in mixture through the adding of conditioners such as dolomite (CaMg $(CO_3)2$). Small quantities of micro-nutrient or trace elements can be incorporated in mixtures so that these trace elements become more easily distributed in the field. Looking at the limitations of organic manures and the disadvantages of mixtures of chemical fertilizer, there is need to into grated the organic fertilizer and inorganic fertilizer to achieve an optimum level of crop production. The basic principle which is to achieve physical stability and chemical stability should be enhanced.

1. To determine the capability of the combination of the residues, inorganic fertilizer and the soil to obtain the optima nutrient status of the soil of Umudike.
2. To determine the level of availability of nutrient to total output of the yam spp.

MATERIALS AND METHODS

Total N (%)	0.11	
Org. C (%)	1.40	
Org. M (%)	2.41

It is a randomized complete block designed and replicated 3 times. The area is prepared by tractors and ridges are formed. We used six different treatments which include, NPK fertilizer, palm bunch residues; poultry manure residues, palm bunch/NPK, poultry manure/NPK, and NPK/Palm bunch/poultry residues. he organic manure (materials) was applied based on the existing rate, that N.P.K 15:15:15, 400kg/ha is equal to equivalent of nitrogen. Also that rice mill waste 30 tons/ha will supply the same 60kg/ha equivalent of nitrogen. The experiment was planted on the following dates; 8th of May 2014 and the second planting was on the 20th of May, 2015 respectively, on mound at one metre apart in a plot size of 6m x 5m. A pre-emergence herbicide application was carried out and followed with treatment application as it is demanded. Two major weeding was carried out and all the management practices observed. The harvesting was carried out 8 months after planting. The yield were subjected to analysis of variance (ANOVA) using GENSTAT discovery edition 3 and significant means separated with LSD at 5% alpha level. The combination was on the normal application single application while for the combination it was at 50:50 dosage and lastly 33.33% for the NPK/PB/PM application.

RESULTS AND DISCUSSION

The result for the year 2014 and 2015 shows levels of awareness in the levels of applications. Comparatively, in 2014, the palm bunch resulted in the highest yield with a total output of 10.40kg, followed by PM with total weight of 8.87kg. In the combinations the PB/NPK out weighted the other with the mean weight of 8.73kg, followed by PM/NPK with a mean weight of 6.69kg and lastly the 3 combination with a mean weight of 6.63kg. In the table for the second year it was quite in variance from the first year result. The total mean yield for PB/NPK tend to out weight every other application with a mean weight of 12.49kg and followed by the mean weight of palm bunch with a mean weight of 10.94kg. Under single dosages, including N.P.K, palm bunch (PM), and poultry manure (PM), the palm bunch showed a high level performance in 2014 and 2015, with the 2014 resulting to 10.40kg and in 2015 with a mean weight of 10.94kg respectively. In all the integrations which include; NPK/PB, NPK/PM and NPK/PB/PM for the two years, the NPK/PB in 2014 yielded the highest weight of 8.73kg and in 2015 it also resulted to the highest out-put weight of 12.49kg. Really from the LSD (0.05%), there was no significant difference from the total result. From the initial soil analysis of the area of cropping it indicated that the soil was acidic since the pH level remained within 5.3-5.7; showing that the level of alkalinity was very low and mineralization will be very difficult.

CONCLUSION

It is necessary and imperative that we start to improve the soil state of the institute by making use of available local resources of origin like palm Bunch in composition with in-organic fertilizer to reduce cost. It will improve the soil physical and chemical properties. The additions of the biosolids of palm bunch in combination with in-organic fertilizer will enhanced the total out-put of the yam and reduce the antagonism association with in-organic fertilizer.

Table 1: Yield on the comparative evaluation of palm bunch, poultry manure and in-organic fertilizer for sustainable yam production

Treatment	2014 Mean weight value (kg/ha)	2015 Mean weight value (kg/ha)
N.P.K	6.69	5.72
Palm Bunch (PB)	10.40	10.94
Poultry manure (PM)	8.87	5.34
NPK/PB	8.73	12.49
NPK/PM	8.65	5.64
NPK/PB/PM	6.63	5.63
LSD	0.3	1.5

ABSTRACT
A field experiment was carried out at the Federal University of Technology Teaching and Research Farm to ascertain the responses of Cucumber (Cucumis sativus) to Poultry Manure and NPK Fertilizers during the 2013 cropping season. The experiment was laid out in a 3 x 3 factorial in Randomized Complete Block Design replicated three times. The treatments include poultry manure rates of 0, 5 and 10 tons/ha while the NPK rates were 0, 200 and 400kg/ha respectively. Data on various growth and yield parameters of Cucumber were measured and subjected to analysis of variance. Mean separation was done using the least significant differences at 5% level of probability. Results indicated that 10 tons/ha of poultry manure and 400kg/ha of NPK fertilizer gave highest number of broad leaves (15.80cm), longest vine (154.83cm), widest fruits (19.56cm) longest fruit (20.77cm) and highest fruit yield of (6.40kg) per plot. Manured cucumber effectively suppressed weeds and branched extensively. Based on these results, it is strongly recommended for farmers to use 10tons/ha poultry manure combined with 400kg/ha of NPK 15:15:15 for best yield returns of Cucumber.
Keywords: Cucumber, Poultry Manure, NPK 15:15:15.

INTRODUCTION

Cucumber is an annual vegetable crop that belongs to the family of Cucurbitaceae which comprises of 90 genera and 750 species (Onyia et al., 2012). It is native to Africa and Asia where its consumption dates back to over 3000 years (Okonmah, 2011). Cumber is an ancient vegetable and one of the most improved members of the Cucurbitaceae family (Thao, 1998).

Cucumber is cultivated for its fruits which are sources of minerals, vitamins A, C, K and B6, potassium, magnesium, phosphorus, copper and manganese (Vimala, et al., 1999). The fruit is eaten alone as salad and in combination with other vegetables. The juice is often recommended as source of silicon to improve the health and complexion of the skin (Duke, 1997). The ascorbic acid contained in cucumber helps to reduce skin irritation (Okonmal, 2011).

Despite the economic potentials of the crop, the full production potentials of the crop in Southeastern Nigeria have not been realized. Low crop yields of the crop have been reported especially in intensive cropping systems due to the imbalance in the use of fertilizers. Also continuous cropping has led to several nutrients becoming deficient (Mahmood et al, 1999).

Reports on the relevance of organic manure and mineral fertilizer in tropical agriculture have been presented by various researchers. Adediran et al. (2005) reported a positive vegetative growth, root development and fruit yield of tomatoes to complementary application of organic manure with mineral fertilizer. Singh et al., (2003) in their report considered nitrogen as one of the major nutrients required by plants for growth, development and yield. Duruigbo et al., 2007 reported that application of 10tons/ha or 15tons/ha of poultry manure significantly increased the aggregate yields of yam/maize/cassava relay intercrop. Also in a similar research, Ibeawuchi et al. (2012) reported that use of NPK 15:15:15 at 0kg/ha and 10tons/ha poultry manure gave the highest cassava yield of 13.38tons/ha, Sorghum 0.113tons/ha and groundnut 0.073tons/ha respectively. The complementary use of organic and inorganic fertilizers has been recommended for sustenance of long term cropping in the tropics (Ipimoroti et al., 2002). Murwira and Kirohman (1993) observed that nutrient use efficiency might be increased by combining manure and inorganic fertilizers. This research paper is thus specifically aimed at evaluation of the responses of Cucumber (Cucumis sativus) to poultry manure and NPK fertilizer combinations in Owerri.

MATERIALS AND METHODS

The field experiment was carried out at the Federal University of Technology Teaching and Research Farm, Owerri in the 2013 cropping season using a 3x3 factorial in Randomized Complete Block Design (RCBD). The poultry manure rates include: 0, 5, and 10tons/ha while NPK fertilizer rates are; 0kg/ha, 200 and 400kg/ha respectively. The area was cleared, marked out and tilled. Poultry manure was applied before planting of cucumber. Cucumber seeds were planted at two seeds per hole at a spacing of 75cm x 75cm.

Data on all growth and yield parameters were measured and subjected to analysis of variance while mean separation was done using least significant differences at 5% level of probability.

RESULTS AND DISCUSSION

The preplanting soil physical and chemical properties are presented in Table 1: Results indicate that the soil pH is 4.80 which is acidic. Nutrient contents of the soil were low indicating that the soil is highly infertile. Highest mean number of cucumber leaves was recorded in the 10tons/ha of poultry manure and 400kg/ha NPK fertilizer at 4, 6 and 8 weeks after planting (Table 2). This agrees favorably with work done by Aduloju et al., 2010, Dada and Fayimminu, 2010, who reported that nutrients from mineralization of organic matter promoted growth and yield of cucumber. Highest fresh fruit yield (6.40kg/plot) was also recorded in plots treated with 10tons/ha poultry manure in combination with 400kg/ha NPK fertilizer (Table 3). The fruit girth also increased proportionately with increase in poultry manure and NPK fertilizer while the lesser the manure rate, the greater the reduction in fruit girth. This is also in agreement with work done by Ayoola and Adeniran 2006. The zero manure and fertilizer treatments produced significantly lower fruit yield of cucumber in all replications.

ABSTRACT
Field experiments were conducted in the 2014 and 2015 early cropping seasons at the University of Calabar Teaching and Research Farm, Calabar, to assess the impacts of polyethene colour and soil solarization duration on weed population dynamics in maize (Zea mays L.). The experiment was a split-plot laid out in Randomized Complete Block Design (RCBD) with three replications. The twelve treatment combinations comprised of three colors of polyethene (white, green, and black) as the main plots, and four solarization durations (0, 2, 4 and 6 week- periods) as the sub-plots. Data were collected on weed density, weed morphological groups and number of seeds per maize cob, and analyzed. Weed density consistently reduced as soil solarization duration increased from 0 to 6 weeks, whereas it was not significantly ($p < 0.05$) affected by polyethene colour in both years . Soil solarization for 4 to 6 weeks significantly ($p < 0.05$) affected broadleaf, grass and sedge weeds in both years. White polyethene significantly ($p <.0. 05$) reduced grass weed population compared to the black in both years. The number of seeds per cob of maize significantly ($p < 0.05$) increased as soil solarization duration increased each year. Compared to the unsolarized control, soil solarization for 2, 4, and 6 weeks increased the number of grains per cob by 18.97 %, 43.71 %, and 91.31 % in 2014, and by 24.87 %, 57.81 % and 105.30 % in 2015, in that order. Interactively, the number of grains per cob was enhanced as the duration of solarization increased among the three polyethene colours, but the white at 6 weeks solarization gave the highest values which were statistically higher than all other treatment combinations indicating superiority.
Key words: Polyethene colour, soil solarization, weed density, weed morphological group, maize

INTRODUCTION

Weed infestation remains a major factor limiting crop production. It has been noted that crops cannot be grown on the soil without the certainty that weeds will thrive (Khan et al., 2002). Weeds generally compete with crops for growth factors (Nwagwu et al, 2000). Weed density and weed types present are among the major weed factors that influence their competitiveness with crops, resulting in reduced yields. The decrease in maize grain yield due to weeds has been estimated at an average of 40 to 100 % in Nigeria, 38.0 % in Africa and 29.2 % world-wide, (Takim, 2012). Effective weed management is therefore a vital practice necessary to ensure optimum grain yield of maize (Narayan, 2012; Tahir, 2014). Manual weeding is the most common weed management method in West Africa. However, the drudgery, high cost and the need for repeated operations associated with handweeding have made the practice undesirable, especially in large scale crop farms. Furthermore, no one method of weed management has been able to adequately control weeds in crop farms at all times.

The use of soil solarization as an efficacious and hazard-free practice for reducing weed infestation has become increasingly popular (Yaduraju, 1993, Marenco and Lustossa, 2000, Pathel et al., 2005) and can be applied to maize production. According to Pokharel and Hammon (2010), soil solarization is a hydrothermal process which takes place in wet soils that are covered with plastic films and allowed to be heated by sunlight. The duration of soil solarization and colour of the plastic films, as well as their interaction, can have varying effects on weed incidence and the performance of a subsequent crop; however, information is currently scarce on this in Nigeria, especially in the southeastern rain forest area, where maize is widely grown as staple crop. This research therefore investigated the influence of polyethene colour and soil solarization duration on weed population dynamics and maize yield in Calabar, Nigera.

MATERIALS AND METHODS

Field experiments were conducted in the 2014 and 2015 early cropping seasons at the University of Calabar Teaching and Research Farm, Calabar, to determine the impacts of soil solarization duration and polyethene colour on weed incidence in maize. Calabar is located at the southeastern rainforest agro-ecological zone of Nigeria (4.5^0N - 5.2^0N, 8.3^0E), about 39 m above sea level and has a bimodal annual rainfall distribution that ranges from 3,000 mm to 3,500 mm with mean annual temperature range of 27^0 C to 35^0 C and relative humidity of 75 % to 88 % (Effiong, 2011). The experimental site, which was in secondary vegetation with predominantly annual weeds, was cleared with machete and the debris packed. The land was mapped out into uniform plot units to meet the design specifications. Raised seed beds measuring 2.9 m x 1.2 m were made, harrowed and levelled using a spade. The split-plot experiment was laid out in Randomized Complete Block Design (RCBD) with three replications. There were twelve treatment combinations comprising of three colors of polyethene (white, green and black) as the main plots, and four solarization durations (0, 2, 4 and 6 weeks) as the sub-plots. The polyethene materials with thickness of 100 microns (100 µ) each were laid uniformly on the respective plots in March each year. The plots for 6 weeks solarization were covered with polyethene first, those for 2 and 4 weeks solarization were covered 2 and 4 weeks later, respectively. At the end of the sixth week, the polyethene films were removed with the unsolarized plots as the control. Short (70 days) duration maize (Oba Super 2) seeds were then sown at 75 cm × 25 cm spacing, two per hole, and later thinned to one, giving a population of 53,333 plants per hectare. Data were collected on weed density and weed flora count at 3 and 6 weeks after sowing (WAS) and the mean values for both weeks computed and recorded. Weed density was determined by placing a 1 m x 1 m quadrant randomly on each treatment plot and the total number of weeds enclosed within the quadrat counted and recorded. The weeds within the quadrat were then harvested and separated into morphological groups - broadleaves, grasses and sedges, and the number of each group counted and recorded. Maize cobs were harvested from six middle plants per plot at 80 days after sowing (DAS), de-husked, and the number of grains per cob counted and the mean recorded. Data collected were subjected to analysis of variance (ANOVA) using the GenStat Package Version 8.1. Significant means were separated using the Fishers Least Significant Difference (FLSD) method at 5% level of probability.

RESULTS AND DISCUSSION

Weed density

Weed density consistently reduced as soil solarization duration increased from 0 to 6 weeks in both years (Table 1). In 2014, weed density was significantly ($p < 0.05$) reduced with every 2-week increase in soil solarization period. In 2015, all solarized plots recorded significantly ($p < 0.05$) lower weed density than the unsolarized control with 6-week solarization duration resulting in significantly ($p < 0.05$) lower values than the 2 - week solarization duration. The generally lower weed density recorded in solarized plots in comparison with the unsolarized control indicates that the soil solarization treatments were effective in weed suppression and supports the report of Pathel et al. (2005), who noted that soil solarization was an efficient way of reducing weed infestation in crop farms. The better weed suppression recorded as duration of soil solarization increased from two to six weeks could be attributed to more solar heat trapped and transmitted through the polyethene into the soil that must have killed more weed propagules over the longer period compared to the shorter durations. This finding agrees with those of Chittapur and Hosmani (2000) and Marenco and Lustossa (2000), who reported progressive decline in weed populations with increasing solarization durations. Pathel et al. (2005) also reported that, soil solarization for 6 to 8 weeks controlled weeds in Chilli in India through the succeeding maize crop.

Weed density was not significantly ($p < 0.05$) affected by polyethene colour in both years, which indicates that the three colours of polyethelene investigated were equally effective in weed suppression. This is further supported by results of the interaction of polyethene colour and solarization duration, in which the use of black, green or white polyethene significantly ($p < 0.05$) reduced weed density at 6 weeks solarization duration, compared to 2 weeks solarization and the unsolarized control.

Weed flora distribution

Soil solarization significantly reduced populations for 4 to 6 weeks significantly ($p < 0.05$) affected broadleaf, grass and sedge weeds in both years Soil solarization significantly ($p < 0.05$) affected the populations of broadleaf, grass and sedge weeds in both years (Table 1). The 6 week solarization duration significantly ($p < 0.05$) reduced the population of broadleaf weeds compared to all other solarization durations in 2014 and compared to 2 weeks solarization and the unsolarized control in 2015. Soil solarization for 4 to 6 weeks in 2014 and for 6 weeks in 2015 significantly reduced grasses compared to shorter solarization durations in that order. In 2014, soil solarization for 4 and 6 weeks significantly reduced sedge weed populations compared to shorter solarization durations, while in 2015; all solarized plots recorded significantly lower sedge weeds than the control. These findings suggest that the effect of soil solarization on the various weed morphological groups becomes more pronounced when the treatment is allowed for 4 weeks or more. This is in line with the report of Seman-Varner and McSorley (2012), that soil solarization for 4 and 6 weeks reduced populations of weeds such as Indigofera hirsuta and Cyperus rotundus.

Whereas the effect of polyethene colour on broadleaf and sedge weeds was not consistent in 2014 and 2015, grass weed population was significantly ($p < 0.05$) reduced by white polyethene compared to the black in both years. This finding suggests that white polyethene was more effective in the suppression of grass weeds compared to the black, and this could be attributed to better light interception and heat retention and transmittance by the white polyethene to levels that could desiccate grass weed propagules as was also reported by Habeeburrahman and Hosmani (1996).

Number of seeds per maize cob

The number of seeds per cob of maize significantly ($p < 0.05$) increased as soil solarization duration increased in both years (Table 1). Compared to the unsolarized control, soil solarization for 2, 4, and 6 weeks increased the number of grains per cob by 18.97 %, 43.71 %, and 91.31 % in 2014, and 24.87 %, 57.81 % and 105.30 % in 2015, in that order. The progressive increase in number of seeds per cob as soil solarization duration increased could be attributed to the superior weed suppression achieved in the solarized plots compared to the control, which increased with solarization duration up to 6 weeks, and reflects an inverse relationship between weed populations and yield of the maize crop. Khan et al., (2002) reported that the yields of crops are usually higher where weed density is low.

White polyethyene resulted in significantly ($P \leq 0.05$) higher number of maize seeds per cob compared to the black or green in 2014. Interactively, the number of grains per cob was enhanced as the duration of solarization increased among the three polyethene colours, but the white at 6 weeks solarization gave the highest values which were statistically higher than all other treatment combinations in both years. This finding indicates that the maize crop generally benefited best from soil solarization with polyethene films when the solatization duration was up to 6 weeks with white the most effective polyethene colour.

CONCLUSION

Soil solarization was effective in reducing weed populations across the three morphological groups (broadleaves, grasses and sedges) especially from 4 to 6 weeks duration in both years. The maize crop benefited best from soil solarization with polyethene films when the solatization duration was up to 6 weeks with white as the most effective polyethene colour.

Table 1: Effect of polyethene colour and soil solarization duration on weed population and number of grains per maize cob in 2014 and 2015 early cropping seasons in Calabar.

ABSTRACT
The field trial was conducted at NRCRI to evaluate the effect of two different fungicides (Nordox and Koside) on the growth and yield of cocoyam (colocassia esculenta) corms and cormels. Data generated were subjected to the analysis for significant differences between treatments. Means were tested using LSD at 0.05 probability level. The finding of this study shows no significant difference in yield with the 2 different fungicide applications. NCe 011 had a significant yield difference against NCe 012. This study recommends the application of both fungicides since they are effective and intensify the cultivation of Nce011.
Keywords: On-farm fungicide, growth, yield, fresh cocoayam

INTRODUCTION
Cocoyam (colocassia esculenta) contributes a significant proportion of the carbohydrate content (starch) of the diet in many regions of developing countries and provides edible starchy corms and cormels. Although, it is a major staple like cassava and yam, research interest on it has been poor compared with cassava and yam (Chukwu et al., 2012). In terms of nutrition, cocoyam has an advantage over root crops like yam and cassava (Foster-Powell et al., 2012). In addition, cocoyam is known to contain considerable amount of protein, starch, vitamins and minerals (Eleazu et al., 2013).The use of fungicide was reported to control Taro Leaf Blight (Chukwu et al., 2011). From this study, the effect of these fungicide applications on the growth and yield of cocoyam was investigated.

METHODOLOGY
The cocoyam varieties used for the study are (NCe 011 and NCe 012). Clean and healthy cocoyam samples were obtained from Cocoyam Programme of NRCRI, Umudike. The materials were planted, application of fertilizer was done 6 weeks after planting, and fungicides were applied after at an interval of 4 weeks after planting. Data generated were analyzed statistically using SAS 2003.

RESULTS AND DISCUSSION
The result in Table 1 shows the effect of fungicide application on the yield and yield components of cocoyam. The result shows that there were no significant difference in the number of corms, weight cormels, total number of corms and cormels and total weight of cocoyam on application of the two treatments. The treatments used were Nordox and Koside. The result in Table 2 shows the effect of fungicide application on the growth and yield of two cultivars of cocoyam. The result shows that there were no significant difference in the No of corms and weight of corms for the two cultivars of cocoyam- NCe 011 and NCe 012. The result also shows a significant difference in the weight cormels, total number corms and total weight of corms and cormels for the two cultivars. The cultivar NCe 012 performed better than NCe011 in terms of weight of cormels, total number corms and cormels and total weight. There was an increase of about 34.50%, 19.21% and 31.43% in weight of cormels, total No of corms and corms, and total weight for NCe 011 and NCe 012.

CONCLUSION
The result shows no significant difference in yield with the 2 different fungicide applications. NCe 011 performed better than NCe 011 in terms. The result therefore recommends the application of both fungicides since they are effective and intensify the cultivation of NCe 011.

ABSTRACT
T*urmeric is an errect perennial plant, grown as an annual crop for its rhizomes (underground root-like stem). It belongs to the same family as ginger (zingiberacae). Turmeric is very important spice, native of india. It is a natural antiseptic, which exhibits great therapeutic properties. The active components of turmeric are curcuminoids, which include mainly curcumin (diferiloylmethane) which is a yellow pigment present in turmeric, demethoxy curcumin and bid emethoxycurcumin. These active principles of turmeric (curcumin and curcuminoids) have been shown to exhibit antioxidative, anti-inflammatory, antiviral, analgesic, anti-bacterial, anti-fungal, anti-protozoal, anti-ulcer, anti-cancer, and hypocholesteremic activities, and thus has a potential against various malignant diseases, diabetes, arthritis, allergies, Alzheimer's diseases and other chronic and hard curable diseases. The purpose of this review is to provide an understanding of the emerging health benefits of turmeric (curuma longa). Recent studies have authenticated the use of turmeric as hepatoprotective, nephroprotective, anticoagulant and anti-HIV to combat AIDS. Turmeric has been found to be used traditionally as a non-toxic plant to bring remedy for the cure of wide variety of diseases. Current research has focused on turmeric's anti-oxidant, hepatoprotective, anti-inflammatory, anti-carcinogenic, cardiovascular, gastrointestinal and anti-microbial properties.*
***K*eywords: Turmeric, Curcumin, Health effects**

INTRODUCTION

Turmeric (Curcuma longa) is a spice native of India. It is the rhizome of an under-ground stem of a ginger-like plant. The plant is a herbaceous perennial, 60-90cm high, with a short stem tuffed in. It's flowers are yellow, between 10-15cm in length. No fruits are known for this plant. The rhizome is yellowish brown, with a dull orange interior that looks bright yellow when powdered. The rhizome measures between 2.5-7.0cm in length, and 2.5cm in diameter, with small tuber branching off. Turmeric requires a temperature of 20 and 30^0 c(68 and 86^0F)and a considerable amount of rainfall to thrive. It is used as a spice, and also a natural colouring agent for food, cosmetics or dye. In the Ayurvedic tradition, turmeric or ''haldi'' works well with the doshas, with its main action being to remove mucus from the system . Turmeric is considered to be one of the most important herbs in Ayurvedic tradition. The extensive survey of the literature reveals that turmeric is highly regarded as a universal panacea in the herbal medicine, with a wide spectrum, of pharmacological activities. It is found to be beneficial in the treatment of a wide range of health disorders like circulatory problems, liver diseases, dermatological disorders, blood purification and other chronic diseases (sirinicasan et al, 1992: Osewa et al). Current traditional medicine claims turmeric powder against gastro-intestinal diseases, especially for biliary and hepatic disorder, diabetic wounds, rheumatism, inflammation, sinusitis, anorexia, coryza, and cough. Turmeric contains curcuminoids which are antioxidants. These curcuminoids are three, all of which are major bioactive components (Curcumin, desmethoxycurcumin and bisdesmethoxy curcumin). The yellow pigmented curcuminoids represent 2-5% of the turmeric root, typically composed of 85% as curcumin, 10% as demethoxycurcumin and 5% as bisdemethoxycurcumin. Apart from turmeric's richness in circuminoid pigments and essential oils (5%), turmeric also contains carbohydrates (69.43%), protein (6.3%), mineral (3.50%), on dry wet basis (Nunes 1989), sarkur 2000 and Olojede 2005). Other naturally occurring constituients of turmeric include vitamin C, vitamin B1, vitamin B2, vitamin B3, calcium, magnesium, potassium, zinc,phosphorus, Ash, fats, iron sodium and water. Turmeric also contains sesquiterpenes, turmorone, atlantone, zingiberione, turmeronol, bisabolene, resins and caffeic acid.

MECHANISM OF ACTION

Antioxidant Effect: Turmeric shows a very strong oxidative property due to its extra ordinary molecular structure. Circumin the best researched active component of turmeric, comprising 0.2 – 5.0% of raw turmeric, is a free radical scavenger. It acts as a shield against certain kinds of environmental toxins. It has been shown that curmumin inhibits lipid peroxidation, using lineleate, a pollyunsaturated fatty acid that is able to be oxidized and form a fatty acid radical. A study of Ischemia in the feline heart demonstrated that curcumin pre-treatment decreased Ischemia-induced oxidative stress and changes in the heart. The antioxidant activity of turmeric is comparable to vitamin C and E. It can protect lipids or haemoglobin from oxidation. An invitro study measuring the effect of curcumin on an inducible protein resulted in enhanced cellular resistance to oxidative damage. Curcumin present in turmeric can protect the DNA against single strand breaks induced by single oxygen.

Turmeric, and curcumin in particular, suppresses the mutagencicity of several common mutagens including cigrate smoke and benzopyrene. (Sondanini et al 1995).

Anti-inflammatory Effects: Due to the extra-ordinary molecular structure of turmeric, it also shows a very strong anti-inflammatory property. Its most important anti-inflammatory mechanism centers on its effects on the prostaglandins (PGs), a large family of potent lipids produced by the body. PG1 and PG2 calm the body while PG3 inflammes the body. Turmeric is a potent inhibitor of cyclooxygenase 5 – lipoxygenate and also 5-HETE production in neutrophils. Reducing these enzymes, means less arachidonic acid metabolism, which means less PG2 ,which equally means less pain and inflammation. Curcumin reduces the neutropils infiltration in inflammatory conditions and inhibit platelet aggression. Turmeric therefore is very good in the treatment of arthritis, rheumatioid arthritis, injuries, trauma and stiffness from both under activity and over activity. A hydroethanolic extract of turmeric extract was recently found to inhibit activation of human dendritic cells in response to inflammatory cytokines (Krasovsky et al 2009). Curcumin has been found to counteract inflammation and irritation associated with inflammatory skin conditions and allergies when applied topically.

Anti-Carcinogenic Effects: Carcinogenesis occurs by means of several biological pathways, and through the de-regulation of hundreds of molecules. Circumin present in turmeric reduces cancer growth by targeting several of these pathways and de-regulation of molecules (shishodia et al. 2007). Studies have demonstrated that curcumin is able to inhibit carcinogenesis at three stages, angiogenesis, tumour promotion and tumor growth. In two studies of colon and prostrate cancer, curcumin was shown to inhibit cell proliferation and tarnor growth. Turmeric and curcumin are also able to suppress the activity of several common mutagens and carcinogens. The anti-caranogenic effect of turmeric have been related to direct antioxidant and free-radical scavenging effects, as well as their ability to indirectly increase glutathione levels, thereby aiding in hepatic detoxification of mutagens and inhibit nitrosamine formation.

The mutagenic induction effect of UV rays has been shown to be inhibited by circumin. It has been proved that the antioxidants present in curcumin neutralize carcinogeric free radicals (Kutton et at 1985)

Hepatoprotective Effect: The hepatoprotective effects of turmeric are mainly due to its antioxidant properties, as well as its ability to decrease the formation of pro-inflammatory cytokines. The hepatoprotective characteristics of turmeric is similar to that of silymarin. Turmeric and curcumin have been found to have reversed biliary hyperplasia, fatty changes, and necrosis induced by aflatoxin production. Soduim curcuminate, a salt excretion of bile salts, cholesterol and bilirubin, as well as increasing bile solubility, therefore possibly preventing and treating cholelithiasis. The choleric activity of curcumin which increases bile output and solubility may be helpful in treating gallstones.

Anti-microbial Effect: Turmeric has been shown to inhibit the growth of a variety of bacteria, pathogenic fungl and parasite. For centuries, turmeric has been used to heal open wounds and infections (Aggarival et al, 2007). The growth of histamine producing bacteria (vibro parahaemolyticus, Barcillus cereus, pseudomonas aeruginosa and proteus mirabilis) was inhibited by turmeric at a 5% concentration (Paremawsam, Thengaradjou and Kannan 2007). Turmeric extract was found to inhibit growth of food born pathogen V.parahaemolyticus, with good sensitivity (Yano, Satomi and Oikawa 2006). Curcumin has been found to have moderate activity against plasmodium falciparum and Leishmania major organisms.

Cardiovascular Effects: Turmeric has wonderful protective effects on the cardiovascular system. These include, lowering cholesterol and triglyceride levels, decreasing susceptibility of low density lipoprotein (LDL) to lipid peroxidation, and inhibiting platelet aggregation. The ability of turmeric constituents to inhibit platelet aggregation is thought to be via potentiation of prostacyclins synthesis and inhibition of thromboxane synthesis. Curcumin can stop the build-up of plaque (atherosclerosis), which can block the arteries and cause heart attacks and strokes. Turmeric effect on cholesterol levels may be due to decreased cholesterol up take in the intestine, and increased conversion of cholesterol to bile acids in the liver.

Gastrointestinal Effects: Turmeric exerts several protective effects on the gastro intestinal tracts. It also inhibits ulcer formation caused by stress, alcohol, indomethacin, reserprine, phylonic and litigation. Turmeric also inhibits intestinal spasm, and increases bicarbonate, gastrin, secretion and panerectic enzyme secretion. In cerulean or ethanol induced pancratitis, curcumin was found also to be able to inhibit the inflammatory mediatiors, resulting in amelioration in disease severity, and measured by histology, pancreatic trypsin, serum amylase and neutrophil infiltration.

A HOST OF BENEFITS OF TURMERIC (curuma longa)

According to Dr Andrew Weil, founder and program director of Arizona Center of integrative medicine. ''The bottom line is that the therapeutic advantages of turmeric are almost too numerous to list :

- Turmeric has been found to have hepatoprotective characteristics which is similar to that of silymarin
- The volatile oils in turmeric exhibit potent anti-inflammatory effects
- Turmeric and curcumin are capable of suppressing the activity of several common mutagens and carcinogens in a variety of cell types in both invivo and invitro studies .

- Constituents of turmeric exert several protective effects on the gastrointestinal tract.
- Extracts of turmeric suppresses symptoms associated with arthritis
- Turmeric extracts and its essential oils inhibit the growth of a variety of bacteria, parasistes and pathogenic fungi
- Turmeric and its constituents affects Alzlaeimer's and Parkinson diseases
- Turmeric,s protective effects on the cardiovascular system include: lowering cholesterol and triglyceride levels, decreasing susceptibility of low density lipoprotein to lipid peroxidation, and inhibiting platelet aggregation.
- Turmeric and its extracts inhibits angiogenesis
- Turmeric oil exhibited potent anti-trypsin and antihyaluronidase activity
- Turmeric enhances wound healing
- Turmeric extract reduces the incidence of cholesterol gall bladder stone formation
- Constituents of turmeric inhibit proliferation of vascular smooth muscle cells
- Turmeric protects against pancreatitis
- Turmeric lower serum cholesterol levels
- Turmeric stimulates muscle regeneration
- Turmeric suppresses the induction of adhesion molecule
- Constituents of turmeric blocks the replication of HIV
- Extracts of turmeric corrects cystic fibrosis defects
- Turmeric oil containing turmerones exhibited a potent antroxidant activity in β-carotene linoleate model system and the phosphomolybdenum method
- Constitutents of turmeric inhibit androgen receptor and androgen receptor (AR)- related cofactor
- Turmeric volatile oils suppresses acute oedema
- Constitutents of turmeric inhibits scorring
- Turmeric constituents inhibit farnesyl protein transferase (FTPase)

CONCLUSION

Turmeric is the unique source of various types of chemical compounds which are responsible for a variety of activities, which include: Anti-oxidant, hepatoprotective, anti-inflammatory, anti-carcinogenic, cardio vascular, gastrointestinal and antimicrobial activities.

Many studies show promising results for the efficacy of turmeric and its active ingredients curcumin against many important diseases. Turmeric has been found to be used traditionally as a non-toxic plant to bring remedy for the cure of a wide variety of diseases. As the global scenario is now changing towards the use of non-toxic plant products, having traditional medicinial use, development of modern drugs from turmeric should be emphasized, for the control and cure of various diseases. Further investigations needs to be carried out on turmeric, in order to explore the concealed areas and their practical clinical applications which can be used to improve human welfare.

ABSTRACT

In the current study the insecticidal activity of powdered orange peel extract was studied against stored millet pest Cryptolestes furrugineus under laboratory condition. The stored pests were introduce to five powdered extract of orange peel (20 g, 40 g, 60 g, 80 g, and 100 g), placed in plastic containers with grain of pearl millet and observed for mortality for 15 weeks. It was observed that the Cryptolestes furrugineus survived for more than 15 weeks in 0 g (control) but did not survive beyond 6 weeks in 100 g of orange powdered peel extract; however, the results indicated the activity of orange powdered peel extract to be insecticidal as well as week dependent. The powdered peel extract was most effective (P < 0.05) against Cryptolestes furrugineus at 100 g causing 100 % mortality in 15 weeks. The results from this study offer great potential as an alternative insecticide that is available, cheap and effective in the control of stored pests. Thus, farmers could store their grains regularly with orange powdered peel extract.

Keywords: Stored Pests, Orange Peel Extract, Insecticide, Cryptolestes furrugineus, Mortality.

INTRODUCTION

Millets are in the family of cereals grown globally with importance across continents and within regions of the world (Igbal et al., 1992). They form a diverse group of small grains cultivated in diverse and adverse environment, mostly in the semi-arid and sub-humid drought-prone agro ecosystem. Production of millets is still at subsistence level by smallholders (farm size) and consumed as staple food and drink in most areas (Onu, 1996).

Millets are high energy, nutritious foods recommended for the health and well-being of infants, lactating mothers, elderly and convalescents. Their good nutritional values including high levels of quality protein, ash, calcium, iron and zinc make millet nutritionally superior than most other cereals (Burkil, 1997).

The insect species of importance in the tropics are pests of stored food grains, including pulses. They establish themselves on undamaged grains of millet (McFarlane, 1988 and Rajapakse, 2006).

The chemical preparations of insecticides contain chlorinated hydrocarbons and pyrethroids (Tayor, 1991). Chemical insecticides usage possesses a health risk; there have been reports of increased residues in grains and development of resistance (Acanvola and Walker, 1982; Atoili, 1998). Some of the chemical insecticides are toxic and misapplication can lead to a serious consequence to human health (farmers) in terms of application (Tayor, 1991; Acanvola and Walker, 1982).

To the rural farmers, the technical knowhow for application of chemical insecticides is not available and the chemicals are expensive and toxic. Hence a need to research for cheaper, formidable and easily available plant alternative that are ecologically safe and do not leave residues in environment.

Orange (Citrus sinensis) is an evergreen tree growing up to 9m. It has leaves throughout the year. Its fruits contain a wide range of ingredients which are rich in vitamin C, flavonoids and volatile oil. Citrus sinensis is an appetizer (Kenferm, 1997). Also, a smoke of the dried peel is used as a mosquito repellent in many villages in Imo State.

MATERIALS AND METHODS

Collection and Identification of Stored Millet Pests

Adult stored pest of pearl millet were collected from naturally infested pearl millet pests from Ekeonunwa market in Owerri Imo State. Collection was by carefully removing the pests with hands and placing them into sample containers with proper ventilation. They were transported to the Entomological laboratory of Imo State Polytechnic Umuagwo-Ohaji for examination, identification and experimentation. The stored pearl millet pests were examined under the light microscope and identified following various identification keys (Acanvola and Walker 1982; Igbal et al., 1992; Hill and Waller 1982). Stored pearl millet pests of the species Cryptolestes furrugineus was used for this study.

Preparation of Powdered Peel Extract

Orange fruits were purchased from the market and the peel removed and allowed to dry at room temperature (away from sun radiation). The dried peels were ground into a powder, using mortar and pestle, and then sieved to obtain uniform sized particles. The residue was discarded and 20 g, 40 g, 60 g, 80 g and 100 g of the powdered filtrate were weighed and used for this experiment.

Effect of the Powdered Orange Peel Extract

A total of 480 healthy stored pearl millet pests belonging to the species Cryptolestes furrugineus were placed in six groups of 20 Cryptolestes furrugineus each, in plastic containers covered with nets in six different treatments ~~of~~ powdered peel extract of 0 g, 20 g, 40 g, 60 g, 80 g and 100 g respectively (Salem et al., 2007).

Each treatment had four replicates. The Cryptolestes furrugineus were observed for mortality at 3 weeks, 6 weeks, 9 weeks, 12 weeks and 15 weeks. The Cryptolestes furrrugineus were considered-dead when they did not respond to pricking with sharp object or when they turned upside down.

Data Analysis

The numbers of Cryptolestes furrugineus alive and dead were recorded in table as mean ± Se and percentage (%) mortality was calculated. Data obtained were subjected to analysis of variance to know differences at 5% level of significance; Duncan Multiple Range Test was used to compare the effect of powdered orange peel extract on Cyptolestes furrugineus.

RESULTS AND DISCUSSION

The results of the effect of powdered orange peel extract on C. furrugineus appeared to be effective as week's progresses. It can be seen from table 1 that a range of 15 % – 100 % C. furrugineus were killed by 20 g, 40 g, 60 g, 80 g, and 100 g of the powdered peel extract while the control (0 g) did not produce any lethal effect on C. furrugineus. However, the 100 g powdered peel extract effectively killed all C. furregineus within 9 weeks, with 100% efficiency. Statistical analysis indicated significant difference (P<0.05) between 20 g, 40 g, 60 g, 80 g, and 100 g powdered peel extracts respectively on their effects on C. furruginues, but no statistical difference (P<0.05) existed between the effects of 0 g and 20 g powdered peel extract against C. furrugineus. The result indicated that 100 g powdered peel extract was significantly (P<0.05) more effective against C. furrugineus in this study. Many other authors have reported the insecticidal effect of various plants extracts Makanuola, 1989; Emeasor et, al., 2005 and Rajapakse, 2006). The insecticidal activity of orange powdered peel extract seen in this study is not surprising because Mwaiko, 1992 and Amusan et al; 2005 reported differently that orange peel extract contained carvicidal properties on mosquito larval.

The high mortality rate recorded by this extract could be due to presence of linalool and d-limonene, which are the active ingredients. These two compounds are reported to be the most effective insecticidal compounds present in the extract. This could be corroborated with the findings of some researchers which indicate that heightens sensory nerve activity in insects thereby causing massive over stimulation of motor nerve that leads to convulsion, paralysis and eventually death (Mwaiko, 1992).

CONCLUSION

The results presented in this study have shown that extracts of orange peel have great potentials as bio-pesticides and could provide suitable alternatives for pest control on stored pearl millet of small and low input agriculture as commonly practiced in tropical countries without degrading the environment. In Nigeria, orange fruits are readily available in our environment and the local markets all the year round for farmers to use and protect their stored products. The fruit extract is safe cheap, easily biodegradable and environmentally friendly. It could provide valuable alternatives to synthetic insecticides in the management of post-harvest insect pests of pearl millet to resource poor farmers.

ABSTRACT
The study was conducted in S.E. Agro-ecological zone of Nigeria to assess the constraints to the management of cassava genetic resources. Cassava genetic resources are lost regularly due to poor management. The sample size was 480 in three states purposely chosen from the zone. Data were collected using structured interview schedule and these were analyzed using descriptive statistics such as frequencies, percentages and ranking. The result showed that 61.5% of the respondents were males and the mean age was 26years. Mean farm size was 2.5ha and only 13.0% of the respondents did not have any form of formal education. About 54.5% of the respondents lose cassava varieties due to low yield; while pests and diseases account for 63.0% as the most natural disasters in the management of genetic resources. Introduction of high yielding cassava varieties also is a major cause of loss of genetic resources. Based on the importance of cassava to man and animals, effort should be made towards it conservation for future use.
Keywords: Cassava, Constraint, Genetic Resources, Management

INTRODUCTION
Cassava is an important crop for more than 900million people in the tropics and sub-tropics (Nassar and Dorea, 1982). Domestication of cassava probably began with selection of large roots, more erect plant types with less branched growth and the ability to establish easily from stem cuttings. The population increase in the tropics and the use of cassava for animal feed and other industrial purposes has resulted in an increased demand for cassava, stimulating the development of diverse projects. To support this, cassava germplasm ought to be available and well characterized and documented. It is necessary to determine cultivars which have low cyanide content and to use them in breeding programmes. Maintenance of materials in the field is often very difficult since it requires year to year cultivations and this result in loss of germplasm through collaboration in all aspects of cassava genetic resources work. Most cassava fields are faced with catastrophically high incidence of viral diseases. Alternative methodologies of conservation of cassava germplasm such as in vitro slow growth, in vitro cryopreservation and seed could be intensified through a network.
The major causes of genetic resources loss are land use change, shift from traditional shifting cultivation to less permanent land tenure systems (Siemonsma and Lemmens, 2009). Others are introduction of high yielding varieties and its effect-replacement of the traditional genetic resources by high yielding crops, road network development, population pressure, leasing of land for other land uses, shortening of fallow periods, etc. Other causes are policy conflict, ignoring traditional customs and lack of awareness and understanding or knowledge about the values of natural resources and their management led to loss of genetic resources in all levels. The worldwide effort was created in part because of the belief that genetic legacy of our ancestors was threatened by modern conditions, especially, record high population, technological changes and infrastructural development (Frankel, 1970).
Projections about genetic erosion in farming systems of centers of crop resources rested on two conjectures. First, it is believed that modern crop varieties would diffuse throughout in these systems and secondly, it was thought that the adoption of modern crop varieties would lead farmers to stop planting land races (Daltrymple, 1986). However, farmers do not necessarily replace local varieties even when they adopt modern crop varieties. Until recently, the only means of conserving these species was in the field genebank, where the material is maintained in the vegetative state. In genetic resources, the techniques of in vitro culture can also be used for collections, disease elimination and multiplication, creation of variability and distribution of materials in aspetic conditions. To be efficiently managed and efficiently utilized, germplasm collections must be well characterized.
Management of cassava genetic resources is expected to result in effect or impact which is any immediate significant changes brought about by a given intervention action or series of actions. Such effects essentially consist of improved management practices of the genetic resources to reduce genetic erosion and enhance farmers' perception and adoption of improved management practices to safe-guard the genetic resources base. Therefore, this study was carried out to assess the constraints to the management of cassava genetic resources in Southeast Nigeria.

METHODOLOGY

The study was conducted in three states of South-east agro-ecological zone of Nigeria. The area lies mainly on plains under 200m above sea level with a human population of about 18.92million people (NPC, 2006). About 60-70% of the people engage in agriculture. Cassava production is the predominant agricultural activities in the states. The states under study were Akwa-Ibom, Abia and Ebonyi, purposely chosen because they each represent the major vegetative zones, i.e. the mangrove swamp, rainforest and savannah. Two agricultural zones were randomly selected from each state; Umuahia and Ohafia zones from Abia. Eket and Oron from Akwa-Ibom and Ebonyi South (Afikpo) and Ebonyi north (Abakaliki) from Ebonyi. In the second stage, two blocks were randomly selected. Finally, ten cassava farmers were randomly selected from each circle, giving a sample size of 160 respondents from each state. There were 480 respondents from the three states.

Data were collected using structured interview schedule for the 480 respondents sampled. Data were collected on the socio-economic characteristics of the farmers and on constraints to the management of genetic resources resulting to genetic erosion. Data collected were analyzed using descriptive statistics such as frequencies percentages and ranking.

RESULT AND DISCUSSION

Socio-economic characteristics of the respondents:

The distribution of respondents according to sex, age (yrs.), household size, farm size, (ha) and educational attainment are shown in table 1. The table shows that 61.5% of the respondents were males. Low percentage of the female folks in the study area may be attributed to their limited access to land and other production resources. About 38.5% of the respondents were in the age range of 41-50years with mean age of 26years. This means that the respondents were in their productive age.

The household size of 3-7 people constituted 65.0%, with mean size of 10. Idiong (2005) reported that large household size enhances the availability and cheap labour in the farm. Farm size of 1-2ha accounted for 39.2% and the mean farm size was 2.5ha. Azih (2004) revealed that small scale farm holdings predominate in Nigeria and account for about 95.0%s of agricultural output. Majority of the respondents had one form of education or the other. Only 13.0% did not have any formal education. Education makes communication easy as educated farmers are known to be less conservative and willing to explore their environment.

Causes of genetic erosion and commonest natural disaster which leads to loss of cassava

The result showed that 54.5% of the respondents lose cassava varieties as a result of low yield, while under commonest natural disaster which leads to loss of cassava, pests and diseases ranked first, accounting for 63.0%. This is shown in tables 2.

It was observed that 63.5% of the respondents identified introduction of high yielding cassava varieties as the major cause of loss of genetic resources. The introduction of improved varieties may have a short term effect on the environment as they tend to break down as a result of biotic and abiotic stresses.

CONCLUSION

Based on the importance of cassava to man and animals, efforts should be made towards its conservation for future use, especially for breeding and accessibility to farmers when needed. Most varieties have been lost due to bad management practices and conservation for not adopting different conservation methods. Collaboration between farmers and government should be improved upon to harness this effort and for future safe-guard of the cassava genetic resources base.

ABSTRACT
The experiment was carried out at agronomy section of Kabba College of Agriculture to investigate the effect of different nitrogen sources on nodulation, nutrient composition, growth and yield of soybean. The treatment consists of two nitrogen fertilizer (urea and N P K) and three animal manures (poultry manure, cow dung and pig manure). All these materials were applied at 20kgN/ha at planting. The growth character observed were plant height, number of leaves, stem girth, leaf area, fresh weight of plant and dry weight of plant. Yield characters observed were pod length, pod number, 1000seed weight, and number of grains per plant, grain weight per plant and yield per land area. Nodule characters observed were fresh weight of nodule and number of nodule produced per plant. Data were also collected on nutrient composition of soybean seed such as N P K, S, protein, oil, and carbohydrate. All the data collected were subjected to Analysis of Variance and treatment mean were separated using Least Significant Difference. The result shows that plot treated with N P K fertilizer at 20kgN per ha gave highest yield of soybean. It is therefore recommended to the farmers in the study area.
Keywords: Nitrogen, Nodulation, Nutrient composition, Soyabean, Manure and Fertilizer

INTRODUCTION
Soybean (Glycine max L.) is called a miracle golden bean because of its nutritive value, especially as a substitute or complement of protein. Soybean is an excellent source of protein and therefore, can supplement protein in human diet; the approximate composition of soybean is 40-45% protein 18-20% edible oil, 24-26% carbohydrate and a good amount of vitamins (Kaul and Das, 1986). It thus can play an important role in supplementing oil – protein deficiency. Soybean has one of the highest nitrogen requirements among the most agronomic crops.
Nitrogen is an integral component of many compounds including chlorophyll and enzymes, essential for plant growth processes. It is an essential component of amino acids and related proteins. Nitrogen is essential for carbohydrate use within plants and stimulates root growth and development as well as the uptake of other nutrients. This element encourages above ground vegetative growth and gives a deep green colour to the leaves (Brady, 1990). It is recognized that nitrogen is one of the key elements of soil fertility. Most of the developed countries are harvesting high yields and maintaining the soil nitrogen level by the application of chemical nitrogenous fertilizer. Soybean, being a leguminous crop, is capable to fix atmospheric nitrogen through symbiosis. However, several studies have shown that the symbiotic N – Fixation is not able to meet high N – requirement of this crop particularly under the Nitrogen deficient conditions. A number of workers (Duraisami and Mani, 201; Kumawat *et. al.*, 2000; Bachhau and Sabale, 1996; Sharma and Misra, 1997) reported the positive role of nitrogen in increasing yield, protein content and nutrient uptake of Soybean.
Soybean is a leguminous crop; there is need to plant leguminous plant in other to improve soil fertility. Nodule production determines the availability of nitrogen to crop at later stage of crop life. The crop has the ability to convert atmospheric nitrogen to the form that can be used by the plant. It also, determines nitrogen content of soybean seed. The work will examine the rate of nodule formation in soybean in Southern Guinea Savannah of Nigeria. Objectives of the study are to determine the effect of different nitrogen sources on nodulation, nutrient composition on soybean seed and on growth and yield of soybean.

MATERIALS AND METHODS
Area of the Study
The field experiment was conducted at Kabba College of Agriculture student experimental field during 2015 cropping season. Kabba is located in the Southern Guinea Savanna Ecological Zone of Nigeria. (07^0 53'N, 06^0 08'E). It has an average rainfall of about 1,570mm per annum with an annual temperature range of 18^0c – 32^0c. The mean relative humidity (R.H) of about 59% and four hundred and twenty seven meter (427m) above sea level.

Field work
The Soybean seeds that was source from Agriculture Development Office, Aiyetoro, Kogi State Nigeria. The experiment was conducted using single field of dimension 14.5m x 11m which consisted of six treatments and were replicated three times. The experiment was laid out in a Randomized Complete Block Design (RCBD).

The treatments consisted of the followings: The experiment consists of six nitrogen sources apply at 20kgN/ha T1= Urea (43.48kg urea/ha), T2= NPK (133.3kgNPK/ha), T3=Poultry manure (555.6kg pm/ha), T4=Cow dung (714.3kg cwd/ha), T5= Pig manure (1250kgpgm/ha), Control (No fertilizer).

The seeds for the experiment were collected from International Institute Tropical Agriculture, Ibadan. Sites were cleared manually using cutlass and later ridged with hoes and in the field, Seeds of Bambara nut were sown on a flat bed. Organic manure were uniformly spread on the flat beds and incorporated with hoes two weeks before planting. Urea and NPK fertilizer was applied at planting. The seeds were planting at the rate of two - plant-per-hole at a spacing of 50cm by 30cm which make up forty- nine stands per plot. Plots were weeded manually at three weeks intervals.

Data analysis

Data were statistically analyzed using GENSTAT. The analysis of variance (ANOVA) was performed to find out the significance of variation among the treatments while the significant difference between mean treatments were separated using least significance Difference at 5% level of probability.

RESULTS AND DISCUSSION

Pre-planting soil analysis and composition of animal manure used

The result of the pre-planting soil analysis showed that the soil was dominated by sand fraction at the surface at 60% followed by clay at 21.6% and silt at 18.1%.The soil was therefore classified as sand clay loam, by this classification, it could be inferred that the soil used for the study was of good drainage and well aerated for good root penetration. The soil pH showed that the soil was slightly acidic in reaction with pH value of 6.2. The organic matter content was low (2.14%) the low organic matter content could be attributed to the effect of erosion and seasonal burning that was very common in the area in early January and March annually. The total N was quite low at 0.19%). The low total nitrogen could also be attributed to low organic matter content (Nnaji et al, 2005). The available phosphorus was quite high at 31.4ppm. This could be as a result of low fixation of p in the study area by sesquioxides or as a result of the parent material. The exchangeable cation of Ca, Mg, K and Na were low. The cation exchange capacity (CEC) was low. Generally the percentage of base saturation was 23.3% and this infers that the soil had low fertility.

Plant height

Nitrogen sources influenced plant height of soybean significantly over control. 1norganic fertilizer influenced plant height better than organic nitrogen sources. Among the inorganic fertilizer tested NPK fertilizer produce taller plant. Plots treated with NPK were not significantly better than plots treated with urea. Animal manure plots were statistically inferior to plots treated with inorganic fertilize except in plots treated with poultry manure. Similar results were reported by Varon et al. (1984), Manral and Saxena (2003). The result also corroborate the finding of L1 and Mahler (1995) who obtained better vegetative development in wheat, most especially when soil was amended with poultry manure. N P K and poultry compete favorably in terms of growth characters of soybean. This could be as a result of many nutrients in both nitrogen sources. Among the animal manure, poultry manure produced tallest plant, followed by cow dung and the shortest plant occurred in plots treated with pig manure.

Number of leaves and leaf area were significantly affected by the different nitrogen sources applied. Plot treated with N P K produced the widest leaf area ($4.8m^2$). All the plots amend either with inorganic or animal manure were better than the control plot, there was no significant difference on stem girth.

Animal manure was significantly inferior to N P K fertilizer these experiments but, compete favorably with urea. The result is in line with the finding of Ogundare et al (2015).

Table 4.3 presented the result the of yield and yield components of soybean. Significant difference were observed in pod length, pod number , 1000seed weight (g) , number of grains weight of grains and grain yield per hectare due to different nitrogen sources, plot amended with inorganic fertilizer (urea and N P K) show better performance in yield and yield characters compared with plot amended with animal manure (poultry manure, cow dung and pig manure). Thought, N P K recorded higher pod number (66.8), grain number (148), grain weight per plant (43.4) and yield per hectare 4840kg (4.8 t/ha) which was not significantly better than plot treated with urea. Among the organic residues (animal manure) cow dung recorded greatest yield which was statistically different from plot treated with poultry manure and pig manure. Control plots were highly statistically inferior to plots amended with either organic or inorganic fertilizer in this study. Poultry manure performs better than either cow dung and pig manure. The better performance of poultry manures in all the growth character observed infers that the plant response to poultry which agrees with earlier finding of Olatunji and Oboh (2012). They reported increase in growth of tomato with the use of poultry manure. The better performance of the inorganic fertilizer in this study could be a result of nutrient released immediately into soil and crop. The findings of smith et al (1986) who reported that legumes crop do not need nitrogen, N P K treated plot perform better than urea treated plots. This observation could result from leaching effect of urea that make the nutrient unavailable to the crop, cow dung was the best animal manure in the experiment and significantly better than either poultry manure or pig manure in terms of yield. The result could attributed to the effects of phosphorus in cow dung which is a major nutrient in seed or grain production plots with no amendment produce the least yield and yield characters in this study. The results confirm that soybean response to different nitrogen sources.

Nodule characters in soybean

Fresh weight of nodule, dry weight of nodule and number of nodule per plant were significantly affected by the different nitrogen sources applied. Plot treated with poultry manure had largest nodule which was followed by N P K fertilizer, than urea and cow dung, pig manure plot had least number of nodules among the amended plots. However, unamend plots control show remarkly low number of nodules. Nodule number increase with the amended nitrogen sources over the control. The findings of Senerirantue et al, (2000) have shown that inoculation and fertilizer use promote plant growth and increase grain yield in soybean. Incorporating 23kg n/ha as the primary fertilizer application and adding 23kg n/ha at the end of flowering does not inhibit soybean nodulation. This show the importance of nitrogen fixation in the tropic even with fertilizer incorporation included. Nitrogen affect nodulation of legume (soybean). Yashima (2003) grain legume in nutrient solution containing 0 – 100 ppm nitrogen in the form of urea and found that maximum number of nodules was obtained at 25ppm nitrogen.
4.5: Table 4.5 presents the result of fresh weight of plants (g) and dry weight of plant (g). There was significant difference in fresh weight of plant and dry weight of soybean due to treatment. The result was not consistent.

Nutrient composition of soybean seed

Significant difference was observed in nitrogen, protein and oil due to different nitrogen sources. However, P, K, S and carbohydrate were not statistically affected by treatment. Though, the result on nutrient composition was inconsistent. Plots amended with urea had highest percentage of nitrogen and oil while plots treated with cow dung had highest percentage of protein. However, unamend plot had the least percentage of nitrogen, protein and oil.

CONCLUSION

Soybean responses to both inorganic and organic nitrogen source irrespective of the type of the soil. N P K fertilizer influenced growth and yield of soybean better than urea and among the organic sources poultry manure was the best. Nodule formation in soybean was also influenced by application of nitrogen sources irrespective of the kind of the sources. Growth and yield of soybean was positively influenced by inorganic and organic manure used as nitrogen sources. NPK fertilizer at 20kgN/ha influenced yield of soybean better than other sources, it is there recommend to the farmer for optimum yield. Further research should be carried out on other agronomy characteristics influence soybeans production.

ABSTRACT
Eleven hybrid white yam genotypes plus three landraces of white yam were tested in the Western experimental field of N R C R I, Umudike in 2014 and 2015, the objectives was to Select high yielding hybrid yam genotypes with desirable agronomic and marketable characteristics, Select genotypes tolerant to pests and diseases attacking yams in the field and to recommend them for multlocational trial across the agro ecological zones for possible commercial yam production. The experiment was laid out in a randomized complete block design with three replications Yam setts weighing 40g were sown 45 cm apart on the crest of the ridges and 10 cm below the soil surface and 100cm between ridges in a plot size of 20m^2. Data were collected on: mean total tuber yield, ware tuber yield and Seed yam. Data on tuber marketability components such as tuber size, tuber surface texture and flesh colour were collected. Pests and diseases reactions of the tubers were scored. Result indicated that Four hybrid yam genotypes (Amo99/064, Amo99/109, Amo99/060, and Amo99/144) yielded more than the three check varieties and should be selected for multilocational trial to evaluate their performance across the agro - ecological zones of the country for possible release for large scale yam cultivation and commerce.
Keyword: hybrid yam, selection, multilocation trial, agroecology and market value

INTRODUCTION

The major aim of yam cultivation by the subsistence farmers is not only for consumption, but also to generate income by selling the yams in the market. However, not all yam tubers are acceptable by the consumers. There are qualities that the farmers as well as the consumer appreciate before the genotypes will be acceptable (Daisy 2000). It is therefore vital to develop hybrid yam genotypes with good agronomic characteristics for cultivation, morphological traits that will be ease for processing for consumption and eye appeal quality for commercial yam production. The genotypes with these qualities must be adaptable across all the agroecologies for commercial yam production. Therefore the objectives of this work was to: Select high yielding hybrid yam genotypes with desirable agronomic and marketable characteristics, Select genotypes tolerant to pests and diseases attacking yams in the field and to recommend them for multlocational trial across the agro ecological zones for possible commercial yam production.

MATERIALS AND METHODS

Eleven hybrid white yam genotypes plus three landraces of white yam were tested in the Western experimental field of N R C R I, Umudike in 2014 and 2015. The experiment was laid out in a randomized complete block design with three replications in an area of land that was mechanically ploughed, harrowed and ridged at 1m apart. Yam setts weighing 40g were sown 45 cm apart on the crest of the ridges and 10 cm below the soil surface and 100cm between ridges in a plot size of 20m^2. The plots were kept weed-free manually. There was no Fertilizer application. Pre-emergence herbicide (Diuron) was used immediately after planting and complemented with manual weeding at 12 weeks after planting (WAP). Data were collected on: mean total tuber yield, ware tuber yield and Seed yam. Data on tuber marketability components such as tuber size, tuber surface texture and flesh colour were collected. Pests and diseases reactions of the tubers were scored. Tuber yield was analyzed using Analysis of variance and means separation was done using standard error of difference means. Tuber Shape and Tuber Surface Texture was scored after determining the tuber shape index (Nwankwo, 2014).

$$TSI = \frac{L}{W}$$

Pests and Diseases were scored using the scale of 1 to 5. where 1=no pests or diseases, 2 =pests and diseases are present in a mild condition, 3= pests and diseases infestation and attack were moderate, 4 = pests and diseases infestation and attack were severe. 5= pests and diseases infestation and attack were so severe that the crop is almost dead.

RESULTS AND DISCUSSION

Tuber fresh weight: The result of the tuber fresh weight is presented in Table 1

Tuber fresh weight: The result in Table 1 indicated high significant (P<0.01) variability in the weight of the classes of tubers. Four genotypes Amo99/064 with mean total fresh weight of 36.6t/ha, Amo99/109 with 47.8t/ha, Amo99/060 with 35,2t/ha and Amo99/144 with 39.0t/ha of fresh weight were significantly (P<0.01) higher than that of the three check varieties (Table 1) and therefore should be nominated for multilocational evaluation

Flesh colour and tuber exudates: The flesh tuber ranges from cream to white (Table 1) with very low oxidation rate after being exposed to the air for 5 minutes. Two genotypes Amo99/040 and Amo99/095A slight turned to brown after being exposed to the air for 5 minutes. The colour could be an index for the acceptability or rejection of yam fufu. The tuber flesh colour of the hybrid yam genotypes including the landraces were all white in colour and would be good in yam flour or in the preparation of pounded yam a prestigious carbohydrate to welcome visitors especially in South eastern Nigeria. The exudates of the genotypes are gummy and non-irritant when it comes in contact with the human skin except Amo99/003 and Amo99/X5 and Adaka.. These are good processing qualities.

Tuber Skin thickness: The tuber skin of all the genotypes including the landraces have skin thickness above 1mm. The tuber skin thickness is not liable for bruises during careful harvesting and loading for transportation or tying on stakes at Rafia barns (Table 1).

Tuber morphology and other tuber surface characteristics: The result of Tuber morphology and other tuber surface characteristics are presented in Table 2.

.**Tuber size:**. The high significant (P<0.01) genotypic mean tuber size variation among the hybrid yam genotypes indicated the extent of fresh carbohydrate accumulation among the genotypes. The length and width of the tubers measures the tuber size which is the dimension, extent or how large the yam tubers were. The yam genotype with the longest tuber length was 99/Amo/056 with 34.30cm and tuber thickness of 9.19cm more than the two landraces (Table 1) which indicated high fresh carbohydrate accumulation as a result of high photosynthetic efficiency more than the two landraces. This indicated high bulking rate of the hybrid yam genotypes.
Tuber shape: The hybrid yam genotypes and the landraces have straight sides with almost circular ends of equal size and a constant circular cross section that can go for as cylindrical shape. This type of shape is not prone to damage during yam harvest and easy for tying on stakes during storage and easy for harvesting since the tubers are not branched. Branched yam tubers are liable for damage during harvesting. All the yam genotypes including the landraces have cylindrical shapes. Hence the tuber shape index is within region of general acceptance (TSI = >1 and < 4). The mean tuber shape of all the hybrid clones was 2.0 which is an indication of cylindrical shape. This shape lends itself for ease of peeling during processing for food than round or flat shape and hence have smooth skin texture (score 1). Yam tuber with cylindrical shape and smooth surface texture command high market prices. However, yam tubers with cylindrical shape grow deeper into the soil and less prone to breakage during harvesting and bruises as it has tuber skin which is more than 1.0mm (Table 2).

Pests and diseases reaction: The pests and diseases reaction of the hybrid yam genotypes show the field reaction of the white yam clones to the foliar and tuber pests and diseases of yam. There were mean mild reaction of the genotypes to yam mosaic virus diseases (with mean score of 1.12) and mild infestation of crickets. Generally, the result indicated that most of the white yam genotypes were field tolerant to the pests and diseases.

CONCLUSION

Four hybrid yam genotypes (Amo99/064, Amo99/109, Amo99/060, and Amo99/144) yielded more than the three check varieties and should be selected for multilocational trial to evaluate their performance across the agro - ecological zones of the country for possible release for large scale yam cultivation and commerce. They have high bulking rate an indication of accumulation of usable fresh carbohydrate more than the Check varieties. These genotypes have white flesh to cream colour, smooth skin and cylindrical shape (TSI = >1 and <4) that is acceptable to consumers and will command high market value. These genotypes are therefore nominated for multi-locational agro-ecological trial

ASSESSMENT OF THE YIELD AND YIELD COMPONENTS OF SOME SWEETPOTATO GENOTYPES AS INFLUENCED BY DIFFERENT LEVELS OF ORGANIC AND ORGANIC FERTILIZER

G. O. Nwaigwe & I. I. M. Nwankwo

National Root Crops Research Institute Umudike
gracenrcri@yahoo.com

ABSTRACT
Eight Sweetpotato (*Ipomoea batatas L. Lam) genotypes were assessed on ten different rates of fertilizers at the experimental station of the National Root Crops Research Institute Umudike in Abia State, Nigeria in 2013 and 2014 cropping seasons to generate information on the of yield and yield components of sweetpotato as influence by organic and inorganic fertilizer so as to select the best nutrient formulation for sweetpotato root yield. The experimental design was split randomized complete block design with three replications. The treatment consisted of three levels of NPK fertilizer rates (100kg, 200kg and 300kg), three levels poultry manure rates (10t/ha, 20t/ha and 30t/ha) and three level combinations of poultry manure and NPK fertilizer at; (5t/ha +50kg/ha, 10t/ha+100kg/ha and 15t/ha+150kg/ha). Data were collected on: Vine length at 8WAP, Number of leaves at 8 WAP, Biomass weight at 12 WAP, Number of saleable roots and saleable root weight. Data collected were subjected to analysis of variance. The result revealed that Poultry manure and Fertilizer rates evaluated were not significant (P>0.05) at all levels of application in all the characters assessed, which showed that those levels of poultry manure and fertilizer rate could be used in root yield production in sweetpotato. However, the results indicated that two genotypes UMUSPO/1 and TIS/87/0087 responded significantly (P<0.01) to the combination of 15t/ha PM and 150kg /ha NPK I5:I5:I5 fertilizer and could be used to enhance the performance of the two genotypes.*

Keywords: Sweetpotato, NPK fertilizer rates Poultry manure, yield and yield components.

INTRODUCTION
Sweetpotato (*Ipomoea batatas L.*), is an herbaceous dicotyledonous plant with creeping perennial vines which is usually grown as an annual for their root tubers. It belongs to the family *Convolvulaceae* (Degrass, 2000) and the 45 genera and 1,000 species present in this family only *Ipomea batatas* is known to be of economic importance as food (Edmond, 1971). It remains a prominent food crop to many rural dwellers especially in Northern parts of the country (Edebiri *et al*., 2001). Nigeria is the third largest producer in the world with China leading, followed by Uganda (FAO, 2004). Despite the contribution of sweetpotato to food security in Nigeria, results showed there is poor yield of only 3 to 8t/ha in the farmers' field (Njoku *et al* 2001, Eke-Okoro 2010) and necessitates the use of fertilizer to enhance yield. The exact dosage of fertilizer for each genotype should depend on the soil type, the environment and cultivars grown (Onwueme, 1988). Okonkwo *et al.,* (2009), showed soil fertility is the bedrock for bumper harvest, food security and economic empowerment of farmers. The shortage and high cost of inorganic fertilizers have limited their use for crop production among the peasant farmers in Nigeria (Tanimu *et al.,* (2007). Result has shown that for increase performance and yield of sweetpotato, NPK 15:15:15 at the rate of 300-400kg/ha is recommended (Nwinyi, 1987), but incidentally this NPK rate (300-400kg/ha) often may not be suitable to optimize crop yield throughout the agro ecologies of Nigeria. Sweetpotato responds well to farm yard manure or compost (Udoh *et al*., 2005). According to Enwezor *et al* (1988), 10t/ha are recommendation for all organic manure in soil of eastern Nigeria. Sweetpotato farmers generally would not apply fertilizers for two reasons first the response of sweetpotato cultivars to different fertilizers has not been clearly established. Secondly the crop is often not paying for the cost of the fertilizer. According to Nedunchezhiyan *et al.,* (2007), tuber size, number of tubers per plant and stand count are strongly related to tuber yield and these are highly affected by changes in environmental conditions. In view of the foregoing challenges, this research is initiated to come out with the best NPK fertilizer rates, and optimum poultry manure/combination of both which will enhance healthy crop growth and thereby translating into higher root yield of sweetpotato.

MATERIALS AND METHODS
Vine Length: The result of the influence of different levels of compound fertilizer NPK 15:15:15 , levels of poultry manure and combination of each levels of the compound fertilizers and each levels of poultry manure on the yield and selected yield components of sweetpotato genotypes are presented in table 1 The result for the combined yield data for the two years showed that at 0t/ha of PM/NPK gave 49.8cm vine length while the highest vine length of 56.7cm was obtained in the combination of 15t/ha of PM + 150kg/ha of NPK 15:15:15. This shows that a combination of 15 /ha of PM + 150kg/ha of NPK 15:15:15 will give considerable vine length for sweetpotato yield. This is because the longer the vine length, the more the production of leaves which is the seat

of photosynthesis which is sent to sink for more tuberous root formation and root number. However, there was high significant (P<0.01) differences on the effect of fertilizer and poultry manure (PM) application on the various genotypes.. The combined mean result for the two years indicated that Ex-Onyunga gave the least vine length at 0t/ha of PM and NPK 15:15:15 fertilizer with vine length of 24.8cm while TIS87/0087 responded very well to 15t/ha PM +150kg/ha NPK 15:15:15 fertilizer which gave combined mean vine length of 84.9cm. This shows that 15t/ha pm +150kg/ha NPK 15:15:15 fertilizer could be used to increase the vine length on TIS/87/0087 for increase in the root yield of the crop.

Number of leaves: It was observed that there was no significant (P>0.05) differences in the number of leaves at 8 WAP with the various levels of NPK 15:15:15, poultry manure and their combination rates. The combined result for the two years showed that at 0t/ha of PM/NPK low mean number of leaves of 36.2 leaves was obtained while highest mean number of leaves was obtained with 10t/ha PM + 200kg/ha NPK 15:15:15 compound fertilizer. This could be used to increase leave number which could increase the leave area for high photosynthesis for which could lead to large tuberous root formation and high number of saleable sweetpotato roots. Sweetpotato genotypes responded significant (P<0.01) differently on the application rate of PM and fertilizer. The genotype TIS/87/0087 responded very well at the application of 10t/ha pm +100kg/ha NPK 15:15:15 fertilizer and 200kg/ha NPK 15:15:15 fertilizer with the combined mean leave number of 53.9 leaves more than other sweetpotato genotpyes.

Biomass: The biomass (root and above ground vegetative) is the biological yield of the sweetpotato crop. The result in Table 1 indicated high significant (P<0.01) differences in the biomass yield of the sweetpotato genotypes.. The combined results for the two years indicated that mean weight of biomass at 12WAP with 0t/ha PM/NPK was 11.4kg while the highest biomass weight at 12WAP was 17.77kg/ha at the application of 15t/ha PM +150kg NPK 15:15:15 compound fertilizer. This showed that 15t/ha PM +150kg NPK 15:15:15 combination was the best level for biomass production in sweetpotato.

The genotype UMUSPO/1 had the highest biomass yield at the application of 15t/ha PM and 150kg/ha NPK 15:15:15 fertilizer which gave 31.41kg and 16.43kg in 2013 and 2014 respectively with combined mean year of 23.9kg biomass. The study observed that there was high significant (P<0.01) differences in the weight of biomass produced among the sweetpotato genotypes and significant differences in the biomass produced by the individual sweetpotato genotypes evaluated (Table 1).

Number of saleable roots:. It was observed that the combined low mean number of root of 11.7 from NRSP/05/3D was obtained at 0t/ha PM/NPK fertilizer while the highest combined mean number of roots of 34.5 was obtained from UMUSPO/1 at the application of 20t/ha PM. Although, there was non-significant (P>0.05) effect of the various levels of application rate and their combination on the number of saleable roots, this indicated that any level of PM and NPK evaluated could be used in the production of number of saleable roots. However, the genotype UMUSPO/1 was significantly outstanding as the genotype that produced more number of roots among the sweetpotato genotypes evaluated.

Saleable root weight: The combined application rate of 15t/ha pm +150kg/ha NPK 15:15:15 gave the highest mean combined mean weight of 4.6t/ha of saleable root yield. This showed that at combination rate of 15t/ha PM +150kg/ha NPK 15:15:15 will give remarkable yield increase of saleable root weight although the non- significant influence of the poultry manure and fertilizer rate indicated that any application of fertilizer rate or combination of PM and fertilizer could be used to achieve considerable increase in saleable root weight in sweetpotato.

However, there were significant differences of the effect of the fertilizer rate and the poultry manure combination on the sweetpotato genotypes evaluated. The 0t/ha of PM and NPK 15:15:15 fertilizer drastically reduced the yield of NRSP/05/3D at a combined mean yield of 2.2t/ha while the yield of TIS 87/0087 was improved with the combined application of 15t/ha PM +150kg/ha of NPK 15:15:15 which gave combined mean yield of 6.8t/ha. This showed that while there was no significant effect of the combination of 15t/ha pm+150kg/ha NPK 15:15:15 on sweetpotaqto weight of the genotype TIS/87/0087.

CONCLUSION

As was found in the study, the different levels of poultry manure and NPK 15:15:15 fertilizer rates had no significant (P>0.05) effect on the yield components of the sweetpotato genotypes except on the biomass weight whereas individual sweetpotato genotypes were significantly (P<0.01) influenced by the application of various levels and rates of poultry manure and NPK 15:15:15 fertilizer evaluated. The result indicated that two genotypes TIS/87/0087 and UMUSPO/1 were significantly influence by the combined application of 15t/ha pm +150kg/ha NPK 15:15:15 fertilizer on the following combed mean year traits: 84.9cm vine length, 53.9 number of leaves at 8WAP and 6.8t/ha of saleable root weight while UMUSPO/1 produced combined mean year biomass weight of 23.9kg/ha and 34.5 mean number of saleable roots at the influence of 15t/ha pm +150kg/ha NPK 15:15:15 fertilizer rate.

EVALUATION OF POST-EMERGENCE HERBICIDES FOR WEED CONTROL IN GINGER PRODUCTION AT UMUDIKE, SOUTH-EASTERN NIGERIA

D.S. Korieocha, C.O. Amadi, J. Ewuziem, E.O. Anaedo & A. Obinna

National Root Crops Research Institute, Umudike.
davesam2k@gmail.com

ABSTRACT
The experiment were conducted in 2014 cropping season at the Research farm of National Root crops Research Institute, Umudike, to evaluate selected herbicides for weed control in ginger production. The soil was sandy loam. The weed species found in the experimental site before clearing the field were broad leave weeds, grasses and sedges. The plot size was 3 mx 2m. The treatment consisted of 9 treatments, 2 post-emergence herbicides applied at 3 rates each: fluazifopbutyl at 0.5,0.8 and 1.0 kg a.i /ha, paraquat-0.3, 0.75 and 0.8 kg a.i/ha, primextra gold + paraquat(1.25+0.4) kg a.i /ha, weeded at 4+ 6 WAP and Unweeded. The manual weeding at 4+6 WAP gave the highest rhizome number/ha. The crop phytotoxicity rating at 8 and 12 WAP was minimal (<10%) have no serious injury to the crop. Application of post-emergence (paraquat) at rate 0.8 kg a.i/ha gave the highest ginger rhizome yield (13.85 t/ha). At 16WAP, paraquat 0.8 kg a.i /ha, sustained an excellent weed control.
Keywords: post- emergence, Ginger and Economics.

INTRODUCTION
Ginger is a monocotyledonous herbaceous perennial plant; its flavouring type is classified as *Zingiber officinale* which belongs to the order; suitaminae and family *Zingiberaceae*. It is a tropical herb extensively grown for its pungent aroma. It is an underground stem or rhizome which is an export crop, value for its powder; oil and oleoresin (NEPC, 1999). Ginger is one of the world's most popular and useful plants, being used for centuries as species for flavouring food and as a medicinal plant.Advance research has proved that ginger could be used to cure certain ailments.Chen et al (2007) reported that ginger compounds are active against a form of diarrhea. The crop is believed to have originated from the southern part of China, but now grown in almost all parts of tropical and sub-tropical world. The objectives is to screen selected herbicides for weed control in ginger production and to determine the effectiveness of the herbicide for weed control in large scale ginger production.

MATERIALS AND METHODS
The experiment was conducted in 2014 at the research farm of the National Root Crops Research Institute (NRCRI), Umudike (05º, 29N, 07, 31̀E and 122 M above sea level). The soil was sandy loam. The weed species found in the experimental site before clearing the field were broad leaves weeds, grasses and sedges. The plot size was 3m x 2m. The land was plough, harrowed and a well prepared bed was made with a planting distance of 20 cm x 20 cm of 20 gm sett size of UGI (yellow) ginger, given a total plant population of 250,000 plants/ha. The treatment consisted of 9 treatments, 2 post-emergence herbicides, applied at 3 rates each, viz: fluazifopbutyl at 0.3, 0.8 and 1.0 kg ai/ha, paraquat 0.3, 0.75 and 0.8 kgai/ha, mixture of primextra + paraquat (1.25 + 0.4) kg ai/ha, weeded at 4 + 6 WAP and unweeded check. Each treatment was replicated three times using a randomized complete block design.
Compound fertilizer (15:15:15 NPK) was applied to all the plots at the rate 400 kg at 4-6 weeks after planting. Plots were visually score for weed control by two independent assessors on a rating scale of 0-10 with 0, representing no weed control and 10-complete weed control, 7.5 was regarded as an acceptable level of weed control. Herbicides were applied at spray pressure of 2.1 bar. Overall volume was 250 litres/ha. Rhizome yields were measured at harvest as well as economic assessment of the weed control treatment using labour, productivity index, available yield index as well as return per naira investment model (Ezedinma *et al.,* 2006).

RESULTS AND DISCUSSION
Weed control
The effect of weed control treatments on weed control at 8, 12 and 16 WAP, phytotoxicity rating at 8 and 12 WAP, weed weight in 2014 are presented in Table 1. The results showed that application of paraquat, 0.3, 0.75, 0.8 kg ai/ha and Atrazine/metolachlor + paraquat (1.25 + 0.4) kg ai/ha, gave an excellent weed control at 8 WAP.

Weed control was excellent at 12 WAP with treatments containing paraquat 0.8 kg ai/ha and Atrazine/metolachlor (1.25 + 0.3) kgai/ha.

At 16 WAP, paraquat 0.8 kgai/ha sustained an excellent weed control, while Atrazine/metolachlor + paraquat (1.25 + 0.4) kgai/ha, paraquat 0.3 and 0.75 kg ai/ha was satisfactory at 16 WAP, when compared with fluazitopbutyl rates.

The crop phytotoxicity rating at 8 and 12 WAP was minimal (≤10%) have no serious injury to the crop. Unweeded control gave the highest weed weight (3.67) kg/ha, followed by fluazifopbutyl at rate 0.8 kgai/ha (1.07) kg/ha.

Ginger Rhizome Yield

Application of post emergence (paraquat) at rate 0.8 kgai/ha gave the best ginger rhizome yield (13.85 t/ha) in 2014 (Table 2). This was followed by manual weeding at 4 + 6 WAP (13.82 t/ha) and plots treated with Atrazine/metolachlor at rate 1.25 to 4) kgai/ha (11.44 t/ha) and paraquat 0.75 kg ai/ha (10.22). But there were statistically different to that of Atrazine/metolachlor at (1.25 + 0.4) kg ai/ha. Unweeded control treatment gave the least ginger rhizome yields (2.89 t/ha).

Manual weeding at 4 + 6 WAP gave the highest rhizome number/ha (12667/ha), followed by fluazifopbutyl 0.8 kg ai/ha (11967/ha). Paraquat 0.3 kgai/ha gave the least rhizome number/ha (3533/ha). Manual weeding gave the highest surviving plant count (93.33/plot), followed by fluazifopbutyl 0.8 ai/ha (87.67/plot). Paraquat 0.3 kg ai/ha gave the least surviving plant count (34.67/plot). The high yield recorded on the herbicides treated plots might be as a result of weed control in the crop after the expiration of the herbicides. Also good land preparation.

The economic analysis of the weed control treatment presented in Table 3, showed that paraqaut 0.8 kg ai/ha out yielded the other treatments. This was followed by the weeded plots and the mixture of Atrazine/metolachlor (1.125 + 0.4)kg ai/ha. Paraquat 0.8 kg ai/ha gave monetary return of N2,058.860 when compare with manual weeding N2,042.100. In most areas availability of labour constitutes a threat to productivity, leaving the option of using herbicides

CONCLUSION

Application of paraquat at 0.8 kg a.i/ha gave the highest rhizome yield (t/ha) and gave the highest income per naira .

nkerechukwuemeka@yahoo.com

ABSTRACT
We evaluated the incidence of cassava mosaic diseases (CMD) across the eleven states in the South-South and South–East Nigeria. There were varying degrees of incidence across the fields and states, ranging from 19.8 – 61.8%. The least and highest incidence were observed in Delta and Ebonyi state, respectively. The aim is to establish low disease pressure sites for the multiplication and generation of virus-free planting materials.
Keywords: Cassava mosaic, disease, Southeast, South-South Nigeria

INTRODUCTION
Cassava mosaic disease (CMD) is the most economically important viral disease of cassava in Sub-Saharan Africa (Legg et al., 2006). It is caused by cassava infecting begomoviruses (CMBs). The disease is wide spread in many cassava-growing countries of the region (Fauquet and Stanley, 2003; Sseruwagi et al., 2005). The disease has been shown to be common in subsistence agriculture with crop losses between 19 – 27 metric tonnes throughout the Sub –Saharan Africa (Legg and Thresh, 2004). It is estimated that over US$1.5 billion per year is lost due to CMD (Thresh et al., 1997). The affected plants are stunted with obvious foliar symptoms and produce no or significantly diminished tuberous root yield (Otim-Nape et al., 2000). Therefore for effective control and management, there is the need for routine surveillance and monitoring on the spread and distribution of the disease.

MATERIALS AND METHODS
A total 250 locations in the 11 states of south-east and south-south Nigeria were purposely sampled in 2015. The states were (Abia, Anambra, Imo, Enugu, Ebonyi (south-east) and Bayelsa, Cross River, Delta, Edo and Rivers (south-south) all in the humid forest agro-ecology.
The incidence of virus diseases on leaves of cassava plants were assessed by walking in an "X" (diagonal) transect manner in the field. Young leaves from thirty plants per field (15 plants per diagonal) were assessed for disease symptoms in an alternating manner by walking along the diagonal. Disease severity was scored on a scale of 1-5 (1 = no visible symptom and 5 = Severe mosaic, leaf distortion and severe stunting) for the presence or absence of virus disease symptoms and severity.

RESULTS AND DISCUSSION
A total of 7471 plants in 250 locations were assessed for virus incidence, of which 2877 (38.5%) were affected with varying degree of virus infection. Moderate mosaic symptom (score 3) contributed the highest (61.5%) infection (Table 1). The CMD incidence across the states ranged from 19.8 to 61.8%. The least mean incidence was recorded in Delta state while the highest was in Ebony state (Fig. 1). Four states (Anambra, Cross River, Ebonyi and Enugu had virus incidences of more than 50% representing 35.6% of the total sample location (Table 1). The implication of this is that, out of every ten samples in each of these locations, five are infected with varying degree of virus symptom. The mean symptom severity score ranged from 1.16 to 2.29. The high virus incidence observed in the fields is of noteworthy as cassava is a vegetatively propagation crop. The possibility of 100% infection is likely in situation where farmers use these infected plants are stakes for propagation. Although CMD is wide spread in all cassava producing area (Fauquet and Stanley, 2003), 23 of the locations were free from virus symptoms. Most likely, farmers in these areas are either planting resistant varieties or adopting the positive selection method. Apart from planting resistant varieties as this was the case in Delta state with the lowest virus incidence, encouraging farmers to practice on-farm positive selection of healthy plants and effective control of the vector whitefly, *Bemisia tabacci* will have the desired impact in the control of this disease.

CONCLUSION
The differences observed in the incidence and severity of CMD across the states will provide scope for generating virus-free planting material and also identify low disease pressure sites for clean seed multiplication.

ABSTRACT
Botanical seed production of three yellow cassava varieties was assessed at three different planting dates. On set of rain (Mid May) Mid July and Mid September on a three by three split plot experiment in 2011 and 2012. Results from the analysis of variance (ANOVA) showed that variety and planting date significantly affected the growth habit and seed production of the cassava varieties used in the experiment. Cassava batch planted in Mid May (earliest) had higher survival rate (89.89, 74.56 and 55.56) maintained better physiological features which in turn yielded significantly higher seeds (785.4, 165.9 and98.0) and gave heavier seed weight (0.11,0.02 and0.01kg) than others. Umucass 37 (variety2) out yielded the other varieties in seed production (461.7 and 762.4) respectively. Although variety1 (Uumcass36) had heavier weight. This has shown that early planting of cassava, varieties not withstanding is the key to optimum productivity in cassava.
Keywords: Cassava, planting date, physiological features and gestation seed,

INTRODUCTION
Nigeria is the highest producer of cassava in the world. It accounts for 55% of 55million metric tonnes global total production in 2013(FAOSTA 2013).Cassava production in Nigeria is mostly done by small house hood farmers on small to large scale family firms located in a wide range of ecological zones between latitudes 30^0N and 30^0S (EL-Sharkawu 1993, 2004), particularly in the humid tropics where its production is favored by the climatic and edaptic features. This wide range of ecological zones is characterized by varied micro climatic factors such as temperature, rainfall, solar radiation and relative humidity, the mean of which gives the climatic condition of a given area at a given time acting synergistically to form the two predominate tropical seasons of the year- the rainy season and the dry season. These two predominate seasons on the other hands determines the planting time of the year. The rainy season is characterized by long period of rains (6 months) and thereby making available adequate moisture for cassava development, moderate relative humidity, moderate temperature, moderate solar intensity and good edaphic conditions which can promote high photosynthetic activities, sustains good crop growth and maintains high yield (Cock 1983, Okogbenin *et al.,* 2003). Although cassava is produced all the year round, higher yield levels are obtained with a longer moisture cycle or with conservation by mulching (IITA, 1982). Generally cassava is propagated by stem and has lost or reduced its flowering abilities in some varieties, yet flowering and botanical seed production are very important in the improvement of the low yielding and highly susceptible land cassava races in use presently. Although flowering and botanical seed production of cassava depends on genotype, yet the potential yield of seeds is highly influenced by the interaction of photosynthetic abilities, growth habit, storage capacity, climatic conditions and time of planting. (Okeke.1981; Ekanayake, and Ginthinguri, 2000, Ceballos *et al*., 2004; Olasanmi *et al*.,2014). There is little or limited information on this subject matter hence this work was design to assess the effect of planting period on the survival rate and seed production of three newly bred pro-vitamin A cassava varieties.

MATERIALS AND METHODS
The experiment was carried out using three yellow fleshed pro- vitamin A cassava genotypes Umucass36 for vareity1, Umucass37 for variety3 and Umucass38 for variety2(where). The investigation was conducted for two consecutive years (2011 and 2012) at National Root Corps Research Institute, Umudike, located at $5^0$29`N and long: $07^0$33`E about 122m or 400ft above sea level in humid rainforest agro ecological zone of Nigeria.
A split –plot design using 3 cassava varieties and 3 planting dates was used and replicated 3 times at eastern farm. The three planting dates used were mid-May representing the early planting, mid-July and mid- September of the two years. Per and post--emergence herbicides were applied using pre-mextra and round up fort at the rate of 1 bottle per hectare respectively immediately after planting followed by 2 other hand weeding. NKP fertilizer 15;15;15 was applied at the rate of 600kg/ha. Fruits were harvested sequentially, sun dried for seeds to shatter, separated and stored in cool place.
Data was collected on survival rate and the number of seeds obtained from each planting period and variety. They were analyzed using SAS version9.2

RESULTS AND DISCUSSION
Table 1 shows the mean survival rate of the planted materials and their seed production.Umucass36 had a higher survival rate (81.11 and 52.77) in both years then the other two varieties and is significantly different

fromUmucass37 and 38 at ($p<0.05$) . Umucass38 significantly out yielded ($p<0.001$) Umucass36 Umucass37 in both years (461.7 and762.4) in the number of seeds produced, although the differences between Umuass36 and Umuass38 is not significant. Umucass36 maintained higher seed weight than the other two varieties (0.070and1.80). Although there was no significant difference (Umuass36 and Umuass38). But both were significantly difference from Umucass37.Time of planting significantly influenced all the parameters considered. The cassava batch planted early had higher survival rate (89.89), gave greater seed number (785.4) and maintained heaver seed weight (0.11) than others (table 2). This result is in agreement with Olasanmi *et al*., (2014) and Byrne et al (1982)

CONCLUSION

In conclusion, to obtain the potential yield of cassava both in tuber and seed production, time of planting cannot be over emphasized.

ABSTRACT
Root-knot nematode, Meloidogyne incognita, is a primary nematode pest of cacao and contributes to retardation of seedling growth, sudden death, plant damage, and concomitant yield losses. Unfortunately, there is no nematicide currently approved for use on this pathogenic nematode. In this study, a series of laboratory bioassays was designed to test the inhibitory and suppressive effects of sterile water extracts of poultry litter compost (PLC) on M. incognita. In microwell assays, M. incognita egg hatch and J2 activity were inhibited by all tested compost extract concentrations (25%, 50%, 75% and 100% extract), with > 90% inhibition in 100% compost extract after 3 and 7 day incubation periods. The study shows the high potential of naturally occurring chemicals present in PLC that should be further investigated as bio-nematicides for their use in sustainable integrated management of RKN.
Keywords: *Theobroma cacao*, *Meloidogyne*, poultry litter compost extract, root-knot nematode

INTRODUCTION
Root-knot nematodes (*Meloidogyne* spp.; RKN) are economically the most important nematodes that attack cacao (*Theobroma cacao* L.) plants worldwide thereby contributing to retardation of seedling growth, plant damage, sudden death, and concomitant yield losses (Campos and Villain, 2005; Orisajo, 2009). Recommended practices for suppressing nematodes on cacao include planting of clean seedlings, avoiding areas where nematodes infest the soil (including under banana), use of nematicides, and development of resistant cultivars (Orisajo, 2009). However, resistant cultivars are not widely available in all cacao-growing areas, and available chemical nematicides have been banned on cacao, so alternative management strategies are needed (Orisajo, 2009, Orisajo and Afolami, 2009). Studies with poultry litter or poultry litter compost demonstrated that these amendments were beneficial for suppressing populations of *M. incognita on cacao*, *Hoplolaimus columbus*, and/or *Pratylenchus penetrans* on vegetable crops and cotton, and of *Meloidogyne mayaguensis* on guava (Orisajo and Afolami, 2009; Everts *et al.*, 2006; Gomes *et al*., 2010). This study aimed to determine whether poultry litter compost produces substances inhibitory to *M. incognita* egg hatch and J2 activity.

MATERIALS AND METHODS
Nematode cultures
Inoculum of *M. incognita* Race 1, originally isolated in MD, was prepared as in Meyer *et al*. (2008). The nematode was grown on pepper (*Capsicum annuum*) 'PA-136' in greenhouse pots containing loamy sand, and eggs for greenhouse and microwell assay experiments were obtained from the roots of 3-month-old plants. Roots were rinsed, immersed in 0.6% sodium hypochlorite for 1 min to release eggs from egg masses, and the eggs were collected by sugar centrifugation and rinsed in water. Eggs were stored overnight at 4° C for use the following day. For the Baermann funnel test, eggs were collected from a 4-month-old plant, placed into a hatching chamber overnight, and the J2 collected and used as inoculum. Eggs for susceptibility test and microwell assays were collected from 3-month-old greenhouse-grown pepper plants (as above) 'PA136' grown in the lab in 250 ml plastic beakers filled with sand. The egg masses were shaken by hand for 3 min in 0.6% sodium hypochlorite. Eggs were then collected and placed into a hatching chamber to collect surface- sterilized J2. The hatching chamber was kept in the incubator for 1-3 days at 4 °C.

Cocoa Susceptibility Test
Cocoa seeds (from Pound 7 cocoa variety) for susceptibility test were obtained from Costa Rica. We could not obtained cocoa seeds from Nigeria based on stringent quarantine regulations. Mucilage and seed coats were removed by the aid of scalpel, surface sterilized in 5% Sodium hypochlorite, rinsed in water and the seeds placed in sterile agar medium. Following the rooting of the cocoa seeds, the roots were cut, transferred to another agar medium and thereafter inoculated with root-knot nematodes (*M. incognita*) eggs two weeks later.

Poultry litter compost

Mature compost was produced in a 3.8-cu m static aerated pile from 3-wk old poultry litter collected from a chicken house after the chickens were removed. The compost pile self-heated to temperatures > 55ºC in the central core of the pile for 4 weeks, and thereafter the temperature declined gradually; at 9 weeks the pile was turned so that the exterior material was placed in the core and the core material was placed on the exterior. The pile reheated to > 50-55ºC for one week, and then gradually cooled to ambient temperature by 13 weeks. The pile was allowed to cure for an addition 3 weeks before the compost was air-dried and stored in covered containers. Composite samples were obtained and analyzed according to standard methods. In preparation for the experiments, the compost was soaked in water (1:1 compost:water, by volume) for 2-3 minutes and clumps were broken up. The compost was placed onto nested U.S. Standard sieves (0.85 mm pore diameter over 0.106 mm pore diameter), broken further with the bottom of a beaker, collected from the sieves, and then washed and collected twice more and air-dried.

Microwell assays

To prepare compost extract, 100 g compost was steeped for 10 min in 100 ml tap water with continual mixing to ensure that the compost pieces were broken up. The mixture was placed onto two layers of cheesecloth, squeezed through to collect the liquid, and the liquid was then centrifuged for 3 min (447 × *g*). The supernatant was collected and centrifuged twice for 5 min (1,188 × *g*). The resulting supernatant was diluted (1:4 in water) and then filtered twice through 0.2 µm sterile filters (Whatman, Clifton, NJ). This was considered the 100% compost extract treatment. Microwell assays were set up in 96-well polystyrene plates, similar to methods described by Meyer *et al*. (2008b). Eggs and previously hatched J2 were assayed in separate wells. Each well received 315 µl of compost extract or of sterile distilled water control, and 35 µl of an *M. incognita* egg suspension (containing ca. 50 eggs) or 35 µl of a hatched J2 suspension (containing ca. 30 J2). Treatments were 0%, 25%, 50%, 75% and 100% compost extract in sterile distilled water (volume/volume). A plastic adhesive sheet (SealPlate®; EXCEL Scientific, Inc., CA) was placed over each plate to prevent evaporation and the plates were incubated at 26ºC. Five wells were used per treatment in each trial, and each experiment was conducted twice. The total was therefore n = 10 for microwell assays. For egg assays, total numbers of hatched J2 and of active vs. inactive J2 were counted 3 and 7 days after immersion of the eggs in the treatments. For assays of previously hatched J2, counts of active vs. inactive were made 48 hours after immersion of the J2 in the treatments.

Baermann funnel tests

Enriched loamy sand soil (16:9 sand : compost that had been steamed and air-dried; composition 82.9% sand, 5.3% silt, 11.8% clay; pH 7.3; 0.8% organic matter) and poultry litter compost (described above) were placed into Baermann funnels, with a total of 50 g per funnel. Six treatments were tested: 0%, 25%, 50%, 75% and 100% compost to soil (by weight), and an additional treatment of 25 g compost layered over 25 g soil. There were five funnels per treatment and the experiment was not repeated. Each funnel received ca. 1,500 J2, and J2 were collected from the funnels three days later.

Statistical Analysis

Data analyzed for the egg assays in microwell plates were total eggs hatched (based on J2 counts), and percent active J2 on Day 3 and Day 7 after egg immersion. For the assays of previously hatched J2, analysis was conducted on percent active J2 at 48 h. The replicate observed number of eggs or percent active J2 were regressed onto percent poultry litter compost extract using SAS PROC GLIMMIX to fit generalized linear regression models or PROC NLMIXED to fit generalized non-linear regression models. Total eggs hatched, for both 3 and 7 days after immersion, was modeled using a negative binomial distribution and regressed onto a sigmoidal, non-linear function of percent poultry litter compost extract. Percent active J2 from hatched eggs, for both 3 and 7 days after immersion, and percent active J2 of observed J2, were modeled using a binomial distribution with Laplace optimization and regressed onto a logit (link) function of percent poultry litter compost extract.

RESULTS AND DISCUSSION

The compost used in the experiments had the following composition: pH 8.0, soluble salts 30.7 mmhos/cm, solids 69.8%, moisture 30.2%, organic matter 37.6% (53.9% of dry weight), total nitrogen 3.18% (4.6%), organic nitrogen 3.07% (4.4%), ammonium nitrogen 0.1068% (0.1530%), carbon 18.6% (26.7%), C:N ratio 5.9, phosphorus (as P_2O_5) 4.75% (6.8%) and potassium (as K_2O) 4.35% (6.23%).

Cocoa Susceptibility Test

Root-knot nematode galls (abnormal swollen of roots) were formed on the cocoa roots two weeks after inoculation and later burst open with nematode juveniles seen in the roots under the microscope (Plate 1). This experiment revealed that Pound 7 cocoa was susceptible to root-knot nematode infection.

Microwell assays and Baermann funnel tests

The pH values of the compost extracts and water control ranged from 7.18 to 7.66. In the microwell assays at Days 3 and 7, egg hatch and J2 activity were suppressed by poultry litter compost extract, as indicated by the regression models (Figs. 1, 2). At Day 3, egg hatch was greatest in the 0% extract (water control), with a recorded mean egg hatch of 41.0. Egg hatch at Day 3 decreased significantly with increasing extract concentration (Fig. 1). After three days of immersion in the treatments, egg hatch was suppressed by 19.2% in the 25% compost extract and 52.7% in the 50% compost extract, compared to water controls. Hatch was lowest in the 75% and 100% compost extracts at Day 3; mean recorded egg hatch was 5.0 and 3.7, respectively. In the 100% compost extract, this was a decrease in egg hatch of more than 90% compared to water controls. By Day 7, more eggs had hatched in 0% extract (water controls) than in water controls on Day 3 (Fig. 1). The mean recorded egg hatch on Day 7 was 74.3 in the water controls. It should be noted that although equal amounts of egg suspension were pipetted into each well, 50 eggs per well was an estimate based on number of eggs per ml rather than an exact count. The total number of eggs per well was subsequently greater than 50. Although egg hatch at Day 7 decreased significantly with increasing extract concentration, the regression models indicated that total egg hatch numbers at Days 3 and 7 were statistically different from each other when eggs were immersed in 0% to 40% compost extract (Fig. 1). However, egg hatch numbers were similar between Days 3 and 7 when eggs were immersed in compost extract concentrations of 45% to 100%. At Day 7, mean recorded egg hatch in the 75% and 100% compost extracts was 6.9 and 5.0, respectively. Therefore, at Day 7, egg hatch was decreased by > 90% compared in the 75% and 100% compost extracts compared to water controls.

The percent of J2 that hatched from the treated eggs and remained active also decreased with increasing compost extract concentrations for Days 3 and 7 (Fig. 2). At Day 3, mean recorded values for active J2 in the 0% and 50% compost extracts were 96.1% and 91.2%, respectively. Also at Day 3, J2 activity was lower in 75% compost (29.6% of hatched J2 were active), and in 100% compost extract only 2.2% of hatched J2 were active. J2 activity was therefore decreased by 69.2% in the 75% compost extract and by 97.7% in 100% compost extract compared with the water controls at Day 3. At Day 7, the percentage of active J2 was generally lower than at Day 3. The regression models indicated that percent active J2 was statistically different between Days 3 and 7 in 0% to 85% compost extract, but statistically similar between Days 3 and 7 at 90% to 100% compost extract. For example, at Day 7, only 57.0% and 32.2% of J2 were recorded as active in 0% and 50% compost extract, respectively. However, at Day 7, 2.0% of the J2 were active in the 75% compost extract, and 4.4% of J2 were active in the 100% compost extracts. These were decreases in J2 activity of 96.5% and 92.3%, respectively, compared with water controls. The effects were not attributable to pH, as the pH of the extracts was normal. The deleterious results are similar to those from a previous study with extracts from poultry manure compost, which demonstrated that an exposure time of just 3 minutes increased the sensitivity of *M. incognita* and *H. schachtii* eggs to infection by *Verticillium chlamydosporium* (Pandey and Sikora, 2000). The authors concluded that secondary metabolites in the extract might act by affecting the egg shell or egg membrane. In the Baermann funnel tests, a mean of 556 J2 was recovered from each of the control funnels that contained only soil. No J2 were recovered from any other treatment. This study shows the high potential of naturally occurring chemicals present in PLC that should be further investigated as bio-nematicides for their use in sustainable integrated management of RKN.

ABSTRACT
The experiment was conducted at the Western experimental farm of National Root Crops Research Institute Umudike during the rainy season of 2015 with the objectives to generate 10,000 to 50,000 viable botanical seeds for the development of variability in yam plants . The parent stocks for the trial were 9 white fleshed varieties of female yam plants namely; Heabalo, Myango, Ame, Amola, Aloshi, Obiaoturugo, Adaka, Faketsa, Hembakwasi, Akuru and one yellow fleshed male yam plant variety Okpani. The varieties were randomly laid out in 3 replicated blocks. Each plot was 4 x 5m^2 with Inter and intra row spacing of 1m by 1m respectively giving a population density of 10,000 plants per hectare. Twenty plants per plot. The parent stocks were staked to enhance flowering and ease for pollination. The plots were kept weed-free by hand weeding throughout the lifespan of the crops. No application of fertilizer to prevent the plants growing too luxuriantly which may delay flowering. The crops were allowed to inter mate by natural pollination. Through this means insects such as Thrips were allowed to do the pollination. The following parameters were assessed namely: number of pistillate flowers, number of capsules per spike, number of seeds per capsule per spike, number of good seeds collected, number of undeveloped seeds, total number of seeds collected, percentage of good seeds per parent, weight of 100seeds collected per family. The result indicated that the objective of generating 10.000 to 50,000 botanical seeds was not realized as a result of number of factors which may include abiotic factors such as inadequate rain/irrigation during the fruiting period, biotic factor such as inability of the insects (Larothrips) to do its job of natural pollination and inherent genetic incompatibility among the varieties. Yam parents with number of good seeds higher than the grand mean will be selected for inclusion in the germplasm for hybrid seeds production.
Keywords: botanical seeds, yam plants, germplasm, flower spike

INTRODUCTION
Food crop improvement by conventional plant breeding without resorting to genetically modified organism technology is the goal in National Root Crops Research Institute, Umudike -Umuahia Abia State- Nigeria. The initial stage before embarking on yam plant genetic recombination is to ask farmers what they want in a variety by using a scientifically structured survey process. After analysing the farmers' responses, the key traits they want in their crops such as taste, colour, shape etc are then identified and yam parents carefully chosen are genetically recombined. Genetic recombination is one of the ways to create novelty in yam genotypes (Martin, 1982) and (Howarth et al., 2013). This could be done through open pollination or through controlled pollination {Akoroda, 1985).. In order to foster this work, 9 parents were constituted in the hybridization block and allowed to inter-mate with the objectives to generate 10,000 to 50,000 viable botanical seeds for the development of variability in yam plants.

MATERIALS AND METHODS
The experiment was conducted at the Western experimental farm of National Root Crops Research Institute Umudike during the rainy season of 2015. The parent stocks for this trial were 9 white fleshed varieties of female yam plants namely; Heabalo, Myango, Ame, Amola, Aloshi, Obiaoturugo, Adaka, Faketsa, Hembakwasi, Akuru and one yellow fleshed male yam plant variety Okpani. The varieties were randomly laid out in 3 replicated blocks. Each plot was 4 x 5m^2 with Inter and intra row spacing of 1m by 1m respectively giving a population density of 10,000 plants per hectare. Twenty plants per plot. The parent stocks were staked to enhance flowering and ease for pollination. The plots were kept weed-free by hand weeding throughout the lifespan of the crops. No application of fertilizer to prevent the plants growing too luxuriantly which may delay flowering. The crops were allowed to inter mate by natural pollination. Through this means insects such as *Thrips* were allowed to do the pollination. *Larothrips dentipes* is the major agent of pollination in a natural hybridization. The following parameters were assessed namely: number of pistillate flowers, number of capsules per spike, number of seeds per capsule per spike, number of good seeds collected, number of undeveloped seeds, total number of seeds collected, percentage of good seeds per parent, weight of 100seeds collected per family.

RESULTS AND DISCUSSION:
Number of female spikes: Significant variability exist in the number of female flower spikes produced by the yam parent stock. Out of a total of 1037 female flower spikes harvested, Obiaoturugo yielded 341 female flower

spikes, followed by Hembakwasi which yielded 174 female spikes while the least was 32 female spikes by Heabalo. However, Hembakwasi with 174 female spikes, Obiaoturugo with 341 and Feketsa with 163 female spikes yielded high number of female flower spikes above the grand mean of 115.2, and these 3 parents could be selected as parents for inclusion in the hybridization block for botanical seed generation either by controlled crosses or by polycross technique.

Number of capsules: The number of harvested capsules are presented in Table 1.The rsult identified high significant ($P<0.01$) variation in the number of capsules produced by the various yam plants. The number of capsules varied from 180 capsules (heabalo) to as high as 803 capsules (Akuru) with grand mean of 340.6 capsules. However, Akuru and Obiaoturugo produced more number of capsules (with 803 and 548 capsules respectively) more than the rest of the parents plants. For high capsule production, these parents should be selected for inclusion in the hybridization blocks.

Number of seeds per family: The high significant ($P<0.01$) variability that existed in the number of seeds per family indicated that out of 13292 seeds harvested from various families, Hembakwasi produced the highest number of seeds numbering 3060 seeds followed by Obiaoturugo with 2428 seeds while the least number of seeds was from Aloshi with 426 seeds. However, Hembakwasi and Obiaoturugo produced more seeds above the grand mean of 1476.9 seeds which represented 23.0% and 18.3% respectively of seeds collected from the parent stock. The least number of seeds harvested was 426.0 from Aloshi which represented 7.8% which was far below the grand mean. Number of seeds per capsule is very important in botanical seed generation. Parent stocks with number of seeds less than the grand mean should not be included in the hybridization block.

Number of quality good seeds: There was high significant ($P<0.01$) variation in the number of good seeds harvested. Number of good seeds harvested varied from 68 seeds for Aloshi representing 16.0% to 1600 seeds represented by 66.0% collected from Obiaoturugo. The grand mean of good quality seeds collected was 463.1. Parents with number of good seeds above the grand mean should be selected for inclusion into the germplasm for yam improvement. Low seed producing parents should only be included if they have special traits that the breeder is interested on for the improvement of the progenies (Table 1).

Seed set: The highest number of seed set was 3060 obtained from the family of Hembakwasi representing 23.0% of the total number of seeds collected. This was followed by Obiaoturugo with seed set of 2428 seeds representing 18.3% of total seeds collected. The least seed set was 426 seeds obtained from Aloshi representing 4.1% of the total seeds collected. Generally, total number of seeds collected was 13292 from 3065 capsules which were in a cluster of 137 flower spikes. Number of good seeds was 4168 representing 31.4% while 9124 were bad seeds representing 68.6%. The seeds were bad as a result of non -fill/under-development. Most of the capsules developed when the yam crop had completed its life circle and as such do not have the time to fully fill the seeds. Some capsules that were produced do not have enough soil moisture to complete its maturation. Therefore time of planting and irrigation facilities are necessary for botanical yam production. Another factor that may be attributed to low yield of good seeds may be biotic factors. The insects *Larothrips dentipes* that pollinate yam plants might not had do their job of pollination as a result of being few in number hence the high percent of undeveloped seeds and incompatibility among the varieties. According to Akoroda (1985), Thrips are relatively inefficient in achieving natural hybridization.

Seed weight: Hundred seeds were taken from each family and weighed, Hembakwasi and Obiaoturugo had the highest seed weights of 1.095 and 1.046 g respectively. This was followed by Amola with seed weight of 0.0990g while the least seed weight was obtained from Ame with 0.001g. Seed weight is a measure of high percentage of germinability and survivability of the crop into seedlings.

CONCLUSION

The objective of generating 10.000 to 50,000 botanical seeds was not realized as a result of number of factors which may include abiotic factors such as inadequate rain/irrigation during the fruiting period, biotic factor such as inability of the insects (*Larothrips*) to do its job of natural pollination and inherent genetic incompatibility among the varieties. These may have accounted for the low percentage in the number of good seeds collected. Yam parents with number of seeds higher than the grand mean will be selected for inclusion in the germplasm for hybrid seeds

production. However, in the next stage of evaluation, the 4168 good Seeds representing 31.4% of total seeds harvested will be evaluated, screened, and identified as genotypes to broaden the genetic base of the yam crop.

ABSTRACT
An experiment was carried out to evaluate a newly introduced pre-emergence herbicide in the management of weeds in potato production during 2011 cropping season. The herbicide was Pendilin with Pendimethalin 500gm/l. EC as active ingredient a pre - emergent herbicide formulated for the control of broad leaved weeds and grasses with a recommended application rates of 2.5-4.0 L./ha. The experiment was carried out at Potato Research Programme experimental field Kuru (09^0 44^1N $08^0$44E and altitude 1351m) during 2011 cropping season. Experimental design was Randomized Complete Block Design replicated three times. Potato variety used as test crop was Nicola a popular variety with the farmers. Result of the effect of the pre emergence herbicides on plant vigour, weed density, weed biomass and yield of potato was significant ($p<0.05$). Pendalin at the rate of 4 liter/ha and atrazine at the rate of 4 liters/ha gave weed densities of 2.11 and 2.67/0.25m^2 compared to the control with a density of 7.00/0.25m^2. Both fresh and dry weed biomass was significantly higher in the control (2.33 and 0.271kg/plot respectively). For the rates, result showed that application of the herbicides at high concentration significantly ($p<0.05$) suppressed the weeds than lower rates and the control irrespective of the herbicides. It is recommended that in addition to pre emergence herbicides, post emergence herbicides be use followed by at least one manual weeding for effective weed management in potato as from the 4-6 weeks after planting. Pendilin is therefore strongly recommended as a pre emergent herbicide to be use in potato production.
Keywords: Herbicide formulation, management, weeds, potato

INTRODUCTION
It has been established severally that weeds are a major problem in crop production generally. Weeds compete with the crops for space, light, moisture and soil nutrients. Weeds can also serve as alternative host for pests and diseases (Agpad, 1987). Weeds are also known to lower human efficiency and cause drudgery (Melifonwu, 1999). Akobundu, (1987) reported that weeds are the most underestimated pests in tropical agriculture that are often been associated with the drudgery that characterized peasant agriculture. Akobundu (1987) stated that weed results in 65% reduction in the yield of root and tuber crops and takes 25% of the total labour use in the production. Nwokocha (1987) had shown that yield reduction of about 50% is possible in potato production as a result of weeds infestation. All these calls for concerted effort at weed control in crop production.
Weeds can be managed either culturally, mechanically, biologically, chemically and through an integrated approach. There are two major ways is which weeds are controlled in Nigeria today, these are manual and chemical. The use of cover crops to suppress weed had also been shown to be effective (Chikoye *et al*., 2001) Manual weeding is capital intensive, time consuming and full of drudgery which had made it unattractive.
New improved agricultural inputs are getting into the market on a daily basis. Herbicides are essential in the management of weeds in potato production. Several herbicides and their rates had been screened and found effective in the control of weeds in potato and other crops production.
There are approximately 140 herbicides active ingredients (Vencill, 2002; Mallory-Smith and Retzinger, 2003). Most of these basic forms of herbicides are further refined and formulated, creating several hundred commercial products. It is natural to evaluate them viz a viz the existing ones in the management of weeds in potato production. The objectives of the study were; to evaluate the new herbicide formulation in the management of weeds in potato and to compare its efficacy viz a viz the existing ones being used in the management of weeds in potato. Lastly to determined the best rate for optimum weed control.

MATERIALS AND METHODS
An experiment was carried out to evaluate a newly introduced pre-emergence herbicide by an agrochemical company (African Agro) based in Kano state in the management of weeds in potato production. The herbicide brought was Pendilin with Pendimethalin 500gm/l. EC as active ingredient a pre - emergent herbicide formulated for the control of broad leaved weeds and grasses with a recommended application rates of 2.5-4.0 L./ha. The experiment was carried out at Potato Research Programme experimental field Kuru (09^0 44^1N $08^0$44E and altitude 1351m) during 2011 cropping season. Experimental design was Randomized Complete Block Design replicated three times. Potato variety used as test crop was Nicola a popular variety with the farmers. Potato was planted at a spacing of 30cm inter and 100cm intra row given a gross plot size of 24m^2. Fertilizer NPK was applied at

planting at the rate of 100kg/ha each of N, P_2O_5 and 40kg/ha K_2O as band application. Atrazine (ai =Atrazine 500SC) a pre-emergent herbicide with a recommended application rates of 2.5 – 4L. /ha was used as a check herbicide. The herbicides were applied after planting (0WAP) using a CP3 knapsack sprayer at the following rates; Pendilin applied at 4, 3.25 and 2.5 liter/ha, Atrazine applied at 4, 3.2 and 2.4 liters/ha and absolute control (No herbicide application). Weed biomass was taken using a quadrat of 0.5x0.5m (0.25m^2) at 6 weeks after planting (WAP). Thereafter the potatoes were weeded manually. Harvesting was done at 12WAP. Data collected were; plant establishment at four weeks after planting (4WAP), a score of weed density and plant vigour, fresh and dry weed biomass at 6WAP, final stand count and tuber yield at 12WAP. Data collected were subjected to analysis of variance and means separated by LSD at 5% level of probability,

RESULTS AND DISCUSSION

Results of the effect of the pre emergence herbicides on establishment count, weed density, plant vigour, weed biomass and yield of potato are presented in Table 1. The result revealed a significant ($p<0.05$) effect in all the parameters measured with exception to plant establishment. Higher rates of the herbicides led to vigorous growing plants as the result shows. Pendilin applied at the rate of 4 liters/ ha and atrazine (check) at 4 liters/ha gave the most vigorous growing plants compared to the absolute control. The effect of herbicides on weed density and biomass shows that they suppressed the weeds. Higher rates irrespective of the herbicides gave significantly low weed densities than the control. Pendalin at the rate of 4 liter/ha and atrazine at the rate of 4 liters/ha gave weed densities of 2.11 and 2.67/0.25m^2 compared to the control with a density of 7.00/0.25m$^{2.}$ Both fresh and dry weed biomass was significantly higher in the control (2.33 and 0.271kg/plot respectively)

Effect of pre – emergence herbicides and rates on fresh and dry biomass of weeds (kg) /0.25m^2 are presented in table 2. Result shows significant ($p<0.05$) effect in the herbicides and rates on fresh and dry weed biomass. Interaction between herbicides and rates was not significant ($p<0.05$). There was no significant difference in the fresh and dry weed biomass between the new herbicide pendalin (1.71kg and 0,155kg/0.25m^2) and the check herbicide atrazine (1.81 and 0.113/0.25m^2) in terms of weeds management though pendalin was numerically better. For the rates, result showed that application of the herbicides at high concentration significantly ($p<0.05$) suppressed the weeds than lower rates and the control irrespective of the herbicides

Herbicides had been known to control weeds if applied effectively without phytotoxic effect on the crops. The low weed densities and biomass mass can be attributed to the herbicides applied as the result shows. As the rate increases, the densities and biomass reduces. This has further been ascertained with higher weed density and biomass recorded in the control. Balthazar and Barium (1986) and Olofintoye (1997) reported that pendimethalin (pendilin) a pre emergent herbicide as for grass – weed control. Yield and yield attribute of the potatoes were also significantly affected. Result shows that there is a positive relationship between herbicides application and yield performance as seen on final stand count, tuber number and weight. Weeds have been known to interfere with normal crop growth and yield leading to low yield. This fact is corroborated by the findings of Akobundu, (1987) who stated that weeds are the most underestimated pests in tropical agriculture and can results in 65% reduction in the yield of root and tuber crops. Nwokocha (1987) had shown that yield reduction of about 50% is possible in potato production as a result of weeds infestation. This shows that weed management translate to high yield.

CONCLUSION

It has being established that weeds adversely affect potato production resulting in low yields. Result of the study revealed that the herbicide Pendilin applied at 4 liters/ha did suppressed weeds infestation in the first six weeks of potato production though not significantly different from the check herbicide (atrazine) applied at 4liters/ha. It is therefore deduced from the finding of this work that pendilin is a credible alternative to atrazine or any other pre emergence herbicide in potato production. For the desire result recommended rates of the herbicide be use for effective management of weeds in potato. It was observed that the potency of the herbicides is shot lived for the period of crop growth.

It is recommended that in addition to pre emergence herbicides, post emergence herbicides be use followed by at least one manual weeding for effective weed management in potato as from the 4-6 weeks after planting. Pendilin is therefore strongly recommended as a pre emergent herbicide to be use in potato production.

ABSTRACT
Potted experiment in screen house was conducted in the dry season of 2014/2015 in IITA Kano Station (11^{0}59'N, 8^0 35'E and Alt. 486.6m) to study the response of some cowpea genotypes to cowpea mottle virus disease on some growth attributes. Twelve cowpea varieties obtained from IITA Kano Station were sown in pots in three replications. Source of virus inoculums was a cowpea plant that had the disease symptom. During the study, the following parameters were observed on weekly basis from 4 weeks after sowing (4WAS): Plant height, number of leaves and Chlorophyll content of leaves, Virus disease severity, number of branches, leaf area and percent dry matter were captured at point of termination of the experiment. Results of the study showed 10 of the 12 cowpea varieties expressed varying degree of cowpea mottle virus symptoms. Remaining two varieties had no disease symptoms. Means of plant height, number of leaves and leaf chlorophyll content were significantly different (P< 0.05) across weeks and among varieties. Their correlation matrices with virus severity indicate negative association.
Keywords: cowpea genotypes, mottled virus, vegetative growth,

INTRODUCTION
Cowpea is an important annual food legume of the Tropics Africa with diverse uses. The young leaves, immature pods and peas are used as vegetables while several snacks and main meal dishes are prepared from the dry grain. The dry haulms and fodder are fed to ruminant livestock in the dry season when feeds are scarce. In addition, the grain is widely traded out of the production areas where it provides cheap and nutritious food for relatively poor urban communities. Cowpea also fixes atmospheric nitrogen through symbiosis with nodule bacterial (*Brayrhizoium* spp.) thus replenishing depleted soil nitrogen and improving soil structure.
Cowpea is well adapted to relatively hot dry environment of the Semi-arid Tropics. For that reason, the crop is considered as highly drought tolerant. In association with cereals and other grain legumes, cowpea contributes to the sustainability of cropping systems in marginal lands of the semiarid areas through fixation of nitrogen, ground cover and soil improvement from plant residues. These features particularly make cowpea an attractive crop for the subsistence farmers of Sub-Saharan Africa, where about 70% of the world's cowpea is grown but where the farmers still faces numerous problem in growing and harvesting the crop. Currently, the world's leading producing countries are Nigeria, Brazil and Niger. According to IITA (1999), Nigeria produces 0.9 MMT annually on a 4.0 million hectares most of which is in Kano, Sokoto and Borno States. Other producing countries in Africa are Beni, Botsuana, Bokinafatso, Cameroon, Kenya, Malawi, Mali and Togo (Singh and Emdem, 1979) Cowpea yields are known to be low in most parts of the tropics because of the numerous constraints associated with its production. Notabe among the production constrains is the insidious effect of viral diseases (Thottappilly and Rossel, 1985). According to Hampton et al. (1997), Cowpea crops are susceptible to more than 20 viral diseases.
The most important factors that constrain cowpea production in the West African sub-region are group of viruses that are mainly transmitted either through the seed or insect vectors. Seed borne cowpea viruses are spread within the field either by aphids or some species of beetle. The most effective control of cowpea viral diseases universally has been the development of improved genotypes with resistance to viral infection. Historically productiveness of cowpea breeder-geneticists describing almost every major virus provides opportunities to develop multiple resistance to diseases, insect pest parasitic weeds (Striga and Aledctra) and drought. Far reaching developments have occurred in plant virology since research started in IITA. Viral gene transfers are now viewed with increased understanding and maturity. General knowledge pertaining *Vigna unguiculata* genetics and germplasm has also expanded. The implementation of these resources has resulted in new improved cowpea cultivars with multiple resistance (Ndiaye et. Al., 1993; Singh et al . 1987; Kim et al. 1986; and Fery and Dukes 1995). Despite this advancement, conventional resistance breeding remains the most practicable measure for controlling cowpea diseases and hence the reason for this research.
The aim of this work is to study the response of some cowpea varieties to cowpea virus in Kano. The objective of this study is to investigate the response of 12 different cowpea varieties to virus inoculation and to assess the effect of virus severities at vegetative growth phase of the cowpea varieties.

MATERIALS AND METHOD

The experiment was conducted in IITA Kano Station screen house (Lat. 11^0 $_{59'N,\ l0ng.\ 8}$ ^{0}35'E and Alt. 486.6m (1595F) in the Sudan savannah agro-ecological of Nigeria. Treatment consisted of twelve cowpea lines that were collected from the International Institute of Tropical Agriculture (IITA) Kano Station, Nigeria. They are Danila, IT 90K-277-2, IT07K-292-10, IT07K-299-6, IT07KD-299-6, IT07K-318-33, IT89KD-391, IT98K-494-4, IT99K-216-24-2, IT99K-573-1-1, IT99K-7-22-2-2, IT98K-499-35

The experiment was laid in a Complete Randomized Design (CRD) and replicated three times. Other materials used for the experiment include river sand, top soil, farm yard manure, pestle plastic pots, mortar and pestle, distil water, filter paper, cotton wool, Leaf area machine, SPAD meter, Meter Balance, and drying oven, 250 ml glass beaker, glass funnel, and 1000 ml measuring cylinder. The necessary agronomic practices such as pot filling, sowing and thinning were observed before mechanicl inoculation of the virus. More so, insect control was done by spraying against Aphids cracivora using Mamdo (Imidodazole) at the rate of 2.0ml in 10.0 liters of water.

Plant measurement, counting of leaflets and measurement of leaf chlorophyll content, virus rating cum dry matter content were also observed. All data captured were subjected to statistical analysis using Statistical Analysis Software (SAS 9.3). Means were separated using Duncan multiple range test (DMRT).

RESULTS AND DISCUSSION

Effect of virus severity on plant height

The result of this investigation indicates that 10 out 12 cowpea varieties tested showed virus disease symptom that was identified as cowpea mottle virus. This could be interpreted as varieties that are lacking in genes that offer protection to virus disease. The two varieties (IT97K-499-35 and IT07K-299-6) that had no virus symptom even at 10 WAS imply resistance virus disease. This finding was similar to the report of Sunusi (2010) when he found no disease symptom on IT97K-499-35.

The decrease in the association between virus severity and plant height was as result of the insidious effect of the virus on the plants by inducing severe stunting in infected plants through shortening of internodes and apical necrosis. This fact is substantiated by the report of Pio-Ribeiro *et al.* (1978) that indicate CABMV and Cu cumber mosaic cucumovirus interacted synergistically to produce stunting in cowpea: a disease characterized by severe yields loss. Also, Niblett and Claflin (1978) and Uyemoto *et al*. (1981) demonstrated that maize dwarf mosaic virus (MCMV) induced necrosis disease that resulted in up to 91% yield loss and death of many plants especially when infection occurred early.

Effect of virus severity on number of leaves

The result of this study indicated that disease symptom was expressed on older leaves similar to the finding of Joseph, *et al.* (2011) when they observed highest disease severity (61.65%) in the old leaves compared to (22.97%) on flag leaves of o.Hyla. The lack of significant differences in the effect of virus on number of leaves was probably due to the early stages of plant development (vegetative). The slight decrease in the number of leaves of diseased infected plants is in agreement with the report of Kareem and Taiwo (2007) where they that CABMV alone and its combination with SBMV resulted in significant reduction in the number of IT86D-719 leaves.

Effect of virus severity on chlorophyll content of leaves

The chlorophyll content in the test plants ranged was within the range of what was reported by Joseph *et al.* (2007). Mean values of chlorophyll content that increased from 32.1 to 50.7 was probably due to the fact that plants were still in their vegetative phase of growth and the virus activity had not attained full blown disease status in the susceptible plants.

Effect of virus severity on number of branches

Branching in cowpea is a function of genetic and environmental influence. In this study, branching appeared to be controlled by a combination of factors such as change in day-length, low temperature and effect stage of growth of the plants. Since the plants had not started flowering at the time of termination of the experiment, only three of the varieties had developed branches.Plant growth in terms of increase in % DM was significant with low and negative level of association with virus severity. This supports the finding of Kollmann *et al.* (2007) that virus significantly reduced above-ground biomass of plants, stem biomass, and higher relative mass of leaves.

ABSTRACT
Rising rural population densities in Nigeria are profoundly affecting farming systems. Localized land pressures being experienced by many rural farmers required polyculture cropping system which this study is aimed to analyze among yam farmers in Yorro Local Government Area of Taraba State, Nigeria. Primary data used for the study was collected from a sample 142 farmers and were analyzed using descriptive and inferential statistics. Results revealed that respondents are small scale farmers characterized by large family size and are well experienced with a mean farming experience of 23 years. Majority (89%) practiced mixed cropping to avoid crop failure and scarcity of land. Production function analysis revealed that the coefficient of multiple determination (R^2) was 0.8451 and explained about 85% of the variations in the output of respondents. Farm size, labour and seed were statistically significant ($p<0.001$).
Keywords: Polyculture, yam, production function, Yorro, Nigeria

INTRODUCTION
Root and tuber crops are important in food security and income for 2.2 billion people in developing countries and crops comprise crop covering several genera. They are staple food crops, being the source of daily carbohydrate intake for the large populace of the world. Root and tuber crops refer to any growing plant storing edible materials in subterranean root, corm or tuber (Oke, 1990) and yam is a member of this important class of food. Yam is an important food crop especially in the yam zones of West Africa, comprising, Nigeria, Cameroon, Benin, Togo, Ghana and Cote divoire. This zone produces more than 90% of the total world production which is estimated at about 20 – 25 million tonnes per year (Sanusi and Salimonu, 2006). Nigeria is the main producer of yam in the world with 70% of the world output followed by Ghana, Cote d' Ivoire, Benin and Togo (International Institute for Tropical Agriculture, IITA, 2015). The crop yield depends on how and where the setts are planted, sizes of mounds, interplant spacing, provision of stakes for the resultant plants, yam species, and tuber sizes desired at harvest. Small-scale farmers in West and Central Africa often intercrop yams with cereals and vegetables (Dumont and Vernier, 2000).

Yam based crop mixture (YBCM) is one of the two common crop mixture systems practised in farming communities of Nigeria. YBCM composed of yam, maize and melon with yam as based crop. Yam, the based crop of YBCM, is an important food crop in Nigeria (Food and Agriculture Organization, FAO, 1999). The crops in YBCM are arable crops which are food crops planted and harvested at maturity within one production cycle or season. However, crop mixture is a viable strategy for spreading the risks of crop failure and labour demands for critical operations of sowing, weeding and harvesting (Eze *et al*., 2009). Yam-based system is a system in which yam production is the predominant rural activity among several other crops, livestock or off-farm production activities.The practice of intercropping is popular because of its advantages over sole cropping which include yield stability and security and higher profitability due to higher combined returns per unit area of land (Ezulike *et al*, 1993). The practice of inter cropping controls erosion and weeds and allows a more even distribution of farm labour than sole cropping and serves as enterprise combination which is a security against crop failure. The cropping combination is also agriculturally compatible (Ibeawuchi, 2004). In 2010, the world harvested 48.7 million tonnes of yam, 95 percent of which was produced in Africa. The biggest yam harvest, globally was in 2008 when world produced 54 million metric tonnes of yam, with Nigeria producing an annual average of 35.017 metric tonnes (FAO, 2011). Rising rural population densities in Nigeria are profoundly affecting farming systems and indeed the overall trajectory of economic systems in ways that are underappreciated in current discourse. Population pressure is linked in one way or another to the shrinking size of most smallholder farms over time; more continuous cultivation of fields, contributing to land degradation and unsustainable forms of agricultural intensification; the rise of land rental and purchase markets and changes in land allocation institutions, all of which are rapidly altering farm structure; and the challenges that Nigeria is currently experiencing in achieving broad-based and inclusive forms of farm income growth. The extent, distribution and exploitation of land are factors that have long been identified as fundamental influences on agricultural development paths and poverty reduction (Maikasuwa and Ala, 2013). Nigeria is typically characterized as land abundant, with the implication that land endowments pose no serious constraint for agricultural development, but our starting point for studying the impacts of population density is the recognition of Nigeria's spatially heterogeneous distributions of rural populations, giving rise to acute localized land pressures being experienced by many rural farmers. The broad objective of the study is to analyze polyculture cropping system among farming farmers in Yorro Local Government Area of Taraba State, Nigeria.The specific objectives were to describe the socio-economic characteristics of yam farmers; identify the various crops in the yam- based intercropping and examine factors influencing output of crops among respondents in study area.

METHODOLOGY

The Study Area: The study was conducted in Yorro Local Government Area of Taraba State, Nigeria. The local Government Area lies between latitude 8.17˚N and 9.7˚N and longitude 11˚ 66˚E and 11˚ 46˚E of Greenwich meridian. The Local Government lies to the North-eastern part of Taraba state, bordered by Zing Local Government to east, Lau Local Government to the North, Jalingo and Ardo-Kola Local Government to the West and Bali Local Government to the South. The Local government has a land area of 21,200 km^2 with a projected population of 60,894 people. The local government has tropical climate marked by dry and rainy seasons. The rainy season starts in April and ends in October. The wettest months are August and September The mean annual rainfall ranges from 800 mm to 1000 mm and the mean daily temperature ranges between 18.8˚ C and 34.4˚C. The dominant soil types in the local government are ferruginous sandy loamy soil. The main vegetation cover of the Local Government is made up of scattered trees, while the topography is essential marked with mountainous land traversed by small streams between them (Taraba State Agricultural Development Progamme,TADP Diary, 2012).

Source of Data: Primary data was used for the study and was collected using structured questionnaire administered to the respondents to collect the desired information.

Sampling Size/Sampling Technique: The population for this study were yam farmers in Yorro Local Government Area of Taraba State. A sample size of two hundred and fifty (250) Yam farmers was considered from the eight (8) farming villages, where one hundred and fifty (150) farmers were selected using proportionate and random sampling technique .

Method of Data Analysis: Descriptive and inferential statistics were used. The descriptive statistics was used to achieve objectives i, ii, iii and v. Inferential statistics (multiple regression) was used to achieve objective iv of the study.Multiple regression analysis was used to determine the factors influencing output of crops of yam-based farming system among respondents. Four functional forms (Linear, Semi log, Exponential, Double log) were tried where Double log gave thebest fit and is expressed as:

$$Y = \beta 0 + Log\beta 1X1 + Log\beta 2X2 + Log\beta 3X3 + Log\beta 4X4 + Log\beta 5X5 + Log\beta 6X6 + \varepsilon$$

Where Y = Output of the ith farmer in grain equivalent X_1 = Farm size (hectares) X_2 = Labour(Mandays) X_3 = Hired labour(mandays) X_4 = Fertilizer(kilogramme) X_5 = Seed(grain equivalent) X_6 = Herbicides(litres) and ε = error term

RESULTS AND DISCUSSION

Respondents' Socio-economics

Summary statistics of respondents socio-economic variables as contained in Table 2 revealed that the minimum age of 18 years with a maximum of 78. Mean age was 46 years. There were variations in the ages of respondents as revealed by standard deviation. Farmers are relatively older and may portend danger to food production in the study area. The finding is in line with the works of Migap and Audu(2012) and Donye *et al.*(2012) that yam production was carried out by the elderly farmers. Government should entensify efforts in the provision of infrastructure in rural areas to attract young people and encourage food production. Furthermore, yam based farming was small scale as evidenced by mean farm size of 2.7 hectares, respondents have large family sizes with a mean family size of 9 people.

Respondents' Cropping pattern and Reasons for Intercropping

Mixed yam production was predominant in the study area (Table 2). Reasons for intercropping may not be far - fetched; fear of crop failure, scarcity of land, rising population and conversion of arable land for construction. Another reason is that the study area is in a moutainous area imposing the necessity for polycultural farming systems. Furthermore analysis in Table 3 showed that Mixing yam with groundnut, sorhgum, millet and cowpea were major cropping combination.

Table 1: Summary statistics of selected socio-economic variables of Respondents

Variable	Minimum	Maximum	Mean	Standard deviation
Age	18	78	46	13.928
Farm experience	12	47	23	13.771

ABSTRACT
The aim of the work was to organize rural farm women to benefit from agricultural extension activities in Umuahia agricultural zone of Abia State, Nigeria. 120 farm women were sampled. There Mean age was 47 years old. 56.67% of the respondents were married. The result revealed that a high proportion of women farmers in the area (75.84%) had completed one form of formal education or the other. The mean household size of the respondents was 7 persons per household. The results of the Likert analysis of the data collected revealed a wide range of agricultural extension activities which the rural women farmers have participated/benefited from in the past. Such agricultural activities included: introduction of new herbicides and pesticides/uses ($\bar{X}$=3.04), better crop rotation practices and fertilizer application ($\bar{X}$=2.87), types of soil and best soil type for planting ($\bar{X}$=2.80) introduction of new seedlings ($\bar{X}$=3.18), crop disease treatment and control ($\bar{X}$=3.27) new methods of crop preservation ($\bar{X}$=3.01). 57.5% of the respondent found extension activities very effective. The findings further revealed that the major organs used in accessing agricultural information by the rural women farmers' in Umuahia zone are posters, radio and television. The result revealed Lack of rural electrification/constant power interruption in communities that have electricity supply and Lack of money to purchase newsletters, leaflets on agricultural information as the major constraints facing rural farm women in accessing agricultural information. It is therefore recommended that the existing women groups in the village should be organized and strengthened to increase women's access to extension services, credit facilities, agricultural inputs and even marketing services
Keywords: Rural Women, Effective Utilization, Extension,

INTRODUCTION

Rural farmers are meant to know and also adopt agricultural innovations relevant to their situations. It is the duty of institutional and government organs (the Agricultural Extension and Research Liaison Services-AERLS, the extension services of the Agricultural Development Project-ADPs, Ministries of Agriculture at both state and federal levels, Media Forum for Agriculture, Cooperative Extension Centres-CEC of universities etc) to ensure that towns and villages in Nigeria have easy access to agricultural information for enhancement of crop productivity and better animal husbandry practice.

The poverty among rural farm women in agriculture are attributable to the following: no access to innovative information, low productivity, poor agricultural produce prices, hence poor farm income, inadequate infrastructure, limited access to credit and other improved farm inputs and land (Ojowu *et al.*, 2007). This is not surprising as women comprise the majority of the world's poor in both urban and rural sectors and the majority of those working in the informal sector (Spiedoch, 2007). Most of innovations do not reach the rural farm women and this has been attributed to lack of effective agricultural information dissemination machinery (Yahaya, 2002). Rural farm women are engaged in several on- farm, off farm and domestic activities, many of them thus become apathetic to attend farmers' union and cooperative meetings through which they could have access to vital agricultural information.

There is need therefore to organise rural farm women in agriculture to effectively benefit from extension. Extension facilitates the access of farmers, their organizational and other market actors to knowledge, information and technologies; facilitates their interaction with partners in research, education, agric-business and other relevant institutes and assists them to develop their own technical, organizational and managerial skills and practices (Christoplos, 2010). According to Anderson and Feder (2010), agricultural extension intends not only to increase productivity and income, but also to organise the rural farm women for effective utilization of agricultural extension activities.

The study was set out to organise rural farm women to benefit from agricultural extension activities in Umuahia agricultural zone of Abia State. Other objectives were to **;** describe socio-economic characteristics of the rural farm women in the study, find out the proportion of these women in co-operative societies, ascertain extension activities that rural farm women have participated/benefited from in the study area, ascertain organs employed in accessing agricultural extension information, innovation or technologies by rural farm women in the study area, identify constraints encountered by the rural farmer women in accessing agricultural information from the study area.

MATERIALS AND METHODS

The study was carried out in Umuahia agricultural zone of Abia State. A multi- stage random sampling technique was adopted.

Two local government areas (Ikwuano and Umuahia North) were randomly selected from the zones; three communities were selected from each of the local government areas; twenty (20) farm women were randomly selected from each of the communities. This gave a total sample size of 120 respondents. The extension agent(s) covering the study area were purposively sampled to elicit information on extension activities in the area. The study employed primary and secondary sources for data collection. Primary data were collected using a well structured questionnaire. The secondary sources of data included text books, journals, internet, conference proceedings, published and unpublished literatures among others. Data generated for this study were analysed using descriptive statistics such as frequency distribution, percentage, mean, and likert-type scales.

RESULTS AND DISCUSSION

Findings from the study revealed that majority (38.33%) of women farmers were within the age bracket of 40-49 years old. Mean age of the farmers was approximately 47 years old. It is evident from the results that most of the respondents were married (5According o the result, a high proportion of women farmers (75.84%) had completed one form of formal education or the other. The mean household size of the women was 7 persons per household. About 67.5% of the farmers had household size of about 4-9 persons per household. Response on farming experience revealed that 89.17% of women farmers have above 5 years of farming experience. This implies that most of the women have been in farming profession for quite some time and are not novice in farming activities. The results further revealed that most of the respondents are small scale cassava farmers as most of them (44.17%) have farm sizes less than 3 hectares and that most (69.3%) of the women had no access to extension services. Monthly, majority (45.83%) have income level ranging between N20, 000 to N40, 000 while only 9.17% have above N60, 000 income levels. By implication, some of the farmers' financial commitment may not be met. Only 35% belonged to a cooperative society while about 65% do not belong to any cooperative. Analysis of the farming enterprise as practiced by the farmers revealed that all the farmers participate in food crop (100%) production, 31.7% produce tree crops and food crops as well, 52% are into livestock production and food crops production while 30% produces both food crops, tree crops and livestock as well.

The results of the Likert analysis of the data collected from the respondents according to Table 4.12 showed a wide range of agricultural extension activities which these rural women farmers have participated/benefited from in the past. Such agricultural activities include: introduction of new herbicides and pesticides/uses with a mean score of 3.0.4 ($\bar{X}$=3.04), better crop rotation practices and fertilizer application ($\bar{X}$=2.87), types of soil and best soil type for planting ($\bar{X}$=2.80) introduction of new seedlings ($\bar{X}$=3.18), crop disease treatment and control ($\bar{X}$ =3.27) new methods of crop preservation ($\bar{X}$=3.01).

The distribution of respondents according to their perception on the effectiveness of extension activities showed that 57.5% of the respondent found extension activities very effective. This could be as a result of the increase in output of farmers. 31.7% also indicated that extension activities are effective.

The major organs used in accessing agricultural information by the rural women in Umuahia agricultural zone included posters, radio, television, leaflets and through extension workers.

The result also indicated that respondents have no access to agricultural information through the community library (82.5%), Newsletters (80%) and extension agents (72%), while On the other hand, respondents agreed to have access to agricultural information through posters (70%), exhibition (79%), and leaflets (69%). Lack of rural electrification/constant power interruption in communities that have electricity supply and Lack of money to purchase newsletters and leaflets (poverty) were the major constraints facing rural farm women in access agricultural information in the area.

CONCLUSION

Cooperative groups are **o**rganized for the promotion of special interest or meet certain needs that cannot be achieved by the individual's effort. They contribute to the dissemination of new ideas, practices and products as well as in sourcing for loan and farm inputs. The existing women's group in the village should be organized and strengthened to increase women's access to extension services, credit facilities, agricultural inputs and even marketing services.

DIVISION OF LABOUR IN COWPEA PRODUCTION IN KANO STATE: IMPLICATION FOR GENDER PLANNING

H.M. Alimi, B. Barau & D. Umar

Federal College of Agricultural Produce Technology
Kano, Nigeria
halibidecs@yahoo.com

ABSTRACT
The study examines the role play by both female and male gender in the production of cowpea in the state. Three local governments were randomly selected from each geological zone of the state. Data were collected from 119 respondents through structured questionnaire and the analysis was done using frequency and percentage. The analyzed results show that majority of the respondents are in their active years (73%), almost 81% are literate while majority of them acquired farmland through common ownership and Inheritance (47%). The study showed that the females are actively involved in direct field production activities such as planting, harvesting, threshing, while post harvest handling such as storage and processing are majorly a female gender role. In order to improve their economic condition effort should be made by all stake holders in the field of agriculture to provide necessary assistance towards facilitating the roles generally played by the female producers.
Keywords: Female Cowpea Farmers, Gender role, Post-harvest handling, Economic improvement

INTRODUCTION
Gender as a concept is used in social sciences to define the roles and activities of men and women. These roles are socially defined by the traditions and a belief of a particular culture.Gender is therefore not synonymous with sexual differences which are based only on biological characteristics. Gender analysis is a tool for understanding and learning more about the activities of male and female in the society, the opportunities and problems they face in performing their activities. The subject of gender, according to Olawoye (2001) concentrates attention on the obligations, privileges and duties assigned to men and women in society and the relationships between them. In the African society, there are tasks meant for men and those meant for women. Gender division of labour is best understood in learning about socio-cultural differences. Gender analysis therefore is not necessarily about developing programs for women, which is the common assumption of the people in the society. It is focused on the relations of both men and women to the social and economic structure of the society. Most farmers in Nigeria operate on the subsistence and smallholder level in an extensive agricultural system; therefore, in the country's food security lies in their hands. Men and women perform different roles in agricultural production. These roles vary from place to place depending on the tribe, culture, religion and geographical location. Women in Africa (including Nigeria) generally play an important role in small-scale traditional agricultural production (Afolabi,2008). Rural women have taken over the production and processing of arable crops and are responsible for as much as 80% of the staple food items.

As reported by Odebode, (2012) an estimates of women's contribution to the production of food crops range from 30% in the Sudan to 80% in the Congo contributing substantially to national agricultural production and food security. Women farmers are the principal labour force on small holder farms and perform the largest share in land preparation, weeding, transporting, processing and marketing of agricultural products. Women therefore contribute greatly to agricultural production in Nigeria as take the lead in most agricultural activities. They make up to 60-80 percent of the labour force. Therefore the significant role they play in meeting the challenges of agricultural production and development are quite dominant and prominent.

Despite their great contributions to agriculture, various findings have reported that women farmers generally, and particularly in Nigeria, lack access to adequate productive resources such as land, credit, agricultural inputs, education, extension services, and appropriate technology, due to various socio-economic factors (Rahman, 2008). According to Ajani (2008), religion in the northern part of Nigeria plays a large role in the division of labor. Among Muslim Hausa-Fulani's community in particular, seclusion norms dictate that women are less involved in outside-the-compound farming tasks (other than harvesting of certain crops by widows or women who have reached menopause).In the northern part of the country a research on involvement of both women and men rice production showed that married women are constrained in their production by their multiple roles and cultural practices which prevented them from direct field production activities. (Ayoola *et al.*, 2011).Generally, Married women of childbearing age do not undertake field work in Kano State; however, they are involved in many other aspects of production. Depending on how strongly seclusion is practiced within an area or a household. Girls, unmarried women (e.g., widows, divorcees), and menopausal women might participate in field work, particularly

in the less physically demanding activities such as planting or harvesting and other activities such as weeding, harvesting, and post-harvest processing are frequently female activities.
Thus, gender has become a critical cross-cutting factor in innovation process to promote equity and enhance the relative access of female and male farmers to necessary resources in programmes targeted at promoting household food security and poverty reduction.
Gender roles in the production of cowpea in the Northern part of Nigeria have not been adequately provided for by research and documentation. It is therefore necessary to assess the existing gender roles in cowpea food chain especially that of the females as well as those factors responsible for any noticeable change thereby enhancing proper planning for the females' producers.

METHODOLOGY

The study was conducted in Kano state of Nigeria. The State is made up of 44 Local Government areas (LGAs) divided into three (3) ecological zones. It is located in the Northern part of the Country and well known for cowpea production. The study population consists of female cowpea farmers. Three Local Government Areas (Gezawa, Ungogo and Kumbotso) were randomly selected from each of the three ecological zones in the state. A total population of six hundred (600) female farmers actively involved in cowpea production was located in the study areas. Forty (40) female cowpea producers were randomly selected in each ecological zone using a sampling fraction of 0.15.About 99 percent of structured questionnaires (119) were finally used for the analysis using descriptive statistics

RESULTS AND DISCUSSION

Table 1 show that Majority 61.4% are between 31-40years of age, while about 6% are 50 years and above. This implies that most of the female cowpea producers are in their productive age. Almost 75% of the respondents are married and twenty –one percent (21%) are widows. a very large proportion has no formal education (almost 81%) with only about seventeen percent (17%) have been exposed to primary education. with a negligible percentage of 2.5% having secondary education. In terms of family size, about 45% have a family size of 6-10 members while almost 35% have an household size of 1-5.The most significant mode of land acquisition is through common ownership and Inheritance (47.1%). Most of the respondent (44%) has 3-5yrs farming experience, while about 38% have 6-8yrs of farming experience.
The above socio-economic characteristics revealed that the respondent consists of a large proportion of women in their productive age, most of whom are married, illiterate and possessing a relatively large family size to support. They can be referred to experienced small scale farmers with access to land based on Inheritance and common Ownership while few of them purchase land for farming.
Table II above reveals that the greater percentage of male involvement is recorded in Bush clearing (46.9%), Stumping (58.8%) and weeding (51.3%),but stumping and weeding are majorly dominated by the male gender with significant contribution by both gender; was reported by the female cowpea producers. More than half of the respondent (51.3%) reported that Tilling is carried out by the female farmers and employed male labourers, while planting (49.6%) can be categorizes as a female job. fertilizer application (58.0%) are carried out by both gender while more than half (52.9%) of the respondents claimed that harvesting is majorly done by the female gender. Post Harvest activities which are Threshing (90.8%), Storage (67.2%) and Processing (66.4%) are performed by the female gender while Marketing (56.3%) can be referred to as a post harvest task handled by both gender in the State.
From the table III, about 98%, 67%, and 63% of the female farmers are involved in the task stated above as a result of quest for financial dependence, changing economic conditions and culture flexibility respectively. Also, almost 41% and 43% of them perform the tasks due to a large size of dependants to cater for and children education. The lower percentage recorded in the latter compared to the former might be attributable to the fact that majority are married and probably receive assistance from the head of their household concerning family members and children's education.

CONCLUSIONS AND RECOMMENDATION

Attempt has been made to examine the division of labour in cowpea production and post harvest handling in Kano state with an emphasis on the roles played by the women folk in the process. The sampled population can be referred to as small scale farmers, who are in their productive age and with a very low level of formal education. Their major access to farmland is through joint ownership and Inheritance, these is in consonant with the work of Lowenberg-DeBoer.J.and Germaine (2008) who posited that women in the north experience a restricted access to farmland while most of them can only boost of Quranic education. A considerable proportion of them have a relatively large number of families to support.
Stumping and bush clearing are dominated by the males; this might be as a result of the labour intensity of the operation. Both men and women were also found to be actively involved in the marketing of the cowpea in the

study area. It was discovered that majority of the female producers are actively involved in field activities such as planting, fertilizer application and harvesting while storage and processing are majorly carried out by the females. This is in contrast with some finding which says women in the northern part of the country are constrained by religion to participate in field activities.

Almost 98 percent of the female were involved in some of the task reported because of quest for financial freedom, indicating a great dependency of the females on their household head for finance. A considerable percentage: 67.2% are also involved due to changes in economic condition while 63% claimed culture flexibility for the division of labour involved in.

Having discovered the active role of the female gender in cowpea chain, all stake holders involved in the planning of rural development should target the female producers. The area of target should include provision of input materials such as high breed seedlings, fertilizers as well as the technical assistance on improved planting and application techniques. In order to ensure the economic development and status of these small scale farmers in terms of post harvest handling, improved storage facilities should be made available by the government and non governmental agencies for food sustainability and enhanced economic well being. The above will increase their participation in the society, and constitute to an overall improved rural economy and development.

ABSTRACT
The study examined the factors affecting female farmers in the production of African eggplant (Solanium gilo) in Abia State. Recent studies have shown a lot of involvement of women in agricultural production in the state. The sampling technique used was multi-stage random sampling procedure. Structured questionnaire was also employed to obtain necessary data required. A total of 12 circles of 10 female farmers each (120 female farmers) were randomly selected and interviewed with structured questionnaire. The study revealed that, out of fourteen independent variables estimated with Tobit model, two variables (year of experience and planting materials) were significant at 5% level while two others (quantity of fertilizers and pesticides) were positively significant at 1% level. The study recommends formulation of policies aimed at timely provision of farm inputs such as improved seeds, fertilizers and agro-chemicals to female farmers to ensure sustainability in the production of African eggplant.
Keywords: Factors, Female Farmers, African eggplant, Production.

INTRODUCTION

Nigeria is blessed with abundant resources which include land, labour and natural resources suitable for agricultural production. At present, she has a total population of over 140,001,542 million people made up of 71,709,853 males and 68,291,683 females (NPC, 2006). Agricultural production engages about 80% of the Nigerian population especially women who spend more than two-third of their time on food production activities. They do most of the work in the areas of primary production, processing, storage, marketing and transportation of crops from the farms to the homes (Ironkwe *et al*, 2007). Women physically produce 70-80% of domestic food crops, hence helping to ensure family and national food security in Nigeria.

In Nigeria, the role of female farmers in agricultural production cannot be over emphasized. Women are predominantly farmers (Tanko, 1995) and have been clearly recognized as fundamental in the field of agriculture (FAO, 2006). The female farmers (women) have been involved in the production of crops because they are highly knowledgeable about sustainable agricultural system and also play key role in preservation and exploitation of biodiversity (Eghereuba, 2004). Female farmers play active role in the food chain and value additions. For example they are found to be deeply involved in processing of cassava roots into various food forms such as garri, fufu, flour, starch, tapioca, doughnuts, cake, chin-chin and others (Aniedu, 2006). The female farmers participate more actively in collection of planting materials, weeding, fertilizer application, harvesting, storage, processing and decision or management of crops in Abia State, Nigeria (Onunka, 2011).

Other studies have demonstrated increased involvement of women farming in Abia State in agricultural production. Involvement of women has also contributed immensely to the increased yam production observed in the country (Aniedu, 2006). Adekaye (1999), reported that the female farmers now constitute the majority of smallholders (the core of agricultural sector), provide most of the agricultural labour, manage many farms on a daily basis and are frequently the head of the household. Saito and Spurling (1992), observed that women work more hours than men regardless of their season, both in farming and non-farming activities. They reported that in spite of the significant roles of the female farmers in the third world countries. Their level of productivity is constrained because agricultural production has been designed in such a fact that the farm managers are men. This is why most policies aimed at making agricultural production or agro-technologies inputs accessible to female farmers in Nigeria were actually directed towards men. This situation has been attributed to gender insensitivity to agricultural development (Onunka, 2011).

The production of vegetables such as African eggplant in south eastern Nigeria is gradually but steadily gaining prominence in the farming system of the area. African eggplant is one of the important vegetables produced in the south-east agro-ecological zone of Nigeria. A lot of work has been done on the level of production of this crop (Kalu, 2007; Akinpelu and Ogbonna, 2007; Nworie and Agbaraevo, 2002; Onunka, 2011). What have not been established or known are the factors affecting of the farmers (female farmers) that produce the vital crop (African eggplant), considering the importance of African eggplant as cherished delicacy, snacks and vegetables in likelihood of farm households in the study area. It is, therefore, expedient to examine the factors affecting female producers of the crop in the state. Hence, the main objective of this study is to examine the factors affecting female farmers that produce African eggplant in Abia State, Nigeria.

METHODOLOGY

The study was carried out in three (3) agricultural zones of Abia State. Abia State is one of the nine States of South East Agro-ecological zones of Nigeria. The name ''ABIA" is an acronym formed from the initial letters of four groups of people; Aba, Bende, Isikwuato and Afikpo (now in Ebonyi State). Abia is bounded in the South by Rivers State, Southeast by Akwa-ibom, sharing boundaries in the North-east with Cross-River State while, in the West and North with Imo, Anambra and Ebonyi States respectively. Abia State is located between latitude $4^{o}.49^{1}$ N and $6^{0}.47^{1}$N of equator and longitudes 7^{o} and 8^{o}E of the Greenwich meridian. The annual rainfall ranges from 1600mm-1700mm, distributed from February to December and mean temperature of 27^{0}c all through the year, highest from February- April (NRCRI, 2006). Abia has land area of 7,627.20 square kilometers, with a population of over 2,883,999 made up of 1,434,193 (55%) males and 1,399,806 (45%) females (NPC, 2006). The population is made up of different occupations but majority of the people are involved largely in agricultural activities which are done at small-scale levels. The farmers cultivate both food (yam, cassava, maize, vegetable etc) and cash crops (oil palm, cocoa, rubber, cashew etc).

The sampling technique was multi-stage random sampling procedure. Structured questionnaire was used to obtain necessary data from the respondent four (4) blocks were selected from each zone and one(1) circle from each block making a total of 12 circles in the state. Subsequently, ten (10) African eggplant female farmers were randomly selected and interviewed with structured questionnaire from each circle and a total of 120 female farmers. Both descriptive (simple percentages, tables etc) and inferential (Tobit model) were used. Tobit was used to estimate the value of Y, as a function of a set of explanatory variables (X). The dependent variable (Y) is the level of quantity produced by the farmers which is censored at zero. To avoid the censoring bias that other tools like Ordinary Least Squared could generate, a Tobit procedure is used because, quantity produced by female African eggplant farmers , use smaller than zero, was not observed. Holloway et al (2004) pointed out that even when a Tobit procedure is used, incorrectly assuming that the true point of censoring in the sample is zero also imparts a bias to the parameter estimates (Okoye et al, 2009)

The variables used in the analysis of factors affecting female farmers and the quantities produced with Tobit model includes;

Y = F(x_1,x_2-----------------x_{14} ei)

Y = Total quantity of African eggplant produced by female farmers (kg).

β_1 = Parameters estimated.

X_1 =Age (in years)

X_2 =Marital status (dummy variables, married = 1, otherwise =0).

X_3 =Education status (years)

X_4=Farming experiences (dummy variables, experience=1, not experience=0

X_5=Farm size (hectare)

X_6=Type of farmer (dummy variable; full time=1, part time=0)

X_7=Wage of labour (#)

X_8=Access to credit (dummy variable; access=1, no access=0)

X_9=Quantity of fertilizer (kg)

X_{10}=Quantity of pesticides (lit)

X_{11}=Access to planting materials/seedlings (dummy variables; access=1, no access=0)

X_{12}=House hold size (in number)

X_{13}=Co-operative membership (dummy variables; membership=1, no membership=0)

X_{14}=Extension visit (dummy variables; yes=1, no=0)

ei=error term

RESULTS AND DISCUSSION

Table 2 revealed that estimated results of the Tobit model out of the fourteen independable variable estimated with Tobit model, four (years of experience , Planting material, Quantity of fertilizers and Pesticides) were positively significantly 1% and 5.0% levels in explaining the socio-economic characteristics of female farmers and quantity of African eggplant produced.

The X value (123.58***) was highly significant at 1% level of probability indicating goodness of fit (table two). Year of farming experience (X_5) and planting material (X_7) indicates a positive sign. This suggests that the increase in the year of experience of farming African eggplant by the female, the increase in the production. Also source of planting material is necessary for the production of African eggplant for increased yield .

Table 1 further showed that quantity of fertilizers X_{10} and pesticides used in the production of African eggplant increase the output of the female farmers. This is an indication of the importance of manure for growth, flowering and fruiting of the crop. Ironkwe and Ewuziem (2010) noted that fertilizer is an important production resort and also an improved technology when applied in the right proportion, will help to increase output of the farmers. On the part of quantity of pesticides used, it implies that for increase output of African eggplant, means an increased quantity of pesticides used. This is because *Solanium gilo* production is faced with several pests and diseases in the state. Maraizu (2007) noted some African eggplant pests (fruit borer, boll worm and leaf eating caterpillar) and diseases (soil born fungi) and recommended some chemicals for controlling them.

CONCLUSION AND RECOMMENDATIONS

The study on factors affecting female farmers in the production of African eggplant in Abia State revealed that year of farming experience, availability of planting materials, fertilizers and pesticides were important in increased production of African eggplant by female farmers in Abia State. It, therefore, recommended that policies be formulated that would make improved seed, fertilizers and pesticides available and affordable to farmers on time. This will go a long way to increase the production of African eggplant by female farmers in the state.

ECONOMIC ANALYSIS OF GROUNDNUT PROCESSING AMONG WOMEN IN KACHIA LOCAL GOV ERNM ENT AR EA OF KADUNA STATE, NIGERIA

I.O. Ademiluyi, S.T Folorunso & G.C. Onuwa

Department of Agricultural Extension and Management,
Federal College of Forestry, Jos, Plateau State, Nigeria
E-mail: *bukkyinkus@yahoo.com*

ABSTRACT
The study examined the economics analysis of groundnut processing among women in Kachia LGA of Kaduna State. Data were collected from a random sample of 70 groundnut processors. The instrument used for the data collection was the questionnaire. It focused on the relationship between input and output and the efficiency of resource-use in groundnut processing. The data were analyzed using production function and resource use efficiency model. Double-log production function was chosen as the lead equation based on the high value of coefficient of multiple determinations (R^2), the numbers of significant coefficient, appropriate signs and the fact that cobb-Douglas production function explains the production theory better than the other functional forms. The estimated coefficients were further used in computing the resource use efficiency. The result shows the coefficient of multiple determination R^2 of 0.748 implying that 25% of the variation in groundnut processing output was accounted for by the inputs included in the model. The study also revealed that MVP of labour, groundnut seed and firewood is less than (<) the MFC. On the other hand the MPV of purchased input is greater than (>) its MFC. This indicates that purchased inputs are under-utilized in the study area. The underutilization of the purchased inputs might be due to improper management practices. It was recommended that conducive environment should be provided to both the producers and processors for sustainability of production and processing levels and to help in using resource efficiently for the attainment of prominent quality of the products.

Keywords: Groundnut Processors, Efficiency Analysis and Production Function

INTRODUCTION

Groundnut *(Arachis hypogea L.)* otherwise called peanut, monkey nut, gobber pea and arachide belongs to the family legumenosea. It is cultivated for its kernels, oil and hay for livestock. The crop is an important source of vegetable oil and supplementary feed for livestock. Oil from groundnut forms a staple part of the diet for many people and the world over. About 40% of the world yield of groundnuts is processed to oil which has a multitude of domestic and industrial applications. The popularity of groundnut oil arose from its attributes like palatability, inability to absorb odours easily like other cooking oils and it does not smoke [1].It is usually used for cooking, for making margarines, for pharmaceutical and cosmetic products as well as a lubricant and emulsion for insecticides [3].The pressed groundnut cake containing 40-50% proteins is mainly used as a meal for poultry feed and the haulms of the crop, reported to be more nutritious than the gross hay, are used to feed livestock in many countries [3]. Groundnut cake is often deep fried or dried to make a snack locally called kuli-kuli. Groundnut flour is used as an ingredient in soups, sweet, confectionaries and puddings. It is rich in oil and protein and has a high energy value.

According to [2] women produce between 60-80% of the food in most developing countries and are responsible for more than half of the world's food production. More so, not only do women produce agricultural products, but they are of key importance in their processing and marketing. Today, rural women are not only obliged to attend to all the household chores, children welfare, nutrition and family cohesion along with farm work but are often desperately driven to adopt a survival strategy to save the household food security from total collapse by supplementing agricultural production with off farm agricultural related activities such as agro-processing. In Nigeria, the processing of groundnut into various products is mostly done by women either for home consumption or for commercial purposes [5]. The most commercial products of groundnut are: groundnut oil, groundnut cake and fried peanut which are sold at market place or hawked on the streets, [6]. The processing of groundnut is a source of income and employment to a large proportion of rural women in northern Nigeria. In Nigeria despite women's pivotal position in agricultural development the significance of their contributions in agricultural production, processing as well as in household food security is often poorly understood and under-estimated [2]. As a result, few specific policies exist to enhance the rural women's access to education, means of production and other services necessary to integrate them in the mainstream rural development programmes. The bulk of oil produced from groundnut in Nigeria is locally produced using traditional methods. The source of raw materials is mainly the local market with hardly any processor growing his own nuts. The demand for edible oil has increase worldwide due to population growth, rising standards of living as well as consumer preferences arising partly from health consideration [7].Therefore, main objective of the study is to analyze the economics of groundnut processing among women in Kachia Local Government Area of Kaduna State, while the specific objective are to: determine the relationship between groundnut processing output and other variables of production; determine the resource-use efficiency of groundnut processing in the study area.

M ETHODOLOGY

The study was conducted in Kachia Local Government Area of Kaduna State. It has a land mass area of 4,632 kilometers square and has an estimated total population of 309,435 in 2014(NPC,2006).It has a Longitude 7^0 45^1Eand $8^0 40^1$E and Latitude 9^0 25^1N and 10^0 20^1N North. The area has a temperature climate of 10^0C while the rainfall distribution ranges from 550-900mm raining season. Crops cultivated include: Ginger, maize, groundnut, soya beans, millet and guinea corn.

A purposive random sampling technique was conducted in four (4) district of Kachia Local Government Area where groundnut processing was prominent. The four (4) districts are: GidanJibir, GidanMana, Bahago, and Gumel. The primary data in the study were obtained from 70 groundnut processors. This structured questionnaire was used to collect data from the processors during 2014/2015 season. Data were analyzed using production functions and resource use efficiency.

MODEL SPECIFICATION

Production Function

This tool was used to know the nature of production process and resources use efficiency in groundnut processing in the study area. In implicit form, the model is presented as follows:

$Y = f(X_1, X_2, X_3, X_4 \ldots\ldots Xn, e)$

Explicit form of the model can be expressed as follows:-

$\text{Log } Y = b_0 + b_1 \log X_1 + b_2 \log X_2 + b_3 \log X_3 + b_4 \log X_4$

Where Y = Groundnut processing, X_1 = Cost of equipment's, X_2 =Labour (man/day), X_3 = Groundnut seeds (kg), X_4= fire wood (kg), bo = constant ,e = error term, b = regression coefficient

Resource use Efficiency

This tool was used to determine resource use-efficiency of some of the inputs used by the farmers. It is determined by calculating the ratio of the marginal value product (MVP) to the marginal factor cost (MFC). The MVP is calculated from the respective regression coefficients using the appropriate formula depending on functional form, while the market price of one unit of the input is the MFC.

$$r = \frac{MVP}{MFC}$$

Where r = Efficiency ratio ,IF = r = 1, resources, employed by the farmer are efficiently utilized, r> 1, resources employed by the farmer are under-utilized, r< 1, resources employed bythe farmer are over utilized

$MVPx_1 = MFC = Px_i$

Where

$MVPy_i = MPPx_i .Py$

$MFC = UFC = Px_i$

Px_i = unit price of extra variable input x , Py = unit price of output, MPPx = marginal physical product of input x_i, MVP = marginal value product of output ,MFC = marginal factor cost ($\Delta TC/\Delta x_i = Px_i$).

RESULTS AND DISCUSSION

Production Function of Groundnut Processing in the Study Area

Double-log production function was chosen as the lead equation based on the high value of coefficient of multiple determination (R^2), the numbers of significant coefficient, appropriate signs and the fact that cobb-Douglas production function explains the production theory better than the other functional forms. The estimated coefficients were further used in computing the resource use efficiency. The result in table 1 shows the coefficient of multiple determinations R^2 of 0.748 implying that 25% of the variation in groundnut processing output was accounted for by the inputs included in the model.

Labour: This variable has a positive coefficient (0.1897) and significant at 10% probability level. This implies that an increase use of labour will lead to increase in output. This agrees with [4] in a title of resource use efficiency in groundnut processing in Sokoto State. **Seeds**: This variable has a positive coefficient (0.759) and significant at 1% probability level. This implies that an increase use of seeds will lead to increase in output. This agrees with [4]. **Firewood**: this variable has a positive coefficient (1. 6176) and significant at 5% probability level. This implies that an increase use of firewood will lead to increase in output. This agrees with [4].

Resource use Efficiency of Groundnut Processing in the Study Area

From the table below, the MVP of labour is less than (<) the MFC. This indicates that labour is over-utilized in the study area. This can be attributed to the surplus family labour available to small-scale groundnut processors in the study area. Also the groundnut seeds and firewood were over-utilized. On the other hand, the MVP of purchased inputs is greater than (>) its MFC. This indicates that purchased inputs are under-utilized in the study area. That is more purchased input need to be used. The under-utilization of the purchased inputs might be due to improper management practices.

CONCLUSION AND RECOMMENDATIONS

The study revealed that groundnut processing in Kachia LGA were not efficiently utilized because most input were over-utilized and under-utilized. It is therefore economical for processors in the study area to reduce the amount of all their resources in their processing and also have proper management practices.

Table 1: Double-log production function result for groundnut processing in Kachia Local Government Area

Variables	Regression coefficient	T-values

ABSTRACT
The study analyzed the production activities of youths in Umuahia North Local Government of Abia State, Nigeria. A multi-stage random sampling technique was used to select a sample size of 120 respondents. Data were collected using a questionnaire and were analyzed with descriptive statistics such as frequency and percentages. The result indicated that cassava production activities that the youth participated most in were weeding operations (95.8%), planting of cassava cuttings (85%) and harvesting (83.3%). Food security (62.5%) and poverty reduction (70.8%) are the major reason for youth's participation in cassava production. There is therefore, the need for government at all levels to be involved in enlightenment campaign to encourage the youths to see cassava production as a good venture.
Keywords: Cassava, production activities, youths, Umuahia

INTRODUCTION

The agricultural sector in Nigeria has witnessed a considerable high level of evolution within the last three decades. This was occasioned primarily by the desire to increase food production in order to enhance self sufficiency and empower the rural youth economically. Nigeria as a developing country has to develop its agriculture, if it is to be reckoned with, within the committee of nations. There is a decline in agricultural production because there is apparent shift of interest from agriculture to the white-collar jobs such as medical practices, pharmacy, teaching, accountancy and engineering, especially among the youths (Torimiro *et al*., 2008).

Youth in Nigeria may be categorized as young men and women between the ages of 13 and 30 years. This is based on the fact that in Nigeria, the expected age of entry into secondary education or vocation apprenticeship training is 13 years and this generally serves as the entry age into the youthful fold. The National Youth Service Corps (NYSC), that was established in 1973 in Nigeria, with the aim of promoting cultural integration by enlisting graduates from higher institutions to undergo a compulsory one year of service to the father land, was also on this premise. One of the regulations of the scheme stipulated that anybody above the age 30 years is not eligible to participate in the scheme. In addition, National Youth Entrepreneurship Summit (NAYES) (2008) defines youth from the age of 14 to 30 with an extension of up to 35 years. World Bank (2006), estimates that about 55 percent of youths reside in rural areas but that this figure is as high as 70 percent in sub- Saharan Africa and South Asia.

Over the years, there has been an advocacy campaign to get the youths more involved in agriculture. Among the agricultural activities the youths can get themselves involved in, is cassava farming or cassava production.

Cassava *(Manihot esculenta)* production is one of the ways to enhance agricultural production and consequently improve the socio-economic well-being of a community, state, nation, and the world at large. Cassava is one of the world's most important food crops. Nneoyi *et al*, (2008) show that cassava accounts for about 70% of the total calories intake of more than half of the population of Africa. Arega, *et al* (2013) confirm this fact by saying that cassava has become the most important root crop in tropical Africa providing food for over 200 million people. In Nigeria, as in most developing countries, it is also one of the most important carbohydrate sources. According to Nweke (2002) in Arega *et al* (2013) eighty percent of Nigerians in the rural areas eat a cassava meal at least once a day; hence it plays a major role in the country's food security.

The high consumption of cassava in the country, led to an increase in the demand for this crop both for food and industrial uses, which exceeds the supply (Odigbo, 2005). Cassava produces acceptable yields on poor depleted soils where other crops will yield virtually nothing; therefore it can be used to take advantage of marginal soils (Alabi and Alabi, 2002). Almost all the cassava produced is used for human consumption and less than 5% is used as industrial raw materials (Ajayi and Onuche, 2005).

Among the problems of cassava production is the aging of cassava farmers (Okezie and Kosikowski in Tonukari, 2004). The current state of cassava production in Nigeria has put a lot of pressure on production of cassava. The Federal Government of Nigeria constituted a presidential initiative on cassava production and export aimed at raising the production level of cassava to 150 million metric tons by the end of 2010. The programme is also expected to assist the country realize an income of US$5.0 billion per annum from the export of 37.6 million tons of dry cassava products such as starch, cassava chips, adhesive and other derivatives. Apart from local demand, there is a high demand for cassava based products in foreign countries. However, the current supply of the cassava has not been able to satisfy foreign market demand (IFAD and FAO, 2005).

Efforts geared towards effectiveness and sustainability of Cassava Production has been without the youths, who should continue, after the adults are gone. Ekong (2003) noted that the youths who have the energy to take up cassava production do not believe or have the knowledge that cassava production can really be a profitable venture. The current challenges in development are so demanding that only the participation of people who are energetic, creative, innovative, productive, and are committed could bring development, should they all be mobilized (Solanke, 2004). These attributes which are critical to growth and development are substantially discernible in the youth. Thus, they constitute the major resource base for any country that wants to embark on any meaningful agricultural and rural development.

Cassava production is labour intensive; this is worsened by scarcity and high cost of hired labour especially when there is need to expand cassava production beyond subsistence level. Incorporating youths into cassava production will facilitate capacity building and empower them for agriculture sensitivity. This will predispose them to a favourable attitude and future career in agriculture especially in developing countries like Nigeria, with high rate of unemployment. This unemployment for the youths is causing a lot of problems like youth restiveness, armed robbery among others vices. Without this, any withdrawal of the aged farmers from cassava production could endanger food security since cassava products form one of the major staples of Nigerians. Therefore, youths need to be encouraged and their interest in agriculture aroused at the International, National, State and Local Government levels.

Studies in the past had concentrated on examining how to harness youths potentials in agriculture (Nnadi and Akwiwu, 2008; Adesope *et al.*, 2007); factors influencing their involvement in cassava production (Adebisi, Owolade and Jatto (2015); preference to agricultural discipline, value addition, marketing (Ugwoke *et al.*, 2005). None has actually investigated cassava production activities of youths, based on the premise; this research work is anchored on. This work addresses the following objectives:

1. ascertain cassava production activities of youth in the study area;
2. ascertain the reason for youths involvement in cassava production in the study area;

METHODOLOGY

The study was carried out in Umuahia North Local Government Area of Abia State, Nigeria. Multi stage sampling techniques was used in the selection of 120 respondents. In the first stage, three autonomous communities were selected, in the second stage two villages were randomly selected from each autonomous community. In the third stage, twenty youths were randomly selected from each village. This gave a sample size of one hundred and twenty respondents for this work. Data was collected using questionnaire, and analysed using descriptive statistics such frequency, and percentages.

RESULTS AND DISCUSSION

Cassava production activities of youths in the study area

Cassava production involved several activities ranging from land clearing, sourcing of the planting material, stumping, soil tillage, planting of the cassava, weeding operations, fertilizer application, and harvesting etc. the youths participates in different activities of cassava production. The Table 1 shows activities which youths in the study area participate in.

The result in this Table revealed that majority (95.8%) of the youths carried out production activities in weeding operation; planting of cassava cuttings (85%), 83.3% were involved in harvesting of cassava tubers (83.3%) and 62.5% were involved in fertilizer applications. Only 16.7% of the respondents participated in supply of planting materials, 18.7% in storage of processed cassava products, and (25.8%) in soil tillage. This implies that youths are actually participating well in cassava production in the study area. The result is in line with Adebisi, Owolade and Jatto (2015) who reported high percentages of youth participation in cassava production in Oyo State.

Reasons for youth involvement in cassava production

The result in Table 2 shows that majority (70.8%) of the respondents were involved in cassava production as a means of poverty reduction. In a similar vein 62.5% choose cassava production as a means of food security. Also the entries in Table 2 shows that 59.2% choose cassava production as a source employment opportunity, and 56.7% agreed that it was for profit/income. With this result, it can be inferred that the major reasons why the youths participate in cassava production in the study area were for poverty reduction, food security, employment opportunity and for profit and income. This means that cassava farming offers benefits such as employment opportunities, food security, profitability and poverty reduction in the study area. This agrees with Adebisi, Owolade and Jatto (2015) concluded that cassava has high potentials for poverty reduction and food security

CONCLUSION

The youths in Umuahia North Local Government Area participate actively in cassava production especially in the areas of weeding, planting of cassava cuttings and harvesting. They are engaged in these activities for the purpose of food security, poverty reduction and income generation. There is therefore, need for government at all levels to be involved in enlightenment campaign to encourage the youths to see cassava production as a good venture especially now that unemployment is a big problem in Nigeria.

Table 1 Cassava Production Activities in the Study Area

ABSTRACT
In line with United Nations declaration of 2016 as International Year of Pulses (IYP), this study tends to key in at the objective three of the declaration that: ''Encourage connections to further global production of pulses''. The study assessed the production of pulse crops among arable crop farmers in Ibarapa area of Oyo State Nigeria. Multi stage sampling procedure was used to select 121 arable crop farmers under the umbrella of All Farmers Association of Nigeria (AFAN). Structured questionnaire was used to collect data on socio-economic characteristics, most cultivated pulse and contribution of most cultivated pulse to household income and intra-household gender redistribution of income. Data were analyzed using descriptive statistics and logit regression model. Results showed that the mean age of the farmers was 51 years. Most (66.9%) of the respondents were male, while 28.8% had no formal education. Almost all (90.1%) of the respondents cultivate one or more pulses as groundnut is identify as most cultivated pulse in the study area. Intra-household allocation behaviour have accumulated evidence that women contributed 39.5% of their income from groundnut to household food security compare to men 22.7% despite their lower income compaere to men. Logit regression showed religion, major occupation, farm size under pulse cultivation and gender peculiarity of the most cultivated pulse to be significantly influenced the adoption/cultivation of the most cultivated pulse (groundnut). The study recommended increased pulse crop production awareness & research, and avoidance of static gender role, but a responsive change in farming system.
Keywords: Pulse, Gender, Intra-household and Income redistribution.

INTRODUCTION
Pulse is the second largest family after *poaceae* earlier known as *Gramineae* in terms of food and vegetable protein source and fodder. (Ali and kumar, 2006). Common pulse crops like soybean, cowpea and groundnut are important legumes grown in virtually all part of Nigeria.
Despite several years of pulses research and diffusion in Nigeria, Nigeria has witnessed spells with upward trends in pulse crop output since 1997(Osho, 2003). This has mainly been attributed to the increased uptake of improved pulse crop varieties and expansion in the area under cultivation. However, the potential productivity level of the crop is yet to be achieved in term of quantity due to degradable cultivation of most pulse crops. In addition, past studies on common pulse crops in Nigeria have also focused on production efficiency (Ousmane B. and Ajeigbe HA. 2009). Therefore, this study is aim at investigating production trend (continuity or discontinuity) of common pulses as a result of substitution advantage over other crops in terms of allocation of resources and other relevant socio-economic variables as a way of explaining production constraints in common pulse crops production in the study area. The main objective of this study was thus to examine factors influencing farmers' adoption of most cultivated or preferred pulse crop cultivation in the study area. Hence, the specific objectives are to: describe the socio-economic characteristics of the farmers in the study area; to determine the contribution of most cultivated pulse to household income and intra-household gender redistribution of income of the most cultivated pulse.

METHODOLOGY
The study was carried out in seven Ibarapa communities of Oyo state. The communities are made up of seven major towns namely; Lanlate, Eruwa, Igboora, Igangan, Idere, Aiyete and Tapa within three local government areas. Primary data was used through structured interview guide to collect responses from the farmers. The sample size for the study was drawn from the study population of All Farmers Association of Nigeria (AFAN) chapters within the selected local government areas using multi-stage sampling techniques. Stage I: Purposive selection of all AFAN members in the three (3) local Government Area covering the seven (7) communities of the of the study area; Stage II: Simple random selection of 50% of the AFAN Chapter covering the seven (7) communities of the study area was to have Ibarapa Central L.G.A and Ibarapa North L.G.A. chapter, with registered members of 535 and 670 farmers respectively. In Stage III, stratified random selection of 10% of the AFAN members in the two (2) selected chapters was used to have 54 farmers from Ibarapa Central L.G.A. chapter and 67 farmers from Ibarapa North L.G.A. chapter. Data

collected was analysed using descriptive statistical tools such as percentage and inferential statistical tools such as logit regression analysis.

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Farmers

The results in Table 1 revealed the mean age of the farmers to be 51 years. Thus, many of the farmers were agile and able bodied characterized with strength. This reason may account for why respondents cultivate various arable crops, including the area of research (Pulses crop) and indirectly contribute to nutritional and socio-economic characteristic of the respondents. Majority (66.9%) of the respondents were male, while 33.1% were female. Some (28.9%) of the farmers had no formal education. Therefore, it can be said that introduction of new ideas and adoption of innovations and technology in the study area will be relatively fall in the hand of the laggard. Most (52.1%) were farmers, 9.1% of the respondents engage in various artisan works as their major occupation. Nearly all (90.1%) of the respondents cultivate one or more pulse crops in the study area, peculiar to their environment, ranging from soya bean, groundnut, cowpea and pigeon pea. The most cultivated pulse or the most preferred pulse in the study area is groundnut with percentage cultivator of 35.5%. Cowpea follows with percentage of 22.3%, pigeon pea is really cultivated by the respondents with 13.2% respondents**.** The peculiarity of the most preferred or most cultivated pulse is considered as men cash crop; while women in the production were confined to the cultivation of other crops with percentage of 73.6%. Furthermore, 86.8% of the respondents claim to regard the most cultivated pulse as family enterprise where men do certain tasks and the women engage in processing. The mean cost of production per hectare by the respondents in the study area was estimated to be N26, 355. Furthermore, mean income per hectare in the study area was estimated to be N63, 836. This reveals the profitability of groundnut production in the study area.

Distribution of Respondents by the Contribution of most cultivated pulse (Groundnut) to Household income and Intra-household Gender Redistribution of Income.

Table 2 presents the results of the contribution of income of groundnut and intra-household income redistribution. It was found that groundnut was profitable to farmers in the study area. Mean groundnut cash income was ₦43,252 for men compared to ₦19, 472 for women. Farmers within Ibarapa North obtained a higher income than farmers in Ibarapa Central, and men had a significantly higher income than women. Nevertheless, women in Ibarapa North had a higher income than men in Ibarapa Central. Since, income from groundnut often came in one lump-sum payment and sold at once after threshing or sold directly. In 2015, for instance, a bag of groundnut (120kg) was sold at ₦25,000. A farmer in Ibarapa Central who earned up to ₦100,000 from groundnut claimed proudly that *''I got so much money from just one harvest of groundnut''*. Intra-household allocation behaviour has accumulated evidence that women's contribution (39.5%) to household food security, nutritional status, health, and welfare of children is of prominent, compared to men (22.7%) despite their lower income compere to men. The findings of this study showed that substantial proportion of women income from groundnut was redistributed into family expenditure a traditionally male responsibility. This finding provide further empirical evidence that women in the study area are actively involved in cultivation of cash crops, and that they earn a substantial share of their income from cultivation of marketed crops, such as groundnut and redistribute their earning into the welfare of the household.

Factors Influencing Farmers' Adoption/Cultivation of Most Cultivated Pulse Crop in the Study Area

The empirical model used to assess these factors or varietal characteristics motivated farmers to adopt or reject the production of pulses in the study area was logit regression model. The model used, integrates only the farmers' socio-economic characteristics and the institutional variable of most cultivated pulse (groundnut) in the study area. Results of the logit model analysis are given in Table 3.

Among the farmers' socio-economic characteristics that were considered; religion, major occupation, farm size under pulse cultivation and gender peculiarity of the most cultivated pulse (groundnut) of the farmers' were significantly related to the adoption/cultivation of the most cultivated pulse (groundnut). The adoption based on religion of the farmers' can be explained by the culture of the people in the study area, as it plays a significant role in adoption process. Groundnut was stated to be culturally preferred and cultivated in the study area. Also, farmers' major occupation was negatively related to adoption. This can be explained in line with alternative means of livelihood of the people in the study area, a slight or more tensed move to their minor occupation may cause decrease in cultivation of most cultivated pulse (groundnut). Furthermore, farm size under pulse cultivation was of paramount importance since there is better contribution to the farmers' income. The differential adoption in cultivation based on gender peculiarity of the most cultivated pulse as specified in the study area opined that ''the most cultivated/preferred pulse is considered as men cash crop, while women were confined to the cultivation of other crops''. This can be explained by gender biases in technology diffusion. Women farmers are not traditionally targeted by extension agents and research and development activities. Innovations are often introduced to heads of households, the majority of whom are men. Thus, access to innovation or information on such innovations is more restricted for women than for men. The implication of this finding is that greater efforts will be needed to close the gender gap in access to, and use of, improved technology. This is important in view of the role of groundnut in intra-household income redistribution, food security and nutrition, and in improving soil fertility in the study area.

CONCLUSION AND RECOMMENDATION

It can be concluded from the results of this study that the most cultivated pulse or the most preferred pulse in the study area is groundnut. Secondly, religion, major occupation, farm size under pulse cultivation and gender peculiarity of the most cultivated pulse (groundnut) of the farmers' were significantly related to the adoption/cultivation of the most cultivated pulse (groundnut). Lastly, the study provides evidence that groundnut production had a positive impact on farmers' income accounting for about half of the total farm income for men as well as women. Hence, women's involvement in groundnut production broadened equity and distributional effect as it was recognized that income in the hands of women contributed more to household welfare, food security, and children's nutritional status.

The study recommended increased pulse crop production awareness & research, and avoidance of static gender role, but a responsive change in farming system.

ABSTRACT
This study deals with analysis of time usage pattern on rural women poverty status in Oyo state. Simple random sampling technique was used to select 120 respondents which comprises of rural women from two Agricultural zones (Ibadan/Ibarapa and Oyo). Descriptive statistic was used to describe scoio-economic characteristics of the respondents, Time diary was employed to know their daily time usage pattern and Probit regression (PR) was used to determine the effect of daily time usage pattern on the respondents' poverty level. The studies revealed that majority (42.7%) of the respondents are farmers with mean household size and farm size of 5 years and 3 hectares respectively. All of them spent the hours of 12am – 5am sleeping, about 60% of them spent the hour of 8am – 4pm attending to their economic activities only (such as farming, hawking, marketing and civil servant) while about 80% of the rural women in the study area spent the hours of 4pm – 6pm attending to housechore work and relaxing. The result of PR revealed that rural women time usage pattern between 12am - 5am and 8am - 12noon, age of the respondent, household size and educational level were statistically significant to their poverty status. In conclusion, educational level and age were the most prerequisite for poverty status. Therefore, the study recommendations that non-economic activities should be included in the system of National Account and government should also intenstify its effort at enhancing human capital development through formal education in order to improve their poverty status.

INTRODUCTION

Inequality is a major challenge to development and an obstacle to achieving the Millennium development goals (MDGs). It takes many different forms, including income inequality, unequal access to and control over property, civil and political rights, and social, cultural, and economic rights. All these forms of inequality possess inherent gender dimensions. One form of inequalities that have received much less analysis but has adverse implication for accessing economic right is that relating to time. The allocation of time between women and men in the household and in the economy is a major gender issue in the evolving discourse on time poverty. Bames (2003) in analyzing the allocation of social roles between men and women, shows first how this allocation leads to time poverty among women, and second how this impact the achievement of the MDGs.

An analysis of "who does what and when" within the normal African household shows that women and girls are responsible for collecting water and firewood, cooking, cleaning, taking care of the children, the infirm and the sick, producing food, and marketing any surpluses. They also dedicate a lot of their time to maintaining social cohesion within the community. All these tasks are considered to be low-status activities unremunerated and unrecognized in the national statistics. Women whose spend all their time performing this task are often considered as "not working".

Poverty as often defined as a deprivation of entitlement through lack of access to economic and social resources as well as to political participation and consultation as a contributor to women's poverty (Blacken, 2002). In Nigeria a study by Onibokun (1996) reveals that the population of households living below poverty line in the four cities of Lagos, Ibadan, Kano, and Onitsha were 63.7%, 62.1%, 35.62% and 87% respectively.

Empirical evidence shows that women participate less in the labour market when employed, they are disproportionately concentrated in unpaid jobs that offer low earnings, as a result of their low skills, burden of household responsibilities and labour market descrimination.(Blacken and Wodon, 2006).

Recent studies found that, even when they have the same human capital and job characteristics as men, women earn on average much less (Bardasi and Wodon, 2005).

Women tend to accumulate both types of work; therefore,they are double burdened and have a higher total work than men. Because women suffer from time deprivation as a result of their multiple roles, they enjoy less leisure time to rest and thereby more likely to be "time- poor". (Bamberger, 2010)

METHODOLOGY

The study was conducted in Oyo State which has its headquarters in Ibadan. The study area covers approximately an area of 28,454km^2 with an estimated population of 5,591,589 people (NPC 2006). It is an inland state in South-Western Nigeria. It bounded in the north by Kwara state, in the east by Osun State and the south by Ogun State.

The study populations were mainly rural women in the study area. Multistage sampling technique was used in selecting the respondent for this study. First stage involved random selection of two (2) zones (Ibadan/Ibarapa and Oyo) from four (4) ADP zones in Oyo state. Second stage involved random selection of two blocks from each block making up the zones (ido and igboora from Ibadan/Ibarapa zone while Offa meta and Iseyin from Oyo zone). Third stage involves random selection of random selection of two active cells each from each zone making 8 cells. Fourth stage involves randomly selection of 15 female from each cell making 120 respondents.

Data for the study were collected from the respondents through the use of pre-test structured interview schedule and time diary. Data were analyzed using descriptive statistics and Probit regression.

Construction and determination of the Poverty Line

Poverty line is the level of welfare which distinguishes poor households from non-poor households (Mukherjee and Benson, 2003)

PCE = TCE/ HHS...(1)

MPCHE = THHE/ TNR...(2)

PL =2/3* MPCHE...(3)

Where:

PCE = Per Capita Expenditure	TCE = Total Consumption Expenditure
HHS = Household Size	MPCHE = Mean Per Capita Households Expenditure
TNR = Total Number of Respondents	THHE = Total Households Expenditure
PL = Poverty Line	

RESULTS AND DISCUSSION

Socio-economic characteristics of the Respondents

The distribution of age of the respondents as presented in Table 1 reveals that most of the respondents (41%) fall between 31- 40 years of age with the mean age of 42 years which shows that majority of the respondents are in their active age and expected to be productive (this was in line with Dipeolu et al., 2009). Also, majority (48.3%) has non-formal education and chose farming with the mean household, farm size and farming experience were estimated at 6 persons, 10 hectares and 8 years respectively.

Time Diary of the Respondents

Table 2 below shows the various time usage pattern of rural women in Oyo State. All of the sample respondents sleep during the hours of 12am to 5am. About 59.0% of the responents were involved in economic activities alone during the hour of 8am to 12noon, 42.5% of the responents engaged in economic activities, leisure, game, relaxing, watching tv or listening to radio between the hours of 12 to 4pm.

Description of variables

A- Sleeping alone
B- Praying, house chores (cooking, care of the kids, bathing, eating)
C- Economic activities, leisure, game, relaxing, watching television or listening to radio
D- Economic activities alone
E- Cooking, house chores, watching television or relaxing
F- Leisure, game, taking care of young, cooking,
G- Relaxing, sleeping

Determinant of poverty line

Total Expenditure of the respondents' households in the study area = ₦6123500/day

Total household size in the study area = 589

Poverty line = ₦58.05/day

Parameter Estimates between daily time usage pattern and their poverty level using Probit model

Probit regression model was used to estimate the effect of daily time usage pattern on the respondents' poverty level. Table 9 below showed the definition and outputs of variables entered into the Probit model. Out of the nine (9) explanatory variables hypothesized only five (5) variables were found to be significant. It reveals that their time usage pattern between 12am to 5am and 8 am to 12noon, age, of the respondent and household size were negatively and statistically significant to their poverty status. This implies that the higher the educational level, the higher they move above the poverty line. It means those women with higher level of education were able to manage their time very well. The study was in line with Ellis (2006) that reported time usage pattern and education have a significant impact on poverty status of dwellers in Africa.

CONCLUSION

The result of the study revealed that most of the respondents were farmers, with average household size of 6 and non-formal education was dominant in the study area. The result of the probit model analysis also relvealed that out of the nine explanatory variables tested to be influencing their poverty status, only five were found to be statistically significant that is the activity between the hours of 12am – 5am, 8am – 4pm, age, household size and their educational level.

Based on the results and conculsion of the study, the following recommendations were made:

i. Non-economic activity should be included in the system of National Account.
ii. There should be human capital development programmes for the women in order to improve their educational level which will improve their poverty status.
iii. Other women empowerment programmes should be organized for the women in order to improve their poverty status.

ABSTRACT
The study assessed the level of womenpreneurship development among women crop farmers in Imo State of Nigeria. One hundred and eighty women farmers were selected using multistage random sampling technique. Data collected were analyzed using descriptive statistical tools of means, frequency and percentage. A 3-point Likert rating scale of high, moderate and low was used. Majority of the women (55.6%) were between the ages of 41-50years. Greater proportion of them had secondary education and a good percentage of them (77.8%) are married with a large house hold size of between 6-10, with more than 20 years of farming experience and a farm size of 2 hectares. Majority of the women farmers identified personal intention, self realization, unstable income, training in agribusiness, access to land, wanting autonomy among others as their key drive for wanting to involve in womenpreneurship development in the state. However, the women farmers identified lack of start-up capital, poor access to entrepreneurship information, limited availability of land, poor access to agricultural information among others as their barriers to entrepreneurship development in Imo State. Inspite of all these barriers, the women still showed high intentions to involve in agribusiness activities (X=2.9). Based on the above findings, the study recommended among others that; entrepreneurship education at all levels should be fostered by policy makers to ensure capacity building for diverse enterprises in agriculture.
Keywords: Womenpreneurship development, Entrepreneurship drive, Agribusiness.

INTRODUCTION

The word entrepreneurship is used to describe a dynamic process of creating wealth (Shailesh et al, 2013). Thus, womenpreneurship is a dynamic process of wealth creation through agricultural production by women farmers. This wealth is created by women who take the major risks in terms of time and career commitment of providing values to some products or services, such products or services may or may not be new or unique but value must somehow be added by the entrepreneur by securing and allocating the necessary skills and resources. In other words, womenpreneurship is the application of energy for initiating and building an enterprise by women (Mishra et al, 2010).

Today in Nigeria an entrepreneur is an innovator who recognizes and seizes opportunities, converts those opportunities into workable ideas, adds values, efforts, money, skills and assumes the risk of competition to actualize the ideas and claims the reward. Entrepreneurship and womenpreneurship are used interchangeably in this study since they convey the same concept. Womenpreneurship is associated with innovative and dynamic developments of women within small, micro and medium agricultural enterprises (SMME) sector (United states department of agriculture, (2011) as quoted in Esiobu et al,(2015). Womenpreneurship is a charismatic concept which is widely defined as a creative and innovative response by women to the environment.

Empirical evidence emerging from some studies on entrepreneurship development in agriculture, (Esiobu et al, 2015, Nwibo and Okorie, 2013, Shailesh et al, 2013) among farmers yielded results that are inconclusive and contradictory. Thus,the study on womenpreneurship development in agriculture among women farmer in Imo State is yet to be established. This has created a deep dearth in research, knowledge and literature,. Hence to fill this gap, it becomes necessary that this study was undertaken, specifically the study identified socio-economic attributes of women farmers in the study area, identified their extent of entrepreneurship drive in agribusiness, ascertained the exempt of intention to be involved in crop production in the study area and identified some constraints to womenpreneurship development drive in agribusiness enterprises in Imo State.

METHODOLOGY

The study was carried out in Imo State of Nigeria, Imo State is one of the states in the south Eastern part of Nigeria with Owerri as its Capital. The state lies within latitude 4.45N and 7^o 15'N of the equator and longitude 6^o 50'E and 7^o 25'E of the Greenwich Meridian, with land areas of 5,530 square kilometers (ministry of land survey and Urban planning, Imo State, (2002). The State has an estimated population of about 4.8 million people and an annual growth rate of 3.35 percent. The major activities of the people include; farming, trading agro-business and other entrepreneurial activities. The state is divided into three geo political and agricultural zones of Owerri, Orlu and Okigwe and has twenty seven local government areas altogether. These divisions are for easy administrative and extension contact purpose (Imo ADP, 2010). Multistage sampling technique was used to select 180 respondents for the study. The first stage involved the purposive selection of the three agricultural zones of the state namely; Owerri, Orlu and Okigwe zones to ensure adequate representation of the entire women farmers. The second stage involved the selection of two local government areas from each of the zones giving a total of six(6) local government areas. In the third stage, a random selection of three communities was involved, making a total of eighteen (18) communities. In the final stage, 10 women farmers who engage in agribusinesses were randomly selected and this brought the sample size to 180 respondents. Primary and secondary data were used to collect the data for the study. Primary data were collected through the use of structured questionnaire and was supplemented with oral interview in places where the respondents were semi-illiterate. Descriptive statistical tools such as frequency distribution, means, percentages and a three point Likert scale ratings of highly (3), moderately (2) and low (1) were used for data analysis.

RESULTS

Distribution of Women According to Socio-Economic Characteristics

The distribution of woman farmers according to their socio-economic characteristics is shown in table 1: The result showed that only woman farmers were the respondents 100% and that most of the women (55.6%) were between the age brackets of 41-50 years. This result revealed that the women are still young and in their productive ages. This coincides with the findings of Onwumere, (2008) who stated that enthusiasm and vigor to be productive are found more in youths. The result also revealed that majority of them 69.4% had secondary education, 16.7% had primary education, 11.1% had tertiary education while only 2.8% of them had no formal education. The finding implies that the farmers have basic educational background which is relevant for adoption of innovations and skills in entrepreneurship development. This result supports the findings of Ani, (2007), Chukwu (2013) and Esiobu et al., (2015) who reported that people with higher education attainment are usually faster in adoption of improved farming technologies. The result also revealed that majority of the women farmers are married (77.8%), 11.1% are single, 8.3% are widowed while a minute percentage 2.8% are divorced. This implies that most of these farmers are responsible enough to decide on the best action to tackle their entrepreneurial activities to cater for the food security of their families. The table also showed that most of the women, (78.8%) have large household size with more than 20 years farming experience (83.3%). The implication of this result is that these farmers must have used the large family size to enhance their experience in the farming activities. This is because according to Onyeneke and Esiobu (2012) who asserted that large household size ensures availability of labor for women farmers to address their labor challenges. The distribution of farmers according to their belonging to cooperative societies showed that majority of the women, 88.9% belonged to cooperative society while 11.1% do not belong to cooperative society. This result implies that these farmers should have easy access to entrepreneurship training and development activities in the study area. It is expected that membership of cooperative society will afford the farmers the opportunity of sharing information on modern farming practices and project a collective demand, and enhance their participation in entrepreneurial activities in agribusiness. The result in the table equally revealed that the women farmers have an average annual income of ₦301-400 (68.9), ₦161-200,000, (11.1%), less than ₦100,000, (6.7%) and above ₦400,000, (3.3%). This result showed that the farmers are low income earners in spite of their large family size. This agribusiness entrepreneurship will be reduced because Fairlie, (2005) in his study reported that farmers with higher farm income would be involved easily in entrepreneurship activities than those of their counterparts who have low farm income. The table revealed that majority of the women are full time farmers (55.6%). Others engage in some other occupations such as sewing (10.0%) hairdressing (6.6%) and trading (27.8%). This result revealed that most of these women have farming as their major source of livelihood. This implies that women who have farming as their major occupation will readily. Participate in any agribusiness which will help to enhance their cropping activities and enhance food security for their households. This is in line with Kareem and Akinbile (2015) who stated that full time farmers will have interest in any effort made to transform their system of agricultural activities which they perceive to be genuine. Studies by Esiobu and Onubogu (2014) asserted the large farm size increase crop production and improve farmers' technical, allocative and resources for efficiency. Therefore large farm size is a positive variable for entrepreneurship development in agribusiness

Extent of intentions to involve in agribusiness entrepreneurship

Table 2 displays the women farmer's entrepreneurship intentions in agribusiness. The level of entrepreneurship intention in agribusiness for the study was based on asking the woman about their various levels of drive or intents to involve in agribusiness active as an enterprise. The assessment was rated in three point- Likert scale of high -3 moderate-2 , and low-1, majority of the woman farmers with a mean score (x) 2.83 admitted to have high intentions of involving in agribusiness entrepreneurship x=0.07 and 0.02 were moderate and low respectively in decision to engage in entrepreneurship drive. The finding implies that in spite of the challenges of farm land and poor enabling environment for entrepreneurship activities, the woman farmers still have the motive and drive to engage in entrepreneurship activities, this goes to show that a greater hope for womenpreneurship development in the study area, especially if there is adequate support from the government and non-government sectors.

CONCLUSION AND RECOMMENDATIONS

This study was carried out in Imo state of Nigeria and it basically assessed the level of womenpreneurship development in agribusiness activities among women crop farmers in imo state of Nigeria .Multistage sampling technique was used to select 180 women farmers for the study, reasonable percentage of the women farmers identified personal desire, self-realization, unstable income, access to fund, wanting autonomy and the rest of them as the key drive into agribusiness. However the women farmers identified lack of capital to start up the business, poor access to entrepreneurship information, limited availability to farm land among others as their major barriers to womenpreneurship development in the state.

ABSTRACT

Gender mainstreaming in Agriculture and women empowerment is central to achieving the goal of raising food production and lessen the burden of food insecurity globally. This study was therefore designed to examine the productivity of female rice-farmers in Adamawa State, Nigeria. Primary data were collected from 180 randomly selected female rice-farmers in Adamawa State. The data were analysed using both descriptive statistics, and stochastic frontier function analysis. Socio-economic characteristics of rice-farmers in the area were identified. The result of maximum likelihood estimates revealed that the factors responsible for technical in-efficiency of female rice-farmers include education, farming experience, and access to credit facilities. The technical efficiency ranges between 0.43 and 0.94 with a mean of 0.8.4. It was thus recommended that, government policy should encompasses measures that promote women farmers' access to agricultural resources and services at affordable prices thereby bridging the existing gender gap among rice-farmers in Nigeria.

Key Words: Technical Efficiency, Gender, Rice, Production, determinants

INTRODUCTION

Agriculture in sub-Saharan Africa remains to a large extent a gendered occupation with men and women engaged in role differentiation in all farming processes (Angya, 2008). The report by National Bureau of Statistics, NBS (2014) indicated that the Nigerian agricultural sector grew at 3.68% and contributed 20.89% to the country's real GDP in the second quarter of 2014. However, agricultural output has increased less rapidly than the estimated population growth rate, and this has resulted in increase in food importation. According to FAO (2013) the importation of rice in Nigeria in 2012 stood at a staggering figure of about 2.8 million tonnes as compared with the total imports of about 1.7 million metric tonnes in 2007. Therefore efforts towards increasing local food production in Nigeria should give prominence to the different roles played by men and women in agricultural activities especially in terms of labour supply. Dia *et al. (*2009) emphasized that the pace of agricultural development in the country is closely related to the factors which affect productivity of women labour. Hence, the empowerment of women and other vulnerable groups in the society is the most effective way of reducing poverty and improving food security. According to Ismaila *et al.* (2010) addressing the continuing decline in local food production especially cereals such as rice, millet, maize etc. will entail acknowledging the contributions of the various intra-household units in the overall production outputs. The separate roles of men and women in the development of agriculture must be critically identified so as to achieve meaningful impact on food production in the country. According to United Nations Development Programmes, UNDP (2010) policies and programmes that ignore differential impact on gender groups are often gender-blind and potentially detrimental to human development. Gender equality therefore, requires a focus on results to improve the well-being of poor rural women farmers.

METHODOLOGY

The study was carried out in Adamawa State, Nigeria. Adamawa state is in the North-eastern part of Nigeria. It shares boundary with Taraba State in the south and west, with Gombe State in the North – west and Borno State to the North. It lies between latitude 7^0 and 11^0 North, and longitude 11^0 and 14^0 East (Adebayo and Tukur, 1999). Adamawa State has a land area of about 38, 741 Km^2 and a population of 3,178,950 people comprising of 1,607,270 males and 1,571,680 females (National Population Commission, 2006). The predominant occupations in the state are farming and livestock herding.

Multi-stage sampling technique was used to collect data for the study. Three Local Government Areas were purposively selected based on their high involvement in rice cultivation in Adamawa State. Six (6) wards were randomly selected from each of the Mubi North Local Government and Fufore Local Government; while five (5) wards were selected from Lamurde Local Government to give a sum of seventeen (17) wards, proportionate to the total number of wards in each of the three Local Governments. Hence, one hundred and eighty (180) female farmers were randomly sampled proportionate to the population of female rice farmers in the study area.

The data collected for this research were analysed using Descriptive Statistics. Given the inherent stochastic nature of rice production, the stochastic frontier production function approach was used to assess

RESULTS AND DISCUSSION

Socio-economic Characteristics of Female Farmers

The result in Table 1 showed that mean age of female farmers was about 36years. This implies that most of the female farmers participating in the production of rice in the study area were within the active age group. I also revealed that about 41% of the female farmers acquired no formal education. The result further showed that 62.22% of female rice farmers were married. This shows that the majority of the female farmers were married. Similar result was obtained by Bamiro and Aloro (2013) that more married couples were involved in rice production largely because of high demand for labour. As shown in the table, female farmers in the area had a mean house-hold size of about 7.

Technical Efficiency of Female Farmers

Technical efficiency is the ability to produce a given level of output with a minimum quantity of inputs under certain technology. It represents the ratio of observed output to the corresponding frontier output (Bamiro and Aloro, 2013). The Maximum Likelihood estimates of production parameters for the female rice-farmers are shown in Table 2. The value of gamma (γ) was 0.713 and statistically significant at 1% level indicating that 71.3% of variation in rice output was as a result of the technical in-efficiency of the female farmers. Also, the sigma squared value was statistically significant at 1% level. This implies a good fit of the model used, and that the conventional production function is not an adequate representation of the data. The Likelihood ratio test confirmed the presence of technical in-efficiency in the rice production by female farmers as shown in Table 3.

The result in Table 2 revealed that farm-size, fertilizer, and hired-labour were statistically significant determinants of rice output at 1% level. Family-labour had a significant effect on rice production at 5% level. Farm-size had a significant and positive influence on the output of rice by the female farmers. This implies that the output of rice increases with an increase in farm-size. Ayoola *et al*. (2011) similarly observed that access to adequate farm-land had a significant and positive effect on rice production especially of female farmers.

Moreover, Table 2 showed that the factors which contributed to the technical in-efficiency of female farmers include education, farming experience, and farmer's access to credit facilities. Access to formal education has been observed by previous researchers as an important factor that influence farmer's efficiency (Onu *et al.*, 2000; Adebayo, 2001; Oladeebo and Fajuyigbe, 2007; Onu and Adebayo, 2010; Ahmadu and Erhabor, 2012; Ogunniyi *et al*., 2012). The result suggests that with improvement in education, the technical efficiency of the farmers will be improved.

The study also showed that female farmers tend to be more technically efficient with more years of farming experience. As a farmer's experience increases, so do his skills in optimally allocating the resources at his/her disposal. The more experience a farmer has, the higher the technical efficiency. Similar findings were reported by Ogunniyi *et al*. (2012) and Ayinde *et al.* (2012). Furthermore, the availability of credit facilities was statistically significant at 1% level, and had a great influence on the technical efficiency of the farmers. Bamiro and Aloro (2013) also identified credit availability as having positive relationship with the technical efficiency of rice farmers. The result in Table 4 revealed that the technical efficiency of female farmers ranges between 0.43 and 0.98 with a mean value of 0.84 which implies that on the average, female rice-farmers had the capacity of increasing their production by 16% given the existing technology.

CONCLUSION AND RECOMMENDATIONS

The study established the existence of technical in-efficiency in the production of rice by female farmers in the study area. The socio-economic factors which contributed to the technical in-efficiency of female farmers include educational status of the farmer, farming experience, and access to credit facilities. The research findings showed that farm-size, fertilizer, and hired-labour were statistically significant determinants of rice output of female famers at 1% level. Family-labour had a significant effect on rice production at 5% level. It was therefore recommended that Government policy should emphasize measures that promote women farmers' access to agricultural resources and services at affordable prices thereby bridging the existing gender gap among rice-farmers in Nigeria.

ROLE AND CONSTRAINTS OF RURAL WOMEN IN AGRICULTURAL DEVELOPMENT IN ABIA STATE, NIGERIA

M. Mazza
National Root Crops Research Institute Umudike, Abia State
Email: ***maryann.mazza@yahoo.com***

ABSTRACT
The study investigated the role and constraints of rural women in agricultural development in Abia State, Nigeria. Multiple random sample technique was employed to select a sample size of 120 respondents (rural women) used for the study. Primary data were generated through structured interview schedule, and analyzed with descriptive statistics such as frequency table, percentage and mean scores. The study revealed that majority of the rural women in the area are literate, have average age of 39 years, and have average farming experience of eighteen years. They also have average household size of 7 persons. From the study the major roles of rural women in agricultural production were planting, weeding, sanitation in farm houses, transporting of produce, land clearing, fertilizer application, harvesting, processing, feeding of livestock and marketing. Major constraints faced by rural women in agricultural development are inadequate capital, excessive workload, lack of agricultural inputs, lack of credit facilities, inadequate land, low soil fertility, poor road network and inadequate extension services. It is therefore recommended that women should be economically empowered by provision of loan and credit facilities to support their efforts in agriculture.
Keywords: Role, constraints, rural women and agricultural development

INTRODUCTION
Many rural women depend on agricultural sales for their livelihood to provide for their families. Large number relies on agricultural products for daily nourishment. Unfortunately, in many areas in Abia state, soil conditions, seed supply and other factors are not ideal for successful farming, which leads to poverty. Agricultural development promotes the proper conditions for farming so that planting, harvesting and processing of crops can be done effectively, which ultimately can reduce poverty and save lives (WISEGEEK.com, 2014). Similarly, Okereke (2013) stated that agricultural development means providing assistance to the crop producers with the help of various agricultural resources. It also includes helping out farmers with regard to animal agriculture, rotational grazing which extends benefits for the protection of natural resources, preserving water by managing livestock, utilization of forage crops right through season and quality production.
Rural women in Nigeria make a significant contribution to food production and to the processing and marketing of foodstuffs (Adekanye, 2013). They produce 60 – 80 percent of food in the country, provide about 80 percent of agricultural labour force and contribute to well being of their households through their income generating activities (Rahman *et al*., 2004). However, these rural women still face formidable challenges to their potential role as a major economic and social force in agricultural development. It is against this background that this study was undertaken to ascertain the roles and constraints of rural women in agricultural development.

METHODOLOGY
The study was carried out in Abia State, Nigeria. It is one of the states in south-eastern Nigeria. The state has a total land area of about 8,000 square kilometers and a population of about 2,833.999 made up of 1,454,195 males and 1,599,806 females and population density of 578 persons per square kilometer (NPC, 2006). Unstructured interview and structured questionnaire were employed in data collection. Multistage random sampling technique was used in selecting 120 rural women from the three agricultural zones of the state namely Aba, Ohafia and Umuahia. Two extension blocks were randomly selected from each zone and two circles from each block. A total of ten rural women were randomly selected from the list of women in each of the selected circles and administered copies of structured questionnaire. Data collected were analysed using descriptive statistics such as frequency, percentage, mean score and role index using a 3 point likert type rating scale of Never involved = 1, Rarely involved = 2, Always involved = 3. The mean score for each of the activities were calculated; any mean score equal to or above 2.0 means full participation. Constraints were realised also with mean score using a 3 point likert type rating, weighted in these order: never – 1, mild – 2 and severe = 3. Mean score response equal to or above the calculated mean score of 2.0 were regarded as major constraints.

RESULTS AND DISCUSSION
Socio-Economic Characteristics
Results in Table 1 show that the rural women had average age of 39 years. This shows that the women are strong and active in agricultural activities. They have mean household size of seven persons. This implies that the women

have large household size. Large household size is an indication of availability of family labour. Adegbite *et al* (2008) stated that large household size in farming communities provide free family labour on the farm. From the result the women had average farming experience of eighteen years. Years of farming experience gives an indication of practical knowledge acquired on how the individual can overcome certain inherent problems associated with farming (Iheke, 2010).

Role of Rural Women in Agricultural Activities

Table 2 shows the role of rural women in agricultural activates in Abia State, Nigeria. The result shows that the major roles of rural women in agricultural activities were planting (2.9), weeding (2.9), sanitation in farm houses (2.9), transporting of produce (2.8), land clearing (2.6), fertilizer application (2.7), harvesting (2.8), processing (2.7), feeding of livestock (2.6) and marketing (2.6).

Constraints of Rural Women in Agricultural Development

Table 3 shows the constraints of rural women in agricultural development. The results revealed that the major constraints faced by rural women in agricultural development were inadequate capital (2.8), excessive workload (2.7), lack of agricultural inputs (2.6), lack of credit facilities (2.5), inadequate land (2.4), low soil fertility (2.3), poor road network (2.2) and inadequate extension services (2.1). These constraints retard women's efforts in enhancing agricultural production, especially the problem of excessive workload. This is in line with the report of CTA (2010) that, despite the efforts of rural women to combine income-generating activities with unpaid household responsibilities, the burden of work form a considerable constraint (in terms of time, mobility and energy) at the expense of their health, well-being and productivity. Other constraints were pest and diseases (1.8), lack of electricity (1.6), poor storage facilities (1.5), low technical know-how in use of technologies (1.4) and poor marketing channels (1.3).

CONCLUSION

The findings revealed that the rural women in the study have average age of 39 years, literate, and had an average farming experience of eighteen years. They have average household size of 7 persons. The study shows that the major roles of rural women in agricultural production were planting, weeding, sanitation in farm houses, transporting of produce, land clearing, fertilizer application, harvesting, processing, feeding of livestock and marketing. Major constraints faced by rural women in agricultural development are inadequate capital, excessive workload, lack of agricultural inputs, lack of credit facilities, inadequate land, low soil fertility, poor road network and inadequate extension services. It is therefore recommended that women should be economically empowered by provision of loan and credit facilities to support their effort in agriculture.

ABSTRACT
Women take part actively in farming activities in addition to their domestic and reproductive responsibilities. However, it has traditionally been difficult for them to obtain production resources necessary for farming. The study was thus designated to assess the production constraints among women cassava famers in Oluyole local government area, Oyo State with a view to specifically describe the socio-economic characteristics of women cassava farmers; assess the contribution of women cassava farmers and identify the constraints faced by women in cassava production. Multi-stage sampling was used to select one hundred and twenty (120) women cassava famers. Descriptive and inferential statistics were employed for data analysis. The result revealed that the mean age of the women cassava famers was 47 years, 72.5% were married, 38.3% had secondary education and majority cultivating on a mean farm size of 2 acres. The constraints encountered by the respondent in the study area include difficulty in land acquisition, unavailability of planting materials, lack of access to credit facilities and extension agent. The study further revealed that marital status and age have significant relationship with constraints faced by women cassava farmers. It is thus recommended that women cassava farmers should be encouraged with provision of necessary modern farm tools to enhance good production.
Keyword: cassava, constraints, women farmers, resources and contributions.

INTRODUCTION

The role women play in agriculture and rural society is fundamental to agricultural and rural development in Nigeria. They play a vital role in food production and food security. FAO (2006) estimated that the rural woman contribute two-third of all the time that is put into traditional agriculture in Africa and 80% of the Yoruba women of the South-Western Nigeria are engaged in farm work growing yams, maize, tobacco, cassava, poultry and fish farming. They also participate in bush clearing, land preparation and weeding in addition to their role in processing and marketing farm produce. Women account for 70% of agricultural workers, 80% of food producers, 100% of those who process basic foodstuffs and they undertake from 60% to 90% of the marketing (Fresco, 1998) and this is why Mgbadu (2002) described Black Africa as the region of female farming per excellence.
Adegeye et al., (2002) asserted that women are active in the cassava industry and that they are more predominant in the processing and marketing than men folk who dominate the production of cassava roots. He further stated that women activities in root production have increased due to men's off farm employment or part-time work off the farm therefore. Women now involve in weeding, harvesting, transportation, storage, processing and marketing. In spite women heavy involvement in agriculture, they are generally faced with a lot of challenges such as social, economic and cultural barriers which limits their opportunities for broad participation. Folasade (1991) emphasized that lack of separate land for women and inadequate contact with extension agents are serious constraints faced by women farmers. Women generally do not own land or other assets and it has traditionally been difficult for them to obtain Bank loans or other forms of credit through the banking system because land tenure system is largely by inheritance. This lack of title to land, according to (Famoriyo, 1979) prevents women from exercising or improving on their expertise in crop production and animal husbandry. With these numerous constraints against women, assessment of production constraints among women cassava farmers is thus important in order to improve women efficiency in agricultural activities. The specific objectives of this study were to describe the socio-economic characteristics of women cassava farmer, assess the contribution of women cassava famers and identify the constraints faced by women in cassava production in the study area.

Hypothesis

Ho – There is no significant relationship between socioeconomic characteristic of women cassava farmers in the study area and constraints faced in cassava production.

METHODOLOGY

The study was carried out in Oluyole Local Government area of Ibadan Oyo State and the population targeted were rural women that engage in cassava production. The sample frame of women who engage in cassava production in six villages randomly selected under the study area was drawn. Twenty (20) cassava women farmers were randomly selected from each of the villages which include (Idi-ayunre, Aba-nla, Aba – Agbo, Olubadan, Olounde, Oke – Ibadan) respectively making a total of 120 respondents used for the study. Primary data were obtained through the use of structured questionnaire and data collected were on the women's socio-economic characteristics, their contribution and constraints. These data were subjected to descriptive and inferential statistics.

RESULTS AND DISCUSSION

Socio-Economic characteristics of respondents

Table 1 shows that the mean age of women cassava farmers in the study area was 47 years but specifically, 25.8% were in the age range 31-40 years, 21.7% were between 41-50 years and l5.0% were less than 30 years of age. This indicates that 62.5% of the respondents fall within the age group of 50 years or less. Over seventy percent (72.5%) of the respondents in the study area were married, 20.0% were widow and 7.5% were single. This indicates that married people look for more ways of making money to cater for their families. Approximately 46% of the respondents in the study area had household size between 4-6 members, 38% between 7-9 members while 11.0% had 10 and more members. Also, table 1 reveals that 38.3% of the respondents had secondary education, 37.5% had primary education and 11.7 had adult education. In terms of experience, 49.2% of the women cassava farmers had 10-15 years of experience and 28.3% had 6-10 years. The mean experience was 9 years. This shows that the women cassava farmers were not new in the production business and it has been argued that more experienced producer could predict the future outcome of production with some probability by considering performance of past years.

Contribution of women to cassava production

Table 2 reveals that about 46.7% of the respondents spent 3 – 4 hours in a day while 35.8% of the respondents spent 5- 6 hours. The mean hour per day was 4 hours and it could be inferred that relatively more time is spent on farm by these women when other domestic chores are put into consideration. Majority (78.4%) cultivated between 1-2 acres of land, 15.9% cultivated 3-4 acres while 13.0% cultivated 5-6 acres. This indicates that most of the women cassava farmers in the study area cultivated small acres of land as mean acre cultivated was 2 acres. This could be attributed to the fact that most of them got their farm land by rent and the available land was shared among larger number of people which resulted to having access to small acres of land. Also, 41.7% of the respondents harvested between 7-8 tonnes of cassava per annum, 33.3% harvested between 9-10 tonnes while 12.5% harvested 4 tonnes or less. The mean harvest per annum was 7 tonnes and as part of the respondents' contribution to cassava industry, more than three quarter (75.8%) engaged in processing aside production. Thus indicates that most of the women engaged in both production and processing of cassava.

Constraints that women faced in cassava production

Table 3 shows that more than half (54.2%) of the respondents find it difficult to acquire farm land while 45.8% of the respondent do not find it difficult to acquire farm land in the study area. This is so because majority (57.5%) acquired farm land by rent and there was no easy access to farm land. Majority (81.7%) of the respondents were using manual farm implements while 18.5% of the respondents use hired tractor to perform their land preparation. This indicates that the level of production will be low for majority and they will not be able to cultivate more farm land even if it is available. It was also reveals that unavailability of planting materials contributes to the constraints faced by women cassava farmers in the study area as 71.7% find it difficult to get good painting materials while 28.3% do not find it difficult to get good planting materials. Higher percentage (53.3%) of the respondents suffer from insufficient credit facility and this indicates that even with access to cooperative loans by some, it is still not enough for them to carry out their farming operation successfully. Table 3 further revealed that majority (71.7%) of the respondents never had contact with extension worker. This agrees with the report of Swanson *et al*., (1984) that women cassava farmers had little or no contact with extension service.

Hypothesis Test Result

Table 4 shows that education and Household size were greater than 0.05 significance value. Thus, there is no significant relationship between them and constraints women cassava farmers faced in the study area. However, marital status and age have P-value less than 0.05 significant value. Thus, there is significant relationship between them and constraints women cassava farmers faced in the study area.

CONCLUSION AND RECOMMENDATION

The overall result of this research work showed women cassava farmers with mean age of 47 years dominate cassava production in the study area cultivating on a mean farm size of 2 acres. It was revealed that on average, they spent 4 hours per day on farm and engaged in processing asides production. Most of their activities were carried out using manual or traditional methods and this was due to general economic challenges of women cassava farmers in the study area. This study further reveals that marital status and age have significant relationship with constraints faced by women cassava farmers in the study area. Base on the study therefore, women cassava farmers in the study area should be encouraged with provision of necessary modern farm tools to enhance good production as majority engaged in manual farming.

ABSTRACT
Gender Sensitization workshops were conducted in 2015 in twelve (12) communities in Kwali and Bwari Area Councils of the Federal Capital Territory (FCT) Abuja, Nigeria. The purpose was to sensitize the project partners and communities involved in the Community Action in Famers Saved Seed Yam (CAY-Seed) project in Nigeria on the need for equal participation of gender groups in seed yam production. Qualitative data were collected by the use of mixed methods, and analyzed with descriptive statistics. Results showed that both male and female farmers participate in seed yam production and marketing, most of the project partners and community members had no previous knowledge of gender. Women play more roles in seed yam production than men and youth. However, some of these roles played by women are complementary roles whereas the men and youth do most of the physical activities. Men have complete access and control of productive assets and income from seed yam production. Women are mainly engaged in the marketing activities even though they do not have access and control of money realized from the sales. The major constraints to seed yam production in the communities include: pests and diseases attack, scarcity of clean seed yams, poor soil fertility, low level of mechanization, and poor infrastructural facilities. It was recommended that more sensitization is required to educate the people on the need to be gender sensitive in their production and marketing activities and also to enhance the women's access and control of productive resources. In so doing, women's potential will be fully exploited to increase productivity and income from seed yam production in the study areas.
Key words: Communication, gender, marketing, production, seed yam, sensitization

INTRODUCTION
Empirical reports have shown that technology development and transfer processes have been gender insensitive and tend to overlook the complex needs and livelihood realities of rural women in agricultural production but concentrate on that of the men (Ironkwe, 2011). This process has failed to recognize the roles and constraints of the various gender groups involved in agricultural production. Consequently, the results of such projects are not sustainable, hence low productivity resulting from low adoption of such technologies developed (Ekop, 2001). Women are farmers, workers and entrepreneurs, but almost everywhere they face more severe constraints than men in accessing productive resources, markets and services. This "gender gap" hinders their productivity and reduces their contributions to the agriculture sector and to the achievement of broader economic and social development goals. Closing the gender gap in agriculture would produce significant gains for society by increasing agricultural productivity, reducing poverty and hunger and promoting economic growth.
Women farmers are often not as efficient as they should be because gender relations frequently do not allow them to be effective decision-makers. Many agricultural policy and project documents still fail to consider basic questions about the differences in the resources available to men and women, their roles and the constraints they face – and how these differences might be relevant to the proposed intervention. Moreover, the implementers of most agricultural projects, are not gender sensitive as a result, it is often assumed that interventions in areas such as technology, infrastructure and market access have the same impacts on men and women, when in fact they may not.
In most parts of Nigeria, yam is regarded as a man's crop, simply because it is a food security crop and huge revenue earner. Women's contribution to yam production is not recognized in the communities. Some research results show that gender is significant and positively related to technical efficiency in yam production with men reported to be more technically efficient (Simonyan and Obiakor, 2012), but the reasons for this is not highlighted in view of the social diversity that exists among the communities. It therefore became necessary to consciously engage and build capacity of women in seed yam value chain. To do this, a programme to sensitize the rural people on gender issues becomes paramount.

Gender sensitization according to Sharma (2014) refers to the modification of behavior by raising awareness of gender equality concerns. It may be seen as the awareness which informed disposition or propensity to behave in a manner which is sensitive to gender, justice and equality issues. Gender awareness therefore requires not only intellectual understanding and effort but also sensitivity and open-mindedness to change one's views and limited perspectives and values. It opens up the widest possible range of life options for both females and males and builds their capacities to be more wholesome and human.

CAY-Seed project is a community action project that aims at improving the quality of farmers saved seed yam for increased and sustainable yam production in the country. As a development project, it aims at a gender responsive research that involves all gender groups in the development, implementation, monitoring and evaluation of its project activities for the benefit of men, women and youths. One of the components of the project is on Gender and Social Dynamics in seed yam production which conducted gender sensitization workshop for the project partners, and the communities participating in the project in the study areas.

Objectives

- To sensitize project partners and communities on the need for equal participation of gender groups in seed yam production.
- To identify gender training needs of the project partners.
- To identify the roles of males and females in seed yam production and marketing.
- To identify their major constraints in seed yam production.

METHODOLOGY

Twelve (12) farming communities were purposively selected from 2 Area Councils in FCT Abuja Nigeria where Yam Improvement for Income and Food Security in West Africa (YIIFSWA) project operated before. The communities in Kwali Area Council include: Kwali, Ijah Sariki, Leleyi Gwari, Kilankwa 1, Kilankwa 2 and Chikuku while those in Bwari Area Council are: Yaupe, Sunape, Panunuke, Guto, Kuzhako, and Tokulo.

Also, a total of 18 CAY-Seed project partners drawn from collaborating institutions like NRCRI Umudike, IITA, Ibadan and MSHR, Abuja were sensitized on gender issues. Qualitative data were collected by the use of mixed methods such as Focus Group Discussions, gender lens, observations, and structured questionnaires from the community members and project partners. Data were analyzed with descriptive statistics.

RESULTS AND DISCUSSION

Results showed that 84% of the project partners had no previous knowledge of gender. Those that knew about it had not given gender issues any kind of serious attention. This revealed the relevance of the sensitization on making the partners gender sensitive in carrying out the project activities. Among the gender training needs identified from the project partners are: gender mainstreaming in project activities, gender roles, needs and constraints in agriculture, gender disaggregation of data and gender based analysis are the most important (Table 1).

In the 12 communities, a total of 715 community members were sensitized. By Area Council, more youths attended the gender sensitization in Kwali while women dominated that of Bwari. On the whole, 334 participants representing 46.71% came from Kwali Area council while 381 representing 53.29% came from Bwari (Table 2).

Result of the study showed that almost all the participants were not gender sensitive in their production processes and relations. In seed yam production activities, it was discovered that women in the communities indirectly play more roles than other gender groups. Although men, do most of the physical activities such as land preparation and harvesting, women also join them but may not do as much as men. In addition to this, women prepare food, fetch drinking water to the farm and take care of the children. The activities of women complement those of men in almost all the areas of production (Table 3).

In the communities, there are specific responsibilities for men, women and the youth. Men in most cases take the responsibility of family upkeep and use of resources including farm incomes, while women are responsible for family care including children needs and food with the youth complementing the responsibilities of the men or women depending whether a boy or girl is involved. Most decisions are taken by the men, the women may contribute if given the opportunity but their contributions are not binding on the men. The youths are not involved in decisions except in female headed households. Men have full access and control of all household resources including labour. In some cases, women and youth have access but no control over family resources. However, in female headed households, the women have limited control but full access.

Major constraints in seed yam production in the study area

The major constraints to seed yam production in the communities include the following:

- ✓ Pests and diseases attack
- ✓ Scarcity of clean seed yams
- ✓ Poor soil fertility
- ✓ Low level of mechanization

- ✓ Poor infrastructural facilities

CONCLUSION

Gender based activities of the CAY-Seed project undertaken in 2015 in Nigeria has shown that women and youth in the seed yam producing communities have not been allowed to express their full potentials. Men acknowledge the importance of women and youths in the household farming activities. Also, most of the project partners are beginning to appreciate the need to give all the gender groups equal opportunities to participate in their primary duties and project activities. With further sensitizations, the communities and project partners will gradually begin to mainstream gender in their project activities.

ACKNOWLEDGEMENT

The authors most sincerely acknowledge the CAY-Seed project management and Bill and Melinda Gates Foundation for sponsoring this research work. We also appreciate all the project partners in Nigeria (NRCRI, Umudike, IITA, Ibadan and MSHR, Abuja) and all the farmers in the communities where this project is being implemented for their cooperation.

ABSTRACT
Imo State is one of the States where rice is produced in southeast Nigeria. In recent times, rice production in the area has fallen short of the demand due to low yield ascribed to low adoption of improved production technologies disseminated by the Agricultural Development Programme (ADP) of the State. This study was undertaken to investigate the adoption of improved rice production technologies in Imo State of Nigeria. Random sampling technique was used in selecting one hundred and thirty (135) rice farmers from the communities where rice is produced in the State. Data were collected with the aid of a well-structured questionnaire, and analyzed using descriptive statistics. The result obtained shows that 73.33%, 67.41%, 78.52%, 86.67%, and 45.4% of the rice farmers adopted improved rice varieties, use of agrochemicals, fertilizer application, optimum seed rate, and mechanical harvesting respectively. The result also identified constraints such as lack of fund and credit facilities (97.04%), tediousness of the technology and risk involve (84.44%), high cost and scarcity of labour (74.81%), poor government support (93.33%) and low farm income (85.19%) militating against the adoption of improved technologies in rice production in the State. human/technology attributes, technical constraint, financial constraints, and poor institutional support as major constraints to adoption of improved rice production technologies in the State. Necessary recommendations such as designing improved rice production technologies that reflect the socio-economic attributes, and complementing agricultural innovations with proper institutional framework for credit mobilization were made.
Keywords: Adoption, Rice Technologies, Farmers, Imo State, Nigeria

INTRODUCTION
The domestic production of rice in Nigeria has not met the demand, leading to food shortage problems. Estimated national demand for rice is put at 5.2 million ton per annum, production is estimated at 3.3 million ton leaving a demand gap of 1.9 million tons which is imported with the attendant drain on foreign reserve (FMARD, 2011). This gap has continued to increase relative to demand. As a result, the Nigeria government invested on developing improved rice varieties for farmers so as to increase production and cut importation of rice. For instance, the National Rice Development Strategy (NRDS) was established to improve domestic production by encouraging farmers to adopt improved rice varieties (NRDS, 2009). To enhance the adoption improved rice varieties and technology options for rice production, and increase the production level of rice, Nigeria also adopted the African Rice Initiative (ARI). African Rice Initiative was established in 2002 to promote the dissemination of improved technologies in rice production in many countries in Sub-Saharan Africa. The Federal Government of Nigeria launched the Presidential Initiative on rice in 2003 aimed at increasing rice production, processing and export. Also, the Federal Government of Nigeria in 2011 launched the Rice Transformation Agenda. The goal of the Rice Transformation Agenda was self-sufficiency in rice production and complete substitution of imported rice by year 2014 (FMARD, 2011). The Rice Transformation Agenda adopted the value chain approach, identified and organized rice farmers to readily access inputs such as improved seeds, fertilizer, agrochemicals and modern methods of rice production from extension services. However, despite all these efforts, research findings still indicate that rural farmers in most cases find it difficult to obtain improved rice production inputs that are suitable to their local conditions (Awotide *et al.*, 2012a; Awotide *et al.*, 2012b; BATNF, 2015). To date, farmers in rural areas especially in southeast Nigeria are still planting non-improved rice varieties despite the availability of improved ones (Onumadu and Udemgba, 2012; Onumadu and Osahon, 2014). This could have negative effect of adoption in view of the fact that if a farmer does not have access to improved varieties, adoption would be impossible and there would be no yield increase.

METHODOLOGY
The study was carried out in Imo State, Nigeria. Imo State is in the southeast zone of Nigeria. The State is made up of twenty seven Local Government Areas and three agricultural zones- Owerri, Orlu and Okigwe agricultural

zones. Imo State lies between latitude 5°12′ and 5°56′ North of the Equator and between longitudes 6°38′ and 7°25′ east of the Greenwich Meridian. It is bordered by Abia State on the east, by the River Niger on the west, by Anambra State on the north and River State on the south. Imo State occupies a land mass of about 5,530 km^2 with a total population of approximately 3.9 million persons (NBS, 2006). Ideato North, Ihitte Uboma, and Oguta Local Government Areas (LGAs) are the LGAs where rice is grown in Imo State. Two-stage random sampling techniques was adopted in the selection of respondents for this. Firstly, three communities were randomly selected from each of the LGAs where rice is cultivated in the State. Secondly, fifteen (15) rice farmers were randomly selected from the communities, making a total of one hundred and thirty five (135) respondents for the study. Structured questionnaire was administered on 135 selected rice farmers. Data collected were analysed using descriptive statistics.

RESULTS AND DISCUSSION

Adoption of Rice Production Technologies

Adoption of improved rice production technologies is presented in Table 1. The table shows that 73.33% of farmers adopted improved rice varieties. This implies that improved rice varieties assist farmers in increasing the yields and production of rice. Adoption of improved varieties by farmers will mean more than just increased rice production and reduced imports, but will contribute to food security and poverty reduction among farmers (Nweze, 2004). Table 1 reveals that 78.52% of rice farmers adopted fertilizer use/application in rice production. Unamma *et al.* (1985), in a survey on farming systems in Nigeria, reveal that fertilization of crops was not new to over 91% of surveyed farmers. This implies that fertilizer plays an important role in faster growth and maturity of improved rice varieties. The amount of fertilizer applied in rice cultivation depends on the qualities and level of residual nutrients in the soil (Maduakor, 1991). The table shows that 45.4% of the farmers adopted modern milling/processing in improved rice technology. The implication is that farmers make more profit since there is the potential to produce clean, less broken, polished rice with improved milling/processing. Rice milling /processing removes the husk and the bran layers from paddy to produce whole white rice kernels that are sufficiently milled, free of impurities and contain a minimum number of broken kernels. Small proportions (26.67%) and (14.07%) of the farmers adopted improved line spacing and ideal planting depth respectively in improved rice production. However, the table reveals that greater (86.67%) percentage of the farmers adopted optimum seed rate. Improved rice planting methods provide advantages in terms of better weed control, more uniform maturation of the plants, higher grain yield under intensive management, and more efficient use of the land for rice innovation system (Barker *et al.*, 1985). The study reveals that 67.41% of the farmers adopted agrochemicals (seed treatment, use of insecticides and fungicides, pest and disease control methods) in improved rice production. Pest and disease attacks are serious problems in rice production (Ekeleme *et al.*, 2008). Pest and disease can cause significant yield loss in rice production. There is need for knowledge of pest ecology and dynamics to allow minimal loss of rice yield to pests and diseases in rice innovation system. About 14.81% of the farmers adopted mechanized harvesting in rice production. Harvesting is a major operation among actors in rice innovation system (Nkama, 1992).

Constraints to Adoption of Improved Rice Production Technologies

Table 2 shows the distribution of rice farmers according to constraints to adoption of improved technologies. Majority of the rice farmers indicated lack of fund and credit facilities (97.04%), tediousness of the technology and risk involve (84.44%), high cost and scarcity of labour (74.81%), poor government support (93.33%) and low farm income (85.19%) as the problems militating against the adoption of improved technologies in rice production in the area. This is an indication that the adoption of improved rice production technologies will be improved if such factors as lack of fund and credit facilities, tediousness of the technology and risk involve, high cost and scarcity of labour, poor government support and low farm income are addressed in the area.

CONCLUSION

Improved rice production technologies adopted by rice farmers in Imo State are use of agrochemicals and fertilizers, and improved rice varieties. Lack of fund and credit facilities, tediousness of the technology and risk involve, high cost and scarcity of labour, poor government support and low farm income are the major problems militating against the adoption of improved rice production technologies in the area. The adoption of improved rice production technologies will be improved if such factors as lack of fund and credit facilities, tediousness of the technology and risk involve, high cost and scarcity of labour, poor government support and low farm income are addressed in the area.

Table 1: Distribution of rice farmers according to adoption of rice production technologies

Improved technologies	Frequency	Percentage
Improved rice varieties	99	73.33
Improved line spacing	36	26.67
Planting depth	19	14.07
Use of agrochemicals	91	67.41
Fertilizer application	106	78.52
Mechanized harvesting	20	14.81
Improved nursery	11	8.15
Timely transplanting	18	13.33
Optimum seed rate	103	86.6
Modern rice milling	49	45.4

YOUTH INVOLVEMENT IN AGRICULTURAL PRODUCTION: FACTORS THAT INFLUENCE CREDIT ACCESSIBILITY AMONG RURAL YOUTHS IN AKWA IBOM STATE, NIGERIA

S.B. Akpan, I.V. Patrick & S.U. James

Department of Agricultural Economics and Extension, Akwa Ibom State University, Nigeria
E-mail: brownsonakpan10@gmail.com

ABSTRACT
The study determined factors that influence rural youths' access to credit in Akwa Ibom State. Data were collected from 300 youths spread across the rural areas of the State. The Logit model estimates revealed that household size, membership in social organization, non-farm income and commercial purpose of farming were positive determined of credit access among youth farmers in the study area. On the other hand, marital status, education, land tenure and farming experience of youths were negative determinants of credit access among youth farmers. Based on the result, it is recommended that, a sound family welfare package should be design in the rural communities to check excessive household expenditures among youth farmers. Also, social capital formation should be encouraged among youth farmers in the region.
Key words: youth, agriculture, credit, accessibility, Akwa ibom

INTRODUCTION
Many analysts believed that agricultural sector is naturally endowed with enormous potentials to absorb unemployed and surplus labour from other sectors of the economy (Akpan, 2010, Naglers and Wim 2014 and Temirbulatova and Moara 2015). Nigeria has vast natural resource potentials in agricultural sector that could sufficiently engross the surplus labour in her economy. However, the manner agricultural innovations are package and presented to farmers to an extent determined farmers' involvement in agricultural activities. Farm credit is example of an agricultural innovation that is essential for agricultural production, and with it, farmers can secure farm inputs such as; farm equipment and hired labour among others and explore the abundant opportunities in the sector (Oladeebo and Oladeebo, 2008, Odoh, *et al.,* 2009). Following the important of credit in agricultural system, tiers of government in Nigeria have attempted to stimulate youths' interest in agricultural production through provision of credit facilities. For instance, in 2008, the Akwa Ibom State government set up a micro credit scheme to assist youths engaged in the agricultural production. Also, in 2011, a gender specific skill development scheme was enunciated to help improve the wellbeing of enterprise female youths in the state, through the provision of soft loans to beneficiaries. Recently, in 2016, the Akwa Ibom State government guaranteed soft loans to poultry farmers and supply varieties of farm inputs. Despite these few incentives; literature still provided evidence of poor credit accessibility among rural farming households in the State (Nwaru et al., 2011 and Akpan et al., 2013). The result of insufficient credit among youth farmers has led to decline in youths' involvement in agricultural activities in recent years and the off-farm income activities have risen instead. The over- all impact of the scenario is the disguised unemployment generated among youths in the urban centers and the underutilization of farm resources in the rural area.

Farm credit is widely recognized as one of the intermediating factors between adoption of farm technology and increase farm income among rural farmers in Nigeria (Akpan *et al.,* 2013). It is one of the fundamental ingredients of sustainable agricultural production; as such its accessibility and demand are among the prerequisites for attaining the national goal of reducing rural poverty and ensuring self -sufficiency in food production in the country (Nwaru *et al.,* 2011 and Akpan *et al.,* 2013). Many researchers have analyzed farm credit in relation with farm household in Nigeria. For instance, Jeiyol et al., (2013) examined various issues related to access to credit by both male and female crop farmers in Benue State. The estimated Logit model revealed that farmers' household expenditure; cost of hired labour, farm size and farm income were significant determinants of access to credit among male and female farmers. Similarly, Akpan et al., (2013) examined the determinants of access and demand for credit among poultry farmers in Ikot Ekpene, Akwa Ibom State. The result revealed that, farmers' age, gender, farm size, membership of social organization, extension agent visits, distance from the borrower's (farmer) resident to lending source, years of formal education and household size are important determinants of access to credit. Recently, Agbo et al., (2015) examined the access to credit by vegetable farmers in Owerri, Imo State. The Logit results showed that education, land tenure, household size, off-farm income and farming experience had significant relationship with farmers' access to credit. However, the few literature reviewed have not dealt with youth farmers. On that premised, this study is designed to identify factor that influence accessibility of farm credit among youth farmers in the study area.

METHODOLOGY

The Study Area, Data Source and Sampling Technique

The study was conducted in Akwa Ibom State. The state is located in the Southern region of Nigeria. It is located between latitudes 4°32[1] and 5°33[1] North and longitudes 7°25[1] and 8°25[1] east. It has a total land area of areas of 7,246km^2. The mean annual temperature of the state lies between 26°C and 29°C and average sunshine of about 1,450 hours per year. Primary data were used and respondents were youths. Combination of sampling methods was used to select respondents. Hence, a total of three hundred (300) rural youths were randomly sampled and used for data collection. Youth farmers are those farmers that fall in the category of 15 – 35 years as defined by the National Youth Council of Nigeria.

Empirical Model

A binary Logit model was used to identify factors that influence probability of youths' access to credit sources (both formal and informal sources) in the study area. Implicitly, the specify model is shown in equation 1:

$$ACC = \left(\frac{P_i}{1-P_i}\right) = Z_i = \beta_0 + \beta_1 EDU + \beta_2 HHS + \beta_3 MAR + +\beta_4 SOC + \beta_5 LAO + \beta_6 FIN + \beta_7 NFI + \beta_8 EXT + \beta_9 PUR + \beta_{10} COS + +\beta_{11} EXP + U_i \ldots\ldots\ldots\ldots..\ldots (1)$$

The marginal effect of the Logit model measures by computing the derivative of the conditional mean function with respect to each explanatory variable as thus;

$$\frac{\delta P_i}{\delta X_i} = \frac{E\{Y|X\}}{\delta X_i} = f(Z_i)\beta_i = f(X\beta_i)\beta_i \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

Variables used in equation (1) are defined as follows:

ACC = Access to credit sources (1 for access and 0 otherwise); **EDU** = Formal education of Youth (years); **HHS** = Household size of farmers (number); **MAR** = Marital status of a Youth (1 for married and 0 otherwise); **SOC** = Membership of a social group (number of years); **LAO** = Land tenure (dummy; 1 for owned land and 0 otherwise); **FIN** = Last season farm income (₦); **NFI** = Non-farm income (Naira); **EXT** = Number of times in contact with extension agent()s in the last farming season; **PUR** = Purpose of farming (1 for commercial and 0 for family used); **COS** = Average wage rate per day of hired labour (₦); **EXP** = Farming Experience

RESULTS AND DISCUSSION

Factors that Influence the Probability of Access to Credit Sources by Rural Youth Farmers in Akwa Ibom State

The Logit model estimates used to identify determinants of youth access to credit sources is shown in Table 1. The diagnostic statistics revealed the log likelihood ratio of 48.55 and is significant at 1% probability level. This indicates that the specified Logit model has a strong explanatory power. The pseudo R^2 of 0.1291 shows that about 12.91% of variability in the dependent variables is associated with the specified independent variables.

The empirical result revealed that, the marginal effect of marital status of youths has a significant negative relationship with the probability of credit access among youth farmers in the study area. This implies that, a unit increase in marital status of youths' reduces the probability of credit access by 17.33% or reduces the log odd of credit accessibility by 53.91%. Married youths will likely have increase household expenditure profile, which could prevent farm expansion and investment as noted by Akpan *et al.*, (2013). Similar relationship was obtained for education. A unit increase in formal education of youth farmers reduces credit accessibility by 1.15% or reduces the odd log of credit access among youth farmers by 5.40%. The result suggests that, increase in years of education of youth farmers exposes them to alternative sources of livelihoods. In the same manner, a unit increase in land ownership among youths reduces credit access by 13.71% or reduces log odd of credit acquisition by 49.15%. This result implies that, farm land ownership is very important in sustaining agricultural activities among youths in the rural areas of the State. Land fragmentation among rural farming households is a serious impediment to positive growth of agricultural sector in Nigeria. This result calls for an urgent move to revisit the current land Act in the country and the rehabilitation of marginal lands in the country.

Also, youths' farm experience also has negative correlation with the probability of credit access among youth farmers in the study area. Hence, a unit increase in youth farming experience reduces the chance of accessing credit by 1.48% or reduces log odd of credit accessibility among youth farmers by 7.25%. Increase in farming experience connotes increase in alternative ways of handling farm operations and accessing as well as adopting more efficient innovations or technology. This reduces the demand for alternative farm input like credit.

On the other hand, the coefficient of youth farmers' membership in social organization exhibited a strong positive correlation with the probability of credit access among youth farmers in the region. This means that, increase in years of membership in social societies increases the probability of credit access by 1.47% or increases the log odd of credit accessibility by 7.34%. As opine by Akpan et al., (2013) and Agbo et al., (2015), social interaction or networking helped to spread information on credit availability among youth farmers. Similarly, increase in youth farmers' non-farm income increases the chance of accessing farm credit among them. A unit increase in non-farm income increases the probability of credit access and the log odd of credit access marginally. The finding shows that farmers are rational, and will like to increase their income continuously. Akpan et al., (2013) reported similar result in Akwa Ibom State.

The result further showed that, youths who are involved in commercial agriculture have higher probability to access farm credit compared to those who are not commercially oriented. The result indicates that, a unit increase in the commercial purpose of farming among youth farmers will result to about 13.03% increase in credit access or 94.31% increase in the log odd in favour of credit access in the region. This connotes that, commercial agriculture is an most important factor influencing youth access to farm credit in Akwa Ibom State. In a similar way, the coefficient of household size exhibited positive relationship with the probability of credit access among youth farmers in Akwa Ibom State. The result means that, a unit increase in household size will lead to about 7.44% increase in the probability of credit access by youth farmers in the study area. Alternatively, the log odd in favour of farm credit accessibility among youth farmers increases by 43.07% for every unit increase in in household size. The finding corroborates the reports of Agbo *et al.*, (2015), Akpan et al (2013) and Jeiyol *et al.*, (2013).

CONCLUSION AND RECOMMENDATIONS

The study has revealed significant policy variables that are important in formulating sound credit policies for farmers in the State. Based on the findings, it is recommended that; a sound family welfare package should be design and implemented in the rural communities to check excessive family expenditure by youth farmers. Youths' groups or social capital formation should be encouraged among youth farmers in the region. Marginal farm land should be developed and farm lands re-distributed to both male and female farmers in the State.

GENDER DIFFERENTIAL AND MARKETING EFFICIENCY AMONG RETAILER HEADS OF HOUSEHOLDS IN MINITUBER YAM MARKETING IN ABIA STATE, NIGERIA

V.O. Onyenobi

National Root Crops Research Institute Umudike PMB 7006 Umuahia Abia State, Nigeria
Email: ***onyenobivincent@yahoo.co.uk***

ABSTRACT
The study was conducted to determine the socio-economic characteristics and the factors influencing the marketing efficiency of male and female retailer heads of households in minituber yam marketing in Abia state, Nigeria. Multistage sampling technique was used for the study. Data collected from 202 retailers heads of households were subjected to simple descriptive, statistical and Ordinary Least Squares (OLS) multiple regression model. Results of the study showed that minituber yam marketing by male and female retailer heads of households in the study area was gender sensitive, profitable and efficient. Fifty-five (55.0) percent of the variations in marketing efficiency of male retailer heads of households and 52.0 percent of the variations in marketing efficiency of female retailer heads of households were significantly explained by the socio-economic variables investigated in the study area. These results called for public policy for increased gender access to improved socio-economic variables that significantly increase the marketing efficiency of the marketers in the supply of minituber yam from minituber yam producers to seed yam producers, and thereby promote economic development in terms of increase in employment, income and food security in the study area.
Keywords: marketing, mini-tuber yam , efficiency, gender

INTRODUCTION
Recent advances in the marketing of root and tuber crops in sub-Sahara Africa had laid emphasis on market participation by farmers in the marketing of cassava (Okoye, *et al*., 2010), sweet potato (Ohajianya and Ugochukwu, 2011) and potato (Sebatta *et al.* 2012). Madueke (2013) reported on market participation by male and female heads of households (middlemen) in the marketing of ware yam in Abia state. This study was directed at minituber yam marketing by male and female retailer heads of households, in order to meet the aggregate demand for minituber yam from seed yam producers, and thereby increase the output of ware yam for food consumption and industrial uses in the study area. Yam (*Dioscorea rotundata*) is an important tropical tuber crop with socio-cultural and economic values. In Nigeria, yam is ethnocentric and is designated a "king crop" among other roots and tubers (Chukwu and Ikwelle, 2000). The crop contributes significantly to national economy and rural income by providing employment to many rural dwellers (Asumugha *et al.,2010*) and cheap carbohydrate staple for over 80 percent of the populace (Nwachukwu, 2008), and reduces poverty level (Emokaro and Law-Ogbomo, 2008). In Nigeria, scarcity and high cost of seed yam are major challenges in ware yam production and marketing and the contribution of yam production to economic development. This has made minituber yam marketing by male and female heads of households assume great importance in meeting the aggregate demand for minituber yam (planting material) from seed yam producers. In Nigeria, both male farmers (74%) and female farmers (26%) adopt the minituber yam technique of seed yam production (Asumugha *et al.*, 2007). Minituber yam technique of seed yam production is more economic and more readily reduces scarcity and high cost of seed yam by supplying planting material to seed yam producers at a seed rate of 8000 stands ha^{-1} (Ogbonna *et al*., 2010) compared to the minisett technique which supplies planting material to seed yam producers at a seed rate of 40,000 stands ha^{-1} (Okoli *et al.*, 1982). Minituber yam ranges in weight from 30 to150 grams realized from 6-10 grams cut setts. It could be planted directly on ridges, mounds or beds, and the average yield ranges from 9 to 11 ton ha^{-1} (Ogbonna *et al*., 2010). It implies that, in Nigeria, effective gender roles in minituber yam production and marketing have implications for increasing the supply of minituber yam (planting material) from minituber yam producers to seed yam producers and thereby increase the production of ware yam for food consumption and industrial uses. In Abia State, efficient marketing of minituber yam by male and female retailer heads of households promotes economic development by meeting the aggregate demand for minituber yam from seed yam producers. The entire minituber yam production, distribution and marketing chain has potential to increase employment, income and food security among the marketers.

Objectives of the Study
The objectives of study were to determine the socio-economic characteristics and the factors influencing the marketing efficiency of male and female retailer heads of households in minituber yam marketing in Abia state, Nigeria.

METHODOLOGY

Data Collection

Multistage sampling technique was used for the study. The three agricultural zones in Abia State, namely Aba agricultural zone, Ohafia agricultural zone and Umuahia agricultural zone were used for the study. The 9 local government areas (LGAs) used for the study comprised 3 LGAs randomly selected from each agricultural zone. The 36 markets used for the study comprised 4 markets randomly selected from each LGA selected for the study. Ten (10) respondents were randomly selected from each of the 36 markets randomly selected for the study. The 360 heads of households selected for the study comprised 158 wholesaler heads of households and 202 retailer heads of households. The respondents were selected from a list of registered marketers (males and females) in each selected markets, with the assistance of the agricultural extension agents and enumerators assigned to the local government areas (LGAs) studied. Well structured questionnaires administered to the 202 retailer heads of households were used to collect cross-sectional primary data on socio-economic characteristics and specific marketing variables influencing minituber yam marketing in the study area.

Data Analysis

Data collected from retailer heads of households were subjected to simple descriptive, statistical and econometric analysis in order to achieve the objectives of the study. Objective i - the socio-economic characteristics of the marketers were analyzed using simple descriptive statistics such as tables, means and percentage values. Objective ii – factors influencing the marketing efficiency of the marketers were estimated using the Ordinary Least Squares (OLS) multiple regression model, based only on data from minituber yam net sellers (household heads whose net sales are positive) (Okoye *et al*., 2010; Onyenobi, 2015). The model is implicitly expressed as follows:

$Y = f(X_1, X_2, ..., X_{14}, e_i)$ ……. (1)

where:

Y = Marketing efficiency of household head (%); X_1 = Age of household head (years); X_2 = Marital status (dummy variable: 1 = married; 0 = unmarried); X_3 = Household size (number); X_4 = Educational level of household head (years); X_5 = Marketing experience of household head (years); X_6 = Cooperative membership (dummy variable: 1= member; 0 = non-member); X_7 = Access to credit (dummy variable: 1 = formal; 0 = informal); X_8 = access to market information (dummy variable: 1 = yes; 0 = no); X_9 = Transportation cost (₦ kg^{-1}); X_{10} = Loading/offloading cost (₦ kg^{-1}); X_{11} = Packaging cost (₦ kg^{-1}); X_{12} = Storage cost (₦ kg^{-1}); X_{13} = Market taxes (₦ kg^{-1}); X_{14} = Net marketing margin (income) (₦ kg^{-1}); X_1-X_{14} = vectors of explanatory variables influencing marketing efficiency of heads of households; e_i = Error term.

Four functional forms of the multiple regression model viz: the linear, exponential, semi log and double log functional forms were fitted to the data. The best-fit regression form was chosen as the lead equation for the study based on statistical and econometric criteria such as the value of coefficient of multiple determination R^2, level of significance of the overall equation (F-statistic), number and level of significance of each coefficient in the model, and sign of each coefficient relative to a priori expectations of the OLS multiple regression model. following other studies (Onyenobi *et al*. 2013; Onyenobi, 2015).

RESULTS AND DISCUSSION

Socio-Economic Characteristics of Male and Female Retailer Heads of Households in Minituber Yam Marketing in the Study Area

The socio-economic characteristics of the marketers (Table 1), indicate that minituber yam marketing by male and female retailer heads of households in the study area was gender sensitive and offered vast employment opportunities for sustained increase in yam production for food security and income in the study area.

Determination and Comparison of the Factors that Influence the Marketing Efficiency of Male and Female Retailer Heads of Households in Minituber Yam Marketing in the Study Area

Table 2 shows the OLS regression results for factors influencing the marketing efficiency of male and female retailer heads of households in minituber yam marketing in the study area, using only data on socio-economic characteristics of net sellers, following Okoye *et al* (2010) and Onyenobi (2015). Among male retailer heads of households (Table 2), the exponential log functional form was chosen as lead equation for the study. The coefficient of multiple determination R^2 of 0.5535 for the lead equation was significant based on the F-value (2.23) that was significant at 10.0 percent probability level. This indicates that 55.35 percent of the variations in marketing efficiency of male retailer heads of households were significantly explained by the variables investigated in the study area. The five (5) socio-economic variables that significantly influenced their marketing efficiency include education level, cooperative membership, packaging cost, market taxes and net marketing margin. The coefficient of educational level (-0.020) was negatively and significantly related to marketing efficiency of male retailer heads of households at 10.0 percent probability level, but not in conformity with *a priori* expectation. This implies that an increase in educational level significantly led to a decrease in marketing efficiency of male retailer heads of household in the study area. This indicates that male retailer heads of households with low formal education increased their marketing efficiency when they belonged to cooperatives.

The coefficients of packaging cost (-1.262) and market taxes (-3.478) were negatively and significantly related to marketing efficiency at 5 percent probability level, in conformity with *a priori* expectations. These imply that an increase in packaging cost and market taxes significantly led to a decrease in marketing efficiency of male retailer heads of households in the study area. The negative effects of packaging cost and market taxes on marketing efficiency of male retailer heads of households in the study area agree with other studies (Fafchamps *et al*., 2002; Anyaegbunam, 2013) on the negative effect of marketing cost on marketing efficiency in the study area. The coefficients of cooperative society membership (0.470) and marketing margin (income) (0.110) were positively and significantly related to marketing efficiency of male retailer heads of households at 1.0 and 5.0 percent probability levels respectively, in conformity with *a priori* expectations. The positive effect of cooperative society membership on marketing efficiency of male retailer heads of households is very informative because cooperative society members have more access to agricultural information, credit and other production inputs as well as more enhanced ability to adopt innovations which increase the level of efficiency in both production and marketing of agricultural produce. The positive effect of net marketing margin (income) on marketing efficiency indicates that minituber yam marketing by male retailer heads of households in the study area was profitable.

This positive effect in the marketing chain provided opportunities for employment, income and food security among male retailer heads of households in the study area.

On the other hand, among female retailer heads of households (Table 2) the semi log functional form was chosen as lead equation for the study. The coefficient of multiple determination $R^2 = 0.5241$ for the lead equation was significant based on the F-value (4.64) that was significant at 1.0 percent probability level. This indicates that 52 percent of the variations in marketing efficiency of female retailer heads of households were significantly explained by the variables investigated in the study area. The six (6) socio-economic variables that significantly influenced their marketing efficiency include household size, educational level, access to credit, transportation cost, storage cost and marketing margin. The coefficients of household size (-0.225), was negatively and significantly related to marketing efficiency of female retailer heads of households at 5.0 percent probability level, but not in conformity with *a priori* expectation. This is because female retailer heads of households with large proportions of people aged 1 to 18 years and over 60 years and invalids usually put more effort in the upbringing and upkeep of their households and less in marketing activities that increase their efficiency. The coefficients of transportation cost (-0.571) and storage cost (-1.537) were negatively and significantly related to marketing efficiency of female retailer heads of households at 5.0 percent probability level, in conformity with *a priori* expectations, and in agreement with other studies (Fafchamps *et al*., 2002; Anyaegbunam, 2013) on the negative effects of variable and fixed costs on marketing efficiency. The coefficients of educational level (0.517), access to credit (0.165) and marketing margin (0.213) were positively and significantly related to marketing efficiency at 1.0, 10.0 and 5.0 percent probability levels respectively, and in conformity with *a priori* expectations. These imply that increase in the positive effect of each of these factors significantly led to an increase in marketing efficiency of female retailer heads of households. This positive effect in the marketing chain provided opportunities for employment, income and food security among female retailer heads of households in the study area.

CONCLUSION

Minituber yam marketing by male and female retailer heads of households in the study area was gender sensitive, profitable and efficient. Fifty-five (55.0) percent of the variations in marketing efficiency of male retailer heads of households were significantly explained by five (5) socio-economic variables (educational level, cooperative society membership, packaging cost, market taxes and marketing margin), while 52.0 percent of the variations in marketing efficiency of female retailer heads of households were significantly explained by six (6) socio-economic variables (household size, educational level, access to credit, transportation cost, storage cost and marketing margin). These results call for public policy for increased gender access to improved socio-economic variables that significantly increase the marketing efficiency of the marketers in the supply of minituber yam from minituber yam producers to seed yam producers, and thereby promote economic development in terms of increase in employment, income and food security in the study area.

ABSTRACT
The study examined the level of participation of women in cooperative organization in Nigeria, with a focus on rural women in Kabba/Bunu local government area of Kogi State. Attention was focused on women involvement in cooperatives as a means of improving their standard of living and as a means of boosting their businesses. The two-stage random sampling techniques were used to select 80 respondents and 8 cooperative organizations, while descriptive statistics and Logit regression analysis were used to analyze data collected from the survey. The result of the descriptive analysis shows that most of rural women in the study area engage in cooperatives, the logit regression analysis indicate that the number of dependants, educational level, distance to the nearest cooperative, cost of transport and expected benefits significantly determined membership of cooperative societies among rural women. In terms of the constraints, inadequate capital, lack of awareness, work load in the household, lack of specialization, lack of training and experience were the most significant challenges women face in cooperative activities. The study recommends that government should provide a policy platform to enhance provision of financial assistance and affordable farm credits to cooperative members, while also promoting public awareness on the importance of engaging in cooperative societies.

Keywords: cooperative, women participation, Kogi

INTRODUCTION
Co-operative societies are service enterprises aimed at rendering service to its members, as defined by International Cooperative Alliance (1995), cooperative is an autonomous association of persons united voluntarily to meet their common economic, social, and culture needs and aspiration through jointly owned and democratically controlled enterprises. The International Labour Organization (ILO, 1995), viewed cooperative as important in improving the living and working conditions of women and men globally as well as making essential infrastructure and services available even in areas neglected by the state and investors-driven enterprises.

The growing need for credit and access to the basic necessities of life and articles of trade led to the formation of most of the co-operative societies. Cooperatives offer women as members the opportunities for participation and influence over economic activities, thus, women gain self- reliance through their participation as well as access to opportunities which they would not have been able to obtain on their own (ILO, 2002). Active participation of women in all function of cooperative including social, economic planning, decision making and implementation plays a significant role in the overall development of society (Sintayehu, 2003). Women form a significant part of the population in the rural areas, and are involved at all stages of agricultural enterprises, (Njar, 1990; Mgbada, 2002; Rahman, 2004).

In spite of the availability of cooperative societies and efforts of government and Non-Governmental Organizations (NGO's) at various levels to support these organizations, it appears that a significant proportion of rural women are either unaware of the existence of such co-operative societies or are lacking in the basic socioeconomic characteristics that form the prerequisite for participation in such activities (Idrisa *et al.*, 2007). This study examined the level of participation of women in cooperative organization and major problems militating against cooperative membership in the study area.

RESEARCH METHODOLOGY
The study was carried out in Kabba/Bunu Local Government Area (LGA) of Kogi State, Nigeria. Data were collected with the aid of a well structured questionnaire. Data collection involved a multi-stage random sampling technique used to select 80 rural women and 8 cooperative societies. In the first stage, four towns were randomly selected (Kajola, Okedayo, Aiyeteju and Aiyewa). In the second stage 20 rural women were randomly selected making a total of 80 respondents. For the cooperatives, 2 cooperatives were selected from each town to give a total number of 8 cooperatives and questionnaires were administered to them.

Data analysis involved the logit regression analysis, mean score, and simple descriptive statistics such as frequency distribution, cross-tabulation and likert scales. The Logit model was used to establish the determinants of cooperative membership, with a linear function of the predictors specified as:

$$\text{Logit}(\pi_i) = X_i^1 B_i$$

Where X_i is a vector of covariates X_1 …………X_n defined in this study as shown in Table 3.
The constraints faced by women membership of cooperative societies in the study area were identified using the mean score, using the following formular:

$$\bar{X} = \frac{\Sigma f x}{N}$$

Where $\bar{X}$= means response, Σ= Summation, f= number of respondents choosing a particular scale point, x= numerical value of the scale point and N= total number of respondents to the item. The mean score was calculated with women responses that were obtained using a four Likert type of scale specified as follows: Strongly agreed (4), agreed (3), disagreed (2), strongly disagreed (1). It was specified that any constraint with a mean score equal or above 2.5 was considered a major constraint while those below 2.5 were considered not a constraint.

RESULTS AND DISCUSSION

Table 1 presents the socio economic characteristics of the respondents described as age, marital status, household size, number of dependants, educational level and self-assessment of poverty. The result shows that the majority of the respondents (63.75%) were married, and between the ages of 20 to 40, suggesting greater involvement of married people in cooperatives perhaps as a result of high family/household economic demand. The result also shows high percentage (80%) of dependants, and high levels of education among the respondents are generally high when compared with the Eastern and Northern regions which recorded only 38% and 28% respectively (Audu *et al*., 2010).

Table 2, presents the distribution of women cooperative societies by modes of operations. The result indicates that majority (50%) of the co-operative membership size ranges between 51-100 members and less than 50 and above 100 have the same percentage which implies that most of the cooperative societies membership size are within 50 – 100. The result also shows that co-operatives in the study area get their credit facilities through savings of members, suggesting that government does not render financial assistant to cooperative societies in the study area.

Table 3 presents the result of the logit regression used to analyse factors that determine cooperative member of rural women. The result shows that number of dependants, educational level, distance to the nearest cooperative, cost of transport and expected benefit significantly determined membership of cooperative societies while age, marital status, household size and occupation were not statistically significant. This suggests that rural women of all ages and marital status could potentially be members of cooperative societies. The finding also suggest that household size does not influence cooperative membership choice of rural women, while number of children or elderly in a household affects the choice of respondent becoming members of cooperative society, indicating that households with larger number of dependants are more likely to be cooperative members. Also, rural women that are more educated are more likely to be cooperative members, while distance to the nearest cooperative affects choice of membership such that the farther the distance and cost of transport to the nearest cooperative society, the less likely their choice of been a member.

Table 4 presents the constraints that militate against women membership of cooperative societies. The result suggests that the major constraints faced by cooperative women in the study area is inadequate capital, lack of awareness and workload, while lack of specialization, lack of training and experience, lack of cooperation/loyalty, and language barrier, lack of information and cost of getting to the nearest cooperative are not among the major constraints.

CONCLUSION AND RECOMMENDATIONS

Despite the barriers militating against women's participation in cooperative societies, their level of participation is not affected as the benefit they derived outweighs those challenges they face. The capacity to expand their businesses in terms of financial needs becomes less of a problem to them because the cooperative societies in which they are members have served as a reservoir of capital where with adequate budget, they can draw out capital for their businesses. The economic empowerment of women through cooperative societies will not only raise the standard of their livelihood but also benefit the entire community in which they live. In view of the findings, the study recommends the following: Government should promote a policy platform to enhance provision of financial assistance to cooperative members in the rural areas especially those who cannot meet the requirements of securing loan from banks. Government should promote public awareness on the importance of engaging in cooperative societies especially in the rural areas. To solve the problem of loyalty, cooperative societies should set up a disciplinary committee which should liaise with law enforcement agencies. Cooperatives members should trained on record keeping, this might involve the services of extension officers. The government should provide support for cooperatives that engage in agricultural activities by providing inputs at affordable rate.

ABSTRACT
This study was designed to estimate and compare the profitability of cassava production by gender in Anambra State. A multi-Stage random sampling technique was used in choosing the sample. Primary data collected from a sample of 120 farmers consisting of 60 males and 60 females were analyzed by descriptive statistics (mean, frequency and percentage) and net income analysis. The socio-economic result indicates that farmers in the area are small scale farming in less than 1ha of land with majority of them attained primary school and had mean farming experience of about 20-23 years. The cassava production provided profit to the male and female farmers as indicated by net income of N40864.31 and N68672.91 respectively. The results calls for policies that aimed at encouraging and increasing the cassava production level of male and female farmers through mechanization, good market facilities, provision of processing plants and soft loan provision to farmers.
Keywords: comparative analysis, profitability, cassava, gender

INTRODUCTION

Nigerian agriculture is characterized by: multitude of small scale farmers, rudimentary farming system, low capital investment, low yield per hectare and inefficiency with which farmers manage resources on their farms to improve crop production (Okonkwo, *et al.*, 2016). Most importantly, due to low capital investment and low yield per hectare, the income from farm is so small that youths are being discouraged to invest on agriculture (Okonkwo, *et al.,* 2016). Perhaps, the alarming situation over the sector especially crop production has prompted government of Nigeria to recently encourage the use of cassava to produce wide range of industrial and food products such as ethanol, glue, glucose, syrup and confectionaries (bread, cake, chin-chin, etc) (Sanni *et, al.,* 2005). Cassava is now one of the most important staple food and cash crops that has played and continued to play remarkable roles in the food sector of Nigeria (Agwu and Anyaeche, 2007). It accounts for up to 40% to 50% of all calories consumed in southern and central parts of Nigeria (FAOSTAT, 2010). The crop is readily adaptable to different environmental conditions and well suited for integration into the farming systems and socioeconomic conditions of Africa (Nweke, 1996a). The crop's ability to provide a stable food base is a function of its flexibility in terms of planting and harvesting strategies and because of its relative tolerance to poor soil and pests/diseases problems (GOG, 1996).

Okonkwo, *et al.,* (2016) reported that cassava production is a profitable enterprise that would better-off the standard of living of farmers as well as improve the economic development of a nation if full concentration would be paid to it. Reports have shown that a higher proportion of cassava farmers, in Nigeria get a higher income from its production than they get from most other major staples (Ezeibe, *et al.,* 2015).

According to Kock and Krysher (2010), gender inequity is a "worldwide problem" and is an extremely significant debilitating factor in many countries of the world over economic development. Past experiences have shown that rural agricultural (cassava inclusive) development programmes or initiative do not affect the lives of men and women equally. Cassava was traditionally among the crops grown by male in Nigeria not until recent time when the female involvement started increasing due to the impact of the crop to economic development of the country (Ewebiyi and Arimi, 2013). Male and female were found to specialize in different tasks in cassava enterprise (Carter and Jones, 1989). Men work predominantly on land clearing, ploughing and planting while women specialized on weeding, harvesting, transporting and processing (FAO, 2009). Women are now known to play more active role in cassava production, processing, storage and marketing than men (Nsoanya and Nenna 2011). Based on these differences in the gender work in cassava enterprise, there should be a significant difference in the profit from the sector by male and female. Therefore because of the apriority expectation on the profit margin, this study was designed to estimate the profitability analysis of the cassava production by gender in Anambra State.

METHODOLOGY

Study Area

This study was conducted in Anambra State, in South Eastern Nigeria, which comprises of 21 Local Government Areas (LGAs) namely: Aguata; Awka North; Awka South; Anambra East; Anambra West; Anaocha; Ayamelum; Dunukofia; Ekwusigo; Idemili North; Idemili South; Ihiala; Njikoka; Nnewi North; Nnewi

South; Ogbaru; Onitsha North; Onitsha South; Orumba North; Orumba South; Oyi. The State is divided into four Agricultural zones; Aguata, Anambra, Awka and Onitsha (ASADEP, 2003). It was created on 27th August 1991; with its capital at Awka. Its population figure was estimated to be 4,055,048, (NPC, 2006); the State has two main ethnic groups; the Igbo with a population of about 3973947 (98%) and Igala with a population of about 811001 (2%) who live in the North western part of the State (ASADEP, 2003).

The area lies within the 6°13' and 7° 9' North and longitudes 7°49' and 7°57' East (Nfor, 2006). It covers a land area of about 4,416sq km of the total land area of Nigeria: about 70% of this is arable land, and less than 55 percent is under cultivation (NPC, 2006). The area lies mainly on plains under 200M above sea level (ASADEP, 2003). It has tropical rain forest vegetation, humid climate and a rainfall of between 152mm- 203mm. It experiences two seasons in a year; from late October to early May marks the dry season while from April to early October marks rainy season (Okorji *et al.*,2012).

Farming is the predominant occupation of the rural inhabitants. The main crops in the State are roots, tubers, cereals and tree crops. Cassava is a crop that grows and thrives in all the agro-ecological zones of the LGAs in the State (PIND, 2011). The State has comparative resource advantage in the production of cassava (ASADEP, 2003): available markets for the sale of products from crops (ASADEP, 2003).

Sample Selection

A multi-stage sampling technique was used in choosing the samples. Anambra agricultural Zone was randomly selected for the study. Secondly from the selected zone, three (3) extension blocks were randomly selected. Thirdly, two villages were randomly selected from each of the block, thus a total of six villages were selected. In the fourth stage, 20 respondents (that is 10 male and 10 female) were randomly selected from each of the village. Thus a total of 120 cassava farmers were selected for the study. The farmers were selected from the list of 350 registered cassava farmers provided by Anambra Agricultural Zone, Anambra State.

Data Analysis

Descriptive statistics such as mean, frequency, and percentages was used to estimate the socio-economic characteristics of the respondents.

The profitability analysis was analyzed using net income (NI) model. The model is specified as follow:

NI = TR-TC

Where; NI = Net Income

TR = Total Revenue (Price x output quantity)

TC = Total Cost (Total Variable Cost + Total Fixed Cost)

Profitability Index (PI) = $\frac{Net\ Income}{Total\ Revenue}$

RESULTS AND DISCUSSION

Socio-economic characteristics of the respondents:

The distribution of respondents according to socio-economic characteristics of the respondents is presented in table1.The results in Table1 show the socio-economic characteristics of the respondents. The results show that the mean age of male farmers was 49 years while that of female farmers was 48years. This implies that the farmers were within their active age therefore, they will adopt any technology or intervention that would gear towards improving their cassava production system. This is because new technology in agriculture requires physically able men and female. This finding is consistent with the findings of Rathmen, *et al.*, (2002).

The result of educational status indicates that 38.33% attained primary school education while 43.33% of the female farmers attained secondary school education. This implies that female farmers had higher level of educational than their male counterparts and therefore would be better-off to cope with cassava production technologies introduced to them than male. Education predisposes farmers to be innovative and puts them in a better position to cope with the challenges of the adoption of new technologies introduced to them (Adewuyi, *et al*., 2013).

Male farmers had an average household size of 5 persons while female farmers had 4. The implication is that male farmers have more persons under their care than the female farmers. This indicates that male farmers would have more labour availability in their household than the female farmers since family size is one of the determinants of family labour or labour force in a society. The report from (FAO, 2011) showed that female headed households had less labour available for farm work than male- headed households because they typically had fewer working age adult members but more dependents.

From the findings, male farmers had mean farming experience of 20 years while female farmers had 23 years. This implies that female farmers had more cassava farming experience than their male counterparts in the area and therefore would tend to adopt innovations on cassava than men.

The mean farm size for male farmers was 1.8 ha while female farmers had 1.2 ha. The results show that arable land was more available to male farmers than their female counterparts. This could be that male farmers had access to farm land than female farmers due to culture. This is consistent with FAO, (2010) who stated that globally women scarcely own land due to norms and custom. The results further show that famers were more of small farm holders since they had farm size less than 5 ha. This is consistent with Onyebinama, (2004) who stated that farmers with less than 5 ha of farm land are small holder farmers.

Profitability of Cassava Production among men and women

The results in Table 2 show the profitability analysis of one hectare of cassava produced from improved cassava production technologies by gender.

The average total cost of producing a hectare of cassava by male farmers was N100232.98, average total revenue was N141097.29 and average net income was N40864.31 with a total cost of N91470.51, total revenue of N160143.42 and net income of N68672.91 obtained by female farmers. The results imply that cassava production was more profitable for female farmers than their male counterparts probably due to the cassava profit orientation training undergone by women during women and youth empowerment training (NRCRI, 2013). The more profit by female farmers indicated that women traditionally are known to play more active role in cassava production, processing, storage and marketing (Nsoanya and Nenna 2011) which in turn provide them with income. Mgbekor and Nwamba,(2013) also noted that women are more involved in virtually all activities like production, processing, and marketing of cassava which provided them with additional income- earning opportunities and enhanced their ability to contribute to their household food security.

The profitability index results show that the male farmers had profitability index of 0.29 while female farmers had 0.43. The implication is that female farmers had higher return to investment capital on cassava production than male farmers. The results also indicate that when a male farmer invests N1 on cassava production, 0.28k will be obtained in return compared to a female farmer who invests N1 on cassava production with 0.43k realized on it. The result is inconformity with the finding of Adeoye *et al*., (2013) who reported that, women are almost entirely responsible for the production of cassava which provides them with additional income earning opportunity and enhance their ability to contribute to house hold food security.

CONCLUSION AND RECOMMENDATION

The results show that farmers in the area are small scale farm-holders that operate on less than 5ha of cassava farm and use mainly rudimentary farm tools for farm work. The results also show that cassava enterprise is a profitable venture to male and female farmers but female had the higher profit margin than the male. The study would be a window to economic development of a nation if fully embraced. This work therefore calls for policy initiative that would gear towards enhancing the cassava production enterprise of Nigeria and other African countries; there should be an establishment of cassava processing plants in cassava production areas in order to improve on cassava value addition and reduce glut thereby increasing the income of the farmers. Cassava production in Nigeria should be mechanized in order to encourage not only the youths into its production. There should be also well established market facilities for sale of cassava products. Finally both government and NGOs should provide soft loan to farmers to encourage large scale production.

ABSTRACT
A survey of the involvement of women in cocoyam production in meeting food demand for the new century was conducted on forty-four households in Ahaba Imenyi in Isuikwuato LGA of Abia State. The questionnaire technique was adopted after random sampling of households in three communities in the area. Of the 44 respondents, 35(79.5%) were aged 31 and above, 26(59.1%) had only primary education, 5(11.4%) had secondary education while 13(29.5%) had no kind of formal education. Also, only 9(20.5%) were civil servants. The rest were either fulltime farmers or combined farming with petty trading. The study revealed that cocoyam production is on the decline in the study area as it ranked third compared with other root and tuber crops. Long-term socio-economic stability of the womenfolk is yet to be fully assured even through historical evidence of women's role as food producers reveal that women have been and still are key players in food production. Women cocoyam farmers are saddled with lots of production and processing problems.
Keywords: Cocoyam, women participation, production, Nigeria

INTRODUCTION
The involvement of women in agricultural production, storage and processing cannot be disputed worldwide. Historical evidence of women's role as food producers in Africa generally and Nigeria in particular does not seem to be fully realized in long-term socio-economic stability (Boserup, 1970; Beringer, 1978; Buvnie and Mehra, 1990; Muchena, 1994; Imoh, 1997). Women contribute significantly to social and economic life, and their income is becoming increasingly necessary to all households yet they are not recognized in development planning (Steady, 1985; Oladunmi, 1992; ILO, 1994). In Nigeria, women farmers participate actively in food production and processing mainly at the subsistence level, with little developed technology inputs and information services.
Cocoyams are grown in many parts of the tropical regions of the world. Nigeria is the world's largest producer of cocoyams, and most of Nigeria's cocoyams are grown in the southeastern part of the country. Cocoyam production has encountered neglect in recent times partly because it is a female crop along with cassava and vegetables, and partly because of inappropriate technology and population pressure. It is regrettable note that of all root and tuber crops in our society, cocoyams seem to have received the least research attention, even in present times. No wonder, it has featured least in national development programmes. The corms of cocoyam contain digestible starch as well as substantial amount of protein, vitamin C, thiamine and niacin. It is also a crop with promising economic value (Knipscheer, et al., 1980). Cocoyam is used as fufu, portage, soup paste. It can be eaten roasted or boiled with palm oil, also the fresh and tender leaves are used as vegetables (Nwagbo, et al., 1982).
In Ahaba Imenyi cocoyam is a female crop. Like all female crops cocoyam production and processing remain undervalued partly because they have not attained commercial or economic value. Since women farmers in the area depend largely on traditional agriculture for subsistence, any meaningful effort for their effective participation and improved living standards must be directed toward improving their production and storage technology. Therefore, there is urgent need to encourage women farmers and to bring them to the limelight of sustainable agricultural development worthy of the new millennium. Thus, this is the basis of the survival on the extent of women participation in cocoyam production.

METHODOLOGY
Three villages (Amaogudu, Amahia and Amainyi) were randomly selected from Ahaba Imenyi a community in Imenyi one of the admistrative units in Isuikwuato LGA of Abia State, Southeastern Nigeria. Isuikwuato is presently made up of three administrative units (Imenyi, Oguduassa and Isuamawo). Furthermore, a systematic random sampling of households with average family size of 9 was carried out and 63 respondents were drawn for the study. However, only 44 respondents were actually available for interview. A set of structured questionnaire administered to married women was used to collect data for analysis. Data were analyzed using descriptive statistics.

RESULTS AND DISCUSSION

Social-economic characteristics of women farmers

Most of the women of this community are farmers and petty traders. Many of them (56.8%) belong to the age group of 31-40 years. While 29.5% belong to the age group 41 -50 years. This implies that the younger women are either away to the cities for greener pastures or are engaged in other occupations. Most of the women had primary education (59.1%), while 29.5% had no formal education (**Table 1**). These findings agree with Monsen, (1991) that women of developing countries are moving into farm activities.

Production of cocoyam in relation to other tuber crops in the area

The major tuber crops grown in the area include cassava, yam, cocoyam and three leaved yams. Cassava, in this community, was a female crop, but today it is being cultivated by both men and women because it has achieved great economic value. It is the number one crop cultivated in the area today. All of the respondents (100%) cultivate cassava. Cocoyam ranks number three tuber crop cultivated in the area (**Table 2**). It has continued to be a female crop, that is, men do not grow cocoyam in the area. The study revealed that only 34 percent of respondents still grow cocoyams. The growing of cocoyam is still done with traditional methods and tools without any scientific improvement. This has resulted in low average yields even at the subsistence level. Cocoyam farming has continued to be on the decline since after the civil war in this country. Respondents gave various reasons for the decline in cocoyam cultivation in the area. Many of the respondents (80%) attributed the change to poor yield. Others (76%) said less social value is attached to its fufu and as a result they pay more attention to cassava farming while 97.7% said that cocoyam production has less economic value when compared to other tuber crops grown in the area (**Table 2**).

Cocoyam Production Problems

The major production problems are those arising from diseases and storage. All of the respondents (100%) said this was the major problem in cocoyam production. Many others (79.5%) responded that lack of planting materials constitute another major problem since most of the coccyams are consumed after harvest (**Table 3**). Also 30% of respondents attributed lack of improved planting materials as part of the problems against cocoyam. It is regrettable that both government and the people have neglected the importance of the valuable crop in our farming systems.

CONCLUSION

It is widely accepted that women play important role in food production generally. It is also acknowledged that productivity on the part of women could be enhanced if constraints on their path are removed. In the case of cocoyam production in our study area, disease control measures, storage facilities and the removal of socio-cultural and economic barriers attached to the utilization of cocoyam will surely increase its production. Secondly is the removal of the existing differential access to agricultural inputs such as extension services, farm implements, and appropriate intermediate technology that will be available and affordable locally. Government should intervene through the mass media as the appropriate information service to encourage the production and the use of cocoyam-based on its nutritional importance. Its uses could be enlarged and commercialized. Research Institutes how mandate is on improvement of this crop like the NRCRI, Umudike should be funded adequately to be able carry out its work. We can have industrial powder and chip from cocoyams. Cocoyam processing industries should be established and agric engineers should be trained by the Federal Government to fabricate cocoyam processing machines. These no doubt will culminate into surplus production and food security.

Table1. Social-economic characteristics of women cocoyam farmers

Social characteristics	Number of respondents	Percentage

CLIMATE CHANGE: CLIMATE SMART TECHNOLOGIES, RENEWABLE ENERGY, GREEN ECONOMY & HEALTH

DETERMINANTS OF CLIMATE CHANGE VULNERABILITY IN SOME RURAL COMMUNITIES OF KATSINA STATE, NIGERIA

H.Y. Ibrahim, H.I. Ibrahim & S.S. Adeola*

Department of Agricultural Economics & Extension, Federal University, Dutsin-Ma, Katsina State
E-mail: sadeola@fudutsinma.edu.ng

ABSTRACT
This study estimates the determinants of climate change vulnerability in some rural communities of Katsina state. A total of 150 respondents were randomly selected from fifteen communities across nine LGA which were purposefully selected for the study. Both structured questionnaires and Focus Group Discussions were used to elicit information from the respondents. Multi-criteria vulnerability index, descriptive statistics and multiple regressions were used to analyze the data. The study shows that 43% of the households in the communities perceived themselves to be more vulnerable to climate change than other households. Unusual rainfall pattern and cropfailure were the major concern expressed by community members due to climate change. The study also shows that amount of credit accessed, Shannon index and membership of association are the determinants of household climate change vulnerability in the study area. The study calls for good policies that will enhance credit access and utilization; diversification of crop production, forming and strengthening of farmer's associations in their areas.
Keywords: climate change, farmers, diversification, Multi-criteria vulnerability index

INTRODUCTION
Climate variability and change according to Abaje *et.al* (2014) is one of the greatest socio-economic and bio-physical challenges confronting the world in the 21st century. Climate change is a long term shift, alteration or change in the type of climate prevailing over specific location, region or the entire planet. In Nigeria, climate change impact is not same in all the regions. The Northern region of Nigeria is more likely to suffer the impacts of climate change than other regions because it is naturally characterized by extreme weather conditions (Sada, 2002). Climate change has affected adversely agricultural production in Katsina State (Adeola *et al.* 2014). This lends credence to the vulnerability of northern region to the adverse effect of climate change. Therefore to approach the issue of climate variability appropriately, Apata *et.al.*,(2009), maintained that, one must take into account rural communities' understanding of climate change, since they are the most vulnerable. Vulnerability as used in this study is the probability of an acute decline in access to food or consumption often in reference to some critical values that defines minimal values of human well-being (Kuku-Shittu *et al., 2013)*. Also, as these local communities perceive climate change as having a strong spiritual, emotional, and physical dimension due in part to their level of exposure. It is assumed that these communities have an inborn, adaptive fore knowledge from which to draw and survive in high-stress ecological and socio-economic conditions. This study therefore aims at understanding the perception of households on their vulnerability to and concern for climate change and well as estimating the determinants of rural household's vulnerability to climate change in the study area.

METHODOLOGY
Katsina state, one of the seven states in the North-western region of Nigeria has thirty-four Local Government areas. The state has land mass of about 24,192 square kilometers and a population of about 6 million peoples. The location of the state falls within longitudes 7^0 30^1E and $7^0 50^1$ E of the Greenwich Meridian and latitudes 12^0 15^1N and $12^0 25^1$ N of the equator. The temperature range within the state is between 17^0C and 33^0C while rainfall ranges from 800mm to 100mm per annum. Crop production and livestock farming are the two major agricultural practice within the state. The agro-ecological zones in the state are Savannah around the wetter parts of the state, Sudan and Sahel in the drier part of the state.

For this study a total of nine Local Government areas (LGA) were purposefully selected; three from each of the agro-ecological zones in the state to capture climatic variability and other characteristics of interest. Fifteen communities were randomly selected from the selected LGA where focus group discussions were conducted to get information on certain indicators as perceived by the community members. Multi-criteria Analysis Vulnerability Index, ordinary lead square regression and simple descriptive statistics were used to analyze the data collected.

Multi-Criteria Analysis (MCA) Vulnerability Index

A vulnerability index was computed using the multi-criteria analysis approach adapted and modified from a study by Mengesha (2013). It combines different socio-economic and bio-physical factors is assessing the vulnerability of households in the study area. For the purpose of MCA analysis, the scores were described in numbers and standardized by converting each value to a Z-score from which a single aggregated (Vulnerability Index) was established. The vulnerability index thus obtained was used as dependent variable against some socio-economic variables to establish the relationship that exist between them. The regression equation is as presented below:

$V_{index} = X_0 + X_1 + X_2 + X_3 + X_4 + X_5 + X_6 + \varepsilon_0$

Where:

V_{index}= Vulnerability Index, X_0= constant of the model, X_1= age of the household head in years, X_2=household size measured as the number of people in the household,X_3= Amount of credit accessed for farm work in Naira, X_4= number of associations that a farmer belong to,X_5= dependency ratio (the ratio of members of household employed to those not employed),X_6= Shannon index (measure of degree of diversification), ε_0= error term

RESULTS AND DISCUSSION

The farming communities are societies where there are different levels of interactions among the households. It therefore means that households are aware of their vulnerability levels relative to some other households in the same communities. Overtime, with respect to climate change vulnerability, according to fig. 1, about 43% of the households believed they feel the impact of climate change more than others. On the other hand, 44% of the household interviewed perceived that they are better than others in terms of vulnerability to climate change. This implies that households in farming communities are aware of the effect of climate change in their farming operations and other activities; in addition to its resultant effect on household welfare. This understanding will aid the implementation of good policies that will ameliorate the adverse effect of climate change on the rural communities.

Figure 2 shows the major concerns expressed by households in the study areas. Ranking highest among these are crop failure and unusual rainfall pattern which are the concerns of more than 80% of the households. Other concerns are increased temperature, low crop yield and animal sicknesses of which about 60%, 60% and 56% of the households indicated as major concerns respectively. These concerns are in line with a priori expectation given that are global effects of climate change and well documented.

A regression analysis was used to investigate the factors that affect climate change vulnerability. The results on table 1 shows only age and farm size as major factors that influence vulnerability.

The R-square of the model is 24% indicating that the independent variables account for about 24% of the variability that occur in the vulnerability of the farming households in the communities studied. The result shows that the amount of credit accessed, Shannon index and number of association that the household head belong to are factors that have significant influence on household vulnerability in the area. The amount of credit accessed, Shannon index and number of associations that the household head belong to are significant at 5%, 1% and 10% levels and are all negatively related to the level of vulnerability to climate change that each of the households experienced. This implies that as each of these socio-economic variables increase the level of susceptibility to the adverse effect of climate change increases. This is in line with the *a priori expectation*. The amount of credit received, the level of crop diversification (Shannon index) and the number of association belong to should help to shield the households from the effect of climate change antecedents on their socio-economic standards.

CONCLUSION

The households have genuine concerns resulting from limate change. Major among these are crop failure and unusual rainfall pattern. The study established the fact that there is a relationship between climate change vulnerability and the variables examined since none of the coefficients is zero. Household size, the amount of credit accessed, Shannon index (diversification) and number of associations belong to are significant determinants of vulnerability to climate change in the study area. The study recommends that in view of the nature of climate prevalent in the study area, government should irrigate more farmlands for the farmers. This will help cater for the failure of crops which in most cases are due in part to delayed or unusual rainfall pattern. Furthermore, it is recommended that policies that will enhance credit access and utilization should be put in place; farmers should diversify crop production and farming activities such as practicing mixed farming in order to reduce risk inherent in single crop or livestock farming. Finally, farmers should form themselves into social associations and strengthened the existing ones

ABSTRACT
The need for farmers to maximally use Climate Smart Agriculture (CSA) to curb the negative effect of climate change is of paramount importance. This study was carried out to estimate the extent to which CSA is been practiced in Ajiwa agricultural zone of Katsina state. A total of 119 questionnaires were administered in six villages across two local government areas. The tools for analysis were descriptive statistics and Adaptation Strategy Use Index (ASUI). The results from the research shows that majority of the respondents are male (94.96%) more than 16 year farming experience (51.26%). Also, the perception of the farmers about climate change indicates that temperature is on the increase, while rainfall is decreasing. Likewise, the effect of climate change on crop yield is negative, while the state of water supply has worsened as a result of climate change. Majority of the respondents also opined that the magnitude of drought in the study area is moderate. The ASUI results indicates that Planting of drought and heat tolerant crops is the most commonly used CSA practice in the study area. This is necessary in curbing the problem of shortage in rainfall, increase in temperature and shortage of water supply posed by climate change. The study therefore recommends that farmers should be encouraged by extension agents and private agencies interested in agriculture to practice CSA frequently in order to boost agricultural production in the face of climate change.
Keywords: Climate Smart Agriculture, climate change, ASUI, temperature and rainfall.

INTRODUCTION

The concept of "Climate-Smart Agriculture" was invented by the United Nation Food and Agriculture Organization (FAO) in 2010. According to the original definition, "Climate-Smart Agriculture" is agriculture that "sustainably increases productivity, resilience (adaptation), reduces/removes greenhouse gases (mitigation) and enhances achievement of national food security and development goals". The term Climate-Smart Agriculture (CSA) has developed to represent a set of strategies that can help to meet climate change challenges by increasing resilience to weather extremes, adapting to climate change and decreasing agriculture's greenhouse gas (GHG) emissions that contribute to global warming (Steenwerth *et al*., 2014).

The need for CSA practices cannot be underestimated as agriculture also contributes to greenhouse gases emission. Smith, *et al*. (2014) posits that cattle and rice production contribute vast quantities of methane that contributes to greenhouse gas emission and also, during the production of synthetic nitrogen fertilizers, Nitrous oxide, another powerful greenhouse gas, is released to the atmosphere and it is also released from soils that are fertilized. The emission of methane and Nitrous oxide from the agricultural sector amount to between 10 and 12% of total global greenhouse gas emissions (Smith *et al*., 2014).

As a result of the above, global yields of maize and wheat have already been shown to reduce by 3.8% and 5.5% respectively since 1980, relative to what they would have been in the absence of climate change due to changing climates (Lobell *et al*., 2011). Although climate change is global, but its impact in less developing countries are more hence FAO focuses its work in these countries, with a mandate that includes helping to eliminate hunger and food insecurity, and increasing the resilience of developing countries to the impacts of climate change on agriculture (Doreen, 2014).

According to Wheeler and von Braun (2013), Global demand for agricultural products, be they food, fibre or fuel, continues to increase because of population growth, changes in diet related to increases in per capita income and the need for alternative energy sources while there is less and less additional land available for agricultural expansion. Agriculture thus needs to produce more on the same amount of land while adapting to a changing climate and must become more resilient to risk derived from extreme weather events such as droughts and floods. They also state that "Adaptation measures such as diversifying crop rotations, integrating livestock with crop production systems, improving soil quality, minimizing off-farm flow of nutrients and pesticides, and other practices typically associated with sustainable agriculture are actions that may increase the capacity of the agricultural system to minimize the effects of climate change on productivity".

To move the concept of "Climate-Smart Agriculture" forward, a number of developed countries, led by the Dutch government and the World Bank, with the US, FAO, and CGIAR playing important supporting roles, sought to create a more formal institution. The first meeting to try to generate enthusiasm for a global alliance was held in

The Hague in 2010, with subsequent meetings in Hanoi in 2012 and Johannesburg in 2013. Despite tepid reception of the idea to create a more formal alliance by most participating countries at each of these meetings, the main proponents have not been deterred in their efforts. Indeed, these same actors are now attempting to create what they call the Global Alliance for Climate-Smart Agriculture.
This research therefore seeks to find out the frequency of usage of CSA practices in the study area as a panacea to reduce the menace of climate change.

METHODOLOGY

This study was carried out in Ajiwa agricultural zone of Katsina State. This zone lies between longitude $12^0 28'$ N and latitude $7^0 29'$ E. It has a mean rainfall of about 400mm and temperature of 34.9^0, while the crops grown in this area include millet, sorghum, maize, soybean, cowpea and seseme. The people in this area speak the Hausa language.
A Multi-stage simple random sampling technique was used for this study. The first stage includes purposive selection of Ajiwa agricultural zone, because this zone is mainly agrarian and has also experience the effect of climate change. In the second stage, two (2) local government areas were randomly selected from Ajiwa agricultural zone. The third stage involves the selection of six (6) villages from the two local government areas already selected. A total of 119 respondents were used for this study.
Data collected for this research were analyzed using descriptive statistics such as percentages, frequency distribution tables and Adaptation Strategy Use Index (ASUI). The ASUI will reflect the relative position (ranking) of each of the Climate-Smart Agricultural practices identified in the study area in terms of their frequency of usage.
ASUI was adapted from Adesoji and Famuyiwa (2010) in Umunna *et al*., (2013). The frequency of use of the Climate-Smart Agricultural practices was expressed using a four-point likert scale, that is, 3, 2, 1, and 0 for Frequently used, Occasionally used, Rarely used and Not used respectively. The formula is as stated below:

$$ASUI = \frac{[(N_1 \times 3) + (N_2 \times 2) + (N_3 \times 1) + (N_4 \times 0)]}{M}$$

Where:
N_1 = Number of farm households that Frequently used a particular Climate-Smart Agricultural practice.
N_2 = Number of farm households that Occasionally used a particular Climate-Smart Agricultural practice.
N_3 = Number of farm households that Rarely used a particular Climate-Smart Agricultural practice.
N_4 = Number of farm households that did Not use a particular Climate-Smart Agricultural practices.
M = n x 3,
n= total number of respondents

RESULTS AND DISCUSSION

The results in Table 1 show that majority of the respondents are male adults with ages between 46 to 60 years, which is an active year for effective farm labour, This indicates that women who engage in farming activity in the study area are few. In terms of the educational status of the farmers, about 47.90%, which is the majority, obtained Quranic education, which is the common type of education in the study area, while 50.42% of the respondents have household size ranging from 11-20 persons. Large household sizes imply availability of more family labour, which is of benefit to the farmer in his farming activities. Majority of the farmers in the study area are well experienced in farming activities, as a large number of the farmers (88%) have been into farming for more than 16 years.
The result in Table 2 shows the perception of farmers on the impact of climate change on their cropping activities for the past five years. Farmers’ ability to perceive climate change is a key precondition for their choice of CSA practice to use. Majority of the respondents (62.18%) ascertained that there is increase in temperature for the past five years. This is in line with *a priori* expectation. It confirms that there is global warming, which has brought about an increase in temperature with negative effect on crop production. About 94.96% of the respondents perceived decreased rainfall pattern for the past five years. Rainfall/precipitation is a vital requirement for agricultural activity and if there is shortage in rainfall, it will definitely affect crop production. This result agrees with Gbetibouo (2011) who found out that over the years temperature has been increasing and rainfall/precipitation has been decreasing due to climate change impact. Also, 89.92% of the respondents affirm that climate change has negative effect on their crop yield, 90.76% said that the state of water supply in their environment has worsened as a result of climate change, while 88.39% stated that the magnitude of drought in their farming environment is moderate. All these indicate that climate change has one way or the other affected the cropping system in the study area negatively. There is therefore the need to use CSA as a panacea to these problems.

The results in Table 3 show the frequency/degree of usage of Climate Smart Agriculture as resilience to climate change impact in the study area. The result indicates that Planting of drought and heat tolerant crops is the major CSA practice in the study based on the ranking, while planting of cover crops, use of organic manure, crop rotation and crop diversification are second, third, fourth and fifth respectively in terms of ranking. Soil conservation techniques and mulching are the least used Climate Smart practices in the study area. The CSA practices used by the farmers may depend on their perception of climate change and its impact on their farming activities. The ranking in Table 3 supports the results in Table 2, as majority of the farmers in the study area carry out their cropping activities using drought and heat tolerant crops, since the major effect of climate change in the study area are increasing temperature, decreasing rainfall and low water supply.

CONCLUSION

The results from this study reveal that the farmers in the study area are practicing the various types of CSA at different frequencies. From the results, it is clear that planting of drought and heat tolerant crops is the commonly used CSA practice in the study area and this is as a result of the challenge of low rainfall, high temperature and little water supply being faced by the farmers. The study therefore recommends that farmers should be encouraged by extension agents and private agencies in the agricultural sector to practice CSA frequently in order to boost agricultural production in the face of climate change.

ABSTRACT
This paper assesses farmers' perception of climate change and adaptation strategies adopted on crop production in Kafur Local Government Area, Katsina State. The study focused on the perceived causes of climate change, nature of climate change, consequences of climate change and adaptation strategies. Multi stage sampling technique was adopted to select 135 crop farmers in 2014 cropping season. Data were elicited from the farmers using structured questionnaire and analyzed with descriptive statistic such as percentages and likert scale. Results obtained revealed that 83.33%, 60% and 62.50% of the respondents indicated burning of fossils fuel from vehicles, deforestation and bush burning as the major causes of climate change respectively. Other causes of climate change perceived by the farmers were desertification/loss of forest resources (47.61%) and erratic rainfall pattern (41.49%). The constraint faced by rural farmers in adapting to climate change were: lack of access to weather forecast on farming season (80.86%), limited access to improved crops and draught resistant varieties (64.4%) and absence of government policy on adaptation programs to rural farmers (54.93%). Indigenous adaption strategies used by crop farmers were use of wet land/valley (81.21%), multiple cropping system (77.10%), and mulching (72.28%). It is recommended that research institutes should train farmers on the use of draught tolerant/resistant varieties and adoption of sustainable land management practices to adapt to climate change.
Key words: climate change, perception, adaptation strategies, crop production, family farming

INTRODUCTION
United Nation framework convention on climate change (UNFCC, 1992) define climate change as a change of climate which is attributed directly or indirect to humans activities that alter the composition of global atmosphere which is addition to natural climate variability observed over comparable time periods. Climate change is one of the most serious environmental threats facing mankind worldwide; it affects agricultural activities in several ways including its direct impacts on food production. Climate change which is attributable to the natural climate cycle and human activities has adversely affected agricultural productivity in Africa (Ziervogel et al. 2006). Available evidence shows that climate change is global but its impact is more in developing countries especially those in Africa, due to their low level of coping strategies (Nwafor, 2007; Jay tap, 2007). As a result of this impact, it is projected that crop yield in Africa may fall between 10-20% by 2050 or even up to 30% due to climate change particularly because African agriculture is predominantly rain fed and hence fundamentally dependent on the vagaries of weather (IPCC, 2007; Deresa et al 2008).
Nigeria is one of those developing countries (Odjugo, 2010) that is susceptible to the varies of climate change impact especially the northern region than other regions in Nigeria due in part to its geographical location. As the planet warms, rainfall pattern shift and extreme event such as drought, floods and forest depletion by fires become more frequent, it aggravates the impact on rural people as they strive to overcome other challenges such as poverty and advance their economic status through increases capacity on crop production. More so, some northern and regional rural areas have not made efforts towards tackling the menaces. Other habits such as deforestation and over grazing on land resources and burning of bush indiscriminately is a common practice among our rural areas that aggravates these impact. Although the issue of climate change on agriculture is not a recent development, there has been little or no efforts aimed at scientifically documenting the existing situations among our rural communities in the northern region.
Federal and State Governments have made some effort to mitigate and adopt strategies on the risk of changing climate. The efforts are still rudimentary especially when compared with the impending catastrophe such as drought, drying of streams, irregular rain patterns, rise in sea level, flooding, heat stress and outbreaks of newly formed disease among rural communities where their major activities are farming and livestock production. It is against this background that this study seeks to x-ray knowledge regarding farmers' perception on causes, constraints and strategies adopted for climate change in Kafur Local Government Area.

METHODOLOGY
This study was conducted in Kafur Local Government Area of Katsina state. It is found 218km away from Katsina, the state capital. And lies between the longitude 26^0 E and latitude 16.2^0 N. kafur has 10 geo-political wards and

two districts with a population of 329,257 (NPC, 2006). The major occupation of the people are farming, trading and livestock production. The major food crops grown are maize, guinea corn, rice, groundnut, cotton and millet. Based on preliminary survey conducted, a multi-stage sampling technique was adopted to select 135 crop farmers. In the first stage, two districts Kafur and Daneji were chosen purposively. In the second stage, three wards, Kafur, Gozaki and Mahuta were randomly sampled out of all 10 wards. In the third stage, three villages were randomly sampled from 3 wards. A sample frame was obtained from the farmer's association and fifteen (15) farmers were randomly sampled from each of the villages selected for the study.

Data for the study was obtained through questionnaire and personal interviews. Information sought included: personal bio data, awareness, perceptions, causes of climate change and measures of adaptations etc.

Analytically, descriptive statistics such as mean, percentage and likert scale were used in analyzing data collected.

Analytical Approaches

A 3 point likert rating scale was used to measure the level of agreement of perceived causes and constraints in adapting to climate change using often (3), seldom (2) and never (1). Respondents with mean score of 2.0 and above imply they are in agreement that the attributes are important while respondents with mean score of less than 2.0 were not in agreement. And a 5 point likert rating scale was used to measure the level of agreement on the perception of the nature of climate change using strongly agreed (5). Agreed (4), strongly disagreed (3), disagreed (2) and undecided (1). Respondents with mean score of 3.0 and above imply they are in agreement that the attributes are important while less than 3.0 were not in agreement.

To determine the mean likert level = Xs = OX. Xs of each item was computed by multiplying the frequency of each response pattern with its appropriate nominal value and dividing the sum with the number of respondent to the items. This can be summarized with equation below

$$Xs = \sum fn/N$$

Where Xs = mean score

$\sum$ =summation

f = frequency

n = likert nominal value

N = number of the respondents

RESULTS AND DISCUSION

The results in Table 1 Show the likert scale analysis of perceived causes of climate change in Kafur Local Government Area. The result show that the burning of fossil fuel, deforestation and bush burning had mean scores greater than 2 except overgrazing and excessive irrigation and chemicals. Burning of fossil fuel, deforestation and bush burning had mean scores of 4.00, 3.33 and 2.96 respectively. This implies that they were in agreement with respect to the response questions. This response show evidence of varying causes of climate changes.

Farmers' Perception on the Nature of Climate Change

The results in Table 2 show the response rate analysis of farmers' perception on the nature of climate change in the study area. The results show that desertification (3.89), erratic rainy season (3.57) and drying of streams and rivers (3.16) were the most important and significant perceived nature of climate change in the area. The mean scores were greater than 3 indicating they are in agreement with the response questions.

Constraints in Adapting to Climate Change

The result in Table 3 shows the likert scale analysis of farmers' constraints on adapting to climate change in the study area. The result shows that lack of access to weather forecast (3.10), limited access to improved/ drought resistant varieties (3.04) and absence of government policy on adaptation (3.01) are the most important constraints on adapting to climate change in the area. The mean scores were greater than 3 indicating they are in agreement with the response questions.

Adaptation Strategies

The result in Table 4 shows the actual adaptation strategies used by the farmers in the study area. The result shows that use of wet land/valley (3.79), multiple cropping system (3.17) and mulching (3.10) were the most dominant system in the study area. This therefore implies that most of the farmers in the study area are aware and use many adaptation strategies to mitigate the effects of climate change on crop production. This result is in line with Molua (2008), Rudolf and Hermann (2009) and Apata *et al* (2009), that the main strategies for reducing climate risk is to diversify production and livelihood systems like soil and water management measures and plant protection measures that are varied to maintain adequate crop yields.

CONCLUSION

The results show that burning of fossil fuels and human activities like bush burning, indiscriminate cutting of trees were perceived causes of the changing climate while the rains are decreasing leading to decreased cop yields in the study area. Respondents perceived the constraints on adapting to climate change to be lack of access to weather forecast and limited access to improved /drought resistant varieties. It is evidenced from this study that crop farmers are experiencing change in climate and they have already devised a means to survive. It is recommended that reliable and effective measures of adaptation need to be implemented and made accessible to end user.

ABSTRACT
The study was carried out to analyze the effects of the socio-economic characteristic of yam farmers on adoption of climate change adaptation strategies in Kuje Local Government Area. Questionnaires were used to collect primary data from yam farmers using random sampling procedure in the 2015 farming season. The data collected was analyzed using descriptive and inferential statistics. Results from the study indicated that only a few of the farmers were aware of the effects of climate change on crop agriculture. However, most of them practiced crop protection measures as a coping strategy to crop failure. Result of the Tobit analysis showed that age, education, household size and awareness of climate change were significant variables that determine the farmer's adoption of climate change adaptation strategies. To forestall crop failure and promote crop agriculture, the study recommends that farmers should be educated about the reality of climate change preferably using their local dialects. Policies aimed at mitigating the effects of climate change should also be implemented.

INTRODUCTION
The issue of climate change has become more threatening not only to the sustainable development of socio-economic activities (including agriculture) of any nation but to the totality of human existence. Various studies by the Intergovernmental Panel on Climate Change (IPCC) have identified Africa as one of the most exposed continents to suffer the devastating effects of climate change because of inadequate adaptive capacity (IPCC, 2007).

The African rain-fed agriculture is viewed by many observers to be the most vulnerable sector to climate variability. Climate change has been a topical issue in the sustainability of environment as crop yield and production becomes very important to economy and human livelihood. The sub-humid climatic zone of Africa permits the cultivation of a variety of crops in a pattern that is responsive to local conditions (Ziervogel *et. al*., 2008 and Onyekwelu *et. al*., 2006). It follows therefore that any change in climate may affect the agricultural sector and other socio-economic activities. Agricultural production and access to food in many African countries is assumed to be severely compromised by climate variability and change in precipitation. The area suitable for agriculture, the length of growing seasons and yield potential, particularly along the margins of semi-arid and arid area, are expected to decrease. In some countries, yields from rain-fed agriculture could be reduced by up to 50% by 2020 (Brett, 2009).

Agricultural production in Nigeria is weather dependent. Climatic variability and change have a direct, often adverse influence on the quantity and quality of agricultural production in Nigeria (Umeghalu, and Okonkwo, 2012). There is observed decline in crop yield and food crop production due to reduction in rainfall and relative humidity, and increase in temperature in Nigeria (Agbola and Ojeleye, 2007). Like other developing countries, the challenge of climatic change and global warming is enormous in Nigeria due to widespread poverty. This paper therefore attempts to analyze the effects of the socio-economic characteristic of yam farmers on adoption of climate change adaptation strategies in Kuje Local Government Area of Abuja.

MATERIALS AND METHODS
This study was conducted in Kuje Local Government Area, Federal Capital Territory, Abuja, Nigeria in 2015. The Area is about 10km from the airport, and about 40km south of Abuja. Kuje Area Council is located on latitude 12^0 11'N and longitude 6^0 42'E. The Area Council comprises of about one hundred and sixty two (162) Communities, widely spread within a land mass of about 1,800 square kilometer and a population of over 420,000. It is characterize by rocky terrain which makes it difficult to access. Most of the indigenes are farmers who produce crops such as Yam, Cassava, Maize, Guinea corn and Rice. They also produce vegetables such as spinach and tomatoes along the river bank. Finally, tree crops grown in the area include mango, cashew and palm trees.

Multiple random sampling techniques was used in selecting respondents for the study. The first stage was the purposive selection of the area council because of the preponderance of yam farmers in the area. In the second stage, ten wards were randomly selected out of which a village was selected from each of the wards. Ten (10) yam farmers were selected randomly from each of the selected villages to arrive at 100 respondents who were considered for the study. Primary data was obtained from the respondents using a well structural questionnaire complimented by oral interview. The questionnaire was an open and close ended type and was designed to obtained data to suit the objective of the study. Descriptive statistics (frequencies and percentages), likert scale and Tobit regression were used to analyze the data.

Likert scale

A 3 point likert rating scale was used to measure the level of response of the respondents to the effect of climate change using 1 to denote Highly intense (HI), 2 to denote Partially intense (PI) and 3 to denote Not intense = (NI). To determine the mean likert level of each item, the frequency was multiplied with its appropriate nominal value and divided by the sum of frequency. The likert scale is expressed as:

$$\text{Weighted Average } X_w = \frac{3(N_1) + 2(N_2) + 1(N_3)}{F} \text{ -- (1)}$$

Where;

X_w =Weighted average

$N_1 + N_3$ = Rating scale

F = Frequency of respondents =100

(ii) The mean score of respondents was set at 2.00 that is

$$X = \frac{3 + 2 + 1}{3} = 2 \text{--- (2)}$$

Tobit regression

The relationship between the socio economics characteristics of the yam farmers and the probability of their adoption of climate change adaptation strategies was analyzed using the Tobit regression model. The model is expressed following Tobin (1958). Tobit decomposition frame work examines the effect of changes in the explanatory variable (Xs) on the probability of adopting measures to adapt to climate change by the yam farmers. The Tobit regression model can be mathematically expressed as follow:

$$V_i = \begin{cases} V_1 = \beta X_i + \varepsilon_i \text{ if } V_1 > V_1^* \\ V_0 = \beta X_i + \varepsilon_i \text{ if } V_1 \leq V_1^* \end{cases} \text{ -- (3)}$$

Where V_I is the number of respondents, V_0 is the limited dependent variable, it is discrete if the farmers don't adopt climate change mitigation measures (it assumes zero value if in this case) and continuous if they adopt i.e equal to V_1*. $V_I^* > 0$ implies that V_i is observed; $V_i^* \geq 0$ implies that V_I is not observed; X_I is a vector of explanatory variable; β is a vector of unknown coefficient and ε_I is an independently distribute error term.

The empirical model used for determining socio economic factors that influenced the adoption of climate change adaptation strategies by yam farmers in Kuje Local Government Area was specified as:

$$V_1 = \beta_0 + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + \beta_7X_7 + \beta_8X_8 + \beta_9X_9 + \varepsilon_i \text{ ------------------------------- (4)}$$

Where:

V_1 = Limited dependent variable, it is the adoption or otherwise of climate change adaptation measures.

β_0 = Constant

β_i = vector of unknown parameters

ε_i = independently distributed error term

$X_1 - X_9$ = The independent variables specified as determinants of adoption of climate change adaptation by yam farmers and defined as follows:

X_1 = Gender; X_2 = Age (year); X_3 = level of education (years); X_4 =House Hold Size (number); X_5 = Marital Status (dummy, single= 0 married=1); X_6 =membership of a co-operative (dummy, yes=1, No=0); X_7 = Farming experience (years); X_8 = Access to credit (₦); X_9 = Awareness of climatic change (dummy, aware = 1, Not aware = 0); e = error term.

The presence or absence of multi collinearity was verified by comparing the number of significant coefficients of the regressors with the coefficients of determination. According to Gujaratti (1995) multi collinearity among the explanatory variables is likely with a high coefficient of multiple determination and very few significant t-ratios of the regressors. This method according to Olayemi (1998) is better than the pair-wise correlations among regressors because high level zero-order correlations are a sufficient but not a necessary condition for the existence of multi collinearity because it can even exist when the correlations are comparatively lower than 0.5.

RESULTS AND DISCUSSION

Effect of Climate Change on Yam Production

The mean of the Likert scale was found to be 2; this therefore implies that any variable in Table 1 whose mean score was ≥2, will imply that such an effect was perceived by the farmers to be highly intense. The variables with a mean score < 2 on the other hand signifies that the effect of climate change on yam production was perceived to be low. Therefore, the farmers perceived that climate change was highly responsible for drought and irregular rainfall often experienced in the area.

Coping Strategies Adopted by the Respondents in the Study area

Result on Table 2 shows the different strategies employed by the respondents to protect their crop from the harsh effect of climatic change. Mulching, mixed cropping and increased fertilizer usage were some of the widely used strategies. Others are shading of the crop, increased used of manure and land fragmentation. This implies that the farmers put in some effort to cope with and/or mitigate the effects of climate change in the study area.

Relationship between the Socio-Economic Characteristics and Adoption of Adaptation Measures to Climate Change by the Respondents

The result of the analysis in Table 3 shows the relationship between the socio-economic characteristics and the adoption of adaptation strategies to climate change by the respondents. The result shows that the log likelihood was 61.130223 and the LR chi 2(9) = 1055. They were both significant (P<0.01). This implies that the socio economic characteristics of the respondents greatly influence their adoption of climate change adaptation strategies. The result shows that the coefficient of age (-0.056) was negative and significant at (P<0.05). This indicates that the older the respondents become, the lesser their probability of adopting climate change adaptation strategies. The coefficient of house hold size was also negative which indicate that when there is increase in the household size, it will lead to a decrease in the adoption of adaptation strategies. This is however not in consonance with the *a priori* expectation. Education and awareness of climatic changes were also significant. The implies that a unit increase in these variables is likely to result to a probability of adopting climate change adaptation strategies by the farmers.

CONCLUSION AND RECOMMENDATIONS

The study established that yam famers in Kuje Local Government Area were aware of the effects of climate change on their crops. They particularly considered the drought and irregular rainfall often experienced as some of the most important effects of climate change. Consequent upon this, they practiced some coping strategies to forestall total crop failure. The socio economic factors that affect their adoption of climate change adaptation strategies include age, level of education, household size and awareness of climate change. To keep the farmers in employment and thus promote agriculture in the area, it is recommended that:

1. Deliberate efforts should be made to educate the farmers about the reality and broad effects of climate change. To this effect; the village level extension services should be reinvigorated.
2. The farmers should have access to weather forecast at all times. This could be through broadcast in their local dialects and finally;
3. Policy issues on climate change should be implemented with the urgency it deserves.

ABSTRACT
The study examined the perceived effects of climate change among yam farmers in the federal capital territory Abuja, Nigeria. Multistage sampling technique was used to select 100 yam farmers for the study. Focus Group Discussion and structured Questionnaire was used to elicit information from the respondents. Data obtained were analyzed using descriptive statistics, 3 point likert scale rating and 5 point likert scale rating. The respondents were within the mean age of 45 years. Farmers major sources of information on climate change were radio and television with means of (2.6) and (2.6) respectively. Farmers perception of climate change on yam production were increased in temperature (mean=4.7), reduced crop yield (mean=4.5), increased frequency of draught t(mean=4.0), increased effect of heat stress on yam (mean=4.7), Intense weed growth (mean=4.2), late tuberisation of yam (mean=4.3), post harvest losses due to climate variability (mean=3.9) and reduction on vegetation cover (mean=3.7). The study recommended that improved agricultural packages developed to help farmer adapt to climate change should be available to rural farmers example use of pest and disease resistance varieties of yam and also serious enforcement of laws and regulations at the local level to prevent indiscriminate bush burning and felling of trees to safeguard the environment.
Keywords: Climate change, perception, Yam farmers

INTRODUCTION
Agriculture is one of the sectors most vulnerable to climate change impact in Africa Falaki *et al*. (2012). Although climate change may affect the agricultural sectors of different countries in different ways, what is clear is that these changes will bring about substantial welfare losses, especially for smallholders whose main source of livelihood derives from agriculture. Across Nigeria, millions of people are already experiencing changing seasonal patterns of rainfall and increased heat.

Climate change as defined by Intergovernmental Panel on Climate Change (IPCC) (2001) as any change or shift in the average weather condition over time has become a global issue in recent times. It manifested in variations of different climatic parameters including cloud cover, precipitation, temperature ranges, sea levels and vapour pressure (FGN 2003). According to Akinnagbe and Irohibe (2014), in most African countries, crop farming is mainly subsistence and rain-fed, but due to climate change frequent and untimely raining affects harvest of produce and thus, food production.

It is evidenced that climate change will have a strong impact on Nigeria-particularly in the areas of agriculture; land use, energy, biodiversity, health and water resources. Nigeria, like all the countries of Sub-Saharan Africa, is highly vulnerable to the impacts of Climate Change (IPCC 2007; NEST 2004). It was also, noted that Nigeria specifically ought to be concerned by climate change because of the country's high vulnerability due to its long (800km) coastline that is prone to sea-level rise and the risk of fierce storms. It is important to identify various effects of climate change in vulnerable communities, which will enable the determination of the extent of risk posed by changing climate on their dominant occupation that is agriculture as well as enhance development, streamlining and up scaling adaptation strategies. This is further necessitated by the fact that the effect of climate change is location specific and these have to be determined in order to develop comprehensive and suitable adaptation strategies which will capture vulnerable communities in developing countries. It was against this background that perceived effects of climate change among yam farmers in federal capital territory were conceived.

Purpose of the study
The general objective of the study is to identify perceived effects of climate change among small-scale yam farmers in Federal Capital Territory, Abuja Nigeria. The specific objectives were to:

i. describe the socio-economic characteristics of the respondents in the study area;
ii. identify the farmer's source of information/awareness on climate change;
iii. determine the farmer's perception of the effect of climate change on yam production;

METHODOLOGY
The study was conducted in Abuja Municipal Area Council of Federal Capital Territory (FCT) Abuja to ascertain the perceived effects of climate change among small-scale yam farmers in Federal Capital territory. Using

multistage sampling technique, Abuja Municipal area council was selected for the study because of its proximity to the researcher and also is one of the major yam growing areas in Federal capital territory in the first stage, in the second stage, five communities namely orozo, karshi, Gugugu, kwoi and Tunga were selected also from the selected area council. The third stage involves the random selection of twenty yam farmers each from the selected communities, giving a total of one hundred yam farmers for the study. Focus group discussion and structured questionnaire were used to elicit information from the respondents. percentages and means were used to analyse objective 1, a 3 point likert scale rating was used to satisfy objective 2 while objective 3 was achieved by the use of 5 point likert scale rating.

RESULTS AND DISCUSSION

Socio-economic characteristics of the yam farmers

The findings in table 1 shows that majority (46%) of the farmers are still at their productive age between the ages of 31-50 years with mean age of 45years. This indicates that the majority of the respondents were within active age for agricultural production. The result is in agreement with the report of Ekwe *et al.* (2006) that most farmers are within the middle-age and vibrant in agricultural production. From the result, the yam farmers had average household size of 10 persons. This indicates that respondents have large household size which will provide adequate labour for farming activities. Household with large size tended to attach greater importance to food security than those with small size. This finding had implication for adoption level of technologies in the study area. It however signified that the farmers had a fairly large household, which could probably supply farm labour. About 61% of the farmers had 1 to 15 years of farming experience, while 38% of them had farming experience of between 16 and 30 years , The mean years of farming experience was 14 years This implied that most of the respondents had been in the farming business for a long time. Years of farming experience were important because management skills improved with experience. Hassan (2008) also indicated that experience in farming increases the probability of uptake of adaptation measures to climate change.

The farmers have different forms or levels of education suggesting that the farmers have some basic literacy, were relatively informed and have some experience in yam production. Education increases one's ability to receive, decode, and understand information relevant to making innovative decisions (Wozniak, 1984). Educated and experienced farmers are expected to be more informed about climate change and respond positively based on their knowledge. This corroborates the work of Maddison (2006) who found that educated and experienced farmers are expected to have more knowledge and information about climate change and agronomic practices that they can use in response to climate change phenomenon. Due to lack of education, a lot of traditional farming practices detrimental to the environment still persist and farmers find it difficult to modify.

Result also indicated that the average farm size was 2.9 ha, an indication that the study covered small scale family managed farm units.

Sources of information on climate change

The results in table 2 shows that the farmers most preferred source of information on climate change were radio and television with average of (2.6) and (2.6) respectively while Newspaper ,extension contact and mobile phones with average of (1.4), (1.6) and (1.3) respectively are not preferred. Radio and televisions were the major avenues through which the respondents sourced information on climate change from. These findings concur with Isife and Ofuoku (2008), who documented that radio, has the highest audience and has the strength of reaching a large population of farmers and other rural dwellers faster than other means of communication. They also noted that television provides farmers with the opportunity of seeing and hearing in the process of learning new ideas. The implication of this finding is that there is need for extension services to rise up to the challenge of information dissemination, (especially as regards the issues of climate change), as this is the central focus of its services. The result from focus group discussion indicated that farmers prefer radio because it was cheaper to use even without electricity.

Perceived effects of climate change on small-scale yam production

The results in table 3 shows that the variables listed were all perceived to be the effect of climate change on small-scale yam production in the study area. They include increase in temperature (mean=4.7), reduced crop yield (mean=4.5), increased frequency of draught t(mean=4.0), increased effect of heat stress on yam (mean=4.7), Intense weed growth (mean=4.2), late tuberisation of yam (mean=4.3), post harvest losses due to climate variability (mean=3.9) and reduction on vegetation cover (mean=3.7).This result is in agreement with the findings of Ayanwuyi et al.(2010) who found out that the dominant impact of climate change include low yield of crop, stunted growth, ease of spread of pest and diseases attack on crops.

Result from focused group discussion shows that high temperature affects yam and makes it to decay and also weeding is one of their major problems because they weed up to five times before harvesting..These are the perceived effect of climate change on yam production.

CONCLUSION

From the findings of this study, it revealed that most of the farmers were aware of climate change. Respondents perceived the effect of climate change to be increasing temperature, reduced crop yield, late tuberisation of yam and increased effect of heat stress on yam etc.. Radio and television were their major sources of information on climate change. It is therefore recommended that system of agriculture and improved agricultural packages developed to help farmer adapt to climate change should be made available to rural farmers. This may include improved varieties of yam, pest and disease resistance yam and also draught tolerant varieties of yam. There should be also serious enforcement of laws and regulations at the local level to prevent indiscriminate bush burning and felling of trees to safeguard the environment.

Table 1: Distribution of respondents on socio-economic characteristics of small scale yam farmers

Variables	Frequency	Percentage	Mean

ABSTRACT
The study was on profitability analysis and fish farming system practices among smallholder in Abakaliki LGA of Ebonyi State, Nigeria. A total of 120 respondents were selected as sample size for the study with the use of purposive random sampling technique. Data were collected from the respondents using structured questionnaire and analyzed using descriptive and inferential statistics. The result of the analysis further indicated that 59.1% of the respondents practiced monoculture. The major sources of farm inputs used by open market, personal, ADPs and Fadama while most of them acquired land through leasing and family. The result of the analysis also showed that the fish farmers sourced their finance mainly from financial institutions (45.5%). Furthermore, the result of the research work also showed that fish farming found to be highly profitable in the study area. The result on constraints hindering fish farming showed according to findings included high cost of feed, lack of credit facilities, lack of technical information, shortage of fingerlings, and inefficient pond management (9.4%). Based on findings of the study, the following recommended that; There is need for government intervention through the provision of soft loan that can be easily accessed by the farmers.
Keywords: Profitability, Analysis, Fish Farming, System, Practices, Small holder, Farmers, Abakaliki, Ebonyi, State.

INTRODUCTION
Fish plays a vital role in feeding the world's population and contributing significantly to the dietary protein intake of billions of the populace (Amao *et al.,* 2006). On a global scale, almost 16 percent of total average intake of animal protein was attributable to fish in 1988 (FAO, 1990). The Food and Agriculture Organization (FAO, 1991), recommended that an individual takes 35 grams per caput of animal protein per day for sustainable growth and development. Fish which contributes 36.6 grams per day of net protein utilization in Nigerian homes is still below the recommended requirement by the World Health Organization (WHO) (Amao *et al.,* 2006). However, the animal protein consumption in Nigeria is less than 8 g per person per day, which is far lower than the FAO minimum recommendation (Niang and Jubrin, 2001). Fish and fish products provide more than 60% of the total protein intakes in adults especially in the rural areas (Adekoya, 2004). In developing countries, fish is a highly acceptable food that supplies as much as 40 percent of all animal protein availability of the countries where fish is the main source of animal protein. Moreover, the poor spend proportionally more on fish than on meat or other sources of animal protein. FAO fisheries report (2005) indicates that fish is very important in nutrition, as it provides vital nutrients and source of animal protein especially to the poor who are unable to purchase other more expensive sources such as beef, pork or chicken. The report estimated that capture fisheries feed about 17 million people at an average annual per capital consumption of 10 kg. Antonio and Akinwumi (1991) and Slang (1973) verified that fish allows for protein improved nutrition in that it has a high biological value in terms of higher protein retention in the body, higher protein assimilation as compared to other animal protein sources, low cholesterol content and one of the safest sources of animal protein. Increasing the per caput consumption of fish in any country benefits health. Fish and fish products are known worldwide as a very important diet because of their high nutritive quality and significance in improving human health (Amao *et al.,* 2006).

Objectives of the Study
The broad objective of the study is to investigate on profitability analysis and fish farming system in Abakaliki LGA, Ebonyi state. The specific objectives of this study included to identify the fish farming systems adopt by fish farmers in the study area; examine the cost and return in fish farming in the study area and analyze the constraints to fish farming in the study area,

METHODOLOGY
The study area is Abakaliki Local Government Area of Ebonyi State of Nigeria. In the course of this research work, multi-stage random sampling techniques were employed in selecting the respondents for the study. The local

government area is made up of seven (7) autonomous communities while four (4) were randomly selected and used for the study. Then ten (10) villages were selected from each autonomous communities giving a total of forty villages. Three (3) farmers were randomly selected from each village and this gave a total of 120 fish farmers selected for the study. Both primary data was collected for the study. Primary data was collected using questionnaire that were administered on 120 fish farmers while secondary data were collected from the existing records of the fish farmers. Data collected for the study were analyzed using descriptive statistics frequency distribution, percentage, and inferential statistics of gross margin analysis.
Descriptive statistics such as frequency distribution, percentage were used to analyze objective (i), (ii) & (iii). Gross margin analysis will be used to analyze objective (iii)

Model specification
Gross margin analysis
Gross margin is stated as

GM = TR - TVC - - - - -

Where;

GM = Gross margin (N)
TVC = Total variable cost
TR = Total Revenue

Profit given by

π = GM - TFC

Where

π = Profit
GM = Gross margin
TFC = Total Fixed cost

RESULTS AND DISCUSSION

Types of Fish Farming Systems Adopted
The result of the fish farming systems adopted shows that majority (52.5%) of the respondents adopted intensive fish farming system in the area. It implies that operation practices in the study area is dominated by intensive system. This indicates that fish farming is taken as a main business and the farmers commit a lot of their resources into it. The result also shows that 35% of them were involved in semi-intensive system and only 12.5% of the respondents were involved in extensive method.

Types of Fish Culture Adopted
Data in Table 2, indicates that most (65%) of the respondents practiced mono culture alone while 35% practiced polyculture only. This is similar to what is generally practiced in most region of Nigeria. This can be attributed to the fact that the same species of fish is relatively easy to maintain and require less technical know-how.

Costs and returns in fish farming
Profit is the most important return and this was determined by subtracting the cost of production from the amount received when the stock is sold. Result in Table 13 shows that the total variable cost of fish production was ₦96725 while and total fixed cost was ₦134500 while the total revenue was ₦943750, the profit was ₦712525. This implies that fish farming is profitable since, the total revenue was higher than the total cost of production. This shows that the business is profitable in line with the level of investment and variable cost minimization.

Inputs used in fish production
From Table 4, majority (45.5%) of the respondents sourced their inputs from open market and other farm inputs from personal (18.2%) while others sourced inputs from ADPs and FADAMA (13.6%). This implies that the strategic approaches used by ADPs, FADAMA and ministry of agriculture in distributing farm inputs to farmers are not quite effective.
From the result, it was observed that majority (40.9%) of the respondents lease their farm land for fish production. Land obtained through inheritance had 22. 7% of the responses, while, family and purchase had 31.8% and 4.5% respectively. Result of the analysis showed that (45.5%) of the respondents sourced their capital from financial institutions while 22.7% of them used fund from personal savings while money lenders and borrowing from individuals had 18.2% and 13.6% the responses respectively. Furthermore, it was observed that (50%) of the respondents used hired labour in the study area while 22.7% of them used family labour in carrying out their fish farming activities. The result also revealed that exchange labour and commercial labour had 18.2% and 9.1% respectively.

Constraints to Fish Farming
The survey revealed that there are many constraints hindering efficient production of fish by the fish farmers. The most serious problems in the study included high cost of feed, lack of credit facilities, shortage of fingerlings and

lack of technical information with 81.8%, 72.7%, 68.2% and 63.6% responses respectively. The result of this analysis therefore corroborates the assertion of Ademuyi et al, (2010); who opined that empirical evidence are abound in economic literatures on factors that affect productivity of fish production, including high cost of feed, shortage of fingerlings and training of farm operators and agro-environmental condition.

CONCLUSION

Based on the findings of the study, it is therefore concluded that is a profitable investment considering the size of the business venture. The result of the analysis further indicated that 59.1% of the respondents practiced monoculture. It is evident that fish farming is capable of creating employment, augmenting income and improving the standard of living of the people. The major constraints identified were high cost of feed, lack of credit facilities, lack of technical information, shortage of fingerlings, and so on. Based on the findings of the study, government promotion on fish farming is not adequate therefore there is need for more public enlightenment while providing soft loans for poor farmers.

Table 1: Percentage distribution according to their fish farming systems adopted

EFFECTS OF CLIMATE CHANGE ON OF HONEY PRODUCTION IN UMUAHIA NORTH LOCAL GOVERNMENT AREA, ABIA STATE NIGERIA

C.I. Okpokiri, C.N. Onwusiribe & N.M. Agwu

Department of Agribusiness and Management, Michael Okpara University of Agriculture Umudike, Abia State, Nigeria
blazes.okpokiri@gmail.com

ABSTRACT
Climate change effect is world over and it's the most serious environmental threat facing mankind. The study focused on climate change effect on of honey production and also the challenges caused by climate change. 240 respondents were randomly selected and interviewed through questionnaires. Likert scale and multiple regressions were the major tools of analysis. It was observed that the major effect of climate change was seen in the reduction in yield which has reduced the returns to honey producers. Household size, education, change timing of rain, number of extension visits, decline in productivity and experience were significant variables that had an effect on profits of honey producers in the area. Government should provide metrological instruments and trained more extension workers who will educate the farmers on ways to mitigate the effects of climate change in the area.
Key words: honey production, climate change, apiculture

INTRODUCTION
The greatest challenge that confronts man and societies today and the generations to come is the issue of climate change. Climate change has become the new reality of our time. It brings with it changes in weather patterns that can have serious repercussions for human beings, upsetting seasonal cycles, harming ecosystems and water supply, affecting agriculture and food production.
Nigeria had her fair share of incidents of climate change which was evidenced in the flooding of Kogi, Bayelsa etc in 2012, loss of jobs, crop failures, among many others. Agriculture in Nigeria is rain feed; variability in climate has increased the incidence of crop failure giving farmers a hard time meeting the consumption in the country. Climate change affect all facet of agriculture and honey production is not left out. Due to frequent and intense rainfall as a result of climate change, bees tend to use more honey to survive owning to the fact that there is reduction in the quantity of nectar available due to long and increased intensity of rainfall. This reduces the income of the apiculturist as the quantity of honey harvested is below the expected (Oyerinde *et al*, 2014).
The study analyzed the problems caused by climate change in the study area and determinants of climate change effect on profit honey production.

MATERIALS AND METHODS
The study was carried out in Umuahia north local government area of Abia State because of high concentration of honey producers in the area. Umuahia north local government area is one of the 17 local government areas in Abia state and is also part of the three agricultural zones abia state is divided into namely; Umuahia, Aba and Ohafia. Predominant occupations in the area include farming, civil service, traders and artisans. A total of 240 honey bee farmers were randomly selected for the study. Multiple regression and likert scale were the major tools of analysis used for the study. Likert scale was used to identify the significant problems predominant in the area while multiple regressions was used to estimate the determinants of climate change effect on honey production.
Multiple regression model in its explicit form is stated as:

$$Y= b_0+b_1x_1+b_2x_2+b_3x_3+b_4x_4+b_5x_5+b_6x_6+b_7x_7+b_8X_8+\ldots+b_nx_n +e i$$

Y= returns of apiculture farmers in naira; X_1 = level of education of the famer measured in years; $X_{2=}$ gender (male=1 and female=0); X_3 = experience of the farmers measured in years; X_4 = household size measured in numbers; ; X_5 = number of extension visit; X_6 = change timing of rain (yes =1, others =0); $X_{7=}$ perception to the level of rainfall (high =3 ,average =2 and low =1); $X_{8\,=}$ perception to the level of sunlight (high =3 ,average =2 and low =1)

RESULTS AND DISCUSSIONS
Climate change effect in the study area
A 4 point likert scale was used to ascertain descriptively the effects of climate change as perceived by the respondents in the study area. Scores were given to the responses as high = 4, average = 3, low = 2, none = 1. The mean point was calculated and used to determine whether a factor was significant or not. The mean point of 2.5

was used as the decision rule. Any factor which has a mean less than 2.5 will be assumed not to have a significant effect of climate experienced in the study area and any climatic effect greater or equal to 2.5 is assumed significant.

The result from Table 1 shows that reduction in yield, reduction in farm income, reduction in storage quality, and reduced production cycle were significant effect of climate change in the study area. Prolonged production, destruction of wild life, and premature ripening of fruits were not significant.

Reduction in yield was the most significant with a mean score of 2.94. Reduction in farm income was 2nd with the mean score of 2.78; reduction in storage quality of produce with a mean score 2.62 was 3rd while prolonged production process was 4th with 2.54 mean score. By this result, it could be concluded that reduction in yield was the major challenge faced by the farmers in the area. This is no surprise as agriculture in Nigeria is rain feed and change in timing of rain fall has a devastating effect on production. This invariably will lead to reduced income and little to no storage facilities in the area is not helping at all. Anyoha *et al* (2013) observed that farmers complained on the reduction in yield as a result of climate change which have affected their profit and in some cases eaten deep into their capital as bills will not stop coming profit or no profit.

Determinants of climate change effect on honey production returns

The semi log regression model was chosen as the lead equation based on the value of the R^2 0.670 which indicates that 67 percent of the total variation in the dependent variable was due to the variability of the independent variables and the number of significant variables. The model is statistically fit based on the value of the F-statistics (2.754) which indicates that the model is significant at 5 percent.

Household size, education, change timing of rain, number of extension visits, decline in productivity and experience were significant variables that had an effect on profits of apiculturist while Sex, rainfall and sunlight were not significant variables affecting the subject matter.

Household size was negatively significant to the returns of honey production at 5% probability level. The higher the household size the more honey consumed which reduces the quantity sold for profit. Also, feeding, school fees, health care etc of the large household depletes the profit. Climate change affects the returns at the farmers disposal as high frequent of rainfall reduces the activities of the bees and this affects the quantity of honey produced which in affects returns. Household labour is not needed as the bees do virtually everything themselves and large household sizes means more responsibilities which reduces profit as concurred by Mbah, 2012 who argued that bloated household size means high responsibility which imposed pressure on the returns of honey producers.

Education was positive and significant at 1% probability level. Apiculture is complicated and not so easy to practice because people are afraid of been stung by bees. Education plays a crucial role in educating the farmer on safe practices, management styles, harvesting, which helps increase the profit of the farmer as he is grounded in apicultural practices. Education enlightens the farmer on the effect of climate change and ways or adaptations he can use to reduce its effect on profit.

Change timing of rain had a negative relationship with profit of honey producers and was significant as 10% probability level. Worker bees gather food during dry seasons and they feed on them during the rainy season. When there is change and frequent rainfall the bees will not leave the hive to source for food and will feast on stored honey there by reducing the quantity of honey harvested which will in turn reduce the quantity sold for profit. Change timing of rain is caused by climate change which reduces the returns of the farmer as bee will not leave the hive in search of pollen under the rain.

Decline in productivity as caused by climate change was significant at 10% probability level and negatively related to returns. Due to frequent and intense rainfall as a result of climate change, bees tend to use more honey to survive owning to the fact that there is reduction in the quantity of nectar available due to long and increased intensity of rainfall. This reduces the income of the apiculturist as the quantity of honey harvested is below the expected. Oyerinde *et al*, 2014 shared the same view.

Experience was positively related to the returns of honey farmers at 10% level of significant. . Experience has taught most of the farmers on the various farm management practices and techniques that could be used in the face of anticipated climate change in the area. Farmers with experience tend to make more profit as they ride the experience curve given that the means of tackling the problems are reasonably known to them. This was line with the findings of onubuogu *et al* (2013).

CONCLUSION

Results from the study showed that Household size, education, change timing of rain, number of extension visits, decline in productivity and experience were significant variables that had an effect on profits of apiculturist. The major climate change challenge in the study area was evidenced in reduction in yield which has affected the standard of living in the area. Government should provide weather measuring equipments to ministry of agriculture and ADP. Meteorologists should be recruited to handle these equipments and educate extension workers and farmers on its use and other weather related facts and Government should emphasize on the "Going green" concept. This implies the use of environmentally-friendly equipment, machines, infrastructure, and technology that produce less of the GHGs.

Table 1: Perception of climate change effect in the study area

	None	Low	Average	High	Total	Mean	Rank
Decreased soil	109 (109)	51 (102)	49 (147)	31 (124)	240 (482)	2.01	6

ABSTRACT
The purpose of the field work was to observe and generate data on the pattern and distribution of rainfall in Afikpo North Local Government Area (LGA) of Ebonyi State for 2015. The L.G.A. is made up of Twelve (12) Autonomous Communities out of which Ten (10) were randomly selected. Research Assistance (RAs) were needed for the field work and Two (2) RAs were purposively selected from the Ten (10) randomly selected Autonomous Communities to give Twenty (20) RAs. Some instruments, among which was a Self-designed recording instrument, were used in the exercise and data were collected and analyzed using frequency Tables and graphs. The result will help to suggest to farmers on how to plan their farming activities in order to among others, minimize losses of farm produce on the farm. Some of the results showed that there was absence of the usual "August break" in the month of August and heavy downpours were experienced between the months of August and October and there was absence of the usual "double maxima" in the months of July and September of the two years. Recommendations, among others, were that farmers should delay planting and commence crop planting after about 4-5 weeks after the first set of rains, they should not allow crops, as has been the usual practice, to dry-up in the farms between the months of September and October to reduce losses of farm produce in the farm.
Keywords: Global warming, climate change, rainfall pattern, agriculture.

INTRODUCTION
The mainstay of Nigerian Economy since independence according to Bureau of Public Enterprise (BPE) (2004), is agriculture, as it accounts for 38% of the non-oil foreign exchange earnings and employs about 70% of the active labour force of the population. Agriculture offers Nigeria the most cost-effective path to growth and development. With its ever extending value chains, agriculture provides jobs to over 60% of the working population, and if well-harnessed could be a sustainable springboard for the much awaited industrialization (Moghalu, 2012). This is because the produce from agriculture when exported to foreign countries earns the country foreign exchange with which acquisition of the necessary items or materials for the industrialization of the nation is made.

For agriculture to be sustainable, there is the need for a favourable climate as an all important ingredient or input in agriculture. The effect of climate, a major requirement in agricultural production need not be over emphasized. This is in consideration of the crucial roles of its various elements, especially rainfall, in relation to agricultural production.

Rainfall, a very essential element of climate has numerous implications for agricultural production of a place (Oga, 2014). This is because its nature (time of commencement in a given period, amount, duration, intensity and distribution) to a very large extent determines the type of and level of agricultural practices and production of a place. According to Emedo *et al* (1995), much of the water for Agricultural production comes from rainfall. Where rainfall is well distributed and in adequate amount, growth and productivity of crops like yam, cocoyam, cassava, plantain, corn, rice and tree crops like rubber, kola-nut, oil palm, citrus, among others, is guaranteed.

According to Nwite *et al* (2007, Oga, 2014) the most important element of climate is rainfall, the amount that falls, how it falls e.g steadily over several days or suddenly in torrential downpours, hence its effectiveness i.e how much of it is available for use by plants. Currently, it has been observed, and even available records have shown that the nature (time of commencement, amount, duration, intensity, etc) of rainfall has not been encouraging. There has been a deviation from the natural pattern of rainfall (Nigerian Meteorological Agency (NIMET), 2016). Sequel to the above discouraging scenario of rainfall as a result of Global warming and Climate change, there is a need to chart a path to assist in mitigating their negative effects and this informed the study. The main objective of this study was to observe and generate data on the present trend and distribution of rainfall in the LGA for 2015. The specific objectives were to examine records of rainfall in 2015 in Afikpo North Local Government Area (LGA) of Ebonyi State and assess the trend of rainfall and its distribution in each month of the year.

MATERIALS AND METHODS

The work was conducted in Afikpo North Local Government Area (LGA) of Ebonyi State of Nigeria in 2015. Afikpo North Local Government Area of Ebonyi State is an Agrarian LGA with a good number of the populace engaged in one form of agricultural production or the other mainly at subsistence level. One of the instruments for data collection was a Self designed recording instrument. The instrument showed the days/dates of each month of the year, 2015. The instrument was faced validated by two Agricultural experts in the Department of Agricultural Technology, Akanu Ibiam Federal Polytechnic, Unwana, Ebonyi State. The experts suggestions were considered in the final design of the instrument. Timing instruments such as Table clock and Wrist Watches were also used
Afikpo North Local Government Area (LGA) is made up of twelve (12) Autonomous Communities. Ten (10) Autonomous Communities were randomly selected for the field work and Research Assistants (RAs) were needed to assist in the work. Two RAs were purposively selected from each of the 10 Autonomous Communities to give a total number of 20 RAs who assisted in examining and recording the parameters considered relevant to the field work.

RESULTS AND DISCUSSION

In Tables 1 and 2 and 3, information available therein show that all the months of the year experienced rainfall except for the month of December.
With regards to duration of rainfall, this was experienced more between the months of August and October for the year covered.
In relation to heavy/moderate rainfall, there were few numbers of heavy rainfalls which lasted for long hours and with much impact between the months of August and October. In terms of moderate rainfall, there was high record of moderate rainfall in the year, 2013. The highest peak of rainfall for the year, 2013 was recorded in the month of August, that of the year, 2014 was recorded in the month of October and that of 2015 in the month of September. There were sharp drops in rainfall after the month of September in 2015. These observations are contrary to popular opinion.

Implications for Agricultural Production

Prior to incidence of Global Warming and Climate Change, available records, information from Focus Group (FG) discussions and personal experiences show that the usual rainfall pattern and distribution in South East zone of Nigeria where Afikpo North Local Government Area of Ebonyi State is located experienced on the average six (6) months of rainfall from the month of April to September with "double maxima" (two peaks of rainfall) in the months of July and September.
But currently, this part of the zone hardly experiences on the average four (4) months of well distributed rainfall. This is evident in Table 1. Also available records, information from (FG) discussions and personal experience have also shown that the rains now commence early in the years between the months of February and March and suddenly disappear thereafter. The rains start again in the month of May increasing gradually in frequency, duration and intensity which fluctuate and with heavy downpours with much impact between the months of August and October. This pattern of rainfall and distribution is not favourable for both crops and livestock production. In a situation where rainfall is expected to last for six (6) months and only about four (4) months of rainfall which are not well distributed in the months of the year may be available, may not augur well for agricultural production. Consequently, crops are not cultivated at the appropriate time. This position is supported by Anam *et al.* (2015) who stated that the rain does not fall in the way it used to, and the crops do not grow the way they used to. With the above trend, some crops such as rice, maize, yam, cassava, etc that require much water to thrive well may suffer, especially between the months of May and June. There may also be absence of crops cultivated early in the year such as early maize due to inadequate rainfall and late cultivated crops such as late maize due to excessive downpours during the later part of the year (i.e. between the months of August and October). Often when crops are cultivated, the rains may come down heavily between the months of August and October, washing and carrying away plants and animal materials and destroying farm lands.
In most parts of the country, the South-East Zone and the LGA inclusive, some farmers allow un-harvested crops in the farm between the months of September and November to dry up and used as future farm inputs or for home consumption. To this regard, these farmers have suffered losses of such crops as a result of rainfall experienced around this period of the year. According to the field work carried out by Oga and Oga (2011, 2012 & 2013) on the Pattern of Rainfall and distribution in Ebonyi State and the LGA, there has been convincing deviation from the usual pattern of rainfall and distribution in both areas. This position was corroborated by (NIMET, 2016).

CONCLUSION

The practice of agriculture is affected by various factors especially climate. The effect of climate is felt through one of its potential elements, rainfall. The rainfall of a place, to a large extent determines the scenario of agricultural production of the place. Currently, the nature of rainfall in relation to agricultural production in the LGA is not encouraging due to the influence of Global warming and Climate change. In order that agriculture continues to play its role as the backbone of a nation's economy, global warming and subsequently Climate change, need to be mitigated. Strategies to be employed in this regard include among others, creating adequate awareness to the public and especially to farmers on the realities of Global warming and Climate change, farmers to delay cultivation of crops to about 4-5 weeks after the first set of rains which now occur early in the year and farmers to avoid setting fire on cut down vegetation on the whole farm but to pack them at strategic places probably on the farm to rot away over time. On the basis of the findings, adequate awareness should be created on the realities of global warming and climate change both for the farmers and public consumption.

ABSTRACT
The study was a survey type of research. Primary data was collected using questionnaires and interviews. The sample size for the survey was 100. Questionnaire responses were analyzed using frequency distribution tables and percentages. Results from the survey showed that Information and communication technologies (ICTs) had positive impacts on extension services in Nigeria since year 2000 boom of use of ICTs. It was also deduced from the survey that there are strategies that could aid improved use of ICTs in agricultural extension in Nigeria and top most on the list was creation of awareness of ICTs tools' uses and benefits in rural areas where majority of farmers reside. The study further highlighted strategies that should be adopted should stake holders want to reposition agricultural extension services delivery in Nigeria in a rapidly changing world.
Keywords: Extension, ICT, evolving, repositioning, effective

INTRODUCTION
Effective communication of agricultural information to farmers is crucial in achieving optimum efficiency in agricultural extension administration and practice in Nigeria, Okeke et al (2015). Agricultural extension is the means through which information of various sorts from relevant agencies are disseminate to the farmers. Arokoyo, (2006) submitted that there was no doubt , that the effective use of information and communication technologies have the potentials of enhancing the performance of Nigeria's extension services,, as it will allow for pluralistic flow in an agricultural innovation system to ensure effective and efficient sharing and exchange of information, knowledge,, and skills among stakeholders.
In a changing world, and with technologies evolving rapidly, it becomes imperative for stakeholders to reposition agricultural extension services delivery, keying into the evolution of these ICTs in other to attain maximum utilization and enjoy its full benefits.
The broad aim of the research was to suggest strategies for repositioning agricultural extension services in Nigeria in the face of rapidly evolving information and communication technologies. The specific objectives of the study however included:
1. To identify the ways extension services delivery in Nigeria could be improved due to use of ICTs tools.
2. To determine ways of improving use of information and communication technologies in agricultural extension services delivery.
3. To identify strategies that could be adopted to help reposition agricultural extension services in the face of rapidly evolving information and communication technologies.

MATERIALS AND METHODS
The population of the survey comprised of agricultural extension officers in Abia state of Nigeria. 120 Agricultural extension officers were randomly sampled, 40 from each of the three agricultural zones in Abia State. Hence 120 questionnaires were distributed to the sampled population. However, 100 questionnaires were properly filled out and returned bringing the sample size to 100.
Where-; n = 100.
Primary data was collected using structured questionnaires and interview of randomly selected respondents within the sampled population. Secondary data was sourced from review of related literature. Questionnaire responses were analyzed using frequency distribution tables and percentages.

RESULTS AND DISCUSSION
Table 1 shows the improvements that came to agricultural services delivery in Nigeria since year 2000 boom of ICTs tools and usage. The results herein identified the improvements which included that farmers rather than wait for extension agents' visits, now get immediate and rapid responses through telephone calls, text messages and instant messages (98%), quick and effective information dissemination and feedback (90%), Improved extension delivery technologies (82%), and Improved networking and collaboration and easier research technologies (78%).

Other improvements stated by the respondents included reduction of cost and stress associated with extension delivery (75%), increased access to global best practices, leading to large scale production (70%), and finally they respondents also stated that use of projectors now makes workshops easier, as farmers are shown technologies real time and on the spot (65%).
Result from table 2 reveals that top on suggestions made by respondents towards the improvement of use of ICTs in extension services delivery included creation of awareness of ICTs tools' uses and benefits in rural areas where majority of farmers reside (98%), improving overall access to ICTs tools (95%), capacity building on use of ICTs for both extension agents and farmers, especially rural farmers (90%), and subsidizing customized ICTs tools to be accessed by farmers (82%). Other strategies outlined in table 2 are, improving quality and service delivery of ICTs backbones and infrastructures like Mobile Network services, GSM services, and power supply, among others (65%) and finally Government polices to checkmate services providers and ensure the deliver on services (60%).
Strategies to help reposition agricultural extension services to cope with rapidly evolving ICTs.
From the responses gathered from interview of key stakeholders within the sampled population revealed that in other to reposition agricultural extension services in the face of rapidly evolving ICTs the following strategies need to be adopted;

1. As attention of majority of mobile telephone users are shifting from voice calls to mobile data services like instant messaging (whatsapp, blackberry messengers, yahoo messengers et cetera) and video calls (skype, ovoo, etc);
1. Agricultural extension officers should be trained on proficient use of these mobile data services.
2. Farmers who have the capacity to learn the act of using these mobile data services should be trained as well.
3. Extension officers can create groups with their farmers within these instant messaging platforms where information sharing and collaboration will take place.
4. Agencies, departments, research institutes and other stakeholders should ensure the host, service and update websites, which should be updated regularly.
5. Stakeholders should make use of twitter accounts so that farmers who have the technical knowhow can follow them and keep to date with information as they are updated in real time.
6. Social media with all these attaining potentials should be fully utilized in agricultural extension and information dissemination.
7. Seminars, lectures, workshops and symposia should be;
1. Conducted using state of the art ICTs to ensure that farmers are shown technologies either on slides or screens.
2. Audio and video conferencing should be incorporated during these capacity building sessions.
3. Stakeholders can partner with telecommunication companies and ICTs tools vendors to manufacture and distribute to farmers customized devices which can help in forming virtual communities and prompt transfer of information and technology.
4. Lectures on farming methods, processing, value addition and packaging can be posted to YouTube for global audience.
5. Bulletins, guides, magazines, journals, proceedings and periodicals aside from being printed on paper should also have online copies for wider reach and global patronage.
6. Agricultural extension departments should launch blogs on the internet.
7. Television and radio viewers and listeners these days are endeared to cable televisions and online radio platforms rather that local television and radio stations, therefore, efforts should be made to air agricultural programs on cable televisions and online radios. Production of these agricultural programs should be done using state of the art digital cameras and editing software and devices.

CONCLUSION
In this age of ICTs boom, the role of efficient and effective dissemination of agricultural information and delivery of extension services to farmers falls on information and communication technology tools. With the help of these ICTs tools farmers are able to receive prompt information about availability of inputs, weather forecasts, forecasts of impending disease or pest outbreak, farming methods, market prices, and technological innovations and so on. Common ICTs tools used by extension workers include Radios, Televisions, Telephones, print media etc. The study identified that ICTs tools had a massive positive impact on agricultural extension services since the year 2000, and further mapped out ways of improving the use of ICTs tools in agricultural extension services. The study acknowledges that ICTs tools are evolving rapidly hence outlines strategies to help reposition extension services delivery in Nigeria in other to cope with these rapid evolutions and achieve maximum utilization.

Table 1: Improvements in extension services delivery due to use of ICTs

Response	Frequency	Percentages (%)
Rather than wait for extension agent's visits, farmers now get immediate and rapid responses through telephone calls, text messages and instant messages.	98	98
Use of projectors now makes workshops easier, as farmers are shown technologies real time and on the spot.	65	65

ABSTRACT

Soybean (Glycine max. L) is now an important cash crop produce in many localities due to its promising performances and productivity in arid areas especially in soils with poor fertility status. There is need for an increased in production with an advent of new varieties that adapt to many ecological characteristics and high yielding; with this, there is need for improved production technologies to meet up with current production trends in the world. The sampling procedure was based on multi-stage random sampling technique in which three districts were selected at the first stage, four villages at second and third stages respectively making a total of 12 villages sampled and 15 respondents were selected from each of the villages, thereby giving a total of 180 respondents as the sample size for the study. The results show that the adoption of improved technologies among the farmers was at low due to low extension agent's participation, lack of finances, poor sources of inputs and so on. Meanwhile efforts should be geared towards campaigning of adopting technologies.

Keywords: Socioeconomic, adoption, soyabean, technology, farmers

INTRODUCTION

Soybean originated from the people's republic of china, other major producing countries include, U.S.A, Brazil and Argentina as it was also introduced to Nigeria in 1908 as reported by (Misari and Idowu, 1995). Soybean (*Glycine max* (L) Merrill) is an important leguminous food crop grown all over the World (Muoneke, 2007). World production of Soybean is estimated at over 300 million metric tons, cultivated in over 100 million hectares with an average yield of 2000kg per hectare (FAOSTAT, 2014). The crop can be successfully grown in many states in Nigeria using low agricultural input. Soybean cultivation in Nigeria has expanded as a result of its nutritive and economic importance and diverse domestic usage. It is also a prime source of vegetable oil in the international market. The world experienced shortage of oil seeds immediately after the World War II which accelerated the drive for increased Soybean production in Nigeria (Dugje *et al*., 2006). Soybean production in Nigeria has expanded as a result of its nutritive, economic and diverse domestic usage and versatility. The crop can be grown successfully in many states of Nigeria using low agricultural inputs (Idrisa, 2009). In the traditional Soybean growing areas, it is most commonly intercropped with cereal crops such as maize, sorghum and millet (Adeniyan and Ayoola, 2006). Soya bean is consumed as food (milk), used for production of edible oil, animal feeds, soybean cake (Awara) and for industrial purposes. Research efforts to improve the existing Soybean varieties, to expand and increase production in Nigeria were initiated in different research institutes from the mid 1970's (Misari and Idowu, 1995). The International Institute for Tropical Agriculture (IITA) conduct research work on Soybean in the 1970's which this has made substantial effort to improve the production output of the crop (Abdullahi,2004). Notable among the good varieties of soybean produced in Nigeria includes: TGX 1955-3F, TGX1955-4F, TGX 1987-62F, TGX1448-2E, TGX1904-6F, TGX1830-2E; and TG X 1485-2E-ID, (Adeniyan and Ayoola, 2006). Idrisa (2009) reported that, with the development of improved varieties, commercial production of soybean has expanded beyond its "traditional home" (Benue, Kaduna, Niger and Plateau) states. . Nigeria is the largest producer of soybeans in West Africa, and cultivation has increased due to its nutritive and economic importance, and the diverse domestic usage. It is also compatible with other common arable crops (Raji, 2007). It is now produced in other states, such as Bauchi, Borno, Jigawa, Kano, Kebbi, Kwara, Nasarawa, Oyo, Sokoto, Taraba and Zamfara states. As reported Rogers, (1993) improved technology is the systematic application of collective resources to solution of problems through the assertion of control over nature and all kinds of human processes. This underlined the rational for the use of improved production technology in the development of agricultural resources to make a better living. Dugje *et al.*, (2006) reported that the agronomic practices which are recommended for soybean production in Nigeria comprises of site selection, land preparation, planting time, spacing and seed rate, fertilizer application, weed control, pest and disease control, harvesting and storage. Yet the adoption of the recommended practices for improved production technologies for soybean production is relatively low (Ani and Undiandeye, 2001). Therefore, it was found imperative to assess the socio-economic factors affecting the adoption of soybean production technologies among soybean farmers in Rano Local Government Area of Kano State.

MATERIALS AND METHODS

The study was carried out in Rano Local Government Area (LGA) of Kano State, Nigeria. The LGA is located between latitudes $11^0 33' 26$"N and longitudes $8^0 35' 00$"E of the equator; therefore, it lies on the Eastern part of the Sudan Savanna zone of the state, KNARDA (Kano State Agricultural Development authority, 2009). The study area covers a land area of 520 km^2 with a population of 145, 439 (National Population Commission, 2006). The study area has dominant features of the dry savanna of Nigeria with two main seasons: the wet and the dry season. The wet season usually starts from June and ends in October with an annual rainfall varying from 200mm in the north to 650mm per annum with an annual average temperature of 29 ^{0}C to 42 ^{0}C (KNARDA, 2009). Soybean cultivation is one of the emerging agricultural activities in the area. There is also significant husbandry of small ruminants as a means of food security and a livelihood practice. The sampling procedure was based on multi-stage random sampling techniques. Among the five selected districts of the study area (Kumurya, Gwamma, Barkum, Kulluwa and Gurjiya), three districts were randomly selected (Kumurya, Barkum and Gurjiya) at the first stage. At the second stage, four villages were randomly selected from each of the three districts, making a total of 12 villages sampled. At the third stage, 180 respondents were selected from each of the villages, thereby giving a total of 90 respondents as the sample size for the study. The data for this study was collected by the use of well structured questionnaires. The questionnaires contain two sections viz: the background information and technical questions. The data for the study was explored through the application of descriptive and inferential statistical tools. The descriptive statistics that was used to summarize the data were percentages and frequencies count.

RESULTS AND DISCUSSION

The socio-economic characteristics of the respondents were examined with respect to their gender, marital status, age, farm size, household size and level of education as presented in Table 1. The study shows that majority (62.20%) were male, while female constitutes only 37.80% of the respondents. This implies that gender was a significant factor in agriculture, because of its vital role in determining farming activities in the study area. In addition, 68.90% of the respondents were married and were in their economically active and productive age (30-49years) representing 71.10% in the study area. This confirms with the report of Amaza *et al.*, (2007) that most of the Nigerian farmers were between 30 and 50 years of age. Also in the same table, it was shown that 57.80% of the respondents cultivated less than one hectare of farmland, while 37.80% cultivated between 1 and 2 ha of farmland and only 4.40% cultivated above 2 ha of farmland. This was in agreement with that of Oriole (2009) who indicated that most of the soybean farmers in Nigeria were small scale farmers, who cultivate less than 3 ha of farmland. The result further shows that most (24.20%) of the respondents had household size of 5-9 members. The implication could be that provision of farm labour could not be a problem among the respondents. On the level of education, the result shows that most (41.10%) of the respondents had formal education. This implies that the respondents could apprehend the improved technologies being disseminated to them. The findings was not in agreement with that of Apata *et al.*, (2010) and Tiwari (2010) who asserts that most of the Nigerian farmers have no formal education. Table 4 shows the constraints against adoption of improved soya bean production technologies by respondents. The result indicated that the majority (54.40% and above) of the respondents agreed that all the variables were constraints to adoption of improved Soybean production technologies with the exception of unavailability of market for produce with 24 respondents representing 35.60%. Notable among the constraints were poor extension services (75.60%), lack of credit facilities (71.10%), and high cost of fertilizer (72.20%). Poor extension services confirm the report by Tiwari (2010) that one of the major constraints of farmers was poor access to extension services. This implies that adoption level of the respondents could be affected negatively. Constraints of credit facilities were also one of the major factors affecting the respondents. This was in agreement with that of Oriole (2004) who stressed that unless credit facilities are provided to small scale farmers, otherwise majority of them are seriously handicapped in adopting new and profitable farm technologies. The high cost of fertilizer among others was also a major constraint. The implication could that the respondents were unable to purchase the input as a result of the high price associated with the commodity (64.40%). However, the result reveals that majority (64.40%) of the respondents disagreed that unavailability of market for produce was a constraint. This could be as a result of the fact that market for Soybean was readily available in the study area.

CONCLUSION

The study indicated that the adoption level of soya bean production technology was on the average in the study area. The socio-economic factors which positively affect the adoption of soybean production technology were sources of information, farming experience and educational level of the respondents. However, the major constraint against the adoption of the technologies include poor extension services, lack of credit facilities and high cost of inputs such as fertilizer, chemicals etc. Based on the findings of the study, the following recommendations were made that; Agricultural extension services should adequately be provided to respondents on soybean production technologies in the study area; Input support services in the form of credit facilities, fertilizer and chemicals should be provided with a view to enhancing adoption of soybean production technologies; Encouragement should be made to form soybean cooperative societies by respondents in order to take advantage of government policies and programmes and lastly awareness campaign should be embark by mass media to encourage farmers to patronise IITA in purchasing of high quality seeds or to open a substation within the axis of the area

Table 1: Distribution of Respondents by Socio-economic Characteristic (N = 180)

Socio-economic Variables	Frequency (No)	Percentage (%)
Gender		
Male	112	62.20
Female	32	37.80
Age (Years)		
30 & below	22	12.20
30 – 39	52	28.80
40 – 49	76	42.30
49 & above	30	16.70
Marital Status		
Married	124	68.09
Single	46	25.06
Widow	10	5.50
Farming Size (Ha)		
Below 1	104	57.80
1 – 2	68	37.80
Above 2	8	4.40
Educational Status		
Primary education	44	34.00

ABSTRACT

This paper assesses the use of radio in receiving agricultural information for agricultural production in Dawakin Kudu Local Government Area of Kano State, Nigeria. A total number of 60 respondents were randomly selected by choosing four farmers from each ward within the fifteen wards in the area. Interview scheduled was used to collect relevant data from the respondents. The instrument used for data collection validated and subjected to reliability test. Descriptive and Inferential statistics (chi-square) were used to analyze data collected. Results showed that majority of the farmers were males, mostly 50 years and below in age with little formal education. Although most of the farmers acquired agricultural information through radio but some had to depend on friends and Extension Agents (EAs) for agricultural information. Farmers' productivity increased by up to 64.8% through the use of radio and some farmers still claimed not having significant improvement in their farming activities through the information from radio. Despite the advantages for the use of radio in generating agricultural information, some farmers identified some problems which include among others, lack of call-in programs on agricultural matters, cost of regular changes of the battery and some programs were not designed to suit farmers' interests. Furthermore, Chi-square analysis showed that only age and level of education had significant relationship with the use of radio. It can be concluded that radio is a useful source of agricultural information but it needs improvement in the areas of service delivery with a view to overcoming the types of programs and creating innovative call-in programs for asking questions.

Keywords: radio, agriculture, information, production.

INTRODUCTION

Radio is powerful communication tool. It has proved to be the most effective media in promoting agriculture and development in rural areas, particularly as a tool for the delivery of quick information. We are living in a world that is saturated by mass media with our environment brimming with data and information (Hutchings and Matthews, 2008). International Food and Agriculture Programme (IFAP, 2004) asserted that about 80 percent of the population who live in rural areas of developing nations depend directly on agriculture for their livelihood. In recent decades, the widespread use of the mass media has resulted in heightening the level of public knowledge in different fields (Buren, 2000). Among the diverse mass media, radio, due to its wide and vast range of listeners, have had an outstanding position particularly with regard to informal teaching, and is considered the best cultural and educational media (Tancard and Verner, 2005).

Rural farmers in Dawakin Kudu Local Government Area of Kano State are not noted to produce enough food, probably due to some constraints that lead to lack of access to timely and up-to-date information which would have enabled them to achieve optimal yield from their farmlands. Lack of access to basic agricultural knowledge and information by rural farmers in Dawakin local government area of Kano State which may be as a result of certain constraints has made these farmers to stick to their old traditional methods of farming system and animal husbandry practice, hence resulting in poor crop and livestock productivity. Information and knowledge are very vital in agricultural development of any community and where they are poorly disseminated as a result of certain constraints, the community's agricultural development becomes highly impeded (Obidike 2011). Therefore, this study is designed to investigate the effects of radio to farmers in Dawakin Kudu Local Government Area of Kano State in accessing agricultural information. Nowadays, access to education, information, knowledge, and communication plays a vital role in the individual and social life as well as human development and inclination towards growth. As a pre-requisite of knowledge, information, recognition and awareness are among the most efficient factors in reaching human development (WSIS, 2005). In Nigeria, the studies conducted by Arokoyo (2003) showed that radio is the major source of information for the farmers of this country.

The broad objective of this paper is to assess the use of Radio on agricultural information to farmers in Dawakin kudu Local Government area. However, the specific objectives are to;

1. describe the socio-economic characteristics of the farmers in the study area,
2. examine the relationship of socioeconomic factors on the use of radio for agricultural information, and
3. identify the major problems affecting the use of radio as a source of agricultural information

METHODOLOGICAL PERSPECTIVES

Study Area

The research work will be carried out in Dawakin Kudu Local Government Area. It is located at latitude 10^0 30N and longitude 7^0 40E and 10^0 35E in the Sudan Savanna of agro ecological zone of Nigeria. Dawakin Kudu lies in South Eastern part of Kano State with a total land mass of $59km^2$. It has a population of 265,950 (census 2006). Dawakin Kudu district shares boundaries with Warawa to the East, Bunkure to the South, Wudil South – East, Kura South – West, Kumbotso to the North – West and lastly Gezawa by the North. (NIPOST.2009).

Sample Size

Random sampling was used in selecting the study sites and respondents. Dawakin Kudu has fifteen (15) wards which are as follows; Dabar kwari, Dan bagina, Dawaki, Dosan, Gano, Gurjiya, Jido, Tamburawa, Tsakuwa, Unguwar duniya, Yanbaru, Yankatsari, Yar gaya and Zogarawa. Four (4) farmers were selected from each ward as respondents of the ward, making a total number of 60 respondents. The respondents were "Full Time Farmers" that are engaged in crop and/or livestock production.

Methods of data collection and Analysis

The data was collected from primary source through which interview was conducted with the help of a well-designed questionnaire as instrument for data collection. Each objective raised for the study will have specific questions under it. The analytical tool adopted for this research was descriptive statistics and X^2 (chi square). Data was collected from the farmers and was analyzed using percentage and frequency distribution to achieve objective 1, 2 and 4 while X^2 will be used to answer objective 3.

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Farmers

Socio – economic characteristics play an important role in providing clear picture of the social and moral activities of the farmers. Socio-economic status highlights the age, marital status, gender, level of education, farm size and household size of the farmers.

Gender has great influence in terms of job engagement most especially in the northern part of Nigeria in which some works were mostly assigned or preferred by one gender over the other. Majority of the farmers (91.7%) were males while only (8.2%) were females. This implies that males use radio more than females in the study area for acquiring information on agricultural activities. The finding disagreed with Okoro (1996) who reported that all the marketers in the area were male probably due to normal and societal values of the study area. The age distribution shows that farmers within 20-30yrs were the majority with 26.7% followed by 25% which are in the range of 42-52, 23.3% were within 31-41, and then 16.7% were within the range of 53-63, only 8.3% were found to be within 64-74. This work disagreed with Maji *et.al* (2012) who stated that farmers age having 44% were the majority with 41-50 years of age. Age plays a significant role in acceptance of any innovation. It is believed that young farmers are ready to accept innovation while old do not accept innovation easily. Marital status can be considered as the level responsibility of an individual. Result shows that married farmers were found to be the majority (95%), while singles were 5%. This implies that majority the respondents (95%) had one form of responsibility or another. This study is in line with that of Ugwuja (2011) who reported that 88.7% of the farmers were married. Educational level in this finds the number of years of formal schooling. The results showed that more than half of the respondents (55%) had primary education, while only 18% had obtained secondary education. This indicates that the level of education of the respondents was low, with none of them having tertiary education. The educational status of the respondents may not likely affect their use of radio as means of receiving agricultural information. This was mainly due to the fact that most of the agricultural programmes broadcasted over the radio were in the farmers' language for better understanding.

Radio Ownership and Frequency of Listening to Agricultural Programs

The result implies that almost all the farmers (90%) owned radio in the study area while only 10% of the farmers had no radio. By relating this with the age of the farmers, it is identified that the farmers that fall within the range of 50 and above do not own radio. When considered the frequency at which the farmers listened to agricultural programs on radio, it was observed that 46.3% of the farmers listen to agricultural programs through the radio monthly, followed by 27.8% that listen to the such programs weekly, while 22.2% listen to the programs fortnightly and the least with 3.7% listen to the programs daily. This implies that majority of the listeners were youth and listened to other programs more than agricultural related programs. But with recent call-in –radio programs on agriculture, the use of radio in receiving agricultural information would likely be used.

Proportion of increase in productivity with the use radio

This is said to be the proportion on how agricultural information received through radio enhance the productivity of the famers

The result shows that the information gathered from the radio programs help the farmers in their productivity. Majority (64.8%) of the farmers responded with increase proportion of 0-30%, 25% of the farmers with proportion of 31-60%, 6.7% of the farmers with proportion of 61-100%.

Results of the X²-Test, Based on the relationship of socio economic factors on the use of radio for agricultural information

The results of the chi-square showed whether the use of radio has relationship on the socio economic factors of the farmers. Age and level of education are the factors to be determined for this test.

Hypothesis:

Ho: There is no significance difference in farmers' levels of education for the use of radio in agricultural production.

Ha: There is significance difference in farmers' levels of education for the use of radio in agricultural production.

Decision:

The null hypothesis is rejected, because Chi-square calculated is greater than Chi-square tabulated at 5% level of significant. Therefore, the Ha is accepted which says there is significance difference in farmers' levels of education for the use of radio in agricultural production. This means that farmers' levels of education plays role in the use of radio in the area.

Hypothesis:

Ho: There is no significance difference in farmers' age for the use of radio in agricultural production.

Ha: There is significance difference in farmers' age for the use of radio in agricultural production.

Decision:

Ho is rejected, because Chi-square calculated is higher than Chi-square tabulated. Therefore, Ha is accepted which says, there is significance difference in farmers' age for the use of radio in agricultural production.

CONCLUSION AND RECOMMENDATIONS

The importance of radio agricultural programs cannot be over emphasized due to its contribution to increase in the whole sector of agriculture. On the basis of the finding of this study we can conclude that the farmers were using the agricultural information they received through radio although the use of radio is associated with some problems, such as giving room for asking questions.

From the study it is clear that, some farmers were aware of some recommended solutions despite the problems of using the radio in receiving agricultural information. The following are the recommended in order to achieve the objectives of using radio as a source of receiving agricultural information.

1. Formal education should be taught to the youths which will increase the use of radio in the area.
2. Agricultural programs on radio should be scheduled to suit the peculiarities of its catchment audience.
3. Call-in programs should be introduced.
4. The radio stations should provide well trained presenters to be hosting the programs.

TABLES

Table 1: Distribution based on proportion of increase in productivity

Distribution	Frequency	Percentage (%)
0 – 30 (%)	35	64.8

EXTENDING ADAPTED YAM MINISETT TECHNOLOGY TO FARMERS FOR SEEDYAM PRODUCTION USING DEMOS: LESSONS LEARNT

J.G. Ikeorgu, B.A. Aighewi & N.G. Maroya

Yam Improvement for Income and Food Security in West Afrca (YIIFSWA) Project, International Institute of Tropical Agriculture (IITA) Ibadan
J.Ikeorgu@cgiar.org; ikeorguj@yahoo.com,

ABSTRACT
Adapted Yam Minisett Technique (AYMT) for clean seedyam production was demonstrated in 146 locations to farmer groups by 4 NGOs in Nigeria in 2015 under the Yam Improvement for Income and Food Security in West Africa (YIIFSWA) project. The YIIFSWA Project aims to raise the productivity of 200,000 farmers in Nigeria and Ghana by 40% in 5 years with a multiplier plan for 3 million farmers in 10 years. Scarcity of clean seedyams is the greatest constraint to increased yam production and the yam minisett technology was developed to address this constraint. Demonstration plots of 300 m^2 or 400 m^2 were manually prepared as ridges or mounds.. Clean seedyams were cut into 40g setts and treated with a mixture of 100g of Mancozeb 80%WP and 70ml of Chlorpyrifos 48% EC in 10 litres of water and cured overnight. The setts were planted between May and July on the crest of the seedbed and spaced 30cm apart. The NGOs were treated as blocks while seed treatment constituted the treatments. Data were collected for sprout count, yield and yield components and subjected to ANOVA for RCBD while differences in means were estimated using SED. Treated minisetts gave 43% more sprouts and 48% higher fresh tuber yield of clean seed yams than untreated minisetts. NGOs that strictly observed recommended cultural practices had higher yields than those who did not. The lessons learnt are that treating minisetts with recommended chemicals before planting, planting at recommended spacing of 30cm and planting during May /June would give highest clean seedyam yields.
Keywords: Adapted, yam, minisett, seedyam and technology

INTRODUCTION
The greatest constraint to increased yam production in Nigeria was identified as scarcity or high cost of seed yams (Okoli et al. 1982, Ikeorgu and Igbokewe, 2003, Ironkwe et al. 2007). That was what led to the development of the yam minisett technique in the early 80s (Okoli et al. 1982). After several years of extending to farmers, Ogbodo, 1985) reported that adoption rate was still below 40%. This was what led NRCRI Umudike to go back to the drawing board and reviewed the minisett recommendation. According to Ikeorgu et al. (2000), the recommendation was made more elastic such that farmers who desired large seed yams as planting material could use minisett sizes between 35g to 50g. Those who desired many but smaller seed yams could stick to 25-30 gram setts, which is the original recommendation.
However, it was discovered that the ADPs who had the mandate to extend the yam minisett technology to the grassroot farmers did not diligently carry out this function. This was more so after the World Bank loan for this purpose was exhausted and extension agents were unable to visit farmers due to lack of mobility or fuel to power their motorcycles. The result was that until 2011, several rural communities in the Nigerian yambelt had not even heard about the yam minisett technology.
The Yam Improvement for Income and Food Security in West Africa (YIIFSWA) project, currently being funded by Bill and Melind Gates Foundation (BMGF) was started in 2011 and aims to increase the productivity of 200,000 rural farmers in Ghana and Nigeria by 40% in 5 years with a 10 year projection of reaching 3 million farmers (Maroya et al. 2014). To be able to increase ware yam production, clean seedyams must be readily available to farmers. We chose to train farmers to produce their own clean seedyams rather than ask them to buy from local markets. This was what informed the use of Adapted Yam MInisett Technique (AYMT) in which farmers chose what size of minisett to use in producing their desired seedyams. This paper reports the lessons learnt from 146 demos carried out by farmers groups in 4 NGO in Nigeria under the YIIFSWA project in 2015.

MATERIALS AND METHOD
Four Non-Governmental Organizations (NGOs): Justice, Development and Peace Movement (JDPM) Oyo Oyo State; Arimathea Foundation for Development (AFD) Lafia, Nasarawa State; Missionary Sisters of the Holy Rosary (MSHR) Idah, Kogi State and Small Holder Oil Palm Farmers' Multipurpose Cooperative Society (SHOP). Umuasua Isuikwuato, Abia State (Table 1) carried out these demos in 146 locations in 2015 through their farmer groups. Each farmer group of between 20 and 30 members manually prepared a 20m x 20m or 20m x 15m demo plot in either ridges or mounds, depending on their prevailing land preparation method. Clean seedyams of farmer preferred cultivars, were purchased from the open market and sorted before cutting into 40 g minisetts setts. The setts were treated with a combination of 100g Mancozeb 80% WP (fungicide) and 70ml

Chlorpyrifos 48% EC (insecticide) in 10 litres of water and cured overnight. The treated setts were planted between third week in May and early July. Minisetts were planted on the crest of ridges (or mounds) and spaced 30cm apart so as to achieve a plant population of about 33,000 plants/ha. We asked the farmer groups to plant 15 ridges with treated minisetts and 5 ridges with untreated minisetts. Where the manually made ridges were too fat, double rows of minisetts were planted on the crests and also spaced 30cm apart, both within and between rows so as to achieve the desired plant population.

All other cultural practices were carried out according to recommendations by Aighewi et al. (2014) and NRCRI (1983). Although most farmers usually intercrop yams with maize and other crops, we specifically instructed that for the purpose of this demo, the minisetts should be planted sole. Some farmer groups used herbicides to control weeds while others weeded manually. The seedyams were harvested between December 2015 and January 2016. Data were were collected on number of sprouted minisetts at 15 weeks after planting, number and weight of seedyams per unit area, for treated and untreated minisetts. T-test for paired data was used to assess the effects of treated and untreated minisetts. Means were compared using SED.

RESULTS AND DISCUSSION

1. Minisett sprouts

The number of sprouted minisetts achieved in treated and untreated demo plots expressed in percentages, are presented in Table 1. Plots where minisetts were treated with recommended chemicals had about 43% more sprouted minisetts than untreated plots. Among the NGOs, there was a higher percentage (75%) of sprouted minisetts in JDPM demos than the other 3 NGOs (68%). However, percent mean sprouted minisetts in demos in the other 3 NGOs did not differ. There is a strong indication from this result that to achieve high minisett sprouts, the farmer must treat the setts with appropriate chemicals.

2. Number of seed yams

The number of seedyams harvested from demo plots of treated and untreated yam minisetts conducted by farmer groups from 4 NGO YIIFSWA partners in 2015, are presented in Table 2. The number of seedyams in treated demo plots was 41.5% higher than those in untreated plots. Significantly more seedyams were harvested by farmer groups in AFD than the other NGOs. Number of seedyams

harvested by MSHR and SHOP did not differ but were higher than those harvested by JDPM. The reason for this observation is obvious. AFD planted at 30cm as recommended and carried out most husbandry practices timely. JDPM had 6 weeks of drought in May/June and therefore planted late into July. But some farmers in JDPM planted at 50cm on ridges because they thought 30cm was too close. Also, MSHR farmers planted at 50cm on ridges and this drastically reduced the plant population per unit area. Although SHOP farmers treated all their minisetts with recommended chemicals and planted double rows, some of the farmers left the treated setts for up to 2 weeks because they had not prepared their seed plots. This reduced the number that sprouted and consequently, the seed yan yields.

3. Weight of seedyams harvested.

The weight of seedyams (t/ha) harvested from treated and untreated demo plots of farmer groups from 4 NGO YIIFSWA partners in 2015, are presented in Table 3.

The result followed the trend fir number of harvested seed yams and showed that treated plots gave 48% higher seedyam yield than untreated plots. However, in MSHR there were no tuber yield differences between treated and untreated plots. This could be due to a number of reasons. Some farmers treat all their setts but still demarcate some ridges as untreated while others selected the head region and planted in untreated plots. The head region has little problem in sprouting whether treated or untreated.

CONCLUSION AND LESSONS LEARNT

When a farmer follows the recommendations for seedyam production using the minisett technique, he will have high seedyam yields. The lessons learnt from this on-farm demo trial to validate the minisett technique could be summarized as follows:

1. To achieve hugh yields of clean seedyam, you must treat the minisetts with recommended chemicals.
2. After treating with chemicals, the setts must be planted not later than 48 hours.
3. Planting at 25cm or 30 cm on the crest of 1m ridges ensures you achieve 40,000 or 33,000 plants/ha, respectively. Where your ridges are spaced wider than Im apart, you could plant double rows of minisetts so as to achieve optimum plant population.
4. Planting the treated setts between end of May and end of June gives higher clean seedyam tubers than later planting.
5. Positive selection to ensure you plant only clean setts is very critical for production of clean seedyams at the end of the planting season.

Table 1: Percent sprouts achieved from 164 demo plots of treated and untreated minisetts conducted by farmer groups from 4 NGO YIIFSWA partners in 2015

YIIFSWA NGO partner	Number of demo plots in 2015	% sprouted minisetts	
		Treated	Untreated
1. Arimathea Foundation for Development (AFD) Lafia, Nasarawa State	39	68.00	42.10

SOCIO-ECONOMIC FACTORS AFFECTING PERCEPTION OF HIV/AIDS EFFECTS AMONG FARMERS AND EXTENSION PROFESSIONALS IN ABIA STATE, NIGERIA

P.E Amadi & E. Blessing

National Root Crops Research Institute Umudike
pearlamadi16@yahoo.com

ABSTRACT

Factors affecting root and tuber crop farmers perception of HIV/AIDS effect of agricultural activities in Abia State, Nigeria was identified. A total of 180 (One hundred and eighty) questionnaires were administered to the respondents in the study area. Data was collected and analyzed using descriptive statistics and chi-squared statistical techniques. Result shows that majority of farmers were females (51.1%) while majority of extension professionals were males (59.9%). Marital status, level of income and education access to ICT and family doctor, professional bodies and sources of information were factors positively affected their perception while location and age were significant at 1% respectively and negatively related to perception of farmers and extension professionals of the effect of HIV/AIDS on agricultural production, processing and marketing. Farmers and extension professionals perceived reduction in the size of land cultivation and increase in price of food as major effect of HIV/AIDS on agricultural production. It was recommended that extension professionals should see HIV/AIDS as one of the challenges facing agricultural extension services and play an "empowerment" role as it affects agriculture to improve HIV/AIDS learning, knowledge sharing and information management among farmers, rural dwellers, as well enhance agricultural production.

Keywords: **Root and Tuber, farmers, HIV/AIDS, extension, processing**

INTRODUCTION

Acquired Immune Deficiency (AIDS) is a condition where the defence "Immune system of persons infected with human immune virus" (HIV) is totally destroyed and which ultimately leads to untimely death (Akpabio, 2005).
Most agricultural operations in Nigeria are driven by human labour. Moreover, labour intensive farming systems with low level of mechanization and agricultural input use are particularly vulnerable to the effect of HIV/AIDS as the economic return to labour tends to be low (Ajeh, 2008). The epidemic further leads to a weakening of rural institutions in their capacity to deliver extension services and has undermined the effectiveness of natural agricultural policies (Topouzis, 2006).
Nigeria, with an estimated population of 144 million has above 6million people living with HIV/AIDS and HIV prevalence rate of more than 540% (Ayeogenika, 2008) (Hlanzel, 2008) reported that more than 800, 000 people have died in Nigeria due to HIV/AIDS and over 80% of infection in Nigeria are through sexual transmission while other modes are through blood transfusion and mother to child transmission. The mandate of agricultural extension services of the National Root Crops Research Institute, Umudike is the dissemination of relevant research information through the use of various extension methods to provide technical/vocational training to farmers, students and agro-based industrialists on specialized areas, like HIV/AIDS as it affects agricultural production.
The mandate of agricultural extension services has always been human resource development with the aim of increasing food production through the introduction of improved agricultural technologies. The challenge currently posed by the AIDS epidemics to agricultural extension are quite unusual as it affects both staffs and clientele (Akpabio, 2005) However, the challenges remains what can be done by extension professionals and other stakeholders to effectively bridge the HIV prevention gap particularly in Abia State where the HIV prevalence rate has continued to increase progressively overtime (ABSACA, 2010). There are several preventions and behaviour change activities that can increase people's awareness and knowledge about HIV/AIDS, they are : Training and Workshops; HIV counselling and testing (HCT) services; production and distribution of strategic behavioural change (SBC) information education and communication IEC materials; Blood safety; condom programmes; community theatre and prevention of mother to child transmission (PMTCT) (ABSACA, 2010). The main objective of the study is to determine the socio-economic factors affecting farmers and extension professional perception of the effect of HIV/AIDS on agricultural activities in Abia State. The specific objectives are to describe the socio-economics of the respondents in the study area.

METHODOLOGY

Abia State is a State made up of 17 LGAs and three Agricultural zones namely, Aba and Ohafia. The State has a population density of 364 persons per square kilometre (NPC, 2006). Agriculture is the major occupation of the people especially in rural areas involving 70% of population. A total of 180 (One hundred and eighty) questionnaire was administered across the selected LGAs (Osisioma, Ummuneochi, Ikwuano, Umuahia South, Umuahia North, Bende and Ugwunagbo) descriptive statistics and Chi-squared were used to analyze the data.

RESULTS AND DISCUSSION

Result obtained from analysis of data is presented in line with the study's objectives.

Table 1.0 Shows that majority of the farmers were females (51.1%) while majority extension professionals were males (59.9%). Thus more women were involved in farming activities while more males were extension professionals. This agrees with Nwakor(2010) that women are usually involved in the most labour-intensive farming activities in Abia State.

Table 2 reveals that 89% of the farmers and 66.7% of the extension professionals were married. This shows that the respondents are responsible, well experienced and productive to do farm work.

Table 1.2 shows that the level of income, marital status and level of education are at 1% significantly and positively related to farmers and extension perception while age and location are significant at 1% and negatively related to the farmers and extension professionals perception. Access to ICT was at 5% and positively related to the farmers perception and significant at 1% and positively related to extension professionals perception, indicating that as access to ICT increased perception of farmers and extension professionals increase. Extension professionals are agents of information communication technology to farmers on adoption of new agricultural technologies and other related issues. Effects on agricultural activities were positively or negatively determined by the factors.

CONCLUSION AND RECOMMENDATIONS

It is concluded that the extension professionals had a higher knowledge and perception of the effect of HIV/AIDS on agricultural activities than farmers in Abia State. Otherwise, farmers' effectiveness, innovativeness and empowerment depend mainly on how committed and knowledgeable the extension professionals are to impact.

Based on the findings of this study it is recommended that both farmers and extension professionals should be encouraged, mobilized, trained and empowered on how to deal with HIV/AIDS related issues as it affects agricultural activities.

ABSTRACT
The study assessed sources of information used by fish farmers in Epe local government area of Lagos State. Data were collected using structured interview guide administered to 116 fish farmers using a multi-stage sampling procedure. The Results showed that the mean age of the farmers was 42years, majority (66.4%) were males, and 11.2% had no formal education. The average household size was 6 persons with mean income of ₦50,413.79k per month while the mean farm size was 3.00 plots. Results further revealed that half (50.0%) of fish farmers did not make use magazines as their sources of information. However, majority (93.1% and 90.5%) of the fish farmers used their personal experience and farmers' cooperative society as their sources of information respectively. Pearson product moment correlation (PPMC) revealed significant relationships between fish farmers' age ($r = 0.031$, $p <0.05$); household size ($r = 0.001$, $p < 0.01$); years of experience ($r = 0.001$, $p < 0.01$) and their sources of information used. It was recommended that fish farmers should form a functional cooperative society to enhance financial stability of their members so as to reduce effects of constraints hindering their access to information.
Key words: Assessment, Sources, Information and fish farmers

INTRODUCTION
The role of information in enhancing agricultural development cannot be over emphasized in agriculture. Information is vital for increasing production and improving marketing and distribution strategies (Oladele, 2006). Access to information is very essential on fish farming technologies, construction and management, breeds and spawning, processing, storage and marketing and financing thereby increased productivity of fish farmers (Ofuoku, et al, 2008). In Nigeria, fish production is not only important as a source of protein, but it also can be used to bring about institutional changes. These changes can offer access to production assets and resources, which can help to empower the poor and directly promote their livelihood (Obeikezie, 1999). Lagos State, in Nigeria is a state with a lot of fishery potentials in the areas of artisanal and fish farming. If a state in the country has adequate information about production increase in fishery and the potential to produce enough fish for the populace, the issue of malnutrition and adequate food supply which is a crucial problem will reduce drastically. The specific objectives are to describe the socio-economic characteristics of fish farmers in Epe Local Government Area of Lagos State; ascertain sources of information used by fish farmers in the study area; determine whether fish farmers have access to information on the needed areas of fish farming in the study area; identify possible benefits derived from information used by fish farmers and investigate factors affecting fish farmers' access to information in the study area.

METHODOLOGY
The study area is Epe Division of Lagos State in South western Nigeria. Epe is located on the latitude 6'31°N and longitude 4°E and lies North east of Lagos Metropolitan area. Multi-stage sampling procedure was used to select fish farmers from the list of fish farmers' association, Lagos State branch. Epe local government was purposively selected due to the concentration of fish farmers in the area. Based on the information received from the Department of Agriculture and Natural Resources, there are about twelve (12) registered fish farmers' associations. Some include Anibire Earth pond fish farmers, Allahu Lateef fish farmers' association, Gold water fish association and so on. Moreover, 50% of the members of association were selected from the total number of registered fish farmers in each association giving a total of 116 fish farmers. Descriptive statistics were used to analyse the objectives while inferential statistics such as Pearson Product Moment Correlation (PPMC) and Chi-square test were used to analyse the hypothesis.

RESULT AND DISCUSSION
Socio-economic characteristics of fish farmers
Table 1 indicated that the mean age of respondents was 42years. Some (31.9%) of the fish farmers were middle aged which ranges from 41 – 50years, while very few (1.7%) were old which were not active in farming. This

implies that the people who were involved in fish farming were young and agile than old and inactive ones. Most (66.40%) of the respondents were male while most (69.00%) of them were married. This implies that fish farming was being handled majorly by male farmers. Some (28.00%) of fish farmers had secondary education completed and few (20.00%) had secondary education uncompleted. This implies that most of the fish farmers in the study area have some level of educational attainment. Majority (95.69%) of the fish farmers had their household size ranging from 1 to 10 persons with mean of 5 persons/household. The relative large size could serve as a source of farm labour. Most (67.24%) of the fish famers earned income of less or equal to ₦50,000:00 per month. This implies that the respondents can still be categorized as average income earners while the mean farm size was 4plots. Most (68.10%) of the fish farmers cultivate between 1 – 3plots of land, with very few (2.58%) of them cultivating more than 6plots. Also, a slight above average (50.86%) of the fish farmers had less or equal to 5 years of fish farming experience while very few (3.45%) of them had between 21 to 25 years of fish farming experiences. This implies that very few of the respondents had more experiences which can improve their production.

Fish Farmers' Sources of Information

The results in Table 2 showed that majority (93.1% and 81.0%) of fish farmers got their information from personal experience and friends/Neighbour/Relatives respectively while above average (56.0% and 55.2%) of the fish farmers did not get their information through libraries and internet facilities respectively. This is an indication that most of fish farmers might not be aware of use of modern technologies as their sources of information. Okunlola (2009) corroborated this assertion while stating that awareness is the first stage of adoption before the respondents developed interest in the technology and later decided on adoption.

Access to Information by Fish Farmers

Result in Table 3 revealed that majority (92.2%) of the fish farmers had access to market information while some (30.2%) of the fish farmers do not have access to information on fingerlings ecological disasters. Market information was of extreme important to fish farmers.

Benefits Derived from Information Used by Fish Farmers

The results in Table 4 showed that majority (90.5% and 88.5%) of fish farmers attested to the fact that increased productivity and access to newly improved technologies respectively were benefits to be derived when they are well equipped with regular information on fish farming whereas few (16.4%) were of the contrary opinion that increased income could not arise as a result of constant use of information regarding fish farming. This implies that quite a large number of fish farmers believed in the possible benefits which could be derived when fish farmers make use of regular information.

Constraints Affecting Access to Information by Fish Farmers

The result in Table 5 revealed that majority (73.3%) of the fish farmers could not have access to information due to high cost of materials in a severe manner while above average (53.4%) of them had no access to information due to inconsistent visit of extension agents in a mild intensity. Whereas, few (14.7%) of the fish farmers did not have connectivity and knowledge on how to operate the internet as a threat. This implies that the influence of these constraints on how fish farmers have access to information could be rated as medium effect.

Relationship between socio-economic characteristics of fish farmers and sources of information used.

Result indicated that significant relationship existed between age (r = -0.200), household size (r = -0.297), years of farming experience (r = -0.317), sex (χ^2 = 12.448) marital status (χ^2 = 122.552), educational level attained (χ^2 = 28.724), occupation (χ^2 = 154.603) and sources of information used. This implies that fish farmers' age and household size determined the sources of information used. This means that fish farmers who are youth could have a greater patronage of sources of information used. Thus, utilization of sources of information depends on farmers' age status.

CONCLUSIONS AND RECOMMENDATIONS

Fish farming in the study area is dominated by male and they are in their active age. Fish farmers have some level of educational attainments. Majority of fish farmers had their information from personal experience and friends/Relatives. It was recommended that fish farmers should form a functional cooperative society to enhance financial stability of their members so as to reduce effects of constraints hindering their access to information; extension agent-farmer ratio needs to be improved upon so that regular and prompt visits could be made.

ASSESSMENT OF ACCEPTANCE OF TECHNOLOGY COMPONENT OF NRCRI'S COCOYAM REBIRTH INITIATIVE AMONG RURAL WOMEN FARMERS IN ABIA STATE

E C. Agoh, J.E Ewuziem, & C.J. Eluagu,

National Root Crops Research Institute Umudike, Nigeria
Email: *echima64@gmail.com*

ABSTRACT
The study assessed the acceptance of Cocoyam rebirth initiative of National Root Crops Research Institute Umudike as strategy for increasing food production among the rural women farmers in Abia State. The aim of the study is to evaluate the component technologies of cocoyam rebirth of NRCRI that has been transferred to farmers in Abia State. These technologies are: cocoyam minisett technology (Goken-rapid multiplication), cocoyam value addition technology (Cocoyam crisps and flour), and cocoyam processing and storage technology. The multistage sampling technique was used in selection of 120 respondents. Primary data were collected by the use of questionnaire; data collected were analyzed with descriptive statistics such as frequency table and mean. The result showed that 70 percent of rural women farmers participated in cocoyam minisett technique, while 69 percent participated in processing/ value addition of cocoyam, more so about 60 percent of women participated in the storage technology. The result further showed high level of participation in production technology of NRCRI Cocoyam Rebith initiative. Theses includes Planting of 7g setts of Cocoyam (Cocoyam minisett technique), (x=3.89), 20cm x 1m planting spacing (x=3.7), Crop mixture with tree crop (x=3.51) and May – June planting time (x=3.27), which were all above the critical mean point score of 3.0. Also the Women farmers participated actively in sub- value addition technology component of NRCRI Cocoyam rebirth initiative because the mean score of the participating rural Women farmers in the technology component (Cocoyam crisps and flour) was 3.81 and 3.67% respectively. More so, the rural women farmers participated actively among the selected sub storage technology component of the project, application of wood ash (x=3.34) and heaping of cormels (3.41).
Keywords: cocoyam, rebirth, technology, participation, farmers, women, rural

INTRODUCTION
Cocoyam is an important carbohydrate staple food in the south Eastern and middle Belt area of Nigeria (Asumugha and Mbanaso, 2002; Eke Okoro *et al* 2005). Cocoyam can be processed into several foods and food products (Hussain *et al* 1984) and also used as food for livestock and as industrial crop for production of alcohol and medicine. Cocoyam is highly medicinal for diabetic patients because it has low starch content, easily digestible, contains protein more than other tubers, convalescents and fortified food for infants (Mbanaso *et al* 2008). Cocoyam is the 3rd most important root and tuber crop after cassava and yam in Nigeria. It is one of the identities of Nigeria. This is because Nigeria has consistently maintained her leadership position as the largest producer of cocoyam in the World. In order to enhance and sustain the productivity of cocoyam, encourage farmers towards participation in cocoyam cultivation and raise their standard of living, a recent effort towards rapid production and enhancement of cocoyam in Nigeria has given rise to the introduction and implementation of cocoyam rebirth project under the cocoyam programme of the NRCRI Umudike and in 2007.

This initiative is a new holistic approach to the perception, research, production utilization and marketing of cocoyam in Nigeria (Chukwu and Nwosu 2008). Among the Igbos, a major tribe in Nigeria, Cocoyam is second to yam in socio-cultural value. For instance in Nenwe communities in Aninri Local Government of Enugu State, Women who are prominent in cocoyam production during the colonial era up to 1970, were conferred with the titles such as `Ekweghe Ede`. This is similar to `Okoji`, Di-ji or `Onyba` titles bestowed on men who are prominent in yam production in the same area. Cocoyam festival is celebrated in some communities in Anambra and Imo States in the Southeast Nigeria (Chukwu *et al*, 2008) Cocoyam rebirth is therefore not just a matter of practicing new technologies but is about adopting a new style of thinking, perceiving and tackling challenges facing cocoyam. Farmers' participation, especially the women farmers who constitute a formidable and significant livewire of peasant farming in Nigeria, to State, Federal and donor sponsored agricultural programme/initiatives is an important factors to sustainable Agriculture in rural Area. Women farmers participation issues are the area of concern at National and local level (Subedi, 2008). Without participation there are obviously no development and no programmme, hence great failure in such programme initiative (Aref *et al* 2010). This study therefore examined the participation and acceptance of NRCRI cocoyam initiative among the rural women farmers in Abia State.

METHODOLOGY

The study was carried out in Abia State; the choice of the study area was informed by its notable position and proximity to NRCRI Umudike. Abia State has a population density of about 2,883,999 persons with a relatively high density of 580 persons per square kilometer, (NPC, 2006). A multi stage sampling technique was used for the selection of respondents. Abia State is divided into 17 administrative blocks called local Government Areas, which is grouped into three (3) Agricultural zones namely: Ohafia, Umuahia and Aba zones. Umuahia Agricultural zone was purposively selected because of the presence and notable position of NRCRI in root crop expansion programme in the zone. Four local government areas (LGAs) were randomly selected from the six LGAs that make up the Agricultural zone. The autonomous communities were selected randomly from each of the four selected LGA making a total of 12 autonomous communities. From the sample frame a random sample of 10 participating women farmers of NRCRI cocoyam rebirth were selected from the twelve selected autonomous communities. This gave a sample size of one hundred and twenty 120 participating women cocoyam farmers. The data collected were analyzed with the use of descriptive statistics (table, frequency, percentage and mean).

RESULTS AND DISCUSSION

Assessments of level of participation of rural farm women in each of the technology component of NRCRI cocoyam rebirth initiative technologies are grouped in to 3 major components according to Okoye *et al (*2009). They are as follows: Goken-rapid multiplication technology production technology, processing and value addition. The result shown in the table below: (a) Rural women participation in production technology component of NRCRI cocoyam Rebirth. The result shows that the participation scores for the different sub-production technology component ranged between 2.79 -4.05. From the result there was high level of participation in production technology among the rural women in Abia State. Also among the selected sub production technology component of cocoyam rebirth initiative of seed multiplication (cocoyam minisett technique had the highest level of participation among the rural women in the study area with a mean score of 3.89. From the table there was an increase in farmers output, income and reduction in cost of planting materials.

(B) Rural women participation in processing/value addition technology component.

From the table result shows that 33.37% and 36.67% of the rural women farmers in the study area always participated in processing/value addition of cocoyam into cocoyam crips, flakes and flour for confectionaries respectively with a mean score of 3.81 and 3.67%. From the result there is an increase in farmers' income.

(C) Women participation in storage technology component:

From the result women participated actively in the storage technology component of cocoyam rebirth with the mean score value of 3.34 and 3.41% which is above the critical mean value (3.0). From the result good storage increase the shelf life of harvested cocoyam.

CONCLUSION

From the result, there is high participation level of production, value addition and storage technology component of NRCRI cocoyam rebirth among the rural women farmers in the study area.

Email: ***agirejo@gmail.com***

ABSTRACT

This study was carried out to determine the factors influencing participation of Agricultural Insurance Scheme among food crop farmers in Federal Capital Territory Abuja, Nigeria. Sampling procedure was employed to select a sample size of 100 farmers and structured questionnaire was used to elicit data from the farmers. The data collected from the farmers were analyzed using descriptive statistics. Majority (79%) of the farmers was male and 88% of the respondents fell within the age group 20 – 50 years with a mean of 36 years. Most (71%) of the respondents were married with majority (57%) having a household size of between 6 and 15 people Most (87%) of the respondents are into crop production while 11% into mixed cropping and the remaining 2% into livestock production. 81% of the respondents had farming experience of over 11 years. 86% of the farmers earned over N100,000. On the awareness level, it shows that 63% of the crop farmers were aware of the existence of Agricultural insurance scheme. The study recommended that effective service delivery by insurance service providers should ensure continuity of farmer's participation in agricultural insurance scheme and also participation by farmers who are yet to participate. More sensitization and enlightenment be created and promoted so as to minimize the risk and uncertainties associated with agriculture.

Keywords*:* Assessment, Awareness, Participation, Agriculture, Insurance

INTRODUCTION

Agriculture can contribute to spurring growth reducing poverty as non-agricultural GDP growth (World Bank, 2008). Agricultural production is subject to many risks and uncertainties. Any farm production decision plan is typically associated with multiple potential outcomes with different probabilities. Many risks directly affect farmer's production decisions and welfare. Agricultural producers face many risks in their economic activity due to weather conditions, plant or animal diseases, price volatility, and policies such as agricultural trade liberalization and restrictions on the use of crop protection products (World Bank, 2005). Weather, market developments and other events cannot be controlled by the farmer but have a direct effect on the returns from farming. Traditionally, farmers have managed risks by using less risky technologies of lower but reliably yielding drought-resistant crops; by seeking diversification both in terms of production activities, on-farm and income generating activities off-farm; and by devising informal and formal risk sharing arrangements (Friedberg, 2003).
Ajakaiye (2001) stated that small farmers in many developing countries of the world including Nigeria are trapped in the vicious cycle of poverty. The cycle is characterized by low income which leave them with virtually no saving capital required in their production technology and this consequently amount to the low status accorded to farmers in the society. However, through Agricultural Insurance, farmers can be saved from these losses or damages to crops or the effect can be minimized. Thus, Agricultural Insurance serves as a means of guiding against loss should the insured event occurs. According to Ray (2001), crop insurance can cushion the shock of disastrous crop loss in bad years and helps to ensure a considerable measure of security in farm income over the years.
Agriculture Insurance looks into low risks and uncertainties which can be effectively managed to the advantage of the farmers in the present and also in the future. This can help in stabilizing agriculture and in fact the economy at large. Agricultural Insurance is therefore a necessary part of the institutional infrastructure essential for the development of agriculture which is mainly at high risk enterprise.

Objectives

The objectives of this study are:

1. To examine the socio-economic characteristics of the respondents.
2. To examine the level of crops farmers awareness and participation in agricultural insurance scheme in the study area.

METHODOLOGY

The study was carried out in the Federal Capital Territory located in the geographical centre of Nigeria. It has a land mass of 8,000 km^2 and lie between latitude 9^o 10^1 North of the equator and longitude 7^o 11^1 East (FCT, 2007). It shares boundary in the North by Kaduna State, West by Nasarawa State and South by Kogi State. A two stage sampling procedure was adopted in selecting respondents for this study. In the first stage, communities with farming households namely; Abaji, Gwagwalada, Kuje, Kwali and Nyanya were randomly selected from the five communities with high farming households in the Federal Capital Territory through the instrumentality of a random number table. In the second stage, 100 farmers were randomly selected from the selected communities in proportion to the number of farmers in the communities. Primary data in this study were collected using a well-structured questionnaire. The data collected were analyzed using descriptive statistics.

RESULTS AND DISCUSSION

The socio-economic characteristic of the respondents directly or indirectly affects their farming operations as presented in Table 1. The analysis shows that majority (79%) of the farmers were male while the remaining 21% were female. The differences in the gender participation are due to the fact that the female farmers had no productive resources such as land, credit facilities, amongst others. The results of the analysis of the age distribution of the farmers in the study area reveals that majority of the respondents fell within the age group 20 – 50 years which was about 88% of the total sample, with a mean of 36 years and those that were above 50 years constituted 12%. This finding is consistent with the outcomes of Ohen and Ajah, (2015), who observed that the mean age of crop farmers in their study area was 35 years. This further implies that the sampled respondents are active and are in their prime and possibly more mentally sound to embrace new techniques and innovations regarding minimizing the risk and uncertainty associated with farming activities.

The result of the household analysis of the respondents is also captured in Table 1. The results indicated that 43% of the farmers had household size of less than 5 people. Those with household size ranging from 6 – 10 constituted 48% of the sampled respondents. Most (87%) of the respondents are into crop production while 11% into mixed cropping with the remaining 2% into livestock production. This suggests that the respondents are more disposed to crop production than any farming business such as livestock production and fisheries development.

The analysis also revealed that 39% of the respondents earned less than N100,000, 14% earned between N110,000 and N200,000. Also the table indicated that 12% of the sampled farmers earned between N310,000 and N400,000, while 11% obtained N210,000 – N300,000.

Awareness and Participation of Crop Farmers in Agriculture Insurance Scheme

Table 2 captured the above. The table reveals that majority (65) of the crop farmers did not participate in the agricultural insurance scheme. This implies that the non-awareness of the Agricultural Insurance Scheme by some of the respondents deprived them the opportunity of participating in the Insurance Scheme and invariably denying them the opportunity of grasping the advantages arising from participation. Most of the farmers who participated in the scheme explained that they were compelled to do so by the bank from which they obtained Agricultural loans. This implies that, most if not all, the farmers may not have much knowledge about the existence of such opportunity and risk handling and managing institution. Therefore, this may possibly call for much sensitization and enlightenment. The table also shows that about 63% of the crop farmers were aware of the existence of Agricultural Insurance Scheme.

CONCLUSION

The study examined the level of crop farmer's awareness and participation in agricultural insurance scheme in federal capital territory, Abuja. The socio-economic characteristics of the respondent shows that Majority (79%) of the farmers were male and 88% of the respondents fell within the age group 20 – 50 years with a mean of 36 years. Most (71%) of the respondents were married with majority (57%) having a household size of between 6 and 15 people. Most (87%) of the respondents are into crop production while 11% into mixed cropping and the remaining 2% into livestock production. 81% of the respondents had farming experience of over 11 years. 86% of the farmers earned over N100,000. On the awareness level, it shows that 63% of the crop farmers were aware of the existence of Agricultural insurance scheme. There is need to properly sensitized the farmers on the need and the importance of Insurance policy by government, non-governmental agro-services providers and insurance company. And also the insurance industry should ensure prompt delivery of their services to farmers.

ABSTRACT
The study was carried out to determine the level of perception of agricultural innovations by small holder farmers in Aboh Local Government area of Imo State. Forty respondents were randomly selected for detailed study. Primary data for the study were generated through structured questionnaire and interview schedule, and analyzed with descriptive statistics, such as frequency table and percentage. The study revealed that majority of the farmers were males, who are young and agile, educated with large household sizes. Majority of the smallholder farmers practice bush fallow and mixed cropping systems of agriculture. Also, majority of the farmers adopted three out of the four innovations identified in the area. Modern farm tools and inorganic fertilizer are the most frequently used innovations identified in the area. However, the work of the extension agents should be intensified, to make available information about more new and modern innovations to the rural small holder farmers in order to increase their productivity.
Key words: Small holder, Perception, innovation

INTRODUCTION
One of the major goals of Nigerian agricultural development program and policies is transition from the low productivity subsistence agriculture to a high productivity agro-industrial economy, through improved technology adoption. That is a shift from traditional methods of production to new technological components and, or even new farming systems. (Hassen, 2014). The need to increase agricultural productivity, so as to meet the ever-growing food and agro-industrial demand of an expanding population is an issue of consensus in Nigeria. Sustainable agriculture therefore has emerged as the key issue in the recent past in Nigeria. The concept of sustainability includes the efficient use of resources, resource conservation and enhancement of environmental quality. Agriculture has to be dynamic to be able to respond to the continuous changes in internal and external circumstances under which it operates.

Such circumstances include changes in land resources, soil vegetation and climate, and the needs of the farming families and the growing population. The federal government of Nigeria recognized the need to develop agricultural innovations that are appropriate to Nigerian environment, and has set up a number of agricultural related research institutes to develop innovations appropriate to crops in different ecological zones in Nigeria. According to Toluyemi (1998) small holders farmers constitute about 60% of Nigerian population, and produces about 90% of Nigeria's food. As a huge number of the poor lives in rural areas, and are engaged in small holding agriculture, attempt to address the rural poor are often geared towards improving agricultural practices, as a means of increasing agricultural productivity, by replacing the old method of farming with a modern and more efficient technique of cultivation (Barla 2013) . Adoption of improved agricultural technology is a tool needed to improve sustainable agriculture, a way of reconciling the necessity for sustainability and profitable food production, improve productivity and food security.

Perception has been described as referring to a range of belief, judgments and attitudes (Sledgers 2008). According to Matanmi (1994), a standard classification for describing the perceived attributes to innovations to small holder farmers are somewhat empirically, interrelated, but they are conceptually distinct-relative advantage, potentiality, complexity, divisibility and observability. However, smallholder farmers in Nigeria are always skeptical about the consequences of change in their knowledge, skill and attitude. The smallholder farmers are described as conservatives in their risk aversion tendencies, they tend to have security as being uppermost in their thought and action (Onuoha et al 1999). Specifically, this study seeks to identify the socio-economic characteristics of the respondents, identify type of farm practices and innovations adopted by the respondents.

METHODOLOGY
The study area is Aboh Local Government Area of Imo State. The soil of the area is deep, well acidic and mostly prone to soil erosion and leaching. It has rich agricultural soil, suitable for cultivation of a variety of tropical crops, including the oil palm (*Elaeis guinensis*). A simple random technique was used for the study. A total number of forty (40) household heads were sampled. Data for the study were obtained from primary source, with the aid of structured questionnaire, and interview schedule. The data collected were analyzed using descriptive statistics such as frequency and percentage

RESULTS AND DISCUSSION

Socio-economic characteristics of the smallholder farmers are shown, in table 1.

The results in table 1 show that the farmers have an average age of 49 years. This shows that the farmers are in their productive years, and will be able to do more work. Majority (65.5%) of the respondents were males. This implies that more males engage in farm production in the area. They have average household size of seven persons. The large household size is an indication of availability of family labour. Adegbite et al (2008) stated that large household size in farming communities provide free family labour on the farm. Greater percentage (93.6%) of the farmers were literate .this implies that majority of the farmers can accept and adopt agricultural innovations to increase farm productivity. Educated farmers are expected to be more receptive to improved farming techniques (Okoye et al, 2004). The result also showed that a small number of the farmers in the higher education group are involved in farming in the area.

The results in table 2 showed the frequency distribution of respondents according to innovations adopted. According to the result, 64.5%, 29.0% and 6.4% of the respondents practiced bush fallow, continuous cropping and shifting cultivation respectively, as the soil fertility management systems, with bush fallow being pre-dominant. 93.5% of the farmers in the area practiced mixed cropping, while a minimal number (6.4%) practiced sole cropping. Also, a minimal number of the respondents (9.6%) allow their farmlands to fallow 2-3 years, while a large number (90.4%) keeps their farmland fallow for only 0-1 year. This is because the number of farmlands owned by a farmer is minimal. The result also revealed that large number (45.2%) of the respondents adopted up to three innovations in the area, and a minimal number (12.9%) adopted up to four innovations. This indicates that the farmers need to be more enlightened about innovations. Modern farm tools and inorganic fertilizer, 100% and 90.0% are the most frequently used innovations identified in the area, while pesticide and improved varieties are less frequently used 6.5% and 3.4% respectively. This indicates that the work of the extension agents is needed to encourage the smallholder farmers to use more of the innovations identified in the area, to increase farm productivity.

CONCLUSION

The study revealed that majority of the farmers were males who are agile and educated, with large family sizes. Little percentage of the farmers adopted the innovations identified in the area. The result therefore call for availability of programs that would improve the effectiveness of extension services, to educate and train farmers on how best to apply and use the innovations available for improved crop productivity.

Table 1: Socio-economic characteristics of the smallholder farmers

Age in years	Frequency	Percentage

ABSTRACT
This study was carried out in Abia State of Nigeria. Four agricultural villages were purposefully selected for the study. Sixty farmers were selected from the agricultural villages. Simple and well-structured questionnaires, oral interviews and site visits were used to collect data for the study. The result shows that majority of the farmers were females. The result equally shows that the farmers did not have sufficient information thus poor knowledge of sun exposure and the consequential skin cancer. The farm activities the farmers most often get involved in were clearing, and harvesting. This has the tendency of exposing them to direct sun. Also most of the farmers make use of fertilizer to enhance the growth of their crops. The result also shows that none of the farmers agreed to have had or suffered any form of skin cancer. Base on the on the result it was recommended that the farmers should be assisted to procure protective clothes such as wide brim hats, clothes made from close knit fabrics which can protect their skin and scalp from ultraviolet radiation.
Keywords: Sun, exposure, skin, cancer

INTRODUCTION
In this part of the world (Nigeria) a lot of farmers do not practice mechanized agriculture because of high cost of these machines and other factors. This means that most farmers carry out their farm practices manually and therefore spend more man hours on carrying out farm activities like slashing, bush burning, ridging, planting, weeding, fertilizer application and down to harvesting in the open fields. These farmers equally trek long distances from their homes to farm on their farm lands and do same while coming back. This whole process of farm activities and trekking are done under the scourging rays of the sun. Although many of the farmers live their houses before sun rise when weather is still cool to get their destination on time, they still work till the sun sets and most of them work till late afternoon before returning back to their homes. This means the expose themselves so much to the scourging rays of sunlight.
This research work intends to look at how these farmers deal with sun exposure and know if these farmers suffer any harm (skin cancer) as a result of this over exposure. This will help to give better understanding of how this can be approached and better knowledge transferred to these farmers with regards to sun exposure and its effects.

MATERIALS AND METHODS
This study was carried out in Abia State of Nigeria. Four agricultural villages were purposefully selected and these include Ikwano, Ngwa, Umuahia North and Umuahia South local government areas. Forty five farmers of ten each were selected from Ikwano, Umuahia North and Umuahia Soth while fifteen farmers were selected from Ngwa village. Simple and well-structured questionnaires, oral interviews and site visits while these farmers where working was used to carry out this research work.

RESULTS AND DISCUSSION
Table 1 shows that majority of the farmers are females numbering thirty while the male farmers are fifteen in number. This shows that we have more female farmers than the male counterparts although during the slashing and ridging process, I observed that it was the male farmers who carried out this particular farm activity. Every other farm activity from planting to weeding to fertilizer application to harvesting was done by the female farmers. From the questionnaires filled and oral interviews, all they farmers know about the issue of sun exposure but do not see it as any harmful threat to their health or life. Rather they see it as part of a normal weather condition they have to work under. They equally see it that working under the sun does not affect their work out put even though it could slow them down but they rather see rainfall as a factor that affects their farm work activities because when is raining, the have to put work on hold but under the sun, the work until tiredness sets in or the are finished for the day. But some of them equally complained that the sunny weather is hotter than what they are used to in the past.
All the farmers said they haven't heard about ozone layer depletion or what it is all about.
All the farmers trekked long distances to their farms and believe it does not in any way affect their work output while working in their farms.
All the farmers said they have never heard of skin cancer before though some said they have heard of the word cancer but not skin cancer.

The farm work activities involves a lot of manual labor from clearing stage to harvesting stage and throughout all this different stages, these farmers do not use or wear any form of Personal Protective Equipment (PPE) to protect themselves and only very few of them change to work clothes when they get to their farms. This exposes them to direct sun rays hitting their skin. Rather the same clothes they wear to their farms are what they wear to carry out their farm work activities and still wear them back home at the end of the day which apart from not protecting them against the sun rays is not hygienically okay.

They make use of fertilizer to enhance the growth of their crops but the disturbing fact here is that they all ticked and said that they use their bare hands to apply the fertilizer to their field crops. This is a dangerous practice that could lead skin irritation or even skin cancer in the long run especially as these farmers do not properly wash their hands with soap in water after the fertilizer application. Some even go ahead to have their meals with their hands thereby ingesting some of this chemicals without knowing it.

All the farmers ticked they have not suffered any form of skin cancer but rather suffer body aches and pains which they believe is as a result of the strenuous activities involved during farm work activities and to this effect, most of them say the just take pain killers.

CONCLUSION AND RECOMMENDATION

The results show that our farmers see sun exposure as part of a necessary weather condition they have to work under and therefore don't believe that it can cause them any serious form ill health. From my oral discussions with them, they have equally not heard of skin cancer and what is all about. Also from the oral conversations and farm site visit I had, it was very obvious that some of them act out of ignorance while others have this I don't care attitude towards protecting their health because they believe something must kill a man be it ill health or disease and therefore see skin cancer as one of those health issues that can kill a man if it really does exist.

I also observed that some of them have this belief that any injury, accident or ill health that occurs to them is as a result of their enemies who don't want their progress or envious of their hard work not because they are not protecting themselves or taking precautions while working. They all held more to their belief especially after I tried to describe what skin cancer looks like when it occurs. They rather likened skin cancer to an illness the call "Acha Ere" in local dialect, and another illness the call "Crossing belt" which they believe is people that hate you use negative spiritual means to inflict this ill health on a person as this sickness leads to one's skin especially the leg decaying gradually.

With regards to PPE, they see it as something that would slow down their work process therefore tagging it lazy man's attitude to work. An example is the wearing of hand gloves during fertilizer application or wearing long sleeve clothing to at least cover their bodies properly. Though some of them complained that wearing some this protective clothing makes the uncomfortable while others complained about sweating a lot while wearing such clothes and would rather not wear clothes because the heat(most of the men agreed on this). With regards to farm shade, they believe the farms are not their homes so once it starts to rain or the sun is too much, they either continue to work under this harsh weather conditions or stop work or trek back home. They all agreed to the idea of at least wearing hats while working to caution the effect of direct sun rays on their heads.

My conclusions are that our local farmers are not aware nor do they believe that sun exposure can cause them any illness called skin cancer. To an extent, some of the farmers believe the word cancer is a curse and not meant for them. They refused the idea of going to hospital for any checkup because they believe that buying *paracetemol* or any other form of pain killers cures them of their body pain because they believe that body pains and aches are the only major ill health they suffer as farmers.

My recommendations for these farmers is for them to try and reduce the amount of time they spend working under the sun. I also recommended for them to work on their farms in the evening times when weather condition is cool and this they didn't agree to because most of them said their farms are farm from their residential homes. Only those that have their small farms in their living compounds agreed to this system.

Wearing of protective clothes such as wide brim hats, clothes made from close knit fabrics which can protect their skin and scalp from ultraviolet radiation. I also suggested long sleeved shirts and trousers which not be really comfortable but they help to protect the skin in extremely hot weather conditions.

Examine of the skin regularly for any unusual changes or suspicious spots on the skin because the unusual signs include any wound sore or patch of skin that won't heal.

To work but at the same time take breaks under a shade when the weather becomes extremely hot.

Table 1:

Farm field farmers	Male	Female	Yes	No
Sex	15	30		
Heard about Sun Exposure			45	0
Heard of Skin cancer before			0	45
Has any of you had symptoms of skin cancer or suffered skin cancer			0	45
Distance to farm fields (btw far and near, all the farmers ticked **far**)			45	0
Do you trek to your farms			36	9
Do you use other means of transportation to go to your farms (vehicle transportation or machine or bicycle ride)			9	36
Does your work activity involve manual labor at the fields			45	0
Do you wear any form of PPE(Personal Protective Equipment) while working			0	45
Do you have work clothes that you change into while you work in your farms			10	35
Are your farm fields sprayed with chemicals (herbicides, pesticides)			8	37
Fertilizer application (almost all officers ticked the use their bare hands for fertilizer application)			45	0
Presence of Farm shades			0	45
Routine medical checkup			0	45

AN APPRAISAL OF DISSEMINATING CHANNELS IN PROMOTION OF IMPROVED ROOT AND TUBER CROPS TECHNOLOGIES IN BENUE STATE, NIGERIA

M.H. Tokula, S. Adeyongu & F. Nwanguma

National Root Crops Research Institute Umudike, Abia State
mhtokula1@yahoo.com

ABSTRACT
The disseminating channels used in promoting root and tuber crops technologies in Benue state of Nigeria were studied using interview schedule and focal group discussion with 30 farmers and 50 students who participated in the programme. Akpa community secondary school Allan and Members of Ojuju cassava farmers' association Okete were purposively studied as major participants. Results of the appraisal showed that Majority of the targeted farmers participated in demonstration plots while agricultural information and inputs diffuse through fellow farmers. benefits derived from the establishment of the Demonstration plots in schools included Practical orientation of students, stimulation of interest in modern agriculture, carrier guidance in agriculture, Identification of different crop varieties and Interaction with scientists. Constraints as observed by teachers/ students included Irregular teachers' salaries, Inadequate number of agricultural science teachers in schools, Exclusion of Agricultural science from compulsory subjects in the state which affected students enrolment for the subject in external examinations. Farmers' varietal quality preferences in order of importance for cassava were high root yield, early maturity and stem yield, while yam had high tuber yield, early maturity and thickness quality when pounded. Based on the findings, it was concluded that the farmer outreach programmes and establishment of the Demonstration plots in schools should be sustained to because of the important roles it plays in Farmer and student productivity.
Keywords: Disseminating Channels, Promotion, Root and Tuber Crops Technologies

INTRODUCTION
The rural dwellers are the producers of agricultural resources of the nations. Information is any message or news, viewed or read or told verbally which add to knowledge, awareness or understanding of some topics. Ifukor (2013). Scientifically information is processed data. It can be loosely defined as that which aids decision making. Channels of information acquisition and dissemination refer to the transfer or exchange of information from person to person or from one place to another. It is an action that produces a reaction, whether positive or negative, communication has taken place. Information sharing is not a one way affair. There must be a sender to transmit the message, and a receiver to make appropriate decisions on how the rest of the exchange should continue. These involved the exchange of ideas, facts, opinion, attitudes and beliefs between people. The ability to communicate and pass on information is a key factor in all cultures whether literate or not. Fayose and Dike (2002) stated that many cultures survived without the written word and effective communication can take place without reading or writing. The apparent influence and resilience of African oral tradition is impressive, but it is of greater importance to the new generation of development practitioners for its theatrical and dramatic form.
Small Holder Farmers live in specific agro-environments. We want to get the right technologies to the right people to help them improve their livelihoods. Most cannot afford high-risk, high-reward behaviors; Bad experiences could shape future adoption behaviors. We need to get the right technologies to the right farmers by being more strategic and business-like in planning for dissemination and monitoring of uptake of agricultural technology Caldwell *et al*, (2013). Moreover, while research is an important element in achieving rural development, its potential contribution can only be realized when other elements are in place. For example, it is doubtful that many farmers will invest in developing land resources without ownership. The incentive framework for the creation and adoption of valuable innovation is also vital. Again, the degree of poor farmers' organizations is crucial here. Only strong farmers' organizations can ensure the adoption and implementation of government policies that reflect their needs and concerns, and create an enabling environment for sustainable production and development.
Without significant adoption, returns on considerable investment in technology development will be very minimal. Realizing that there are benefits accruable in the cultivation of root crops in Nigeria, efforts must be put in obtaining good production level. However, there are lots of constraints in achieving this target. Iyagba (2010)

METHODOLOGY
An appraisal of the disseminating channels was carried out with the aid of interview schedule administered on the participants in the demonsration plots, and school outreach program in Benue State. Akpa community secondary school Allan and Members of Ojuju cassava farmers' association Okete were purposively studied as major

participants in the School outreach, Demonstration plots and Farmer Participatory Trials. Rapid Rural appraisal method was adopted through Focal group discussion using 30 farmers and 50 students who participated in the programme.

Results And Discussion

The result of the appraisal showed that the benefits derived from the establishment of the Demonstration plot in schools included:

- Practical orientation of students
- Stimulate interest in modern agriculture
- Carrier guidance in agriculture
- Identification of different crop varieties
- Interaction with scientists

Constraints- view of teachers/ students

- Irregular teachers' salaries
- Inadequate number of agricultural science teachers
- Exclusion of Agricultural science from compulsory subjects in the state has affected students enrolment for the subject in external examinations

Suggestions/ Comments

- Make agricultural science compulsory
- Supply tractor and implements to familiarize students with them and remove drudgery
- Time of establishment of Demonstration plots and research trials should be made to suit school calendar to facilitate plot maintenance
- Re-introduce young farmers club

Problems identified by Farmers with the cassava and yam production includes:

Cassava

i. Difficulty in identifying of cassava varieties in the field
ii. Lack of mechanization in planting, harvesting and peeling of cassava
iii. Low stem yield/vigour of some pro vit A cassava variety
iv. Scarcity and High cost of improved cassava stem cuttings
v. Low knowledge of market channels and linkages for sale of cassava roots and stems
vi. Mixture of cassava, yam and sweetpotato varieties in the farmers' fields
vii. Loss of cassava stem to fire in the dry season
viii. Harvesting of cassava in the dry season and drying up of the stem cuttings

Yam

ix. Scarcity and low knowledge of Seed dressing chemicals recommended for yam minisett
x. Low knowledge of Proper planting method for the yam minisett
xi. Mixture of yam varieties in storage
xii. High cost of seedyams
xiii. Annual Procurement of seedyams
xiv. Scarcity of yam minisett treatment chemicals
xv. Low knowledge of the practice of yam minisett

Farmers' observation /comments on the effectiveness of the disseminating channels

1. **Demonstration plots, Farmer Participatory Trials and cluster Group Farms**

i. Cassava stem cuttings supplied are not usually labelled, this often leads to mixture of varieties in farmers' fields
ii. Poor crop establishment especially when improved stem cuttings are not delivered to farmers or planted in good time after cutting from the source fields.
iii. The sizes of the demonstration farms are not large enough. It should be at least 1 ha to enable farmer groups have enough starter packs to aid rapid adoption
iv. Plans for the establishment of Demonstration farms should be made early to enable farmers select good plots

2. **Radio and Television programmes**

i. this has been very good both in content and timing
ii. No television programme on agriculture in the area
iii. the critical storage problem of yam should be addressed in the radio programme especially mixture of seedyams in storage

3. **Agricultural Shows, Farmer field days, workshops and seminars**

i. Very few farmers participate in these activities

Results in Fig 1 showed that majority 85% of the farmers participated actively in the demonstration plots while 80% interact with fellow farmers for information and input sharing. Fig 2 revealed that farmers' varietal quality preferences in order of importance for cassava are high root yield, early maturity and stem yield while Fig 3 showed that preferences for yam quality included high tuber yield, early maturity and thickness when pounded.

CONCLUSION

Based on the findings, it was concluded that the establishment of the farmer outreach programs and Demonstration plots in schools be sustained because of the benefits as stated by the student group which included Practical orientation of students, Stimulation of interest in modern agriculture, Carrier guidance in agriculture and Interaction with scientists. Majority of the targeted farmers also participated in demonstration plots while agricultural information and inputs diffuse through fellow farmers. Farmers' varietal quality preferences in order of importance for cassava are high root yield, early maturity and stem yield while yam has high tuber yield, early maturity and thickness quality when pounded.

ABSTRACT
the study was on outreach assessment and effects of international fund for agricultural development micro enterprise financing (ifad) in abia state, nigeria. data were collectedusing structured questionnaire and ifad publications. data were analysed with the use of simple statistical tools such as percentages and frequency distribution and the measures of outreach indicators.the result showed that major criteria used by ifad in selecting their beneficiaries were members of cooperative/farmers group, availability of farmland space, being a farners and residency in ifad designated site. in addition, majority of those that reached with ifad microenterprise financing were women. the reason for this could be to improve the economic status of their family and to enable them gain access to new information. however, outreach/participation density in the state was 0.00887.this result suggest that in every 1000 people about nine (9) persons benefitted from ifad microenterprise financing programme.the result shows that there was increase in farm sizes, yield and total returns after beneficiaries access ifad microenterprise financing. these increases could be attributed to effective utilization of ifad microenterprise technologies and extension personnel among the beneficiaries.

INTRODUCTION
Agriculture is a key sector in the Nigerian economy (Tasie, 2012). Its importance is particularly glaring in a developing economy like Nigeria where land and labour resources are relatively abundant and the industrial sector is poorly developed (Tasie, 2012). The contribution of agriculture to overall development especially in developing countries like Nigeria include provision of increased food supplies, provision of gainful employment, provision of capital and capital formation, increasing foreign exchange for development and increasing rural welfare. The agricultural sector's contribution to economic growth and sustained rural development remains to be fully exploited (FMARD,2006). The contribution of agriculture to GDP was 64%in 1960, declined to 35% in 1988, and presently, the agricultural sector in Nigeria contributes less than 30% to GDP, with crop production accounting for an estimated 85% of this total, livestock 10%, with forestry and fisheries contributing the remaining 5% (Awotide and Akerele, 2010).
Despite these importance, agricultural production and food supply in Nigeria is still lagging behind, as a result of low utilizations of modern inputs by farmers, unavailability and inaccessibility of farmland as well as non-mechanized nature of the prevailing agricultural production system (Ogbe and Mejeha,2012).
IFAD (2002) opined that causes of food insecurity and famine were not so much failures in food production, but structural problems relating to poverty and to the fact that the majority of the developing world's poor population are concentrated in the rural areas. Therefore in order to improve the national economy, entrepreneurs who are farmers should be supported to expand their scale of production through micro finance (Akpokodje and Olomola, 2000).
Microfinance services, particularly, those sponsored by government have adopted the traditional supply –led subsidized credit approach mainly directed to the agricultural sector andnon farm activities, such as trading trading, tailoring, weaving, blacksmithing, agro-processing and transportation. Although the services have resulted in an increased level of credit disbursement and gains in agricultural production and other activities, the effects were short- lived due to the unsustainable nature of the programme (Iganiga, 2008)
In order to protect marginal and inefficient farmers/entrepreneurs the federal government of Nigeria with respect to food security and agro enterprise development signed agreement To solve these problems, the Federal Government went into a funding agreement with International Fund for Agricultural Development for the funding of small-scale farmers in Nigeria. The International Fund for Agricultural Development (IFAD), a specialized agency of the United Nations, was established as an International Financial Institution in 1977 as one of the major outcomes of the 1974 World Food Conference. The conference was organized in response to the food crises of the early 1970s that primarily affected Sahelian countries of Africa (Tesie,2012).

The conference resolved that an International fund for Agricultural Development should be established immediately to finance agricultural development projects primarily food production in developing countries.
In this context, IFAD was created to mobilize resources for programmes that alleviate rural poverty and improve nutrition. Unlike other international financial institutions which have a broad range of objectives, the Fund has a very specific mandate to combat hunger and rural poverty in developing countries. To achieve this objective, IFAD cooperates and collaborates with government agencies and parastatals such as Agricultural Development Programmes (ADP) and Ministries of Agriculture and Rural Development. IFAD-assisted programmes in Rivers state and Nigeria are generally deemed credible, highly relevant and effective, with positive impact. As a consequence, it is generally accepted that the Fund has a distinct and catalytic role in improving the livelihood of both subsistenceand market-oriented small-holder farmers and producers. This belief is supported by ADP (2005), Mejeha and Nnanna (2010) and Tasie (2008). The broad objective of this study was on outreach assessment and effects of International Fund for Agricultural Development Micro enterprise financing (IFAD) in Abia State, Nigeria.Specific objectives include; determining the Criteria Used in Selecting Beneficiaries by IFAD,Outreach/outreach density of IFAD Micro-financing among respondents and in the state and Effect of IFAD Micro-enterprise financing among Entrepreneurs in the study area

METHODOLOGY

The study was conducted in Abia State, Nigeria with a focus on the outreach and the effect of IFAD microenterprise financing. This study covered a period of eight years (2005-2013). Primary and secondary data were used in this study. The list of beneficiaries was obtained with help of staff of IFAD. From the lists 90 beneficiaries were randomly selected and structured questionnaire were used to collect data from the beneficiaries while the secondary data were got from the IFAD publications and other written documents. Data were analysed with the use of simple statistical tools such as percentages and frequency distribution and the measures of outreach indicators. Outreach of the target beneficiaries in the state using the outreach indicators model. A similar outreach model was used by Lafourcade *et al* andYaron*et al* (1997). The model is shown in equation (1)

$$\text{Outreach level} = \frac{\text{Number of beneficiaries(Male/Female)}}{\text{TargetPopulation for the programme}} \text{--------------(1)}$$

In order to ascertain the extent to which people in the state are involved in IFAD microenterprise financing, outreach/ participation density is used. It is given as follows;

$$\text{Participation Density} = \frac{\text{Beneficiaries (Males/Females) in the programme}}{\text{Total population in the State}} \quad \text{------- (2)}$$

RESULTS AND DISCUSSION

Criteria Used in Selecting Beneficiaries by IFAD

This phase analyzed the criteria used by IFAD to select their beneficiaries. The major criteria considered based on this finding is presented in table 4.10
Table 1 shows the major criteria used by IFAD in selecting their beneficiaries. The Table shows that 100% of respondents selected were farmers that reside in IFAD recognised site and were members of cooperative/farmers group.The reason for this condition could be due to the application of joint liabilities /principles and the ability to monitor the activities of beneficiaries. In addition, membership of cooperation could aid in ease of fund/ other input administration. Furthermore,98% 0f the respondents indicated that the availability of farmland space is another criteria used in selecting beneficiaries. The use of availability of land space could mean a one of the sure way of proving that a benefiting Entrepreneur is ready for business.

Outreach of IFAD Micro-financing among respondents.

The outreach of IFAD micro-financing among the beneficial entrepreneurs was analyzed using the outreach indicator.
The outreach indicator is stated below. This includes number of beneficial clients, % of males and females.
Table 2 shows that 42.64% of the respondents who were reached withIFAD micro enterprise financing were males while 57.36% of those reached with IFAD micro enterprise financing were females. This means that majority of those that benefitted from IFAD microenterprise financing were women. The reason for this could be to improve the economic status of their family and to gain access to new information. In addition,extending micro enterprising financing could also ensure an upscale of their leadership, technical, entrepreneurial and managerial skills.

Outreach Densityof IFAD Micro-financing in Abia State to clients

In order to determine the outreach density of IFAD programme in the state, participation density measure as used by Mejeha and Ogbe (2008) was adopted and the result presented in Table 3
Table 3 show the outreach density which Mejeha and Ogbe(2008) referred to as participation density as another measure of outreach. It is used to estimate the extent to which people in the state are involved in the IFAD microenterprise financing programme in Abia State. The Outreach/participation Density is used to ascertain the

number of microenterprise financing beneficiaries in every 1000 people (males and females) in the State. Table shows that outreach/participation density in the state was 0.00887.This result suggest that in every 1000 people about nine (9) persons benefitted from IFAD microenterprise financing programme. The higher the value of outreach/participation density the more is the outreach achievement. Among the males, the outreach/participation density is less than that of the females. For equal participation density to be achieved; more people in the state should be given credit facility.

Effect of IFAD Micro-enterprise financing among Entrepreneurs in the study area

The effects of IFAD Microenterprises financing among the entrepreneurs in the study area were analyzed using the before and after descriptive model, to show particularly the difference in output.

Table 4revealed the effect of IFAD microenterprise financing among the benefiting entrepreneurs. The result shows that farm sizes increased with a marginal increase of 0.1345ha after accessing IFAD funding. In addition, there was a difference of 2821.02kg after accessing IFAD funding. This value indicates a positive impact of IFAD micro enterprise financing among entrepreneurs. Finally, there was a difference of 526094.46 after accessing IFAD microenterprise financing. Difference in total returns could be due to the utilization of IFAD microenterprise technologies and extension personnel among the beneficiaries.

CONCLUSION

It is concluded that operators of IFAD programme in the state should sustain the use of the programme criteria in selecting clients. This will help keep the programme objectives and goal. Operators of the programme should increase their level of outreach in the state especially among women. This would help in the promotion of food security and economic welfare of the beneficiaries. Finally, IFAD technologies and extension personnel should be used among beneficiaries of the programme.

Table 1: Criteria used in selecting beneficiaries by IFAD

Criteria	Frequency	Percentage
Membership of Cooperative/Farmers group	90	100
Availability of land Spaces	89	98.9
Be a farmer/reside in recognized IFAD programme site	90	100
Total	90	100.0

RADIO, THE MOST EFFECTIVE AGRICULTURAL DISSEMINATION CHANNEL

A. C. Mbanaso, R. O. Chimbo. C. Nsofor & E.O. Ene

Media and publicity unit FSRP and Extension National Root Crops Research Institute Umudike

ABSTRACT

The study was conducted to ascertain how effective Radio is compared to other communication medium. A simple random sampling technique was used to elicit information from the respondent. Data collected from 260 respondents were analyzed using descriptive statistics. The result of the study shows that radio (74.38%) is the most effective medium for agricultural dissemination because of its unique characteristics and features. Radio is easily accessible, affordable, covers wide range of people within a space of time, mobile and user friendly in nature. It is therefore the best medium for information dissemination in both rural and urban areas.

Keyword: **Radio*, Agriculture, Dissemination, Channel***

INTRODUCTION

Communication has remained a vital tool for human existence and survival. It transmits ideas, feelings and information from one person to the other in form of messages.

Communication can also be said to involve the interchange or exchange of messages in form of ideas or information from and among different categories of people (Nwosu, 1987). In an organization, information flows forward, backwards and sideways therefore communication refers the ways this information flows within the organization. However, a break-down in the communication channel leads to an in-efficient flow of information. For example, if employees are unaware of what the organization expects of them, this could cause employees to become suspicious of motives and changes in the company.

There are different types of communication which includes print and electronic media.

Over the years, Radio has been proven to be the most effective medium of communication due to its effectiveness in reaching a wide audience at a very fast rate. Radio plays an essential role in communication today by remaining available when other communication channels such as the television, Newspaper and Internet are rendered in accessible by weather or other interference.

The production level of the Nigeria farmers depends largely on the kind of information available to them. Therefore, information and the availability of multiple channels of getting vital information are integral part of agricultural development, this is the reason why extension workers use radio for communicating information on new methods and techniques, giving timely information about the control of crops, pest and diseases, weather forecast, marketing news etc and for this purpose, talks, group discussion, folk songs dialogues and dramas are usually organized.

Agriculture has always been a highly knowledge-intensive sector that requires continuous information flow. Therefore, effective extension services, education and communication services are probably some of the key strategies for sustaining agricultural growth, strengthening food security and combating hunger and malnutrition.

METHODOLOGY

The study was conducted in Abia State. Abia State is one of the thirty six states of the Federal Republic of Nigeria. The state is located in the South East gro-ecological zones of Nigeria and lies approximately between longitudes $7^{0}00`$E and $8^{0}00`$E and latitude $4^{0}45`$N and $6^{0}17`$N of the equator (NPC, 2006).

The study was conducted in 3 local government areas of Abia state, namely Umuahia North, Umuahia South and Aba North simple random sampling techniques was used to select 88 respondents from Umuahia North, 80 respondents from Umuahia South, 86 respondents also from Aba North, making a total number of 260 respondents for the study. Data was collected from the respondents through well structured questionnaire and interview schedule. Data collected was analyzed using descriptive statistics like frequency, percentage and means.

RESULTS AND DISCUSSION

Table 1 which is the socio-economic characteristics in the three Local Government Area (Umuahia North, Umuahia South and Aba North) ranges from 50 years and above (91.73%) while the youth are the lowest from the age of 21-30 years with 2.06 percentages.

The highest number of farmers in the three local government areas are married (57.85%) this is because most married people need to farm in order to provide for the family and they use their children for labour mostly, this makes the number of farmers that are married to be higher than others. The lowest is single (8.26%) because a good number of them do not have children to use for labour.

Table C shows that most of the farmers are literate (40.08%) this is because most of them do not have certificate to work as civil servants and they resolve to farming while the lowest is tertiary, with (10%) because few of them at the university are farming in order to help pay their school fees.
Table 2 which is the distribution of respondent on sources of information revealed that radio is the highest used medium for getting information, (74.38%) this is because radio is easily accessible, affordable, mobile, covers a wide range of people in diverse medium while the internet is the lowest (4.13%) because most of the farmers are illiterate and do not have access to internet, could not read and could not operate the system or computer.

CONCLUSION

In summary, the study reveals that radio is the most effective agricultural dissemination channel in Abia State as disclose in Table 2 earlier, farmers in Abia State have complete access to agricultural information and lots more through radio because of its affordability, accessibility, mobility, wide range coverage etc. radio is therefore important and useful in reaching out to farmers as well as constitute methods of notifying them of new development and emergencies. It is equally important in stimulating farmers' interest in new ideas and practices. Radio also provides to an illiterate valuable instructions and education in agriculture, health population control, sanitation and other aspects of daily life.

Table 1: Distribution of respondents according to socio-economic characteristics

Age (Years)	Frequency	Percentage (%)
21-30	5	2.06
31-40	6	2.47
41-50	9	3.71
50 and above	22	91.73

FACTORS INFLUENCING ADOPTION OF IMPROVED CASSAVA PROCESSING TECHNOLOGIES BY WOMEN IN AKOKO - EDO LOCAL GOVERNMENT AREA OF EDO STATE, NIGERIA

S. Abudu & E.O. Idehen

National Agricultural Extension and Research Liaison Services, ABU, Zaria.
E-mail: ***abudusuleman@gmail.com***

ABSTRACT
This study analyzed the factors influencing adoption of improved cassava processing technologies by women in Akoko-Edo Local Government Area of Edo State. Random sampling technique was used to select 121 women cassava processors for the study. Descriptive statistic and multiple regression used to analyze the data. The result revealed that 66.1% of the women cassava processors were about 60years old, 46% had secondary education, 64% had no extension contacts and 72.7% of the respondents belonged to co-operative societies. The mean level of adoption was revealed to be high with an average of 2.7. The study also revealed that age, processing experience, affordability, compatibility and complexity significantly influenced adoption with an R^2 value of 0.83. It was therefore recommended that cassava processors should utilize their memberships in cooperative societies by organizing joint contributions to assist themselves financially in order to increase their level of adoption.
Keywords: Adoption, cassava processing technologies, Edo State.

INTRODUCTION
The process of increasing the efficiency of agricultural production through improved agricultural technologies depends mainly on the extent to which farmers can incorporate improved agricultural practices (technologies) into their farming operations (Sasore, 2005). It has been commonly shown that acceptance of new farming practices takes place over time (Nweke, 1994). When a new farming practice is introduced in a community, not all people adopt it at the same time. Some farmers, no matter what, would continue to practice traditional agriculture and therefore, are inevitably poor such as adoption of cassava processing techniques by women in Edo State (Nweye, 1990).
Due to the important roles women play in economic development, one would expect that pride is accorded to women in the nation's development programme. Rather, available evidence suggests that women access to resources such as improved agricultural technologies remains severely limited (Oyewole*et al*., 1986). Consequently, they are faced with problems of under production and inadequate transportation for their farm produce. Although, significant breakthroughs have been achieved worldwide in the area of improved food processing technologies, but Nigerian women still rely on traditional methods of processing ((Nweke*et al*., 2004). For instance, traditional processing methods of cassava are so laborious that a number of improved cassava processing technologies have been put in place to reduce the drudgery of traditional processing methods. Thus, this study was designed with the general objective of analyzing the factors influencing women's adoption of the improved cassava processing technologies in Akoko-Edo local government area of Edo State.

METHODOLOGY
This study was conducted in three villages (Ibillo, Lampese and Ojirami) in Akoko-Edo Local Government Area of Edo State. The Local Government has an area of 1.371km^2 and a population of two hundred and sixty two thousand, one hundred and ten (262,110) people (NPC, 2006). The projected figure for 2015 is four hundred and twenty two thousand, three hundred and sixty two (422,362). Akoko-Edo was chosen because it is an agricultural area where women are largely involved in cassava processing business. A reconnaissance survey was conducted in the study area. The sample frame of women who were using the improved cassava processing technologies in the three villages under study was 1,206 comprising of 418 in Ibillo, Lampese 362 and Orjirami 426. In each of the sample frame of the three villages, 10% of the women cassava processors were randomly selected comprising of 42 in Ibillo, 36 in Lampese and 43 in Ojirami amounting to a total sample size of 12
Descriptive statistics (percentages and frequency distribution) was used to describe socio-economic characteristics of the respondents, determine the level of adoption, and identified the constraints encountered by the women processors using improved cassava processing technologies in the study area. Multiple regression analysis was used to determine the socio-economic factors that affected the women's adoption of the improved cassava processing technologies in the study area. The explicit regression equation is given as:
$Y = a + b_1X_1+b_2X_2+b_3X_3+b_4X_4+b_5X_5+b_6X_6+b_7X_7+b_8X_{8+}e$. Where;
Y = is the number of technologies adopted by the respondents.
X_1 = Age (in years)
X_2 = Years of schooling

X_3 = Processing experience (in years)
X_4 = Extension contact (number of extension visits)
X_5 = Membership of cooperative societies (number of years spent)
X_6= Affordability of technologies
X_7 = Compatibility of technologies
X_8 = Complexity of technologies
X_1 to X_8 = Independent variables as defined in the general and explicit equations above
b_1 to b_8 = Regression coefficients of X_1 to X_8
a = constant term
e = error term
Three-point scale was used to determine level of adoption. The mean level was obtained by adding together 1+2+3=6, which was divided by 3 to get a mean score of 2. Therefore, mean score equal or above the cut-off mean of 2 was regarded as high and mean score lower than 2 was regarded as low

RESULTS AND DISCUSSION

The results in Table 1 revealed that, majority (66%) of the respondents belonged to the age group of 41-60 years. These age groups could be regarded as the economically active group in which their energies could be utilized for productive purposes. Similarly, majority (46%) of the respondents had secondary years of schooling which implies that there was the possibility of understanding the adoption and usage of improved cassava processing technologies by the respondents in the area. The study also revealed that, majority (53%) of the respondents had been in cassava processing from 6-10 years which implied that cassava is one of the major crops cultivated by people in the area and cassava processing is the predominant occupation of the women as a result of their long stay in the business. The result showed that, majority (64%) of the respondents never had any extension contact. This implied that the performance of the extension agents in the area was poor. This agreed with the report of sasore (2005), that women processors had little or no contacts with extension agents in his paper presented in 2005. The study revealed that 73% of the women cassava processors had spent 10years and above in cooperative societies. This implied that the respondents had been involved in one co-operative society or another for a long time.
The result in Table 2 showed the mean of mechanical grater (3.83), power screw dehydrating press (3.83), mechanical sifter (3.28), gari fryer (1.56), and stitching machine (0.84). These findings indicated that the levels of adoption of mechanical grater, power screw dehydrating press and mechanical sifter were high while the levels of adoption of gari fryer (toaster) and stitching machine were low. This implied that the general level of adoption of improved cassava processing technologies was high with an average of 2.7.
In Table 3, multiple regression analysis revealed that five factors had significant influence on adoption which were age, processing experience, affordability, compatibility and complexity. It was found that age (.019) affordability (.021) and Compatibility (.044) had significant influence on adoption at 1% level of probability, while processing experience (.025) and Complexity (.010) had significant influence on adoption at 10% and 5% level of probabilities respectively. The result of this study therefore showed that the cumulative contributions of these variables to the adoption of improved cassava processing technologies had coefficient of determination (R^2) value of 0.83. This implied that all the variables together, explained about 83 percent of the total variability in adoption.

CONCLUSION

The result of this findings revealed that adoption of improved cassava processing technologies comprised of young literate women processors who had long years of experience in cassava processing, had few contacts with extension agents and belonged to one cooperative societies. Level of adoption was high with an average mean of 2.7. The results showed that age; processing experience, affordability, compatibility and complexity were the most important factors that influenced adoption of improved cassava processing technologies in the study area.

RECOMMENDATIONS

i. Women processors should utilize their membership of cooperative societies effectively by contributing together in order to assist themselves financially
ii. Government should provide the women processors with grants to enable them purchase privately owned improved processing technologies.
iii. Government should carry out sensitization programmes to educate the women about the uses of improved processing machines especially Stitching machine and Toaster in order to improve their level of adoption.

ASSESSMENT OF THE JOB PERFORMANCE OF FRONTLINE EXTENSION WORKERS IN IMO STATE AGRICULTURAL DEVELOPMENT PROGRAMME (ADP)

C.L, Njoku[1] & P.E., Amadi[2]

[1]Michael Okpara University of Agriculture, Umudike
[2.]National Root Crop Research Institute, Umudike
chukzy2013@yahoo.com

ABSTRACT
An assessment of the job performance of frontline extension workers in Imo State Agricultural Development Programme (ADP) was asses in 2015 with the aid of questionnaire. The three (3) zones that constitute Imo ADP were covered on the study. All frontline extension workers in Imo ADP formed the sample for the study. Data was analyzed using frequency counts, percentages and correlation analysis. Result showed that the respondents were rated highest on regular attendance to forthrightly training. About 36.11% were in the ages of 41 and 50 years, while majority of them were male. Also about 75% of the respondents were married with household size of 4 and 6 members. About 26.85% had HND as their level of formal education while 1 and 10 years was observed as their years of extension experience. Correlation result showed no significant relationship between personal characteristics and job experience, hence acceptance of the hypothesis. It is recommended that respondents should be encouraged and motivated to put in more effort to boost their job performance in Imo State ADP.
Keyword: Assessment, job performance, extension, workers, ADPs

INTRODUCTION
Agriculture is the major and most certain path to economic growth and sustainability. The importance of agriculture cannot generally be over-emphasized in Nigeria and Imo State in particular. Agricultural extension plays an indispensable role in the process of raising agricultural productivity and small holders' welfare. It has been described as the Kingpin in the process of technology generation, transfer and utilization (Nahdy, 2002).
Nigeria can be said to be a county with an extension system in constant evolution. The search for permanent panacea to the problems relating to technology generation, transfer and utilization/diffusion brought the ideal of Agricultural Development Project in 1975. The success recorded in the first and second implementation of ADP led to the full implementation of ADPs in all the States in Nigeria (Unanma *et al*, 2004). The ADP had employed the Training and Visit (T&V) system of managing the extension service in Nigeria. Frontline extension workers are the Block extension supervisors and the extension agents who execute the T&V system of managing the extension service in Nigeria. The introduction of Unified Agricultural Extension Service (UAES) was introduced in 1991.
Under UAES, frontline extension workers are assigned the responsibility of informing, advising and teaching farmers new and improved agricultural practices as well as providing feedback under them every forthrightly on a fixed day within the week with a view to disseminating production recommendations to them. He/she attends Forth Right Training (FNT) meeting where farmers responsibility of the frontline extension workers to encourage the farmers to try recommended practices. Despite, all these efforts by government, the agricultural sector in Nigeria has not achieved the desired result. Some of the reason that is attributable to this includes: inadequate funding, inadequate technology development, high extension to farmer ratio and lack of functional infrastructure in the rural areas (Nwachukwu and Ekwe, 2011).
Furthermore, due to poor agricultural productivity seen in Imo State and Nigeria in general led to the study of job performance of frontline extension workers to ascertain how far they have discharged their duties. Specifically, frontline extension workers personal characteristics will be described, job performance assessed and relationship between personal characteristics and job performance ascertained. The hypothesis, there is no significant relationship between some selected personal characteristics and job performance of frontline extension workers was tested.

MATERIALS AND METHODS
The population for the study was all the frontline Extension Workers in Imo State Agricultural Development Programme (ADP). All the three agricultural zones that constitute Imo ADP were covered in the study. Data for the study were drawn using questionnaire. A simple random sampling technique was used to select respondents for the study. To assess the performance of the respondents, each sampled respondents were rated by his immediate supervisor on a five-point likert rating. The five point on the scale were 1= very low, 2= low, 3=average, 4= high and 5= very high. The mean performance score for the respondents was calculated by dividing

the total performance score by the number of respondents. The job performance level was computed by dividing the grand mean score with the different performance variables on the questionnaire. Frequencies, percentages, mean scores and correlation analysis were used to analyze data collected in the study. Statistically significant relationship for correlation was tested at 0.01 probabilities.

RESULTS AND DISCUSSION

The personal characteristics of frontline extension workers are presented in table 1. Majority of the respondents were in the age range of 41-50 representing 36.11 percent of the sampled respondents. 61.11 percent were male, while 75 percent of the respondents were married. HND was observed as the level of formal education with household size of 4 and 6 members representing 26.85 and 45.37 percent respectively. Years of extension experience ranged between 1 and 10 years representing 54.63 percent of the sampled respondents.

Data in table 2 shows the mean scores of different job performance variable of frontline extension workers in Imo State ADP. The job performance level as computed was 4.11, out of the 10 job performance variables 6 fell above the performance level which shows that their job performance were rated slightly above average. This finding conforms with earlier study by Ekumankama *et al*, 2007, who found that job performance of EAs in Imo State ADP were rated average.

Result from table 3 showed that there was no positive relationship between personal characteristics and job performance of frontline extension workers in Imo State ADP. Since the correlation coefficients were negative. The hypothesis of no positive relationship between personal characteristics of frontline extension workers and the performance in Imo ADP was therefore accepted.

CONCLUSION

From result of the study, we therefore conclude that frontline extension workers in Imo State ADP were rated slightly above average. We can also conclude that their personal characteristics do not in anyway increase the job performance. Since the performance was rated slightly above average, it is recommended that they should be encouraged and motivated to put in more effort to boost their job performance in Imo State ADP.

Table 1: Distribution of frontline extension workers according to their personal characteristics

Variables	Frequency	Percentage (%)
Ages (years)		
21 – 30	14	13.89
31 – 40	22	29.63
41 – 50	29	36.11

ABSTRACT
This study was carried out to evaluate determinants of soil conservation technologies adoption in Abakaliki LGA, Ebonyi State. A multi-stage sampling technique was used to select one hundred and twenty respondents. Data for the study were collected using structured questionnaire. The result of multiple regression analysis revealed that age, educational status, household size, farm size and farmers training were the major determinants of adopting soil conservation technologies in the study area. Again, the result also revealed that cover cropping, alley cropping proper land preparation, agro-forestry, application of manure, re-vegetation and minimum tillage were soil conservation technologies adopted by farmers in the area. Based on the findings of the study, some recommendations were proffered.

INTRODUCTION
In Nigeria, Land degradation is one of the major challenges in agricultural production, especially in eastern part of the country. According to Pagiola, (1999) and Shiferaw *et al.*, (2009) land degradation in the form of soil erosion, deforestation, overgrazing, salinization and alkalization contributes significantly to low agricultural productivity and low income. The implication is that food insecurity and poverty will increase in the country especially, eastern part of the country. Prager and Posthumus(2010) stated that soil degradation can have serious negative impacts on agricultural production and the environment. Gebremedhin, (2004); Takie, (1999); FAO, (1985) pointed out the causes of land degradation include such factors as population pressure on resources; poverty; high costs or limited access of farmers to fertilizers, fuel and animal feed; insecure land tenure; limited farmer knowledge of improved integrated soil and water management measures; and limited or lack of access to credit.In order to protect soil resources from erosion, considerable efforts should be made to ensure the life continuity in the future in the area. World Bank (2007) asserted that achieving sustainable pathways out of the downward spiral of land degradation and poverty requires that farmers adopt profitable and sustainable land management practices, or pursue alternative livelihood strategies that are less demanding of the land resource. In eastern Nigeria, soil conservation is considered to be of top priority not only to maintain and improve agricultural production but also to achieve food self-sufficiency.Recognizing the seriousness of soil erosion problems and the necessity of improving soil fertility and increasing agricultural productivity. As a result, the achievement of soil and water conservation measures is below the expectation and the country loses tremendous amount of fertile top soil and, threat of soil degradation is alarmingly broadening. This is partly attributed to the biophysical, socio-economic, institutional and policy factors.The introduction and implementation of soil conservation programs and technology adaptations need to consider the socio-economic, physical, institutional and agro-ecological factors affecting farmer's willingness to adopt and use these technologies. So, the rehabilitation of land degradation is extremely important since the livelihoods of many Nigerians are entwined with land resources.

Objectives of the study
The broad objective of the study was toassess determinants of soil conservation technologies adoption in Abakaliki LGA, Ebonyi State
Specifically, the objectives are to:
i analyze determinants of soil conservation technologies on adoption among small holder farmers
ii identify the adopted soil conservation technologies.

METHODOLOGY
The study is Abakaliki Local Government (L.G.A) of Ebonyi State. In the course of this research work, multi-stage random sampling techniques were employed in selecting the respondents for the study. Stage I: Four (4) communities were selected out of the total of seven (7) communities thatmade up the study area. Stage II: Five (5) villages each in the four selected communities were selected to make a total of 20 villages used for the study. Stage III: Finally, twenty (20) villages selected, six (6) farmer respondents each were randomly picked to given the total of 120 farmer respondents.

Data for this research was collected from primary data. The primary data was collected using structured questionnaires and interview schedule for the sake of illiterate farmers. For the purpose of the study, descriptive and inferential statistics. Regression analysis was used to analyze the objective one. Likert scale was utilized for objective two. In accordance with this study, the model is specified effect of socioeconomic characteristics of farmers on their level of adoption in Abakaliki local Government Area of Ebonyi State.
The regression Model is specified thus
$Y = f(x_1, x_2, x_3 \ldots x_n)$ … Implicit form
$Y = a_o+a_1x_1+a_2x_2+a_3x_3 \ldots\ldots a_5x_5$ + et. Explicit form
Where Y = credit utilization
X_1 = Age (years)
X_2 = Educational Status (years)
X_3 = Household Size (number)
X_4 = Farm size(ha)
X_5 = Farmers Training
et = error term

RESULTS AND DISCUSSION

Determinants of Soil Conservation Technologies Adoption among Small Holder Farmers

Result of multiple regression analysis (table 1) shows that the coefficient of determination (R^2) was 0.826 (82.6 %) and adjusted R^2 was 0.0803 (80.3%), this means that about 82.6% variation on the dependent variable was influenced by the combine effect of the independent variable (X1 –X5). The high value of R^2 82.6% signifies that the independent variable had positive effect on the dependent variable and important variable where not omitted from the regression model used. Age of the farmers had a positive coefficient and was significant at 5% level of significance. This is true because younger farmers would be more accommodative to new technology and would invest in new and long term innovations. Education status of the farmers took a positive sign and statistically significant at 1% probability level. This implies that there was high level of adoption on soil conservation technologies among the educated farmers in the catchment than less educated ones. The *a prori* expectation was met because educated farmers are presumed to have exposure to modern technologies and innovation and are more receptive to new ideas and more willing to adopt. The coefficient of farm size found to be positively signed and also statistically significant at 1% level of significance. From the result, farm size found had a positive influence on adoption of soil conservation technologies in the area. Household size bore positive sign and statistically significant at %% level of probability. Therefore household size of the farmers would influence the decision of farmers to adopt the decision of farmers to adopt the soil conservation measure give family labour is the whole supplier of the required labour for undertaking the farming and soil conservation operation. Farmers training had a positive influence and statistically significant at 1% level of significance. This is a major determinant in soil conservation technologies adoption especially with respect to prior resource farmers who are not educated.
From the result of the analysis, it was observed that cover cropping, alley cropping , proper land preparation, agro-forestry, application of manure, compost, re-vegetation and minimum tillage with the following mean score of 3.2, 3.1, 2.9, 2.8, 2.7, 2.6, and 2.5 respectively. This implies that they will be increase in agricultural productivity and high level of income among the small holder farmers in the survey.
Table 4 indicate that the cause of soil erosion were intensive cultivation (X=3.2) overgrazing (X=3.0), Heavy rainfall (X=2.9), deforestation (X=2.7), over population (X=2.6) and lack of modern farm tools (X=2.5). This supported findings of Addisu et al, (2015). The implication is that they would be increase in low agricultural productivity including food insecurity and poverty.

CONCLUSION

Based on the findings of the study it was concluded that age, educational status, household size, farm size and farmers training as a major determinants of adopting soil conservation technologies in the study area. Again, the result also revealed that cover cropping, alley cropping proper land preparation, agro-forestry, application of manure, re-vegetation and minimum tillage were adopted in the farmers as the major soil conservation technologies.

RECOMMENDATIONS

Based on the findings of the study the following recommendation was made;

1. Government agencies and NGO's shouldcarryout sensitization for the farmers to form groups to benefit from institutional credit facilities to enhance adoption of soil conservation technologies.
2. There is need for organizing seminars, workshops and conference which will enhance the knowledge of farmers on oil conservation technologies
3. Extension agent should always visit the farmers and educate the on what to do and what not to do.

ABSTRACT
This study investigated the determinants of the adoption of improved agricultural practices in yam production by small holder farmers in Ezza North LGA, Ebonyi State. A Multistage purposive sampling techniques was employed to select a total of 120 respondents. The primary data were collected for the study through structured questionnaire and interview schedule organized for illiterate farmers in the study area. The result of the analysis also identified mixed cropping (8.6%), crop rotation (8.5%), improved land preparation and planting yam seeds (7.9%) and others as improved agricultural practices adopted by the respondents. The research work also revealed factors influencing the adoption of improved agricultural practices such as access to improved farm inputs, access to farm land, availability of extension service, level of education, access to credit facilities, farming experience, low interest rate and access to information and training. The result also indicated that government policies and economic factor, personal factor, and institutional factor were the major constraints militating the farmers to adopt the improved agricultural practices. Based on the findings of the research work, some recommendations were proffered.
Keywords: Determinants, Improved, Agricultural Practices, Adoption, Smallholder

INTRODUCTION

Yam production is one of the main agricultural activities in West Africa, and the region contributes between 90% and 95% of world production (FAO, 2006). In Nigeria, yam is the most important food crop in terms of output value. It plays a key role in guaranteeing household food security. The yam sector in Nigeria is definitely important for household and national income as well as food security. Yam **(Discorea *spp*)** is an important tuber crop in Nigeria where it is produced as food and cash crop (Asumugha and Eluagu, 1991). Agricultural technology plays a vital role in enabling agriculture to become more productive and sustainable. Sustainable agriculture is an agricultural system adapted to a particular area so that crop and animals production do not decline over time and are reasonably stable over normal fluctuations of weather (Donahune and Troch, 2003). The improved agricultural practices are innovations, genetic improvement, mechanized farming equipment, improved and high yield varieties, integrated pest management control, soil mapping, precision dosing of fertilizer, agricultural advisory systems, post harvest technologies, efficiency in land use among other and including ICT facilities, can play an important role in agricultural development. The efficiency in the use of technology generated and disseminated depends on effective communication which is the key process information dissemination (Harper *et al.*, 1990). Angawu (1992) reported that improved agricultural technologies disseminated to farmers in Enugu State, Nigeria include harvesting of yam, storage in barn, pest control in food crop farm, site selection/bush clearing/packing, weeding of early season crops, disinfections and restocking of day-old chicks, early maize cultivation, and improved soil conservation in food and cash crops. Low improved agricultural practices by most small-holder farmers, described level of increase in agricultural productivity has been difficult to achieve. The use of agricultural technologies affects the rates of increase in agricultural output (Ekpere, 1994). It also determines how the increase in agricultural output impacts on poverty levels and environmental degradation. Therefore, the focus of recent research has been to find better agricultural practices. Increased technology development and adoption can raise agricultural output; hence improved household food intake improved. Food intake can also improve the functioning of the human body and the performance of a healthy, normal life which will increase work output (Caswell *et al.*, 2001) Agricultural technology development is an essential strategy for increasing agricultural productivity, achieving food self-sufficiency and alleviating poverty and food insecurity among small holder farmers in Nigeria.

Onwueme, (1982) stated that despite the major agricultural research breakthroughs, adoption of the improved agricultural technologies to farmers is a major challenge for both researchers and technology transfer agencies. He opted that the low utilization of improved technologies by smallholder yam farmers may be a factor responsible for their sub-optimal production levels. Declining crop yield among the small-holder yam farmers is probably because the improved production technologies and innovations are not reaching the farmers or that they are not being adopted. Feder and Slade (1984) stated that agricultural innovation diffusion is largely affected by information available on the innovation, relative to its adoption.

Objectives of Study

The broad objective of the study is to identify the determinants of the adoption of improved agricultural technology practices in yam production by small scale farmers in Ezza North Local Government Area, Ebonyi state.

The specific objectives are to:

i. identify the existing improved agricultural practices among the yam small scale farmers;
ii. examine the determinants of the adoption of improved agricultural practices by smallholder yam farmers;
iii. identify the constraints associated with yam farmer's adoption of improved agricultural technology practices.

METHODOLOGY

The research was conducted in Ezza North Local Government Area of Ebonyi State, Nigeria. The farming activities they engage in are crop farming-oil palm, yam, cassava, rice, rubber, rice, mango, okra, cocoyam while the livestock farming include-fish farming and animal husbandry.

Multistage purposive sampling techniques were adopted to select a total of 120 yam farmers that were used for the study. The first stage involves the random sampling of (10) Agricultural Extension circles (communities) in the study area. In the second stage, were four sub-circles (villages) were randomly selected from each of the ten (10) circles (autonomous communities) selected in stage 1, a total of 40 villages were selected in this stage. Finally, three (3) contact yam farmers were purposely selected from each of the selected (villages). Therefore, a total hundred and twenty (120) yam farmers were used for the study.

The data for the study were collected primary data were used for the study. The primary data were collected using a well structured questionnaire and oral interview schedule

Data obtained for this study were analyzed using both descriptive and inferential statistics. Descriptive statistics such as frequency, table and percentages were used in analyzing objective I, II and objective III were analyzing using factor analysis

RESULTS AND DISCUSSION

Improved Agricultural Practices Among the Yam small holder farmers

Data in Table 1 indicate that the improved agricultural practices adopted by yam producer include mixed cropping (8.6%), crop rotation (8.5%), improved land preparation and planting yam seeds (7.9%), inorganic manure (fertilizer) (7.9%), organic manure application. (7.7%), alley cropping (7.5%), cover cropping (7.3%), site selection/bush burning/ packing (7.3%), improved yam seed varieties (6.8%), harvesting of yam and storage in barn (6.9%), disease control (6.3%), green manure (5.6%), and tuber multiplication technology (yam minisett) (5.1%). It implies that yam small scale farmers have adopted mixed cropping and crop rotation as a major improved agricultural practice in the study area. According to Ekumankama (2000), mixed cropping especially yam and cassava based mixtures are traditionally practiced in many farming systems in the eastern region of the country. It is worthy of note that level of improved agricultural practices adoption by farmers is high. As a result of high improved agricultural practices employed by most small scale farmers, the desirable level of increase in agricultural productivity with be achieve.

Determinants of the adoption of improved agricultural practices by yam small scale farmers

The analysis of the data collected shows the factors influencing adoption of improved agricultural practices include; access to improved farm input (13%), availability of extension services (12.9%), access to farmland (12.9%), level of education (12.7%), access to credit facilities (12.6%), farming experience (12.3%), Low interest rate (12.1%) and access to information and training (11.5%). This is true because the availability of subsidized improved farm inputs would serve as the basic motivating factor for technology adoption. The positive relationship of educational level and farming experience as a factor of technology adoption implied that adoption of improved agricultural practices tended to be accepted by experienced farmers as they understand the importance of technologies in farming.

Constraints Associated with yam small scale farmers in adopting the improved agricultural practices

Table 3 shows the varimax rotated constraints limiting and adopting the improved agricultural practices among yam small scale farmers. The data obtained in the based on the responses of the respondents. In this regards, the variable were grouped into three (3) major constraints, namely; factor 1 (Government , Policies and Economic factor), factor 2 (Economic and personal factor),and factor 3 (institutional factor). Factor 1 was named due to the variables that loaded high under it. They include; government inconsistent of policies (0.814), lack of credit facilities (0.660) and lack of awareness of improved practices (0.332). After critical consideration, factor 2 was named economic and personal factor because the variable that loaded high under it related to economic and personal factor. These include; high cost improved farm inputs (0.790), and lack of interest (0.712). Under factor 3, the identified constraining variables were; lack of extension service (0.803), poor infrastructure (0.649), and Government inconsistent of policies (0.509) which was named institutional factor.

CONCLUSION

The study showed that access to improved farm input, access to farm land, availability of extension service, level of education, farming experience, access to credit facilities are the most significant determinants of the adoption of improved agricultural practice in the study area. Factor analysis was utilized to determine the constraints limiting the adopting improved agricultural practices and it was observed that government policies, economic factor, personal factor and institutional factor were found as the majority constraints affecting adoption of improved agricultural practices in the study area.

Based on the findings of this study, the following recommendations were made;.

I. Government should work with the farmers and involve them in distribution of necessary improved farm input for agricultural production.

II. Extension agent should be trained and empowered to educate farmers on how to use different improved agricultural practices.

III. The government should consider granting incentives and assistance to the agricultural sub-sector and to the farmers in form of credit as these would enable them take action to use improved agricultural practices.

Table 1: Percentage distribution on improved agricultural practices among the yam small holder farmers

Improved Agricultural Practices	Frequency(n=120)	Percentage
Alley cropping	82	7.5
Green manure	61	5.6
Crop rotation	93	8.5
Mixed cropping	94	8.6

ABSTRACT
The study examined the socio-economic factors influencing the adoption of simple agricultural technology in Kwara State. 154 farmers were purposefully selected at random in 2 LGAs (Ifelodun and Irepodun) for this study. Data were collected by means of questionnaires and analyzed using descriptive and inferential statistics. The result revealed that about 58.5% of the respondents are within middle age, 72.7% are literate which implies that they are in a better position to be aware of, understand, comprehend and adopt simple agricultural technologies. The study also revealed that about 67.5% of the respondents did not belong to any farmer/cooperative organization. The multiple regression result indicates that the coefficients of sex and cooperative society, relevant, aspiration were found to be influencing the adoption of simple agricultural technologies at 1% and 5% level of significant. Poor finishing, publicity, feedback and extension were identified as constraint to adoption of these technologies. It was concluded that the respondent's interests in adoption of simple agricultural technology is high because it contributed to increase in their livelihood, income and make their work faster and efficient.

INTRODUCTION

In Nigeria, farms and farmlands have become smaller and fragmented due to increase in population growth rate. This increase in population has outstripped growth in agricultural output thereby resulting in low productivity which may be attributed to low adoption agricultural research results and technologies that can increase farmer's productivity.

Technology adoption means different things to different people. To some, technology adoption is viewed as a consistent process, the key to enabling hesitant users to successfully adopt and use technology. Adoption of any innovation is not a one step process as it takes time for adoption to complete. The duration of adoption of a technology vary among economic units, regions and attributes of the technology itself. Therefore, adequate understanding of the process of technology adoption is necessary for designing effective agricultural research and extension programmes.

According to Rogers (1983), adoption of technology can be viewed as a 5-step process. The 5 steps are:

Awareness: Potential users learn enough about the technology and its benefits to decide whether they will use the new technology or not.

Assessment: Potential users evaluate the usefulness and usability of the technology, and the ease or difficulty of adoption.

Acceptance: Potential users weigh the advantages/disadvantages and decide whether to acquire and adopt or use the technology, or decide not to adopt the technology.

Learning: Users develop the skills and knowledge required to use the technology effectively and may search for further information about it.

Usage: Users demonstrate appropriate and effective use of the technology to its fullest potential.

Erebor (2001) highlighted some factors affecting the rate of adoption of technology as follows:

Level of education: The more educated a farmer is, the higher the rate of adoption of new technology. It will take a longer time for an illiterate farmer to accept new ideas in farming.

Attitude of the farmer: Most farmers that develop positive attitude toward new technologies are more likely to succeed than those that do not respond at all.

Financial status of a farmer: Experience has shown that wealthy farmers are ever willing to accept and experiment in new farming technologies than very poor or peasant farmers.

Size of the farm: The bigger the farm, the higher the rate at which a farmer will be willing to accept new ideas and the smaller the farm, the lower the rate of adoption of new technology.

Presence of extension worker: The presence of extension worker within the farming community may help the individual farmer to accept the new ideas or techniques in farming.

Result of demonstration plots: The result from demonstration plots, particularly, if it is a good one will promote the acceptance and adoption of the innovation but when the result is not good, farmers will abandon the whole idea concerning the technology.

However, the rate of adoption of technologies is very low due to the unwillingness of the farmers to take risk of using new technologies with the fear that it will lead to losses or reduction in output. In view of the above, it becomes imperative to intensify efforts on adoption of research results and technologies for sustainable development and farmer's profitability through adoption of superior technologies and research packages. It is against this background that, this study sought to provide answers to the following research questions: what are the socio economic characteristics of the farmers? and how can the socio-economic characteristics of farmers influence the adoption of simple agricultural technologies?

METHODOLOGY

This study was carried out in Ifelodun and Irepodun Local Government Areas (LGA) of Kwara State, Nigeria. The major source of livelihood and occupation of the people in the area is farming (KWSMI, 2002 and Mohammed, 2008). A multi stage random sampling technique was used. Ten (10) communities were purposively selected in the study area. Second stage involved randomly selection of 154 farmers who serve as the sample frame. The data used for this study was basically primary data. This involved the use of an interview schedule with a structured questionnaire administered to the farmers. Descriptive statistics such as frequency, percentage and mean were used to analyzed the socio-economic of respondents while the regression analysis was used to determine the relationship between farmers socio-economic factors in relation to adoption of simple agricultural technologies. The model is express implicitly as:

$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8)$

where:

Y = adoption of simple agricultural technologies

X_1 = age of farmers

X_2 = Sex

X_3 = Marital status

X_4 = Experience

X_5 = Family size

X_6 = Source of Information

X_7 = Educational status of farmers

X_8 = Association among farmers

RESULTS AND DISCUSSION

The findings from the study indicated that the adoption of simple agricultural technologies is majorly in the hands of the female. About 58.5% of the respondents are within middle age and they are expected to be energetic, mentally alert, actively involved in processing activities. The study further revealed that the average household size of the respondents was 4 implying that they have enough family labour to contribute to agricultural production. This revealed positive relationship between family size and adoption. The data on educational status revealed that majority of the respondents about 72.7% are literate this implies that they are in a better position to be aware of, understand, comprehend and adopt simple agricultural technologies. It is also established from the study that majority of the respondents are full time farmers and farming is their major source of income. About 67.5% of the respondents did not belong to any farmer/cooperative organization. The implication is that potential of social network has not been fully utilized.

The multiple regression result indicates that the coefficients of sex and cooperative society, relevant, aspiration were found to be influencing the adoption of simple agricultural technologies at 1% and 5% level of significant. Poor finishing, publicity, feedback and extension were identified as constraint to adoption of simple agricultural technologies.

CONCLUSION

Agricultural development depends, to a great extent, on the willingness and ability of the farmers to make use of the new technologies. The findings in this study clearly shows that the respondent's interests in adoption of simple agricultural technology is high because it contributed to increase their livelihood, income and make their work faster and efficient. The contribution of a technology to economic growth can only be realized when and if the new technology is widely used. The result from the findings of the research work shows clearly that the level of adoption of simple agricultural technologies as evident from the respondent's is remarkable.

ABSTRACT
The study assessed adoption of ICTs among male and female farmers in Ohaukwu Local Government Area of Ebonyi State. Multi-stage random and purposive sampling techniques were used to select 120 respondents, comprised of 60 male farmers and 60 female farmers respectively. Primary data which were collected with the aid of a structured questionnaire were used for the study. Data were analyzed using descriptive statistics. The result of the study showed that male and female farmers have different levels of awareness on the available ICT facilities in the study area, however, the male farmers have higher level of awareness on ICT facilities such as radio (70%), mobile phone (90%) and television (60%) as against female farmers whose awareness level is more on mobile phone (80%) and radio set (53.3%). Moreso, the result indicated grand means of $\bar{X} = 2.45$ *and* $\bar{X} = 2.35$, *which are below the cut-off point of 2.5 for both male and female farmers respectively, suggesting that although the male farmers appear to have higher level of adoption of ICT facilities than their female counterparts, the overall adoption level is low. The test hypothesis attested to the significance difference between the male and female farmers on their extent of adoption of ICT facilities in the study area. The male and female farmers accepted that some factors influenced their decision to adopt ICT facilities into farming operations. However, these factors influenced the male farmers more than the female farmers. The study recommends provision of ICT support infrastructures at the rural area by the government, inclusion of gender mainstreaming ICTs programmes into extension service delivery to improve male and female farmers' knowledge and skills for effective adoption of ICTs; and formation of cooperative society to enable farmers pull their resources together to acquire modern ICTs in order to effectively harness the opportunities offered by facilities in agricultural production.*
Keywords: **Adoption, Farmers, Male, Female, ICT Facilities.**

INTRODUCTION
That ICTs play an important role in African development is now well documented. For instance, the use of telephone services because of its wider access has engendered social inclusion through employment generation and improvements in social services including fishing and farming practices has been documented (de Silva, Ratnadiwakara and Soysa, 2009; Jensen, 2007). Access to ICTs (such as telephones) has helped to remove barriers of isolation of individuals, enhance their chance of economic inclusion and thus 'provide diverse avenues for women's social, political and economic empowerment (UNDAW, 2003). However, most of these studies have shown uneven forms of the benefit that accrue to men and women from social engagement and economic participation, particularly to those living in remote rural areas in developing countries (Mottin-Sylla, 2005). The gender disaggregation based on nationally representative data on ICT access and usage is extremely limited but essential to verifying or challenging underlying assumptions about access and utilization of ICTs, gender equity and development. Most of the studies in recent years on women's access and usage of ICTs argued that there is a significant gender divide, particularly in developing countries. A study carried out in 2005 by the Gender and ICT Network, reveals that, globally, women's chances to benefit from the advantages of the information society are one third less than men's (Mottin-Sylla, 2005).

A number of studies in recent years have sought to understand gender similarities and differences in access and usage of ICTs. Gender and technology studies have found that men and women adopt and use technology differently (Gefen and Straub, 1997; Venkatesh and Morris, 2000). Men's decisions to use technology are more strongly influenced by their perception of usefulness, while women's decisions are based more on perceptions of the technology's ease of use (Venkatesh and Morris, 2000). However, men and women may view the same mode of communication differently. Ironkwe (2011) argued that gender deals with the social relationship between men and women and how these relationships are negotiated in the production of goods and services. However, it is important to note that such gender relationship exist among farmers with respect to access to ICTs. Farmers' personal characteristic and socio-economic status, which are determined by gender related factors, constitute critical factors in technology utilization process (Chukwu, 2007).

Moreso, in the past decades, there was little sex disaggregated data to demonstrate disparities between men's and women's access and use of ICTs, although no one contested that was the case. Despite various attempts to quantify the digital divide along gender line in recent time, it seems there is little or no rigorous and consistently empirical verifiable data, beyond very limited census-type data by national statistical offices, on which to assess the progress made towards determining gender specific factors influencing the adoption of ICTs in farming activities. It is against this backdrop that this study was embark upon to assess influence of gender on adoption of ICTs among farmers in Ohaukwu L.G.A of Ebonyi State, Nigeria. Specifically, the objectives were to: identify existing ICTs and farmers awareness in the study area; assess the extent of adoption of ICTs among the male and female farmers; and ascertain factors that influence the adoption of ICTs among male and female farmers in the study area. The study hypothesized that there is no significant difference between the levels of adoption of ICTs among female and male farmers in the study area.

METHODOLOGY

The study was carried out in Ohaukwu Local Government Area (L.G.A) of Ebonyi State. The Local Government Area is one of the thirteen (13) Local Government Areas of Ebonyi State. It is made up of fourteen (14) autonomous communities and three (3) clans. Its Headquarter is located at Ezzamgbo which is 13km away from the state capital. The area has a land area of 517 km^2 and a total population of 19, 6337 peoples (NPC, 2006). Geographically, the L.G.A lies within latitude 4^0N and Longitude 8^0E of Ebonyi State.

The mean temperature is between 27^0C and 28^0C and the prominent climatic seasons are rainy season, lasting from April to October, and dry season, lasting from November to March (Nwagbo and Onuchekwa, 1988). The vegetation of the area is the derived Savanna type. Farming constitute the major occupation of the people found in the area, though significant number of the population engaged in non-farm occupation such as civil and public services, building and construction, trading and transportation among others. Major crops grown in the area include yam, cassava, vegetable, maize, oil palm, and sweet potatoes.

Multi-stage sampling involving random and purposive sampling techniques were used to select a total of 120 respondents comprised 60 male and 60 female farmers. Primary data were used for the study, which were collected through the use of structured questionnaire and interview schedule. Descriptive statistics of frequency table, percentage and mean were used to analyze objective I, while mean score derived from 4-points Likert scale was used to analyze objectives (ii) and (iii). The null hypothesis was tested using t-test statistics.

RESULTS AND DISCUSSION

To determine the existing ICT facilities in the study area, a list of the facilities were provided for the respondents to check and indicate the available facilities based on their level of awareness.

The result in Table 1 shows that male and female farmers have different level of awareness on the available ICT facilities in the study area. However, it was observed that male farmers have higher level of awareness on the availability of ICT facilities such as radio (70%), mobile phone (90%) and television set (60%) as against female farmers who are aware of mobile phone (80%) and radio set (53.3%). The higher awareness level among male farmers is not unconnected with the patriarchy society, which allows men as the head of the households to make decision concerning the entire household in addition to capital assets acquisition through inherit and other cultural means. This practice hinders women access to information on productive assets. However, the high awareness of the farmers on ICT facilities such as mobile phone and radio more than other ICT facilities is because of its wider coverage of its network, reach and affordability. In addition, the ease with which mobile phone can be used and the positive impact in terms of facilitating quick access to communication must have influence its high awareness. The finding collaborates that of Ezeh (2013), who reported that over 95 percent of the farmers in Southeast, Nigeria testified to the existence and awareness of radio, mobile phone and television.

To ascertain respondents' extent of adoption to existing ICT facilities, a list of ICTs were provided for the respondents to indicate their extent of adoption.

Table 2 shows the mean score distribution of male and female farmers based on their extent of adoption of ICTs in the study area. The result shows the grand means were below the cut-off mean ($\bar{X} = 2.45$) and ($\bar{X} = 2.35$) for both male and female farmers respectively. This suggests that although the male farmers appear to have higher extent of adoption of ICT facilities than their female counterparts, however, the farmers' overall extent of adoption is low. The analysis indicates that the most ICT facilities adopted by the male farmers were mobile phone ($\bar{X}$ = 2.89), radio ($\bar{X}$ = 2.80), television ($\bar{X}$ = 2.77), cassette recorder/player ($\bar{X}$ = 2.70) and newspapers ($\bar{X}$ = 2.65), while the female farmers adopted more of mobile phones ($\bar{X}$ = 2.70), radio set ($\bar{X}$ = 2.64) and television ($\bar{X}$ =2.54) facilities in the study area. Similar finding has been reported by Ezeh (2013), who observed that farmers in Southeast, Nigeria adopted ICTs such as radio, television and phones to a reasonable extent in their farming activities. The poor extent adoption of ICTs may be attributable to the low level of access and cost associated with ICTs adoption in addition to absent of ICTs support facilities such as electricity. Moreso, the study reveals that farmers access and utilize more of conventional ICTs for obtaining agricultural information than the contemporary ICTs. This is consistent with Adejo and Haruna (2009). This situation has grave consequent for agricultural production in Ohaukwu LGA of Ebonyi State and Nigeria in general. According to Nchuchuwe (2012), the problem of underdevelopment in agricultural sector of Nigeria and sub-Saharan African countries is attributable to the inability of a large portion of her population to access and effectively deploy ICTs for agricultural development.

Data in Table 3 reveals that the t-values for male and female farmers on their extent of adoption of ICT facilities were 25.756 and 27.187 respectively, which is less than the t-tab of 2.042. This implies that male farmers have higher extent of adoption of ICT facilities than the female farmers in the study area. Hence, the alternative hypothesis was accepted that there is significance difference between the male and female farmers' extent of adoption of ICT facilities in Ohaukwu LGA of Ebonyi State.

To determine the decision of male and female farmers to adopt ICT facilities, the farmers were provided with the list of possible factors that influence the adoption of ICT facilities. The summary of the result is presented in Table 4. The result in Table 4 shows that both male and female farmers accepted that some factors influenced their decision to adopt ICT facilities into farming operations. The factors that influenced the male farmers were: educational attainment ($\bar{X}$ =2.7), income level ($\bar{X}$ =3.5), affordability of ICTs ($\bar{X}$ =3.32), farm size ($\bar{X}$ =2.67), availability of power supply ($\bar{X}$ =2.63), knowledge of ICTs ($\bar{X}$ =2.95), ease of use ($\bar{X}$ =2.56), compatibility with previous experience ($\bar{X}$ =2.68), relevance of ICTs to farming activities ($\bar{X}$ =2.85), durability of facility ($\bar{X}$ =2.51) and availability of ICTs ($\bar{X}$ =2.74). While female farmers were influenced by educational attainment ($\bar{X}$ =2.62), income level ($\bar{X}$ =3.23), affordability of ICTs ($\bar{X}$ =2.85), availability of power supply ($\bar{X}$ =2.56), knowledge of ICTs ($\bar{X}$ =2.74), ease of use ($\bar{X}$ =2.83), relevance of ICTs to farming activities ($\bar{X}$ =2.74), and availability of ICTs ($\bar{X}$ =2.63). From the analysis, it was observed that male farmers have more factors that influenced their decision to adopt ICTs than the female farmers. For instance, the male farmers admitted that all the eleven items influenced their decision to adopt ICT facilities as against female farmers that were influence by eight items. This scenario probably may be attributed to the inability of women to have direct ownership of many ICT facilities as such they access it indirectly through their husbands.

CONCLUSION

The study observed that the most available, accessed and utilized ICTs in the study area are radio, mobile phones and television. However, the level of adoption of these facilities is generally low. Notwithstanding, the male farmers have higher extent of adoption than their female counterparts. Hence, the study concludes that there is significant difference between male and female farmers' extent of adoption of ICT facilities in the study area. It was also observed that a number of factors influenced the decision of male and female farmers to adopt ICT facilities at a disproportionate level in favour of the male farmers. Some of these factors include: educational attainment, income level, affordability of ICTs, farm size, availability of power supply, knowledge of ICTs, ease of use and relevance of ICTs to farming activities among others. Based on this, the study recommends provision of ICT support infrastructures at the rural area by the government, inclusion of gender mainstreaming ICTs programmes into extension service delivery to improve male and female farmers' knowledge and skills for effective adoption of ICTs especially in rural areas; and formation of cooperative societies to enable farmers pull their resources together to acquire modern ICTs in order to effectively harness the opportunities offered by ICT facilities in agricultural production.

USE OF EFFECTIVE COMMUNICATION TECHNIQUES IN AGRICULTURAL EXTENSION TECHNOLOGY TRANSFER SYSTEM IN NIGERIA

S. Abudu & E.O. Idehen

National Agricultural Extension and Research Liaison Services, ABU, Zaria
abudusuleman@gmail.com

ABSTRACT
Agricultural extension technology transfer system largely depends on effective communication techniques with the aim of disseminating information and improved agricultural technologies to the people both in developed and undeveloped countries. Despite the existence of extension institution and technology transfer programmes in almost every developing country, coverage of farm families is still very limited. This is due to low quality of developing countries' extension programmes and ineffective communication techniques which consequently lead to the underutilization of improved agricultural technologies. It is against this background that this paper examines the use of effective communication techniques in disseminating agricultural extension messages to farmers. Based on the findings, it is concluded that timely and adequate dissemination of improved agricultural technologies requires effective and reliable communication techniques and recommended that the use of radio and cell phones contacts should be given more priority as well as organizing workshops or seminars to sensitize farmers in the use of communication techniques.
Keywords: **Effective communication techniques, agricultural extension, technology transfer, Nigeria.**

INTRODUCTION
It is recognized that emphasis on information and communication strategies can create a wide range of opportunities for participation of farmers' uptake of new farming technologies. This strategy provides basis for empowering the rural farming populace to understand and track new farming technologies for possible diffusion of research results and recommended practices which can lead to farmers' adoption for increased productivity. Upon this, Arokoyo (2005) defined agricultural extension as an advice and assistance given to the farmers and his families through educational procedures in order to improve their production efficiency, income, level of living and uplifting the education and social standard of the farmers. Incorporation of appropriate multi-channel communication strategies into extension programmes can improve this situation. Although, many information units already exist in developing countries' extension programmes, Olowokere (2006) posited that communication techniques are devices used in passing information from the teacher/trainer to the learners with the use of mass media, audio visual aids and printed materials. The skills of communication competence are essentially participatory. Participation has to do with the people's active involvement in every phase of development process. With their involvement, the people assume responsibilities for determining and shaping their own destinies. Thus, for development to be attained, nurtured and sustained, efforts must begin in collaboration with the beneficiaries. Participatory communication is the bidirectional sharing of ideas, information, knowledge and experiences among people. Therefore, in underlining the critical role of participation in both communication and development, Otitolaye (2006) reasoned that people-oriented development can only realize its full potentials if rural people are involved and motivated in information and knowledge sharing through mass media channels.

Use of effective communication techniques in disseminating agricultural extension messages to farmers
An important objective of agricultural extension and technology transfer system in Nigeria is to disseminate useful and practical information relating to agriculture, ensure practical application of such knowledge and mobilization of farmers' resources for the purpose of improving their welfare (Rogers, 1999 and Yekini, 2006). One of the strategies employed in achieving this, is through the use of effective communication channels among researchers, extension agents and farmers. Some of these strategies are radio, television, newspaper, Information and Communication Technologies (ICTs), internet connection and use of phones. The mainstream of agricultural extension service worldwide remains the development of the rural sector and improvement of the living conditions of farming household through increased farm production. It does this by providing the rural farmers with relevant and applicable research-based technologies. This is usually accompanied by technical information with which farmers are assisted to understand the potentials of the technologies and acquire the needed skills for their implementation, in order to successfully achieve this task.

Radio in rural development
Radio serves as an important medium in disseminating agricultural extension messages in both rural and urban centers. According to Olowokere (2006), an average rural or urban person listen to radio for more than three hours in a day. Also, many people spend more hours with the electronic media than they spend with other human beings in the community and carry out less reading and learning. Despite the importance of radio in community development, it has one major problem in its transient nature. For instance, it has a little reference value. Once a

programme is over, to recall the message of the radio may not be easy. Also, radio is like a one-way traffic by continuously talking without waiting to know whether anybody is listening or not and keeps talking even if nobody is within. This is why complex details in agriculture cannot be explain in radio programmes. However, radio is widely and cheaply used in agricultural technology and information dissemination to a large number of people scattered all over the country.

Radio is the most potent mass communication medium with its monumental success and potentials in educational projects in several developing countries of the world such as Mexico, Thailand, Philipines, Kenya, Gabon, Nigeria and other nations. In Nigeria for instance, over twenty radio stations have been added to the existing ones since the year 2000 when deregulation of the broadcast media was fully implemented (Omotayo, 2005). Access to radio is extensive compared to any other ICT with four (4) out of every ten (10) persons living in the rural areas (Oryokot, 2003). Radio transcends illiteracy barrier, geographical barriers, distances and time. Its broadcast can be picked instantly by the listener regardless of bad roads and barriers. It is because of the versatility of radio in communication to the grassroots level that made most governments of many developing countries to give radio the highest priority as an effective means of reaching the people even in the remote areas. Radio is used in public enlightenment programmes such as health, education, politics, agriculture, public awareness campaigns and other community development programmes. Some of the most successful public campaigns in Nigeria through the use of radio were: the change over from left hand drive to right hand drive, the change from British units of measurement to the metric system etc.

Radio in the dissemination of farm innovations

In agricultural extension work, radio is one of the most important and most effective sources of disseminating agricultural innovations in developing countries. In Nigeria, radio is next to extension agents in the transfer of agricultural technologies or research results to farmers. Some research evaluation studies determine the effectiveness of extension communication medium in disseminating information of improved farm practices to farmers in Nigeria showed that radio remains the major source of communication (NAERLS, 2010). Radio brings about widespread awareness and sustains the interest of the farmers. In Nigeria, radio programmes cover farming activities such as irrigation systems, production, processing and marketing of agricultural produce.

Television

Television, just like some other communication medium, passes both moral and immoral messages. The critical factor therefore, is how its potentials can be harnessed. Its unique characteristic of sight, sound, motion and consequent demonstrative power is a living testimony of its capacity to sensitize, convince and mobilize its audience socially, morally, psychologically, emotionally and otherwise. The attention given to television at every point of use can be understood in the direction of its attraction to all categories of audience and the reason for its abuse. Television has been regarded as a very important and powerful media for acquisition of knowledge in all spheres of life. Television has the power of sound and vision (audio visual) and these attributes make it useful in extension work, demonstrating technologies and video training (Omotayo, 2005). Documentaries on television are usually accompanied with pictures which are synchronized alongside with narration or explanation for the purpose of stimulating the audience's understanding of the message (Adebowale, 2009). Therefore, on this background, television can be relied upon as an effective communication channel through which agricultural technologies could be transferred to the farmers both at the rural and urban areas.

Newspapers

Although, most Nigeria's newspapers are biased in favour of the minority elites and literate people, this is because the language of the newspaper is of high standard and too advanced for easy comprehension of the rural farmers. But, if properly designed, formatted and packaged for rural developmental purposes, considering the educational level of the rural farmers, newspaper would be one of the most important medium to communicate improved agricultural technologies to farmers. This can be achieved by ensuring that all Nigeria's newspapers are translated into various local languages of the rural people for easy understanding. This can further be improved by specially packaging all agricultural related information into what can be called community newspaper. These community newspapers would be directed and master minded only in the rural areas and by the rural people. However, in whatever form it is made, newspaper can be used to perform advocacy role of sensitizing agricultural extension policy makers for development- friendly initiatives and decision making. Above all, it can be relied upon as an important medium of communicating agricultural ideas and improved farm practices to the rural farmers.

Information and Communication Technologies (ICTs)

There is a growing interest and excitement for the role and potential of ICTs in extension agents' development. ICTs can provide farmers' access to agricultural extension agents and agricultural information for best practices. Most ICTs in agricultural extension services are centered on mobile technologies, principally through subject matter specialists. The idea is that, because farmers will have control over the mobiles and how they choose to use ICT extension, they will be reaching out for the services they want through farmer-line. Therefore, for the achievement of any meaningful impact of agricultural development through ICT application, Michiels and Van

Crowther (2001) emphasized that appropriate application of ICT into farmers' learning programmes is imperative. They also included that the communication technologies should be channeled towards realizing their needs at hand. Where such is enhanced, the ICT would be said to contribute to reducing the digital division between rural and urban farmers at individual, group and community levels. Key improvements stem from information. Therefore, ICTs can be used for enhancing agricultural production at different value chain levels such as increase in efficiency, productivity and sustainability of small scale farms. Among others, communities and farmer organizations can be helped through the use of ICTs to strengthen their capacities and make them more responsible to their constituencies when negotiating for inputs, prices, land claims, rights and infrastructural projects. ICTs widen accessibility, in that; it enables the rural communities to interact with other stakeholders, thus reducing social isolation. Given the importance of ICT in facilitating effective and timely information delivery, it has witnessed wide application in nearly all human endeavours (Adebowale, 2009). However, in Nigeria, extension has not brought a clear picture of effective and timely information delivery services to rural farmers. If information is not timely or effectively disseminated, adoption of technology may be hampered. This may also retard farm outputs and worsen food insecurity.

Mobile Phone in Agriculture

Mobile phone plays a vital role through information supply and communication in agriculture especially in the area of marketing. The service of GSM has proven highly successful as it improves the relationship between farmers and the buyers of their produce (Arokoyo, 2005). In particular, it strengthens the farmers' role in the negotiation process, and the buyers' ability to spot the best available market opportunities. The mobile telephone has witness a meteoric rise in Africa over the past few years. It has shown the highest growth rates anywhere in the world (Farell, 2003). It is the latest development in the communication industry in which the global system of mobile telecommunication (GSM) has successfully replaced the table or desk phone especially in the third world countries. Today in Nigeria, most rural farm families and communities have access to GSM.

CONCLUSION AND RECOMMENDATIONS

It has become imperative for extension to exploit the opportunities offered by this digital age. For timely and adequate dissemination of improved agricultural technologies, effective and reliable communication techniques are required. For extension workers to however make effective use of any communication technique in extension message delivery, they certainly need to have not just a good understanding of the communication process, but also the operating procedures. It is also incumbent on them to know what role each can play in extension programmes in order to be effective and successful in extension message delivery. Hence, the following recommendations should be considered:

i. Based on the findings of the study, it is recommended that the use of radio and cell phones contacts should be given more priority since they are the most widely used by farmers.
ii. Extension agents should regularly organize workshops or seminars to sensitize farmers in the use of communication techniques.
iii. ICTs should be integrated into agricultural policies and supportive programmes
iv. Local language based-information should be mostly used while using any of the communication medium in disseminating agricultural technologies to rural farmers.
v. Adequate training and re-training of extension workers on information communication media should be accorded high priority.

ABSTRACT
This study was conducted to examine the effect of declining attention to research and development on employment decisions of the academic staff of National Root Crops Research Institute Umudike. This became necessary as a result of observed low morale of the research staff of the institute which has led to some of the scientist switching their service o the universities. Data used was generated from record of researchers who transferred their services to the universities. The study employed descriptive statistics to describe the data collected. The result shows that 12.8% of scientist who holds PhD has already transferred their services to universities. Most of the researchers (50%) are within the age range of 51-60yrs and the major attractions are enhanced salary packages and brighter prospects for career progression among others. Among the cause of this exodus is poor funding of research and a very narrow top in research career progression. It was therefore concluded that the exodus is most likely to continue giving the prevailing circumstance unless the government will quickly react to this by ensuring the new agricultural policy sufficiently recognize the research sector.

INTRODUCTION
Job satisfaction is the level of the contentment a person feels regarding his or her job. This feeling is mainly based on an individual's perception of satisfaction. Job satisfaction can be influenced by a person's ability to complete required task; the level of communication in an origination, and the way management treats employees. Schermerhorn (1993) defines job satisfaction as an affective or emotional response towards variousaspects of an employee's work. The author emphasizes that likely causes of job satisfaction includeStatus, supervision, co-worker relationships, job content, remuneration and extrinsic rewards, promotionand physical conditions of the work environment, as well as organizational structure.Similarly, some reports have shown that job satisfaction refers to an individual's feeling or stateof mind giving heed to the nature of the individual's work. The author further explains that jobsatisfaction can be influenced by a diversity of job dimensions, inter alia, the quality of the employee'srelationship with their supervisor, the status of the physical environment in which the individual works, degree of fulfillment in work.
Some of the theories relating to job satisfaction may further illustrate the complexity of issue and help the understanding of how management may positively affect job performance through job satisfaction. Under this theory there are the big five personality attributes introduced by Goldberg (1990). These five traits include Extraversion, Neuroticism (or emotionality stability),agreeableness, conscientiousness and openness. Research has shown a strong correlation between these five factors and job satisfaction. For determining job satisfaction and job performance, Core self-evaluation theory has four facets included self esteem generalized self efficacy, locus of control and emotional stability (low neuroticism). This theory again links personality attributes and practices with motivation, job satisfaction and job performance. All three dispositional theories recognize the connection between job satisfaction, motivation and performance but focus on the attributes of the person entirely. Thus, the dispositional theory suggests that some people will be satisfied, motivated and high performing at work regardless of how poorly managed while other people will not be happy no matter how greatan organization. However, the data indicates that despite the correlation, personality can only explain less than half of the level of job satisfaction. This tells us that there are likely some elements within organizational control which can affect employee job satisfaction.
Another theory is the Hygiene Theory by Fredrick Hertzberg (1974) on job satisfaction and employee motivation which can tie the principles of the disposition theory together with the influence management has on job satisfaction, performance and motivation.) There are two factors relating to motivation in the workplace; satisfaction and Satisfiers relate to the content of the work such as "achievement, recognition for achievement, interesting work, increased work, advancement. Dissatisfiers are related to how employees are treated and include such items as "company policy and administration practices supervision,interpersonal relationships, working conditions, salary, status, and security Herzberg (1974).
If we combine this theory with the disposition theory we can more clearly see a model for job satisfaction in which some satisfaction or dissatisfaction is inherent in the nature of each individual worker, some satisfaction comes

from the content of the work and some dissatisfaction comes from the way they are treated. Managers have some influence on the level of satisfaction by fostering achievement, recognizing achievement, making the work interesting, giving employee's responsibility and providing for opportunities for growth and advancement. More importantly, managers concrete dissatisfaction with inequitable pay, poor organisational personal policies, working conditions or job security. The importance of each of these job dissatisfiers relates to the frequency it occurs and the intensity of the shortfall. In other words a policy that treats employees poorly every day is a bigger dissatisfier than a policy which treats them poorly only once per month. Moreover, the severity of the dissatisfier affects the importance of that dissatisfier. Therefore, if pay is at such a level that people cannot meet their basic needs, then pay would overshadow all other dissatisfiers and eclipse job satisfiers.

The most important demographic variable that receives huge attention in job satisfaction research is sex. A number of empirical studies on job satisfaction have suggested that female workers have lowerlevel of job satisfaction than their male counterparts because male officials dominate most of the publicorganizations.Another common demographic variable studied is educational level. Most of the researches on therelationship between education level and job satisfaction yield consistent findings. Especially Griffin,Dunbar & McGill (1978) found that workers with higher educational level would tend to be moresatisfied with their job than workers with lower educational level. The third commonly identifiedvariable in the research on demographic characteristics is age. Worker's age has been found to have a negative impact on worker's job satisfaction (Buzawa, 1984). This means that younger workers are more satisfied with their jobs than their senior counterparts.The fourth and final variable is the job assignment of a public official. Public officials have different interests, and these are sometimes satisfied on the job. However, the more public officials find that they can fulfill their interests while on the job, the more satisfied they will be with those jobs. For example, a recent study result showed that university graduates were more satisfied with their jobswhen these were consistent with their university majors than when these fell outside their fields of interest (Vandenberg & Lance, 1992).

Researchers and almost all the members of staff of the National Root Crops Research Institute had or enjoyed some level of job satisfaction. Research work were properly if not hundred percent funded. The Institute became a place where everyone wants to associate with. The environment was inviting and conducive for work. Staff welfare was adequately taken care of; Casual staff was not left out, some of the casual workers were converted to Permanent staff. Staff members in lower cadre encouraged to further their education. Promotion comes as at when due with the benefit accrued to it.

However, recent developments show that National Root Crops Research Institute Umudike became a pitiable Institute because both researchers and non-researchers started experiencing downward trends in welfare issues. The glory of the previous year's seemed to be departing. Staff salaries were slashed down, promotions comes as at when due but without benefits and no arrears in view, Causal worker were laid-off, the environment that used to be very neat has become a dumping ground. Poor funding of research work and necessary issues that enhances the growth of staff members became a common issue. This paper therefore examined the effect of declining attention to research and development on employment decisions of the academic staff of National Root Crops Research Institute Umudike.

METHODOLOGY

The study was carried out at National Root Crops Research Institute Umudike, using records of recent exodus of researchers to universities. The analysis was based on the socio economic characteristics of age, rank and remunerations of PhD holders that left the Research Institute for Universities. Data collected were analyzed with descriptive statistics.

RESULTS AND DISCUSSION

Influence of Exodus on numerical strength of PhD Holders

The result shows that 12.8% of the PhD holders in National Root Crops Research Institute left for the Universities. This is represented graphically in figure 1. This implies that these scientists were apparently no longer satisfied with the job they were doing in the institute. For these ones, switching to university is a greener pasture. This shows that one of the dissatisfiers described by Herzberg (1974) came into play. For this to happen, they must have seen either better conditions of service or brighter prospects in the universities. The implication of this is that of looming brain drain in research Institutes. Some of these scientists attribute this to the current poor remunerations and the inability to assess research funds.

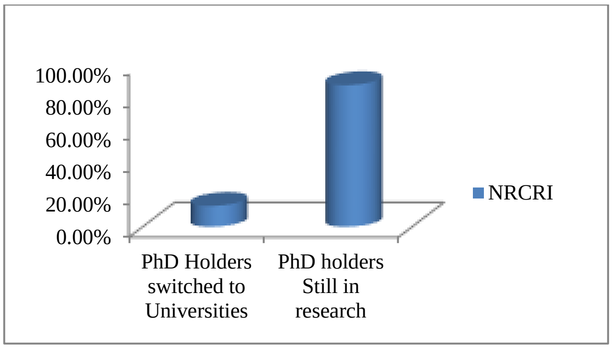

Figure 1: distribution of PhD holders switch to Universities

Exodus based on Age

The age distribution of the scientists that switched their services to universities is shown in figure 2. From the result, most of the scientists (50%) are within the age range of 51-60yrs. This means that the affected scientists are almost at the peak of their careers, which goes to suggest that they are experienced scientists. Altogether, over 80% of these scientists are above 40yrs. This means that the most active researchers are involved in this exodus, implying that the institute will require over 6yrs to replace them, and this will lead to heavy financial involvements in the midst of dwindling resources.

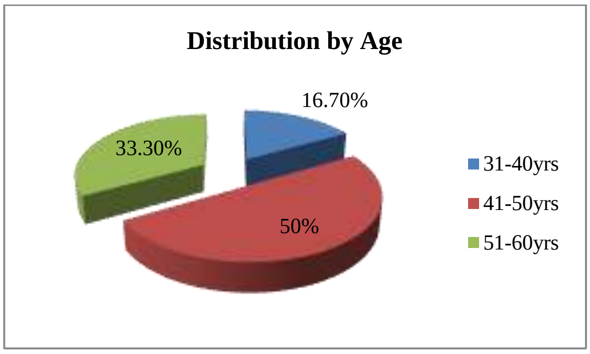

Figure 2: Distribution of scientists by Age

Exodus based on rank, position offered and remuneration

The entire affected scientists belong to the senior cadre. The result presented in table 1 shows that those involved were senior research officers, principal research officers and assistant directors. The table also shows the ranks offered to them in the university. It shows that they were offered enhanced positions with better salary packages. This could be the motivation for their decisions. Of course, labour is dynamic and skewed toward area of higher attraction in terms of remunerations.

Cause of exodus

Among the reasons for the exodus, enhanced salaries and better prospects for career progression appeared to be more prominent. This is shown in table 2. Also, 75% of the affected staff are of the opinion that the Research and development institutions in Nigeria are poorly managed.

CONCLUSION

Job satisfaction has been subject of great interest among behavioural scientists, Human research and management researchers over period of time. Number of organizational, individual, and psychological factors has been identified to enhance satisfaction level. However, these factors have been revisited time and again and job satisfaction determinants information is still inconclusive. This has led to develop a conceptual model and test it in developing country like Nigeria to assess the magnitude of different factors that might enhance job satisfaction of employee in Research Institute work setting. The current switch from research institutions to universities has serious developmental implications especially now that the Nigerian economy is begging for diversification. Technologies that will turn around the economy for good are developed in the research institutes. When researchers move to universities, their research activities and interest will also move from applied research to basic research.

Table 1: Distribution of scientists based on position offered and remunerations

Rank in NRCRI	Salary Ranges	Rank offered in University	Salary Ranges	Freq	%
Senior Research officers	₦1,460,163 - ₦2,120,427	Lecturer 1	₦1,649,508- ₦1,826,664	2	33.33
Principal Research officers	₦1,833,967 - ₦2,588,927	Senior Lecturer	₦3,091,500- ₦3,658,380	2	33.33
Assistant directors	₦3,363,134 - ₦4,452,271	Senior Lecturer /Associate Prof.	₦3,768,216- ₦4,417,068	2	33.33
Total				6	100

Table 2: Perceived causes of transfer of service to universities by researcher in NRCRI Umudike

Reason for transfer	Percentage
Better remunerations	100
Career progression/opportunities	100
Pride	10
Easy job performance	45
Poor management of R&D	75

ABSTRACT

The study was carried out in Umuahia North LGA of Abia State to examine the effect of gender differentiated education on the manpower need for the teaching of vocational education subjects. All the public (government owned secondary schools) in the study area were involved in the study. There were 17 public secondary schools in the LGA. Three vocational subjects, Agricultural Science, Fisheries and Animal Husbandry were studied in all the secondary schools in the LGA. There were a total of 517 teachers in the LGA of which 72 were vocational subject teachers. Secondary data was used to obtain the information needed for the study. The data was subjected to descriptive statistical analysis and chi-square. Result of the study showed that most of the vocational Agricultural teachers were females. Also males and females were not equally distributed in the different vocational subjects. As more males (54.05 per cent) were involved in the teaching of agricultural science, there were more females (90.48 percent and 64.29 per cent) in Fisheries and Animal Husbandry respectively. Chi-square analysis was used to determine the level of difference in male and female participation in the teaching of vocational subjects showed that there was no significant difference between the number of male and female vocational subject teachers as the table X^2 (7.82) was more than the calculated X^2 (4.5) at 0.05% confidence level and 3 degree of freedom.

INTRODUTION

Formal education which takes place within the enclosure of a school started in Nigeria during the colonial period especially through the missionaries. The major aim of education as purveyed by the colonial administrators and missionaries was to produce teachers for the missions as well as low level manpower especially interpreters for the administrators. To this end the 3 'R' subjects (reading, arithmetic and writing) occupied major parts of the school syllabus. Schools commonly known as the grammar schools were established to prepare students for the General Certificate of Education at the ordinary level. The grammar schools were fashioned in such a way that they did not accommodate subjects that will expose the learners to technical skills. Most of the youths who passed through the secondary grammar schools were grossly deficient. The educational dispensation which the colonial masters set up was criticized on several grounds. The neglect of vocational education in that system was a major criticism. At the political independence of Nigeria, there was a realization that the type of education inherited from our colonial masters needed a critical re-examination of the worth: of content, objectives, relevance, methods, administration, evaluation, and so forth. This according to Ezeobata (2007) brought a national aspiration that gave birth to a new educational system of education commonly referred to as the '6-3-3-4' system of education. Among other innovations, the system provided for pre-vocational and vocational curricular offerings at the junior and senior secondary schools respectively. For the first time in the history of education in Nigeria, vocational and technical education subjects were, as a matter of national policy, to be offered side-by-side, and hopefully, enjoy parity in esteem with the more academic courses hitherto run by the secondary grammar schools under the old colonial-based system of education (Elebe, 2011). The vocational education curriculum was aimed at helping the secondary school leavers to imbibe technical skills that would prepare them for non academic and civil work after school.

Vocational education is that aspect of education that gives its recipients an opportunity to acquire practical skills as well as some basic scientific knowledge. Oni (2007) defined vocational education as that type of education, which fits the individual for gainful employment in recognized occupation as semi-skilled workers or technicians or sub-professionals. Vocational education could be regarded as that aspect of education, which provides the recipients with the basic knowledge and practical skills needed for entry into the world of work as employees or as self-employed (Oni 2007). Vocational education therefore nurtures skills that are necessary for agricultural, industrial, commercial and economic development and thus builds a self-reliant nation. According to her two of the aims of vocational education as stated in the Nigerian National Policy on Education (1981) are to give training and impart the necessary skills leading to the production of craftsmen, technicians and other skilled personnel who will be enterprising and self-reliant; and to enable Nigerian young men and women to have an intelligent understanding of the increasing complexity of technology.

The importance of teachers in the achievement of the objectives of vocational education in Nigeria cannot be over stressed. This is because teachers interpret the curriculum content and transfer the needed technical knowledge and skill to the students. Specifically, teachers have been referred to by Oyedeji (1998) as an agent of innovation. The development of the teacher as a necessary manpower for the development of vocational education is very vital. Laboratories, equipment, instructional materials, infrastructural facilities, studio and even the workshop may be available in abundance but without the trained manpower that will man these facilities, learning cannot take place. According to the National Policy on Education (FRN, 2004), no education system may rise above the quality of its teachers. Therefore, manpower development in science education is paramount to sustainable development. Manpower development according to Ogbaunya and Usoro (2009) is a process of improvement that embraces all those activities that are geared towards the growth and improvement of skills, knowledge and attitude of personnel. A teacher who is not currently in tune with modern trend is a danger to the system. Staff development in terms of continuing education appears rather very poor, haphazard, politicized and lack continuity. Dryaklor (1994) asserted that teachers need to be retrained two to six times in lifetime to keep abreast with changes in his profession. The initial attempt by the Federal Government of Nigeria to retrain teachers for the implementation of the vocational education curriculum was a failure because such teachers were swallowed by the brain drain syndrome as they never came back and even those that came back settled on for other jobs that are taught to be greener pastures rather than the teaching profession.

Aside the problem of shortage of teachers for the teaching of vocational education subjects, there also seem to be a level of gender stereotype in the choice of specific vocational subjects. Despite the uncountable contributions of vocational education to national development, social malaise of gender dichotomy is most often discovered in the participation of people in the teaching and learning of the vocational subjects. This has tremendous effects on the quality and quantity of teachers teaching the vocational science subjects in Nigerian Secondary Schools.

In developing countries of Africa, most crucial to any education that involves manual labour is a favourable attitude. Factors such as cultural tradition, early childhood socialization, parental expectations, the actual handwork involved in manual labour, the reward that go with it, the behaviour and attitude of teachers, and as well influence the attitude the children towards acquiring the vocational subjects. This paper analysed the influence of gender differentiated education on the choice of any vocational education subjects as a teaching subject.

METHOOLOGY

The study was carried out in Umuahia North Local Government Area of Abia State. Survey design was used for the study. Abia State is in the South East geopolitical zone of Nigeria. All the public secondary schools in the Local Government Area were involved in the study. There were seventeen (17) of such public secondary schools in the study area. Three vocational subjects that were commonly studied in all the schools in the LGA were Agricultural Science, fishery and animal husbandry. There were five hundred and seventeen (517) teachers in the public secondary schools in LGA of which seventy two (72) of them were vocational subject teachers. Secondary data was used for the study. The secondary data which included annual returns from schools, school nominal rolls and other books were collected from the statistical unit of the Abia State Secondary Education Management Board (SEMB). Data collected from the study was analysed using simple descriptive statistical tools and the chi-square.

RESULTS AND DISCUSSION

Table 1 shows the distribution of the vocational education teachers in Umuahia North LGA according to their gender. According to the table, 62.50 percent of the teachers of vocational education in the study area were females while 37.50 percent were males. This gives a ratio of approximately two female teachers to one male teacher (2:1). Analyses of the gender of vocational education teachers in Umuahia North LGA show that there were more female teachers teaching vocational education than male teachers in the Local Government Area. The result is indication that both gender (males and females) are involved in the teaching of the vocational subjects. The more number of females than males participating in the teaching of vocational subjects is a proof that there is a twist of events from the hitherto held assumptions that the males are more involved in the vocational and technical education subjects than the females (Jones and Dindia, 2004). The more number of female teachers that are involved in the teaching of the vocational subjects however may be an indication that even in subject areas as important as the vocational sciences the endemic problem of male exodus from the teaching profession still persist (Adeyemo, 2010).

Table 2 is a distribution of the teachers according to their gender and area of specialisation. The table shows that 51.39 percent of the teachers of vocational subjects in the study area were in Agricultural Science. However 54.05 percent of them were males while 45.95 percent were females. Those that had Fisheries as their area of specialisation and teaching subject accounted for 29.17 percent of the population of which majority (90.88

percent) were females thus male teachers in the subject area accounted for only 9.52 per cent. Also the table shows that of all the teachers of vocational education, 19.44 percent of them were teaching Animal Husbandry of which 64.29 per cent of them were females while 35.71 per cent were males. The result showed a level skewed distribution of the manpower for the teaching of the vocational, as more of the men opt for and teach agricultural science which is often taught to be more tedious, laborious and tasking .

That more men than women opting for agricultural science as a teaching subject is suggestive that the bias and phobia which women have against the study of agriculture and the practical work associated with it still lasts. The result further agrees with the assertion that ordinarily female students tend to have preference for the Art subjects and such vocational areas as Home Economics while the males are found in the Sciences and the Science related subjects such as Agricultural science, Biology, Chemistry, Physics, Mathematics and the Engineering courses while the females are found in the Languages, Humanities and the Arts (Ikeoji, Agwubike and Disi, 2007).

Table 3 is a Chi-square analysis to determine if there is a statistical difference in the number of male and female teachers of vocational education subjects in the study area. The result shows that at 5 percent confidence level and degree of freedom 0.05, the calculated Chi- Square (4.5) is less than the table Chi- Square (7.82). The null hypothesis that there is no significant difference in the number of male and female teachers of vocational education is accepted while the alternative hypothesis is rejected.

Although numerically there were more female teachers than male teachers of vocational education subjects in the secondary schools in Umuahia North LGA of Abia State, but the differences in the number was not significant as to have undue impact on teaching and learning of the vocational subjects in the study area. The result however shows a shift from the status quo where there was the dominance of males over females in the field of science and vocational technical subjects (Hays and Farhar 2002). The result perhaps is an indication that the gender gap that exist between the males and females in the study of vocational technical subjects is being closed to the extent that at least more women than men are getting involved in the teaching of the vocational sciences.

CONCLUSION

The role of vocational education in the entrepreneurial, social and overall economic development as well technological advancement of Nigerian and other developing countries of Africa cannot be over emphasized. Thus vocational technical education should to a great extent be regarded as the hob of technological and industrial development of any nation. No matter the state of the art equipment imported for the teaching of the vocational education subjects, without well grounded teachers, the expected result will not be feasible. In Nigeria nay Africa however the choice of specific vocational subjects as teaching subjects of specialisation is stereotyped along gender lines. This ultimately will affect the quality of output of schools that offer the vocational courses as subjects of study in the secondary schools. Concerted efforts should be made to address the skewed participation of males and females in the teaching of these important subjects as indirectly some vocational areas have been labelled as women's area while others should be left for the men. To heave this burden the government and other bodies involved in the education of the child should articulate and implement programmes that will disabused people's mind of the age long assumption that certain academic responsibilities are for a certain gender while others should be left for the other.

ABSTRACT
The assessment of information services in addressing challenges facing poor resource farmer in the Northern Guinea Savanna of Nigeria was conducted in the adopted villages of NAERLS, Ahmadu Bellow University, Zaria. Survey method was adopted for the study using stratified random sampling technique for selecting the respondents. Structure questionnaire was used in collecting data which was administered to small holder farmers in the Sakadadi (150 respondents) and Tudun-Iya (150 respondents) of NAERLS adopted villages respectively. Data collected were analyzed using descriptive statistical tool. Findings reveal that the extension services provided had enhanced welfare (30.0 %) and economic growth (25.5 %) of the small holder farmers compared to their welfare before the villages were adopted by NAERLS. Therefore, the study recommended the employment of profession to assist extension agents in information delivery and use of modern information machineries to enhance access to information in the study area.
Keywords: Information service, poor resource farmers, challenges, welfare, economic growth,

INTRODUCTION
Information service is an important and powerful commodity in any human community especially farming community. Information services are the key ingredient to accomplish the potentials of people at the grassroots, re-align their thought processes and mobilize them for their welfare and economic growth, environmental activities, which will in turn increase the standard of small holder farmers. According to Opara (2014), certain characteristics of information services make it a critical development resource. These are its ability to act as a dynamic force that drives the recipients to action; extend the knowledge base of its recipient; increase and broaden the perceptions of its users or recipients; enhance their competencies through the knowledge and skills they gain; improve their self-esteem; and also its ability to be regenerative and versatile. Evidence has shown that small holder farmers need unhindered access to information services to make informed decision-making especially agricultural production (Issa and Salman, 2012).
In addition to information services on agricultural production, small holder farmers require accurate and reliable information services on health, economic and social issues. Unfortunately, rural people who are in majority lacks access to information services necessary for their improved welfare and increased productivity. According to Egbe (2014) the main features of small holder farmers are depression, degradation and deprivation due to low and unreliable information exchange which hinders their agricultural productivity. As a result, any rural villages are immersed in poverty and food insecurity. Therefore, information service is necessary to lift them out of poverty and improve agricultural production. This implies that small holder farmers' welfare and economic growth is dependent on the availability and access to information for effective decision making. This study sought to assess whether information services have improve small holder farmers welfare and economic growth through agricultural production in NAERLS adopted villages.

MATERIALS AND METHODS
The study was conducted at two Adopted villages (Sakadadi and TudunIya) of the National Agricultural Extension and Research Liaison Services (NAERLS), Zaria, Nigeria. The sites were located at Sakadadi in Sabon Gari Local Government Area of Kaduna State and TudunIya in Futua Local Government Areas of Katsina State. They were located within longitudes (11º 23' N) and latitudes (7º 22' E) for TudunIya adopted village and longitudes (11º 11' N) and latitudes (7º 43' E) for Sakadadi adopted village. The study areas have a mean temperature of 21.05ºC (minimum), 33.47ºC (maximum), and relative humidity of 55.23 %. The annual rainfall was 1100 mm which distributed between May to October and a mono-modal rainfall pattern. The main soil sub-group is TypicHaplustalf which was derived from Pre-Cambrian Crystalline basement complex rocks with some quanternary aeolian deposits (Malgwi *et al*., 2009). The soils of the study areas were generally slightly or mildly acidic, less leached soils and low to medium in fertility (Odunze, 2006). The vegetation in the study areas is dominated by few of fire-tended and fire-tolerant trees with an understory of shrubs and more of grasses. Farming constitutes the major socioeconomic activity of the study locations.

This work employed the use survey method. In order to achieve the objectives of this study, three hundred and twenty research questions were formulated. Out of the three hundred and twenty research questions formulated; one hundred and sixty each were administered to the two communities. The instrument used for collecting data was questionnaire which was administered to three hundred respondents that were purposively selected for this study because of scatter nature of the small holder farmers' settlement and difference in occupation. The data collected was analyzed based on four (4) point rating scale using frequency and percentage. The options were; Strongly Agree (SA), Agree (A), Disagree (D), Strongly Disagree (SD)

RESULTS AND DISCUSSION

Percentage of information services available

The result on information services available to the NAERLS adopted villages dwellers is presented in Table 1. The result shows that orientation/instruction services is the major information available to small-holder farmers (41% Sakadadi and 44 % Tudun-Iya). Others are current awareness service (33 % for both adopted villages) while referral services is the least service. This result implies that orientation/instruction services and film show enhance the welfare economic growth of the rural dwellers in both adopted villages than other information services because they are presented in the format that farmers appreciates. This also suggested that the main purpose of information services in any rural settlement is to provide relevant and pertinent information desired to improve rural welfare and economic growth. This result is in line with the view of Igwe and Onah (2013), who opined that dissemination of useful agricultural information to farmers in developing countries has not been effective due in part to weak information services and presentation in a way that farmers will understand them.

Use of Information Services for Poor Resource farmer

Result of Table 2 shows that majority of the respondents (34% and 36%) makes effective use of information service (orientation/instruction services) for providing basic techniques to farmers on how to improve in their farming system, also enhance their knowledge in agronomic practices for arable crops production and welfare in both locations. Whereas, film show and referral services as a means of providing information services to the farmers least contributes to the welfare and economic growth of the rural dwellers especially Tudun-Iya adopted village. By implication, this shows that the films show and referral service were not satisfactory due to inadequate facilitates and service provision. Harande (2009) observes that "the rural populace suffers from acute low productivity, social and economic retrogression due mainly to ignorance which is also a direct consequence of either inadequate or total lack of information provision to them". Information services that will greatly enhance their productivity, transform their community into a lively and enlightened one, and empower their economic base, may not effective and relevant, if the information services are not fashioned towards their set objectives.

Challenges in Information Services Delivery for poor resource farmers

Table 3 shows the challenges in information service delivery for improving rural welfare and economic growth of the adopted villages. The results indicated that majority of the respondents agreed that there is no information center and inadequate facilities for information services delivery in both villages. Whereas, the data also shows that 30 % of the respondents disagreed that the information provider find it difficult in reaching out to the farmers because of poor road but from the rating it shows a kind of laxity on the part of information provider. Similar, observation was found in both locations in terms of difficulty in gathering the rural dwellers in a place for information services delivering. The result revealed that the majority of the respondents agreed that the challenges militate against information services delivery due to illiteracy and inadequate facilities. Nchuchucwe and Adejuwon, (2012) reported that the condition of rural dwellers in Nigeria and indeed in the developing countries is pathetic; traces of abject poverty and discomfort can be seen conspicuously. These are evidence of poor information service delivery due to some challenges like acute shortage or absence of social amenities and essential commodities that will make the life of rural dwellers bearable. This could explain why rural dwellers adopt "rural-urban drift" as an alternative and solution to this terrible condition.

CONCLUSION

Effective information service delivery and coordination as well as adequate infrastructures are the essential ingredient for improving the agricultural production of the poor resource farmers. Information service in Nigeria's rural communities must be recognized and empowered. The paper concludes that information service enhanced the welfare and economic growth of the poor resource farmers in the NAERLS adopted villages. On the strength of the findings, the study recommended that information professional should be employ to assist the extension workers in information delivery in the rural areas because they are capable of identifying the types of information that would be good to rural dwellers. In addition, there should be consistent training using modern information technology and effective implementation of information service policy.

ABSTRACT
The study investigated determinants of Information Communication Technologies (ICTs) among rural farm families in south east agro ecological zone, Nigeria. It examined the socio economic characteristics of the respondents, analyzed their access to ICTs use and its determinants. Multi stage sampling technique was used in selecting a total of 240 respondents. Data were collected through interview schedule and analyzed with inferential statistics. Results indicated that the ICTs accessible in the study area were GSM phones (M=2.81) and Radio (M=2.64). in addition, result further revealed that the gender, age, education, income, extension contact, affordability farming experience and household size were the major determinants of the use of ICTs among respondents in the study area. Therefore, the study recommends that ICTs should be made accessible to them to source agricultural information easily. When this is done, it will enhance their productivity and arrest food insecurity in the society.
Keywords: Rural households, ICTs and farming families.

INTRODUCTION
Agricultural growth is essential for fostering economic development and feeding growing populations in less developed countries like Nigeria. The increasing prospect of agriculture in the face of increasing population and economic situation have continue to encourage interest in family farming as a livelihood option among many Nigerians. FAO (2014) defined family farming as a means of organizing, agricultural forestry, fisheries, pastoral, aquaculture production which is managed and operated by family and relied on family labour including men's and women's. Unfortunately, most family farming does not maximize the benefit of their investment due to lack of or poor access to information on the farming methods, quantity and quality of produce traded, commodity and input prices and credit sources which results in opportunistic behaviour by traders, input dealers etc. In the absence of infrastructure, family farming face problem of adverse selection that limit the performance of agricultural commodity and input markets.

In south east agricultural zone, family farming constitutes of the majority of farming community. Most of them produces small marketable surplus and are geographically dispersed. Market access is one of the most important factors influencing family farming in Nigeria. Access to new and better paying markets for agricultural products is vital in enhancing and diversifying the livelihood of subsistence farmers. In the absence of information, small holder producers face adverse selection that limit performance of agricultural commodity and input markets and in turn the participation of subsistence farmers in these market. Information and Communication Technology offer the ability to increase the amount of information provided to all participants in the agricultural sector and decrease the cost of disseminating the information (Kurtenbach and Thompson 2000). ICT in the agricultural sector facilitates knowledge sharing within and among a variety of agricultural networks including researchers, exporters, extension services, traders and farmers. The use of ICT can progressively reduce the costs of managing information, enabling individuals and organizations to undertake information related tasks much more efficiently and to introduce innovations in products, process and organizational structure in agricultural sector in Nigeria. However, it reveals a certain number of disparities among subsistence farmers according to their socio economic situations, gender and other factors associated with ICT use in agriculture will enable the development of strategies to promote ICT use and increase the effectiveness and efficiency of information use in agricultural sector (Yekinni and Olaniyi 2007). This justified the objectives of this paper which consists of investigating the determinants of ICT use by subsistence farmers in south east agricultural zone, Nigeria.

METHODOLOGY
The study area was south east agro ecological zone of Nigeria. The south east zone is located within the longitude $5^{0}25^{E}$ and $8^{0}51^{E}$ and latitude $4^{0}20^{1}$N and $7^{0}25^{1}$N. It is bounded in the west by the river Niger, in the south by Atlantic Ocean and in the north by Kogi and Benue states. The zone occupies a lead area of about 109.524sqKm representing 11.86% of the total land of Nigeria (Ekong 2008). The region supports a wide variety of agricultural production such as crops, agroforestry and livestock.

Multi stage sampling procedure was used in selecting 2 states from the zone (Enugu and Ebonyi states). Ebonyi state is made up of three agricultural zones namely Ebonyi north, Ebonyi central and Ebonyi south while Enugu state is made up of Enugu, Agwu and Nsukka zone respectively. From each zone, 1 local government area was randomly selected, followed by a selection of 1 block and 2 cells from each LGAs and a random selection of 20 farm families from each cell in each state, thereby bringing the total number to 240 respondents. Data were collected with the use of interview schedule and later analyzed with descriptive and inferential statistics like multiple regression.

The explicit form is expressed below

$Y=f(X_1, X_2, X3, X4, X_5, X_6, X_7, X_8+e)$
Where
Y= dependent variable (use of ICT among farm families
And $X_1 - X_7$ (Independent variables)
X_1= Gender (male 1, female 0)
X_2= Age (measured in years as supplied by the respondents)
X_3= Income (measured in naira for major occupational respondents)
X_4= Educational level (number of years of formal education of respondents)
X_6= Extension contact (number of times visited by extension agent in a year)
X_7= Farming experience (measured in years)
X_8= Household size (number of people living with the respondents)
e= error term

RESULTS AND DISCUSSION

Table 1 shows that the coefficient of gender $(0.0018)^{xx}$ had a postive and significant relationship with ICT use at 5% level. This implies that gender has direct influence on the use of ICTs in family farming. The coefficient of age $(0.003)^{xxx}$ was positive and significantly related to use of ICTs at 1% level of probability. This implies that as farmers age increases the use of ICTs in farming increases. This result is not in consonance with the findings of (Ahmad, 2010; Adeniyi, 2007) who reported that younger age adopts innovations more rapidly than older ones. Coefficient of income $(0.000)^{xxx}$ was postive and significantly related to ICT use in family farming. This is in line with findings of Obey (1995) who reported that gross income the amount of influenced adoption ability of farmers to adopt new farm practices depends on their financial position. The implication is that the higher the income, the more likely the respondents may seek more information on better practices to improve their farming activities. The result also revealed that educational level has a positive coefficient of $(0.000)^{xxx}$ at 1% level of probability. This implies that farm families with well educated members are more likely to use ICTs in accessing agricultural information than those who are not. This finding is in line with (Akuchugu *et al* 2012) who found out that in Ghana the maximum level of education within the farm household was found to have positive relationship with the probability of adoption and significant at 1%. In contrast, Auta *et al* (1992) found out that there was no significant difference between literate and non-literate farmers in their adoption behaviour. Also extension contact $(0.000)^{xxx}$ was positive and significantly related to ICT use. This implies that the higher the number of extension contact to the farmers the higher the level of use of recommended practices. But if the extension contact is low, the use of ICT become necessary. Affordability of ICT $(0.000)^{xxx}$ was positive and significantly related to ICT use at 1% level of probability. This revealed that the lower the cost of ICT to farm families the higher the use in sourcing agricultural information. This research finding is in line with Ojo (2009) who found that a positive contribution of technology affordability to adoption of recommended cassava production practices. Farming experience $(0.002)^{xx}$ has a positive and significant relationship with ICT use in sourcing agricultural messages. Farm families with high farming experience adopt recommended practices more than the inexperience farmers do.

The coefficient of multiple determination, F-value shows proportion of the variation explained by the model which gave a value of 0.0885 as per the R-square adjusted value. This implies that there is an existing relationship between Y variable and other X variables, where 85 % of the variables observed was explained by the model, while the remaining 15 % was accounted by the error term. Therefore, the model is fit for study.

CONCLUSION

From the findings ICTs present farm families with opportunity to reach a wider audience therefore ICT intervention such as provision of an accessible rural pay phone can play a significant role in enhancing the ability of poor rural farm families to contribute to national agricultural production and post-harvest activities.

Hence, it is recommended that there should be more effort in order to bring ICT nearer to farm families, and also facilities to ease of use of ICT device and facilities.

DETERMINANTS OF FERTILIZER USE INTENSITY AMONG SELECTED ARABLE CROP FARMERS IN IKWUANO LOCAL GOVERNMENT AREA, ABIA STATE, NIGERIA

E. I. Offor, K. C. Igwe & U. C. Joseph

Department of Agricultural Economics, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria **offorevelyn53@gmail.com**

ABSTRACT

The study analyzed determinants of fertilizer use intensity among arable crop farmers in Ikwuano Local Government Area of Abia State, Nigeria. Primary data were obtained from 80 arable crop farmers randomly sampled from 8 villages in the study area. Descriptive statistics and multivariate linear regression analysis were used to analyze data collected. The result showed that the fertilizer use in the study area was moderately high due to enormous demand on the limited land in the study area. Age, gender, educational level, household size and price of fertilizer were the significant factors that influenced fertilizer use intensity among the arable crop farmers. The study recommends that government and policy makers should invest on increased knowledge and skill of farmers through avenues such as field days, extension agents contact with farmers or any other capacity building mechanism. Rural credit should be emphasized in order to mobilize savings and maximize the availability of credit to the farmer and to facilitate the distribution and uses of fertilizers, the agro-services centers should be opened in the rural areas. In addition, mechanism should be put in place to ensure that the subsidized fertilizer reaches the right target at the subsidized price. Fertilizer records at state and local government level over the years could be scrutinized to ensure and instill a sense of accountability and determine the true fertilizer situation at the levels.

INTRODUCTION

Soil, which is the top most part of the earth, is an essential resource for mankind particularly agricultural, whose activities are carried out intensively on soil. The level of crop yield depends largely on the fertility of a given soil. According to Oguwole *et al.*, (2002), the inability to incorporate soil improvement technique into farming practices degrade the soil. It does not only frustrate efforts at achieving higher productivity but also undermine the carrying capacity of the environment to sustain the welfare of humans. It is obvious that environmental sustainability and sustainable agriculture brings about wellbeing of the people, particularly the rural dwellers whose basic survival are hinged upon by environmental dynamics. The environment in its various conceptualization includes the social, physical, economic, political and policy environment (Adebayor, 2006). As a matter of fact, this environmental component has impact on the welfare of resource-poor rural farmers, consistent depletion of soil nutrients in several rural farming communities has prompted the unavoidable reliance on chemical fertilizers in order to sustain crop production. The use of chemical fertilizers have made significant contribution to increase production largely. Akpoko, (2004) noted that traditional bush fallow system as well as inaccessibility to other soil improvement techniques like organic manure, mulching, zero tillage, minimum tillage have been sustainable hence make the use of organic fertilizer popular. Although organic fertilizer has impacted greatly on crop yield and enjoys wide spread among farmers, inorganic fertilizer has become a major source of soil nutrient improvement for many farmers, but its high cost made it inaccessible to arable crop farmers. These has resulted to low level of production among framers. Halley (1992) had noted that many Nigerian soils have no sufficient qualities of nutrient necessary for high yield in crops. Therefore, fertilizers are the key to rapid improvement in agricultural production and productivity (Husain, 1987).

In recent times, there is an increased awareness of the use of chemical fertilizers in order to augment for the depleted soil nutrients and sustain soil fertility for crop yield. This has led government to increase budgetary commitment to fertilizer procurement. However, procurement of chemical (organic fertilizer) by government is just a subset of the fertilizer-rural farmer-livelihood matrix. Accessibility of rural farmers to the procured fertilizer is the most important issue. Okoji and Ayichi, (2000) opined that the major bottlenecks to fertilizer accessibility are inadequate physical infrastructure, absence of well-organized rural institutions to handle input-distribution, political interference, fraudulent practices by staff of ministry and local government directly involved in fertilizer distribution and delay in procurement due to cumbersome procedure and bureaucratic process in decision making. These have affected the availability and usage of chemical fertilizers. Hence the main objective of the study was to examine fertilizer use intensity among arable crop farmers in Ikwuano Local Government Area of Abia state, Nigeria, using the fertilizer use intensity (FUI) adopted from Maingwa *et al*. (2007) and Olayide *et al*. (2009), estimate the determinants of fertilizer use intensity.

METHODOLOGY

The study was conducted in Ikwuano LGA of Abia State, Nigeria. The main occupation of the people is farming. The major crops cultivated are cassava, melon, yam, maize, rice vegetables and cocoa which is an important cash crop. A simple random sampling technique was used to select 8 communities from the LGA. Thereafter 10 respondents each were selected randomly from the 8 communities to give a total of 80 arable crop farmers for the study. The arable crop farmers in the study area cultivate the following crops either solely or mixed cropping; cassava, maize, fluted pumpkin, okra, pepper, green, water leaf and yam. In specific terms, three objectives were realized. Objective 1 on the socio-economics was realized using percentages and tables. Objective 2 on the fertilizer use intensity was achieved using the fertilizer use intensity (FUI) adopted from Maiangwa (2007) and Olayide (2009) stated thus

$$FUI = \frac{\text{Quantity of fertility used by the farmer measured in Kg}}{\text{Area of land cultivated by the farmer measured in hectare}}$$

Objective 3 on the determinants of fertilizer used intensity was realized using multivariate linear regression analysis. The model is stated thus

$$FUI = B_1Age + B_2GEN + B_3EDU + B_4HHS + B_5LANS + B_6PRD + B_7OUT + B_8PANI + U_i$$

Where FUI = Fertilizer use intensity, X_iAGE = Age of farmers (in years), X_2GEN = Gender of a farmer (1 = male, 0= female), X_3EDU = level of education (years), X_4HHS = Household size of farmers, X_5LAN = Land size cultivated by farmers (in hectares), X_6PRD = Perceived price of fertilizer by farmers (1 = high price, 0 = low price), X_7OUT = Output of fertilizer (in Naira (₦)), X_8PANI = Poultry owner (1 = owned poultry enterprise, 0 = otherwise) and U = error term

RESULTS AND DISCUSSION

Socioeconomics characteristics of the fertilizer users in the study area

Table 1 shows that the average farmer in the study area had a mean age of 43years. This implies that they are of active age, which could be positively related to farming and the adoption of new technologies like fertilizer usage. This is in line with the study of Nwaiwu *et al.* (2004) whose work on problems and prospects of large scale plantain banana marketers production in Abia State shows that the farmers were at their middle age of 46 years. Male dominated their female counterparts in the use of fertilizer with a percentage of 80 to 20 respectively. This is expected because the farm lands are usually owned by the men. The farmers in the study area were literate with a mean value of 11.8year. This implies that most of the farmers spend about 12years acquiring formal education. The level of education will reflect their technology adoption level positively. The arable crop farmers in the study area had a mean value of 0.43hectare of land. This implies that, they are smallholder farmers. The result is similar to the findings of Nwaiwu *et al* (2004), who observed that plantain/banana farmers in Abia State are smallholder with a mean value of 1.4hectares and therefore they are limited in capital, scope of operations and production. The arable crop farmers in the study area had a mean income of N76,487 per annum. This implies low income level of the farmers. This could be the reason why they could not have savings that could be reinvested into their farm business, hence appear to operate in a somewhat vicious cycle of poverty. The findings showed that 85% of the farmers use fertilizers representing more than half of the sampled farmers and this implies that the farmers adopted the use of fertilizers in the study area. Only about 50% of the sampled farmers do not use fertilizers.

Level of Fertilizer Use by Sampled Farmers

Table 2 showed that 52.6% of the arable crop farmers use a minimum of 50kg fertilizer. The mean value obtained was 88.9kg. This implies that the level of fertilizer usage in the study area was moderately high indicating high demand for fertilizer because fertilizer is one the important technologies used in increasing food production (Obiesesan *et al.*, 2013).

Determinants of Fertilizer Use Intensity among Arable Crop Farmers

From Table 3, age of the arable crop farmers was significant at 1% level and had a positive relationship with fertilizer use intensity (FUI). This implies that a unit increase in the age of the farmers increases the fertilizer use intensity by 0.4867. It also means that older farmers use more fertilizer than younger farmers. This is in line with the findings of Ugwuja *et al.*, (2011). Also, gender was significant at 1% level but inversely related to fertilizer use intensity. This indicated that a unit change in the gender of the farmers will change the fertilizer use intensity by 137. This showed that majority of the farmers were female, as females tend to be involved in cultural practices during farming. Education level was significant at 1% level and was positively related to FUI, indicating that higher educational level influenced higher fertilizer use. This is in agreement with (Njoku, 2005) who reported that education correlates positively with adoption of improved practices. This is expected since most of the farmers in the study were educated The coefficient of household size was significant at 10% level and had positive relationship with FUI. This implies that, the higher the number of the household size of the family, the higher the use of fertilizer by the family. This conformed to *a priori* expectation because higher household members would require more food and this would mean more fertilizer use to grow more crops. Price of fertilizer was significant at 10% level and was positively related to FUI. This implies that a unit increase in price of fertilizer would increase the use of fertilizer by 0.077. This is contrary to *a priori* expectation. It is plausible however because fertilizer is an essential commodity to these farmers and as demand for fertilizer increases, its prices also increases but would not stop farmers from using them. This is contrary to the work done by Obisesan (2013) who reported that farmers use more fertilizer when the price of fertilizer is low than when the price is high. The R^2 value was 0.906 indicating that about 90.6% of total variation in the dependent variable was explained by the exogenous variables in the model. The F-ratio was also significant at 1% level. This indicated the goodness of fit of the model.

CONCLUSION

It is concluded that arable crop farmers in the study area were at their active age, literate, had mean income of about N76,487 and showed high use of fertilizer despite its high cost. Age, education and household size were significant factors that had positive relationship with fertilizer use intensity while high cost of fertilizer, limited access to credit and inadequate supply of fertilizer were the constraints to fertilizer use by farmers. Therefore, it is recommended that government and other policy makers should initiate capacity building programme to increase knowledge and skill of farmers through avenues such as field days, extension agents contact with farmers; emphasize rural credit mobilization to boost farmers savings and maximize the availability of credit to farmers; establish functional agro-services centers near to rural areas as sources of fertilizer supply to farmers, by this government can monitor the distribution and uses of fertilizer and ensure that subsidized fertilizer reach the farmers that need them at subsidized price. Fertilizer record at state and local government level over the years should be scrutinized to ensure and instill a sense of accountability and determine the true fertilizer situation at these levels.

ABSTRACT
With the collapse of prices of crude oil, many investors in Nigeria are repositioning their investments into the non-oil sectors of the economy. Agriculture remains the solution to resuscitate and revamp the Nigerian economy. In order to achieve these, all efforts need to be put in place to ensure that agricultural global best practices and technologies are transferred to the farmers easily, promptly, effectively and efficiently using social media since it has taken over the way we communicate in our world today. The survey showed that there are potentials to be enjoyed if social media is used in agricultural extension services delivery in Nigeria. The research also identified challenges that might hinder harnessing these potentials in agricultural extension delivery in Nigeria. The study further highlights strategies to be adopted in order to overcome the challenges and better maximize the potentials of use of social media in agricultural extension services delivery.
Keywords: Social Media, Potentials, Agricultural, Extension, Services, Delivery, Strategies, Challenges, Maximize, Technology, ICTs.

INTRODUCTION
According to Iannacone (2001), social media is a set of technology platforms that have the ability for people to communicate more easily, sharing ideas, videos and other materials which might be from elsewhere or their own user generated content. Ahlgvist et al (2008) as cited by Suchiradipta and Saravanan (2016), focuses the definition of social media on three basic components which are content, communities and web operationalise social media as the interaction of people and also creating, exchanging and commenting on contents in virtual communities and networks. Social media is seen as a collection of online communication channels dedicated to community based input interaction, content-sharing and collaboration. Information and communication technologies have long been used in agricultural extension delivery for facilitating communication, and innovation brokering between farmers and extension workers, and of its numerous applications. Social media is the most recent addition; Social media has already impacted the wind of global development, making people more informed and aware. Introduction of social media to agricultural extension services delivery is still very recent but the promises is showing are huge.

This paper aims at identifying the potentials of social media and how best these potentials could be maximized for agricultural extension in Nigeria. This specific objectives of the paper are to: identify the potentials of social media in agricultural extension services delivery in Nigeria; ascertain the challenges facing effective use of social media in extension services delivery in Nigeria; highlight the strategies that would be adopted in order to maximize the potentials of the use of social media in extension service delivery in Nigeria.

MATERIALS AND METHODS
The research is a survey type. The population of the survey comprised of agricultural extension officers in Abia state of Nigeria. 120 Agricultural extension officers were purposively sampled, 40 from each of the three agricultural zones in Abia State. Although 120 questionnaires were distributed but the study used only 100 questionnaires, which were properly filled out and returned bringing the sample size to 100.

Data collected were analyzed using frequency distribution tables and percentages.

RESULTS AND DISCUSSION
Table 1 shows that respondents identified several potentials agricultural extension services delivery will enjoy when they incorporate social media usage in their operations. These potentials as elucidated included: Efficient and prompt feedback (98%), Easy and quick communication (95%), Encourages collaboration irrespective of geographical location (90%), Reaching out to global audience (85%), Creation of discussion groups and virtual communities among global and local colleagues (78%), Creation of knowledge pool in real time (60%), and finally Provides interactive and multimedia content support (56%).

Responses as shown in Table 2 identified several challenges facing effective utilization of social media in agricultural extension. These challenges included: poor support infrastructure (95%), these support infrastructures include but not limited to power supply which is very epileptic in Nigeria today and is the backbone powering both devices and installations that ensure that the internet is up and running to enable social media function. Majority of farmers who are majorly domiciled in the rural areas are illiterate (90%), hence lack technical know-how on the use of these technologies. Mobile data and internet service access charges are still very expensive (90%), making it difficult for the few who are able to use these technologies to stay online always and benefit from its potentials. Many a times those who have the knowledge and are able to purchase the devices and internet access are faced with very poor signals and service by internet service providers (80%), the signals are poor, slow or totally unavailable most of the time. Another challenge identified is unwillingness of both extension officers and farmers to adopt change in technology (75%), as they seem to be very comfortable with traditional methods they are used to. The effect of this is that they will not benefit from the amazing potentials these technologies have to offer, as those who change with changing times tend to key in first to the numerous benefits these new technologies present.

Results from Table 3 identified strategies that could be adopted in order to maximize the potentials of social media to agricultural extension service delivery. Top of these strategies to combat the challenges identified in table 2 above. Included: subsidizing enabling devices so that both farmers and extension officers can afford them (100%), the cheaper these services are made, the more people key into using them and better results are achieved. Intensive farmer education (97%), and Capacity building of agricultural extension officers (95%), as this will enable both farmers and extension officers acquire the technical know-how to be able to use these social media technologies better. Rapid awareness campaign on benefits and uses of social media in agricultural extension services delivery (82%), is also a key strategy that will help spread the word on the potentials and benefits accruing from use of social media technology in agricultural extension services delivery. Improvement of government policies to improve internet service delivery (77%), is another key strategy, as the government need to ensure that service providers render services worth subscribers' money paid, by putting in place policies to checkmate their excesses.

CONCLUSION

The role of agricultural extension services delivery to the farmers is such that it serves as a link between developers of the technologies and the farmers as well as input sources and market forces as agricultural extension service delivery connects farmers to the technical know-how needed to achieve maximum production. In developed countries, agriculture is highly commercialized and ICTs including the use of social media are used to ensure quick and timely information dissemination and feedback. However, in Africa and specifically Nigeria, the reverse is the case. The results of this survey has highlighted several potentials that could aid extension service to the use of social media in agricultural extension service delivery, top of which is that social media ensures for easy and quick communication between farmers and extension services workers. Some challenges facing use of social media in agricultural extension services delivery were elucidated and they include but not limited to poor support infrastructure and illiteracy. Finally, the research highlighted some strategies to be adopted in ensuring full maximization of the potentials of use of social media in agricultural extension service delivery and top on the list of these strategies is subsidizing, enabling devices so that both farmers and extension officers can afford them.

Table 1: potentials of social media to agricultural extension delivery

Potentials	Frequency	Percentage (%)
Reaching out to Global Audience	85	85
Creation of knowledge pool in real time	60	60
Creation of discussion groups and virtual communities among global and local colleagues	78	78
Provides interactive and multimedia content support	56	56
Ensures efficient and prompt feedback	98	98
Ensures easy and quick communication	95	95
Encourages collaboration irrespective of geographical location	90	90

ABSTRACT

The study assessed growth enhancement support (GES) scheme in Benue State, Nigeria. The population of the study included all cassava farmers that participated in the scheme in Benue State. Multistage sampling was used, and a combination of purposive and simple random sampling techniques was used in selecting a total sample size of 180 participants. Primary data collected were through the use of questionnaires. Percentage and mean were used to analyze data. The result of the findings showed that the majority (70.6%) were male and married (90.6%). The farmers mean age was 54 years and were literate (75.5%). The mean farming household size was 8 persons and had farm size of 3.4 ha. The scheme made great changes in food productivity (M=2.81), farmers' access to farm inputs (M=2.62). Farmers had high level of satisfaction on the scheme's participation processes on GES scheme awareness (M=2.74), registration process (M2.18) and quantity of cassava stems (M=2.02). Major challenges identified were poor awareness (M=2.72), mixed up of names of registered farmers (M=2.99) and poor mobile phone possession and usage (M=2.53). It was recommended that more awareness and adequate training be given to farmers for them to participate actively for other farmers to join in the scheme.

Keywords: assessment of GES scheme, participation, cassava, Benue State.

INTRODUCTION

Agriculture has been the mainstay of Nigerian economy for several years and is still contributing significantly to the Gross Domestic Product (GDP) of the country (Patachu, 2012). Subsistence level lifestyle in rural areas is a daily concern for many people. A way out of this is to boost agricultural production through developing and empowering people to design and manage their own developmental activities. Growth enhancement support (GES) scheme was initiated by the Federal and State Government under the Agricultural Transformation Agenda (ATA) for the provision of subsidized inputs to farmers in Nigeria (FRN, 2013) to help farmers in their developmental activities.

GES, a special agricultural scheme of the Federal and State Governments, is aimed at delivering subsidized farm inputs to farmers and facilitating a shift from subsistence to commercial farming. It was designed as a component of the ATA of the Federal Government in 2012. The ATA is the government policy measure to realizing food security and increasing household income for farmers at the micro level. With GES, the government seeks to withdraw from direct fertilizer purchase and distribution, and introduce an alternative system of distribution built on the voucher system. Under the scheme, registered farmers receive e-wallet vouchers with which they can redeem fertilizer and seeds from agro-input dealers (Fertilizer Suppliers Association of Nigeria (FESPAN), 2012).

Adesina (2012) noted that GES is a strategy by the Federal and State Government under the ATA to provide subsidized inputs to farmers and ensure that the financial burden is shared between government and farmers. The scheme is also aimed end the unwholesome activities of middle men who, over the years, had been diverting the products to other countries thereby denying farmers the benefits of increasing their productivity over the years. In addition, the GES scheme represents a policy and pragmatic shift within the existing Fertilizer Market Stabilization Programme and it puts the resource constrained farmer at its centre through the provision of series of incentives to encourage the critical actors in the fertilizer value chain to work together to improve productivity, household food security and income of the farmers (Federal ministry of agriculture and rural development (FMARD), 2013).

Benue State, Nigeria started participating in the scheme in 2012 in which both maize and cassava farmers benefited in the scheme. The questions are: to what extent had the scheme achieved its laudable objective in the provision of farm such as fertilizers and improved seeds at subsidized rate especially to farmers in Benue State, Nigeria? What are the farmers' perceptions of changes brought about by the scheme on food production as well as access to farm inputs? What are the farmers' level of satisfaction and participation in the scheme? What are the challenges to effective participation of the scheme? This study seeks to provide answers to these questions as a means of validating or otherwise of the policy.

METHODOLOGY

The study was carried out in Benue state, Nigeria. Benue is made up of 23 local government areas (LGAs). The population of the study includes all cassava farmers that participated in the scheme in Benue state, Nigeria. Multi-stage, purposive and simple random sampling techniques were used in selecting a total sample size of 180 respondents.

The first stage involved the purposive selection of three LGAs (Makurdi, Otukpo and Katsina-Ala) that are notable for cassava production activities in the state. In the second stage, three communities were purposively selected from each of the three local government areas due to their high cassava production activities. They include Agan, Gaadi and Adeke for Makurdi LGA, Allan-akpa, Ugboju-ehaje and Okete for Otukpo LGA and Mbacher, Michihe and Katsina-ala in Katsina-ala LGA. This gave a total of nine communities.

The third stage involved the selection of twenty GES Scheme beneficiaries using simple random sampling from each of the selected communities. This gave a total of 180 farmers that serve as sample size for the study. Primary data were obtained through the use of questionnaire administered to farmers.

RESULTS AND DISCUSSION

Socio-economic Characteristics of the respondents

Result in Table 1 shows that the beneficiaries in the study area were largely male (70.6%). This implies that more male farmers participated in and benefited from the GES. This is because women are restricted to domestic activities such as processing of agricultural produce and childbearing and upbringing. It was also found that about 30% of the respondents fall within the age bracket of 51-60 years. According to FAOSTAT (2006) people between 15-64 of years are considered as economic productive or active age. Majority of the respondents were married (90.6%). The predominance of married individuals agrees with a study by Uddin (2014) which revealed that 85.8% of Edo farmers were married. This implies that they are ready to improve livelihood and that of their families, since marriage is associated with occupational stability and more responsibility. In terms of educational qualification, 24.4% had no formal education, 29.4% had primary education, 23.3% has secondary education and 22.8% has tertiary education. Level of educational attainment can increase the ability of the farmer to access and interpret relevant information about agricultural innovations, which lead to efficient use of agricultural to enhance productivity. Oluwatayo (2009) found out that education has significant relationship with farmers' level of awareness to innovation, diffusion and adoption of innovation. The area was characterized relatively by large household size (42.8%) with more than 8 family members. This result is line with Amaza (2000) who found that household members supply labour bulk of the farming and other operations. Members of the household play a key role in dissemination of information as most of the GES farmers go to know about the scheme through members of the household. The study also found that majority of the respondents (55.6%) cultivate on small land areas of 3-4 hectares. Furthermore, 35.5% cultivate on plots of less than 1-2 ha in size.

Cassava farmers' perception of changes brought about by the scheme

Table 2 shows that the respondents agreed that the scheme brought great changes in the following activities: increase in yield (M=2.81), access to fertilizers at subsidized rate (M=2.62), and access to improved seeds (M=2.64), better quality of fertilizer (M=2.44) and the use of e-wallet in input redemption (M=2.53). This implies that the scheme made great changes in food productivity and farmer's access to farm inputs such as fertilizer and improved seeds.

Farmers' level of satisfaction on the scheme's participation processes

Table 3 shows that the cassava farmers had high level of satisfaction on the scheme's participatory processes/activities in the areas of GES scheme awareness (M=2.74), registration process (M= 2.18), and quantity of improved cassava stems redeemed (M=2.02). However, the farmers had unsatisfactory participatory process/activities in the areas of timely access to information on the scheme (M=1.93), redemption process (M=1.53). This implies that farmers are not satisfied with some of the scheme's participation. This is an indication, for instance that farmers were given adequate awareness for massive participation in the scheme; and there was untimely access to information on the scheme in many cases. The redemption process was rigorous and disappointing in many cases and in different locations. Quantity of fertilizer (2 bags of 50kg- 1NPK & Urea) allocated/redeemed was not enough for the majority of farmers that cultivate 1hectrare of land and above.

Major challenges in participation of the scheme

Table 4 shows the mean distribution of identified challenges to effective participation of the scheme in the study area. The result revealed that mixed up of names of registered farmers (M=2.99); poor awareness (M=2.72) poor mobile phone possession and usage (M=2.53); lack of registration forms for all practicing farmers (M=2.71) poor network (M=2.73); lack of logistics to get farmers in rural areas registered (M=2.70);

transportation (M=2.76), difficulty in redeeming input (M=2.75); late supply of agro-input (M=2.56) and inadequate number of fertilizers supplied at redemption centers (M=2.62) were the major challenges. This implies that despite some success stories of the scheme, it still faces some serious challenges which should be taken into considerations for it to stand a test of time.

CONCLUSION

The result of the findings showed that the majority (70.6%) were male and married (90.6%). The farmers mean age was 54 years and were literate (75.5%). The mean farming household size was 8 persons and had farm size of 3.4 ha. This scheme brought great changes in increase in yield, access to fertilizers at subsidized rate and access to improve seeds. Farmers had high level of satisfaction on the scheme's participatory processes and activities in the following GES scheme awareness, registration process and quantity of improved cassava cuttings. The identified major challenges to effective participation on the scheme includes poor awareness, poor mobile phone possession and usage, poor network, difficulty in redeeming input, late supply of agro input and inadequate number of fertilizer supply at redemption center. Based on these findings, the following recommendations were made: more awareness and adequate training be given to farmers by the extension arm of the scheme for them to participate actively and for other farmers to join in the scheme; managers of the scheme should ensure early provision or supply of fertilizers and improve seeds to farmers for optimal utilization and finally, since network possesses great challenges, the authority should use alternative means such as voucher cards to ensure that farmers get their messages and packages.

ABSTRACT
This study determined the major components of Artisanal fishers' Perceived Usefulness (PU) of Short Message Services (SMS) in coastal South-West, Nigeria. Principal Component Analysis (PCA) was used to determine the key determinants of PU in the study area. A multistage sampling procedure was used to select 77 artisanal fishers for the study. Primary data were obtained with interview guide. Results showed that the mean age of the respondents was 38.61 years and majority (87.0%) had primary education. The mostly used mobile phones were Visafone (93.5%) and Techno (77.5%). The main respondents PU were that SMS-FI would suite and address their location based information needs ($\bar{x}$ = 5.36) and SMS-FI would address their fishery related needs ($\bar{x}$ = 4.29). PCA revealed that PUI (0.706), PU11 (0.767), PU13 (0.813) and PU15 (0.738) were highly correlated and were major determinants of artisanal PU of SMS. It was recommended that SMS is accessible, timely and should be based on the need of the fishers.

Keywords: Principal Component Analysis, Short Message Service, Artisanal Fishers

INTRODUCTION
The advent of modern Information and Communication Technology (ICTs) has undoubted revolutionilised information flow globally and this had made information available and accessible by the users (Banmeke and Oose, 2012). It is believed that ICTs holds the solution to the challenges of globalization in whatever form they are manifested. According to Technical Centre for Agricultural and Rural Cooperation (CTA) (2000), efficient information dissemination remains the key to bridge the gap between the developed and underdeveloped countries.

In recent years, there has been a rapid growth of mobile phone network in developing countries. Currently, mobile telephony is the predominant mode of communication in developed world (Fasina and Alfred, 2013). The global mobile penetration rate was estimated at about 76 per 100 inhabitants in 2010 International Telecommunication Union (ITU, 2011). Poor developing countries are increasing part of this spread. Importantly, use of mobile phone is making quick inroads in rural areas where most the people lives. Short Message Service (SMS), an aspect of mobile telephone service is a very important communication tool that can be used to serve several purposes. It is understood as text based read on small mobile phone screen, typically capable of presenting 15 to 20 characters per line. The messages are written with numeric keypad on the phone with message restricted to 160 characters in length. Short Message Service –Fisheries Information (SMS-FI) are set of messages developed based on the identified information needs of artisanal fishers and these messages are disseminated to the fishers in their local languages.

SMS-FI comes in recognition of the important contributions of fish to the food security of about 200 million Africans (World Fish Centre, 2005). Artisanal fishing accounted for more than 80%, aquaculture has less than 8% while industrial fluctuate around 13.9 to 5.0% (Federal Department of Fisheries, FDF, 2011). However, before the advent of mobile phone and SMS, artisanal fishers had extremely small possibility to communicate with others while in the sea. They are usually cut off from all activities and ties from families. The need for a channel through which they can communicate amongst them become very vital. It is therefore imperative to understudy the importance of SMS and its usefulness in information dissemination among the fishers. Perceived Usefulness (PU) of artisanal fishers is the degree to which to which they believe they using a particularly system will enhance their performance. PU has been used extremely in information research and has strong empirical support as an important predictor of technology adoption. (Mathieson, 1991). The specific objectives were to identify the types of mobile phone used, determine the respondents' perceived usefulness of SMS-FI and to determine the major components of artisanal fishers' PU in the study area.

METHODOLOGY
The study was conducted in coastal southwest, Nigeria. The 3 states are Lagos, Ogun and Ondo states. The states have a combine coastline of approximately 853km facing the Atlantics Ocean. Multi-stage sampling technique was used to select respondents for this study. Three (3) Local Government Areas (LGAs) namely

Ibeju-Lekki, Ogun waterside and Ilaje were selected purposively from Lagos, Ogun and Ondo respectively. This is based on the fact that these LGAs were along the same coastline. Two fishing communities namely; Akodo and Orimedu were selected from Ibeju-Lekki, Okun Ileti and Igbeki were selected from Ogun Waterside while *Enu Amo* and Holy centre were selected from Ilaje LGA. Watson, (2001) sampling technique at confidential level of 95% with an estimated 50% variance was used to select 77 artisanal fishers for this study. Primary data were collected with the aid of interview guide and data were subjected to descriptive and inferential statistical analysis.

RESULTS AND DISCUSSION

Production characteristics of Respondents

Results in Table 1 showed the production characteristics of the respondents. The mean age of the respondents was 38.61 years. This is explicable because the study has to do with coastal fishing and mature male are able to withstand the stress of fishing on the sea. This is in consonance with Udoh and Nyienakuna (2008) who posited that coastal fishing is dominated by matured male. The table further showed that 87.0% of the respondents had primary education, this indicates that primary education is the basic educational status of the respondents. The mean years of experience of artisanal fishers in coastal fishing were 17.84 years. From this finding, it implies that there were respondents with substantial fishing experience that have better approaches in carrying out their fishing activities. As regard artisanal fishers income made per trip, their mean income was ₦ 53.077 per trip. It was observed that about 2 to 3 fishers operate a single Outboard Engine and the money is shared accordingly. From this result, it is pertinent that fishers made more income but the cost of fueling the engine and repairs was very high. Majority (92.9%) indicated that they use encircling gill net which the size determines the types of fish catch.

Types of Mobile Phone Used by Artisanal Fishers

The type of mobile phone used by artisanal fishers is presented in Table 2. Artisanal fishers indicated they mostly used mobile phone as follows Visafone (93.5%), 77.9% used Techno phone, 54.5% used Nokia phone. This observation implies that most of the artisanal fishers across the coastal communities in the study area prefer Visafone mobile phone. It was found that Visafone mobile network service is very active within coastal communities. Some of the artisanal fishers explained that the nature of their job is very hard and Visafone mobile phone had helped them with the problem of fluctuating network services. Muhr and Nordstrom (2007) corroborate this finding that improved access and ownership of mobile phone improved artisanal fisher livelihoods

Perceived Usefulness (PU) of SMS-Fishery Information

The perceived usefulness of SMS- Fishery Information by respondents indicates that the respondents were of the view that SMS-FI suite and address their location based information needs ($\bar{x}$ = 5.36), SMS-FI would address their fishery related needs ($\bar{x}$ = 4.29), using SMS-FI would improved their fishing performance ($\bar{x}$= 4.66), also others indicated that if they are sent SMS-FI it would be accessible ($\bar{x}$ = 4.64), SMS-FI would be advantageous ($\bar{x}$ = 4.56) while others accounted that SMS-FI would support critical aspect of their fishing work ($\bar{x}$ = 4.52). These findings concur with the position of Guriting and Ndubisi (2006), that PU refers to individuals' perception that using a new technology well enhances or improve his/her performance. The implication of these findings to agricultural communication is that the PU of artisanal fishes is an important predictor of whether or not they will accept SMS-FI in their fishing activities.

Principal Component Analysis for Perceived Usefulness of SMS-FI

The Principal Component Analysis (PCA) of artisanal fishers' Perceived Usefulness (PU) of SMS-FI presented in Table 3. The major aim of PCA is to reduce information idleness and reduction of the dimensionality. Eigenvalues greater than one was considered. Five (5) variables are retained in the analysis and it accounted for 81.32% of the variability. The PCA model of analysis allows us to transform the 15-dimensional space into 5-dimensional space losing about 18.68% of the information in the original variables. As shown in Table 4, the factor loading using the rotated factor matrix. The first PC (factor 1) is highly correlated with 4 of the original variable that is, PU1 (0.706), PU11 (0.767), PU13 (0.813) and PU15 (0.738). These 4 items represent the weighted average of the efficiency of information seeking. Also, the fisher educational status would enhance their use of SMS-FI in their fishing activities. This is in agreement with Oose *et a*l., (2015) that artisanal fishers within coastal south, Nigeria were literate.

CONCLUSION

Based on the outcome of the analyzed results, it was concluded that SMS is accessible, timely, and advantageous to the need of the fishers. Also, the PU of artisanal fishers of SMS influences their adoption. It is therefore recommended that extension agents and relevant stakeholders should disseminate information to farmers via SMS.

ABSTRACT
The agricultural sector in Nigeria is bedeviled by dearth of information. This is evident in poor perfomance and slow pace of technology transfer by the extension agents to the end users of technology. This study examined the relevance of information technology in extension service delivery in katsina state, Nigeria. Primary data was used to elicite information using pretested and structured questionaires from 128 respondents selected through multi-stage sampling. Descriptive statistics and likert scale were analytical tools used. The result shows that extension workers are male dominated in the study area, highly educated and experienced. The result from the likert scale indicate that their mean scores were below the decision point x=2.0.This implies that the use of internet as an ICT tool is poor in the study area.The study concludes that information communication technology is relevant to extension delivery in the study area. The study recommends that government should formulate policy that will create an enabling working environment for capacity building among extension agents and greater access to internet facility at the grass root level. Workshops, conferences and seminars should be organized to train extension agents in the use of internet technology which will improve efficiency in their work.

Keywords: Accessibilty,Information Communication Technology, Extension Delivery, Katsina State, Nigeria.

INTRODUCTION

The agricultural sector has been recognized as the major driver of economic growth and development. Nigeria's government over the decades has neglected agriculture, hence no plausible effort had been made to make the sector great. Rather still, there had been diversified interest, and this has made her economy to be oil dependent. However the recent crashed in the prices of oil in international market has awaken interest towards agriculture as a means of diversifying the economy. Over 75% of agricultural production is produced by the rural farming households whose means of livelihood depends only on cultivation of crops and livestock production. Agricultural extension deliverables remain the only way through which these rural farmers will be informed of latest agricultural ideas. Knowledge of innovation can make them improve in agricultural production and competitive; in addition to subdue the challenges impose by technological advancement. It has been observed that there is gross inadequate extension personnel that will serve the poor farmers and update their knowledge in Nigeria. This is evidence in poor performance and often resulted in upsurge of poverty and under performance of agriculture sub-sector of the economy (Adetunji, 2013). Local production of agricultural produce is therefore possible if the necessary stakeholders for agricultural production are provided with information and knowledge that will help to create a network that encourages information and knowledge sharing.

Despite the increase in information occasioned by information communication technology, agricultural sector is still bedeviled by dearth of information. This is evident in slow pace of technology transfer by the extension agents to the rural farmers who are the end users of technology. Rural farmers especially at the grassroots still record poor harvest and low quality of farm produce. Some of the major problems encountered by farmers are occasioned by insufficient information by the appropriate agency, poor awareness of available information, or inability of most farmers to effectively utilize and apply the information to boost their farming operations. The resultant effect of these problems are low agricultural productivity, poor marketing and pricing of agricultural products. These aggravate poverty and hunger among rural farming households' food shortage.

This study therefore intends to assess the extension delivery to rural farming households in katsina state, Nigeria. The objectives are to: describe the socio-economic characteristics of agricultural extension agents; ascertain the accessibility of internet services by the extension agents and the level of application of the Internet by the agricultural extension agents.

METHODOLOGY

This study was conducted in Katsina State. Katsina state is located in the North West Geo-Political Zone of Nigeria. It has a population of 7,452,629.

A two-stage sampling technique was used to select the respondents for this study. The list of all the extension workers in the state was obtained from Katsina State Agricultural and Rural Development Authority (KTARDA). In the first stage, a purposive sampling method was used to select Agricultural extension workers from the three Zones of Katsina State Agricultural and Rural Development Authority (KTARDA). The second stage involved a random sampling of thirty-six (36) respondents from zones I (Ajiwa), thirty-six (36) respondents from zones II (Funtua) and thirty-six (36) respondents from zones III (Dutsin-Ma) of KTARDA making a total of one hundred and eight (108) respondents for the study.

Analytically, descriptive statistics such as mean, media, mode and percentage, and likert Scale was used to analysed the data.

RESULTS AND DISCUSSION

The result in Table 1 revealed that the respondents have the mean age of 44years. This indicates that extension worker in the study area were predominantly young people who are active. This finding is similar to that of Alocha, *et. al* (2013) who reported that extension agent from this age were in their active years and still have more productive years to put into the extension work. The results showed that all the respondents were literate. Majority of them 32.4% and 25.0% had center certificate and OND/NCE certificate respectively.This finding is in corroboration with Yakubu, *et. al* (2013), who reported that extension agents in Kano State were literate and could utilize ICTs to improve their work as change agents.

The extension agent were male dominated, 90.7% are male while 9.3% are female. This reveals the low involvement of women in extension service delivery. The years of experience also shows that 52.8% of the extension agents had been in the job for 21years and above. The mean working experience of the extension agents was 18 years implying that almost all the extension workers in the State had longer years of working experience and this gave them advantage of appreciating the role of internet technology in extension work. This finding agrees with that of Salau and Saingbe (2008) who reported that extension workers in Nasarawa State had longer working experience. This also implies that the extension agents had knowledge to analyze between how it was without internet and what the present scenario is with the use of internet

Frequency of Internet Usage by the Respondents

Results in Table 2 show the distribution of the extension agents on the frequency of internet usage. From the table, the extension workers that used Social network for knowledge update and to sought information were in the majority with a mean score of 1.68. This was followed by the use of Search engines with a mean score of 1.55. Getting information from recreational center from friends and through interaction was popular in the study area. The table shows that extension workers with a mean score of 1.33 used the internet as recreational to obtained information and news that will be helpful to them. Those that used Websites ranks fourth with a mean score of 1.55. Online chatting gained prominent among the extension workers as a good number of them with mean score of 1.20 engaged in chatting using social media such as facebook, whatsapp, and twitter among others. The use of the E-mail was also popular among the respondents. The table shows that extension agents with a mean score (1.00) was versatile in the use of electronic mail as means of communication. The respondents were found to be those that frequently asked questions. Those who were found in this category were with the mean score of 0.78. Extension agents in the study area were also found to be using Internet Telephony. Those who were found in this category were found to have a mean score of 0.56. Furthermore, Professional Blog is rarely used as a means of information dissemination in the study area. The mean score of those who were using Professional Blog is 0.53. Lastly, online public access catalogue was the least used internet facilities in the study area. The mean score of extension agents using public access catalogue is 0.48. Comparing their individual means to grand mean (1.04), it shows that the frequency of internet usage among the extension workers in the study area is low because it is only in social network, search engines, recreational, websites and online chatting that internet usage was high in the discharge of their duties. Their internet usage was very low in other internet facilities. This could be attributed to low internet accessibility in the rural areas. This finding is similar to that of Chukwunonso, *et. al* (2012) who reported that lack of Internet access in most of the rural areas in Adamawa State.

CONCLUSION

It can be concluded from the study that extension agents in the study area utilized internet services to a very low level in their extensions service delivery, since their mean scores were below the decision point x=2.0. It is also established that the extension agents in the study area are not aware of the fact that internet technology can be used to accomplish many functions in extension service delivery. In the light of the finding, the study makes the following recommendation: government should formulate policies that will stimulate Nigeria working environment and enhance the capacity of extension agents and enable them to access internet facility at the grass root level. This will go a long way to improve the extension delivery system. Workshops, conferences and seminars should be organized to train the extension agents in the use of internet technology which will improve efficiency in their work.

Table 1: Distribution of Respondents according to Socio-economic characteristics (n=108)

Characteristics	Frequency	Percentage (%)	Mean
Age (years)			
20-29	4	3.7

ABSTRACT

The study was a survey type of research. Structured questionnaires were distributed to women farmers within the 3 agricultural zones in Abia State (Aba, Umuahia, and Ohafia). The responses from the questionnaires were analyzed using descriptive statistics. The result of the survey showed that Information and communication technologies (ICTs) were beneficial to the women farmers. Top on the list of benefits was that ICTs brings education to rural areas where majority of Nigerian women farmers reside and also ensures speedy delivery of local and globally available information. The sampled women made recommendations on ways to improve delivery of ICTs to Nigerian women farmers. These recommendations included encouraging the government to subsidize ICTs tools to make them affordable for the women to purchase and use. The respondents also advocated sensitization of women on benefits and empowerment roles of ICTs especially rurally located women. The study also highlighted the several empowerment roles played by ICTs on women; top of which included knowledge empowerment, information base, wealth creation and economic empowerment.

Keywords: women, agriculture, empowerment, ICTs, benefits, roles, recommendations.

INTRODUCTION

Women make essential contributions to the agricultural and rural economies in all developing countries (FAO, 2011). These roles played by women in agriculture vary considerably between and within regions and are changing rapidly in many parts of the world; where economic and social forces are transforming the agricultural sector. In Nigeria, the involvement of women in agriculture has attracted greater attention in recent years. Hence the need to develop a suitable extension service delivery system that is gender specific and tailored to women farmers cannot be over emphasized.

Information and communication technology(ICT) is the term that describes communication devices such radios, cellular phones, computers, satellite systems, et cetera, as well as the services and applications associated with them (Ezike and Chigozie-Okwum, 2014). Akinpelu (2008), stated that information and communication technology has been promoted as an important tool in ensuring that marginalized groups, particularly women are included in the development of global information society. Because of its unique benefits, ICT have been recognized as a tool for empowering women. However women still have challenges using ICT. While some believe it is a male affair, others cannot comprehend the seemingly complexity of the technology. The results of the survey aim at showcasing the several roles ICT play in empowering the Nigerian women in agriculture.

MATERIALS AND METHODS

The research is a survey type. The broad aim of the survey was to identify the roles of information and communication technologies in the empowerment of the Nigerian women in agriculture. However, the specific objectives included to determine the benefits of information and communication technologies to the Nigerian women in agriculture; to identify ways of improving the delivery of information and communication technologies to the Nigerian women in agriculture and evaluate the roles of Information and communication technologies in the empowerment of Nigerian women in agriculture.

The population used for the survey comprised of women in agriculture in Abia state of Nigeria. 120 women were randomly sampled, 40 from each of the three agricultural zones in Abia State. Hence 120 questionnaires were distributed to the sampled population. However, 100 questionnaires were properly filled out and returned bringing the sample size to 100.

Where-; n = 100.

Primary data was collected using structured questionnaires. Secondary data was sourced from review of related literature. Data collected were analyzed using histogram, frequency distribution tables and percentages.

RESULTS AND DISCUSSION

The results of the survey are presented and discussed below:

The results as shown in Table 1 show that information and communication technologies are very beneficial to the Nigerian women in agriculture. These benefits as deduced from the research results included bringing education to rural areas, where majority of women in agriculture reside (98%), ensuring speedy delivery of local and globally available information (95%), allowing large number of women in agriculture to communicate directly, cheaply and speedily (92%), reduction of cost and time spent on information dissemination (90%), and increasing access to global best practices (85%). Other benefits as identified from the research results as presented in table 1 are, round the clock access to funds as made possible by e-banking (75%), promotion of networking and collaboration among women irrespective of their location (72%), and ease in modern research methods of data collection, analysis, and reporting (65%).

Results from Table 2 above highlights some recommendations made by the sampled women on ways to improve ICTs delivery to the Nigerian women in agriculture so that they can benefit from the use of these ICTs tools and subsequently be empowered by them. The results show that 100% of the respondents agreed that ICTs services delivery will be improved if Government should subsidize ICTs tools so that it can be more affordable for Women in Agriculture. Some other recommendations made included; sensitization of women in agriculture especially the majority stationed in the rural areas on benefits of ICTs tools (98%), Increasing the availability of ICTs especially to rural areas so that rural women in agriculture can benefit (95%), funding women groups in agriculture to enable them acquire and benefit from ICTs (92%), driving more awareness campaigns on empowerment roles of ICTs to be carried out nationwide especially in rural areas (88%), and finally capacity building on the part of the women in agriculture (70%).

The survey identified the roles played by ICTs in the empowerment of the Nigerian women in agriculture. The sampled population all agreed that information and communication technology play vital roles in empowering women in agriculture especially in ensuring that knowledge base is constantly updated (85%), the women also identified that ICTs empowers them by widening their information base and source (70%). Other empowerment roles played by ICTs as identified by the respondents include wealth creation (35%), economic empowerment (35%), and promoting them by paving a way for online business (30%). 25% of the respondents stated that women could engage in e-learning which will advance their skills and empower them educationally. Other empowerment roles as seen from the result in figure 1 above are e- commerce (15%), where they respondents identified that women could get more financial empowerment and independence if they engaged in buying and selling over the internet. 10% of the respondents said women in agriculture could advertise their goods and services hence reaching a wider audience through the use of ICTs like radios, televisions, telephone calls, text messages, instant messages and through the vast array of services provided by the internet.

CONCLUSION

Women play a vital role in agriculture and agricultural development in Nigeria. The women in agriculture program seeks to improve agricultural extension services for women, and ensure that extension services have female extension workers at every level operation. These women in Agriculture need all the empowerment and support they need and can get, in other to perform their duties diligently as this will lead to greater production and in ensuring food security in Nigeria.

The survey identified that ICTs, is beneficial to the Nigerian women in agriculture and hence the respondents made recommendations on how best to improve and ensure better delivery of ICTs to women in agriculture in Nigeria. The research enumerated several empowerment roles played by ICTs to the Nigerian women in agriculture which included but not limited to; knowledge empowerment, wealth creation, increased information base, e- learning and fostering online business.

Table 1: Benefits of ICTs to women in agriculture

Benefits of ICTs to women in agriculture	Frequency	Percentage (%)
Ensures speedy delivery of local and globally available information.	95	95
Reduces cost and time spent on information dissemination.	90	90
Makes for easy data collection, analysis, and reporting of research	65	65
Access to global best practices in farming, storage, processing and marketing of agro- produce.	85	85
E- Banking enables access to funds round the clock.	75	75
Brings education to rural women, where majority of women in agriculture reside	98	98
Allows large number of people to communicate directly, cheaply and speedily	92	92
Promotes networking and collaboration among women in agriculture irrespective of geographical location	72	72

ABSTRACT
Agriculture which is the Science, Art or Practice of cultivating the soil, producing crops and raising livestock and in varying degrees the preparation and marketing of the resulting products is of great importance to the society, particularly to Nigeria which has a teaming population. Because of the importance of agriculture to society and the economy of Nigeria as a whole, it is desirable that continuous research be carried out in order to improve on the variety of agricultural produce so as to make available high yielding and resistance free varieties desirable for the expanding and dynamic society of Nigeria for enhance income, poverty reduction, export and good living. One of the missions of public research institutes is to generate knowledge technologies and products that promote the public good. Traditionally this has been achieved by practicing the "Open Science Policy" which means that scientists at public research institutes completely disclose all their research discoveries and innovations to the scientific community and made it available for commercialization at no cost (that is zero technology fee or licensing fee) through Extension Agents. However, in some instance there is need for Intellectual Protection (IP) even for the public research. One of the Instances where protection makes economic and social sense is when the protection of IP helps in promoting public – private cooperative relationship and speeds up the development of new products and services. If for instance, a public research institute generates a technology or product with great potential social benefits but requires huge financial resources or business structure to further develop and market this major scientific breakthrough, then the public's interests are best served by protecting and restricting its use. This is necessary to give protection to the private sector which will be the vehicle through which the technology or product may be made available for public consumption. It is not gain saying that there can be no talking about economic diversification without talking of partnering with the private sector for mass production of improved varieties for consumption as well as export. There is no doubt that we are in a globalised world that is intensely knowledge driven in which Nigeria as a developing country can favorably compete given an appropriate and well informed and reformed IP Law and Policy that would advance human and economic development. Your IP which is the creation of your minds is a tangible asset that can be used to generate income for your parastatals and of course attract loyalties even for yourselves. This could reduce total dependence on government for research funds as well as enhanced multiplication of improved varieties for enhanced commercialization.
Keywords: Intellectual property, national, research institutes

INTRODUCTION
In its bid to position, coordinate and facilitate the development and application of IPRs policies and practices in National Agricultural Research Institutions, the Agricultural Research Council of Nigeria (ARCN) outlined the following comprehensive draft IP Rights Policy Guidelines on IP issues in relation to Plant Variety Protection, Technology Transfer, Commercialization of IP or Technologies, Human Resource Development, Incentives and Benefit Sharing (ARCN 2009).

Plant Variety Protection
The IP Protection of plant varieties of ARCN, including the extant varieties, will be secured under the relevant Act. It is noteworthy here that the draft law does not specify which Act is relevant. It is my opinion that the Act meant here should be the enabling Act on IP in Nigeria, There is also no legislation on plant variety protection in Nigeria for now. This in turn will enable a more rapid and effective transfer of plant varieties to the end users. However, a decision can be taken by the ARCN even after the plant variety protection (PVP) certificate has been obtained as to whether a particular variety will be transferred for commercial use through exclusive or non-exclusive licences or it will be placed solely in public domain to meet some specific national need or situation. Where it is considered necessary in public interest to specifically promote some ARCN verities for food and nutritional security or for diversifying agriculture, special steps will be taken as may be deemed fit by the competent authority. This should *advert* the fear of granting IPR on plant variety as farmer's right will also be adequately protected.

Registration and protection of plant varieties of filed, horticultural and agro forestry crops, developed by ARCN institutions, which meet the essential criteria for their protection, will be obtained by the institutions in the name of ARCN, under the law. The period for which the PVP title of the protected varieties will be maintained will depend on the actual performance or adoption of the variety. This will be periodically reviewed by the concerned Institutes Technology Management Centre's (ITMCs) or Zonal Technology Management Centre's (ZTMCs). and decided by the respective ITMUs or ZTMGs ARCN will maintain the IPR portfolio of its varieties, hybrids or transgenic in a transparent manner. ARCN may file PVP applications for sole ownership over its plant varieties for firstly, the varieties developed in ARCN institutions(s), the hybrids developed in ARCN where the parents of hybrid belong solely to ARCN, and the transgenic where the transgenic events are carried out in ARCN institution(s) and the initial variety and gene sequence(s) or events belong solely to ARCN. ARCN may file joint application with others, such as, NARIs or FCAs or other concerned organizations/institutions/research establishments in the public or private sector for varieties which have been developed through collaborative efforts. Where it has been decided to file joint applications, the same will be taken up on mutually agreed terms between ARCN and the other collaborators or research partners. Where the collaborator(s) or research partner(s) assign a jointly developed plant variety to ARCN for protection and further management, ARCN will file PVP application as sole applicant. However, it shall include the names of the research partners as the breeders of the candidate variety in the PVP application. In other cases, ARCN as well as the other collaborator jointly responsible for developing a plant variety will be the co-applicants. ARCN will share benefit accrued from commercialization of that variety with the collaborator(s) research partner(s) on mutually agreed terms. Where the collaborator or research partner is an international agency or a foreign client, and the variety hybrid or transgenic is developed in ARCN, the ownership and the licensing rights will be determined on mutually agreed terms. The Memorandum of Understanding (MOU) with the collaborator or partners will be executed by ATMC at the ARCN headquarters. Other terms and conditions, and limitations of the MOU will be entered as per the mutual agreement. As ARCN will be the institutional breeder and the applicant in the PVP application for each of the plant varieties developed in its set up, it will also discharge any liability in respect of benefit sharing as may be determined by the PVP Authority; compensation for under performance, if any and any other liability that may be fixed by the PVP Appellate Tribunal, or any court of law.

Registration and Protection of Extent Varieties

An extant variety is the variety available in Nigeria which is either (i) notified under the relevant law, or (ii) a farmers' variety, or (iii) a variety about which there is common knowledge, or (iv) of any other variety which is in public domain. The following procedure may be followed for registration and protection of extant varieties of ARCN in relevant cases. ARCN institutions shall provide all the necessary information required under the law/rules for registration of extant varieties developed by them to ARCN. This will include the particulars required for the National Registrar of Plant Varieties, such as the denomination of the variety, names of breeders involved in its development, pedigree details salient features of identity vis-à-vis most similar varieties, zone(s) of adaptation, performance limits under specified situations particularly for Distinctiveness, Uniformity and Stability (DUS) traits, along with a referral seed sample. ARCN will further verify the database of extant varieties developed and maintained at the Bureau with the information received from different institutions and supplement the information with the molecular profile of the variety if available. Authenticated seed samples of the variety will also be developed in the active and base collections at the national gene bank at ARCN on immediate basis. Availability of adequate quantity of nucleus/breeder seed will be simultaneously ensured. ARCN will also ensure that the seed samples of all extant varieties are available for registration as well as conservation purposes. At the earliest, ARCN will take action so that proposal(s) for registration of all extant varieties of ARCN which have not completed 15 years from the date of their notification under the law are kept ready in all respects. Application(s) for registration and protection of these extant verities shall be made as soon as possible. In a specific case where there is common knowledge about a variety developed by ARCN which is not notified under the law, or it is already in public domain, such matters will be brought before the competent authority at the ARCN headquarters for decision. But for the extant varieties other than those described above for example farmers; varieties or some varieties of common knowledge no direct role of ARCN is stipulated.

Registration and Protection of New Varieties, Hybrids or Essentially Derived Varieties

The Principal Investigator (PI) plant breeder will inform the respective ITMU or ZTMC at the institution early about the availability of any prospective material developed by him or her which can qualify for a new distinctive, uniform and stable crop variety. The following are to be provided by the PI or Breeder.

1. The salient particulars of the prospective varietal material along with name(s) of most similar varieties will be provided by the PI or Breeder.
2. In case of a hybrid or appropriate information on parental line, this shall also be provided by the PI or Breeder.
3. In case of transgenic variety, information will be provided with respect to the initial variety and its parents, the gene sequence including the promoters and their source, and the transgenic events.

4. In case of seed propagated crops, the above early information will be given at least for months prior to the next crop season alter duly completing the harvest, seed processing and storage, appropriate statistic analysis and interpretation of result of the previous crop storage, appropriate statistical analysis and interpretation of results of the previous crop season. In case of vegetative propagated crops like sugarcane such information will be given while the crop is still standing.

The Institutions by way of follow up action will through the ITMUs or ZTMCs prepare the lists of prospective varieties of their respective institutions proposed by Plant Breeders, and prepare schedule of assessment of these material in the next crop season involving ITMU or ZTMC and other co-opted crop specialists from within or outside the institution. The ITMC or ZTMC will make necessary recommendations for follow up by the concerned scientists or institution on the basis of assessment of the potential varietal materials in the experimental plots as per given schedule, consideration of the performance data in station and cooperative trials in the previous years. DUS parameters vis-à-vis the most similar varieties and some extraordinary or exceptional merit seen in the varietal material, if any, based on which it can be taken up for filling PVP application at an early date. ITMC or ZTMC will also advise on the finalization of a suitable denomination for the deemed variety, which should be unambiguous and in conformity with the requirements of PVP Law. Decision to file PVP Application: Normally, the process of filling application for registration and protection of varietal materials recommended by the ITMC will be taken up by the concerned institution as soon as the variety has been identified in the ARCN workshop. Therefore, the basic information required for filling the PVP application should be kept ready by the respective ITMUs in consultation with the concerned Pant Breeders. ARCN will thus normally prefer filling its applications for variety protection only when there is satisfaction with respect to the outcome of Value for Cultivation and Use (VCU) of identified varieties. In exceptional cases, on a case-specific merit basis, early application can be filled by ARCN institutions for registration and protection of prospective varietal materials.

In case of new varieties and hybrids, PVP application will be filed differently from and that for the essentially derived varieties under the relevant provisions of the law. Nucleus and Breeder Seed: The PI or Breeder will accord priority to the production and maintenance of nucleus seed of the prospective varietal material(s) reported to the ITMU or ZTMC as candidate varieties for PVP. The concerned institutions shall take up production of breeder seed of prospective varieties (most promising varieties in advance varietal trials), one year prior to filing the application for their registration. Performance Limits. All concerned Breeders or Scientists shall specifically provide the performance limits under each of the different environments/situations that are considered suitable for cultivation of the variety proposed for registration and protection under the law. This would be necessary to avoid any uncalled for litigations and compensation for under performance.

Maintenance of Seed or Propagation of Protected Plant Varieties

Concerned institutions or breeders will be responsible for the maintenance of varietal purity, and will ensure the availability of breeder seed for public supply or commercial use, as applicable. On Variety Registration and Protection, Concerned ITMUs or ZTMCs will undertake and pursue the needed steps under the law required for seeking registration and protection of plant varieties.

Maintenance of the Protection

The ITMUs or ZTMCs will maintain the PVP titles secured by them by payment of requisite recurrent fees to the registrar. The ITMUs will undertake periodical reviews and decide on further maintenance of titles by payment of requisite fee based on actual performance of variety, further licensing potential of the variety in Nigeria or abroad, potential use of the variety for further variety development programme, or any other specific or relevant criteria considered appropriate for the purpose.

Farmer's Rights

All matter related to farmers' rights arising in the protection of plant varieties by ARCN will be taken up or resolved as per the provisions of the law. A Mechanism of IP monitoring and watch will be developed. The ATMC may assist the ITMUs or ZTMCs and wholly or partially outsource the task of IP watch. In the event of suspected infringement of protected ARCN variety, the concerned institution(s) will take initial action at their own, or in consultation with the ZTMCs or ATMCs. All cases of litigations where ARCN is made a defendant will be taken up by the concerned institutions that have protected/maintained the IP under the disputed case. Institutions will, if required, seek assistance of ARCN legal adviser or other legal experts. In all cases the institutions will notify and keep the ARCN headquarters informed of any such dispute. In all cases of litigation where major stakes of ARCN are involved, ATMC will take up the matter with the assistance of empanelled experts or other competent experts on need basis.

Technology Transfer and Commercialization of Plant Varieties

On the procedure for improving access to plant varieties by end users based on national priorities and issues of food and nutritional security, ARCN may decide to place a plant variety solely in the public domain or else it may be licensed for commercial use on exclusive or non-exclusive basis. However, registration and protection of all protectable varieties will be ensured under the Plant Variety Protection (PVP) and Farmers' Right (FR) Act before placing them in public or commercial domain. For commercialization of plant varieties broadly the general guidelines for technology transfer or commercialization of IP enabled ARCN technologies will be followed. ARCN will make the specific considerations in the commercialization of its plant varieties as they can have direct impact on issues of food and nutritional security and farm income**s.** For other consideration**,** all the registered varieties will be transferred for cultivation and use through open access or commercialization. No plant variety will be transferred or commercialized before its registration and protection under the PVP and FR Act.

ARCN may consider any appropriate proposal for the grant of exclusive Licence to a private seed company or public seed agency for commercialization of its protected plant variety abroad. All such varieties of ARCN institutions which have commercialization potential abroad shall be assigned to ATMC and licensed under suitable arrangements or agreement keeping in view the interest of Nigerian farmers and national priorities.

1. Advance breeding material or parental lines shall not be transferred or licensed on exclusive basis. These will first be registered with the National Centre for Plant Genetic Research (NCPGR) before any material transfer or licensing will be done.
2. Normally, commercialization of an ARCN variety will be done by same institution or zonal institute that has secured the PVP title. However, where more than one ARCN institutions are involved or interested in the commercialization of the same variety, or where they are given this specific responsibility in public interest by the ARCN, these institutions will mutually settle the sharing arrangements.
3. ARCN institutions will obtain assistance or advice of ATMC or ZTMC, if needed, particularly for any legal opinion or market information.
4. The parametric values of all successful licenses will be recorded in the institutional/zonal central database.
5. ATMC will evolve suitable mechanisms for quick disposal of plant variety licensing cases at different levels in ARCN.

Other Related Matters

Standard records of generic stocks at the research institutes or colleges along with confidential records (codes) where applicable shall be maintained in signed and countersigned notebooks or registers. Suitable data sets will also be documented in the institutional, zonal or central database. All confidential information, such as codes, etc. will be kept safely and would not be revealed by individuals or institutions except through confidentially agreements which will expressly mention the purpose for sharing such information and other terms and conditions.

Concerned breeder or other ARCN scientist will report all matters of infringement or suspected infringement of plant variety rights in their knowledge to the respective ITMUs, ZTMCs or ATMC as appropriate. Concerned ITMUs or ZTMCs will handle the cases reported to them or other apprehended cases either on their own or with the assistance of ATMC. Further legal action, if required will be taken with the approval of competent authority.

The commercialization of plant variety portfolio will be monitored by ITMUs or ZTMCs or ATMC. The relevant developments or matters of concern, etc. will be critically observed and addressed. ATMC or ZTMCs will develop a mechanism of market watch. ATMC will plan, organize or assign suitable impact assessment studies on socio-economic impact of the commercialized plant varieties or hybrids of ARCN in different crops and regions of the country.

Technology Transfer/Commercialization of IP Technologies

Procedures for Technology Transfer or Commercialization

A central database of the IPR enabled technologies will be at the ATMC. The concerned institutions or zonal institutes will make entries of all new cases in their respective datasets as soon as the process for their IPR protection is started. They shall also update the status of IPR protection maintenance in the data set from time to time. The entire ARCN IP database will be suitably inter-linked to the NARIs and Federal Colleges of Agriculture (FCA) through intranet, at the earliest opportunity. Notwithstanding the fact that only a small proportion of protected IP generally meets with commercial success world-wide, the ATMC and ZTMCs or ITMUs will make efforts for technology commercialization with the primary objective of technology transfer to end-users. Depending upon factors such as technology etc. a decision will be taken by the competent authority whether the technology will be placed in the public domain through open access, or it will be transferred to end-users through commercialization. The ITMUs or ZTMCs or ATMC shall develop a system of registering industry, enterprises or cooperatives for technology transfer or commercialization of ARCN Technologies. Registration of area, discipline or zone-wise potential licensees from industry, enterprises or cooperatives will be undertaken by inviting applications through advertisement. The registered entities will be informed of the IPR enabled technologies available from time to time for transfer through commercialization. A nominal registration fee will be charged and the registration renewed annually. Concerned ITMUs will disclose the salient features of technology ready for commercialization. The technology disclosure for commercialization will be made in a confidential agreement. The ITMUs, ZTMCs or ATMC will also advertise the IP enabled ARCN technologies available for commercialization by suitable means. The IPR enabled ARCN technologies ready for transfer or commercialization will be given publicity through web portals of federation or Chambers of Commerce, and other organizations for wide reach to interested clients. The IPR enable technologies will be transferred for commercial purposes with suitable understanding or agreement or contracts with the concerned parties. Specific terms of licensing can be negotiated. Commercialization will be undertaken either by ITMUs of the concerned institutions that have the requisite expertise and experience or the concerned ZTMCs or ATMC. Commercialization in foreign countries shall be undertaken by the ATMC.

CONCLUSION

The administration and practice of Intellectual Property and Intellectual Property Rights in National Agricultural Research Systems is a very veritable tool for effective and proper utilization of research results and innovations through public - private partnership relationship which should make mass production and commercialization possible for the benefit of the masses, the scientists and even for exports which should increase the Gross Domestic Product of Nigeria. We are in a globalised world and the earlier the National Agricultural Research Systems in Nigeria cue's in the global positive issues relating to agriculture, the better for the system. However, it is my view that the use of Technology Transfer Offices in the various National Agricultural Research Institutes headed by intellectual property professionals and intellectual property lawyers to enhance proper coordination and collection of new research results and innovations for patenting will be more effective than the use of Institute Technology Management Committees (ITMC), Institute Technology Management Units (ITMU), Central Technology Management Committee (CTMC), Zonal Technology Management Committee (ZTMC), Zonal Technology Management Unit (ZTMU),

ABSTRACT
The study determined the use of mobile phones to disseminate agricultural information between extension agents and farmers in Oyo State, Nigeria. Structured questionnaire and interview sessions were used to obtain data from 120 extension agents. Descriptive statistics was used to analyze the result obtained. Male and female extension agents in the state comprised 85% and 15% respectively. The highest age range was between 31 – 40 years with 46.7%. Majority of the respondents (98.3%) had tertiary education and 74.2% had put in less than 10 years of service with the ADP. Almost, all the respondents (98.3%) owned personal mobile phones. Those who owned ordinary phones were 67.5 while 32. 5% had phones with multi-media effects. Those who used their phones for agricultural messages were 92.5% and information sent in order of importance are notice of meetings (96.7%), feedback to famers' questions (93.3%), offer of solution to farmers problems (91.7%) and prices and cost of products (90%), notification of disease and pest outbreak (82.5%) and introduction of new technologies (81.7%). Voice calls (59.5%) and short messages systems (40%) are the mobile phone technologies used mainly by respondents. The average time spent in calling a farmer by all respondents is less than 2 minutes. The weekly amount spent on the recharge cards are below N1, 000 (60.8%). Only 4.2% received official allowance for recharge cards. All the respondents agree that mobile phones enhance general access to information, and 83.3% believed that it reduces the number of group meetings. The use of mobile phone enhances information and technology transfer and should be encouraged by all stakeholders in agriculture.
Keywords: Mobile phones, Agricultural messages, Dissemination, Technology

INTRODUCTION

Information and communication technology (ICT) play a major role in bringing agricultural information to rural communities, especially in the delivery of information and technical advice to farmers through extension services. There are many technologies with potentials to improve the economy of the rural farmers, in research institutes that are kept in their files and shelf. Interactive forum for research, extension agents, and farmers is either inadequate or not efficiently done due to inadequate funding. Agricultural extension is an important means of enabling farmers to benefit from agricultural research and development by taking the interventions and innovations to them. Survey has revealed that only 5.7% of farmers have access to information from the extension workers, and this clearly shows that the current number of extension workers is inadequate to meet the needs of farmers. Also, it has been discovered that the use of mobile phones play a very useful role in fulfilling the information needs of farmers, most especially among marginal and small ones (Lawal, 2008) Extension workers to farmers have the ratio of 1:3000 farm families, and inadequate mobility are another constraints to dissemination of research proven, findings and relevant agricultural technologies that aim at providing solutions to poverty, hunger, and malnutrition in Nigeria (Bolarinwa and Oyeyinka, 2011). The use of mobile phones can help facilitate the link between research and extension (Chauhan,2006). Based on the foregoing, the study attempted to determine the use of mobile phones in the transfer of agricultural information by the extension agent in Oyo state of Nigeria. It examined the information types delivered by agricultural extension to farmers, its effects and constraints in its usage.

METHODOLOGY

The study was carried in Oyo state, in Nigeria. The population of the study consisted all extension agents (155) in Oyo state Agricultural Development Programme (ADP). The list of all extension officers in the 4 administrative zones in the state ADP which are Oyo, Ogbomoso, Saki and Ibadan/Ibarapa were obtained to be 34, 29, 36 and 56 respectively. giving a total of 155. All of them were purposively selected for the study. However, only 120 questionnaires were recovered. The primary data was collected through the use of questionnaires and in-depth interview with key informants. The data collected was analyzed using simple descriptive analysis such as frequencies and percentages.

RESULTS AND DISCUSSION

Table 1 below indicates that 15% of the extension agents were of the female gender, while 85% were males. Their highest age range was between 31-50 years with 72.5% while, 9.2% were above 50 years. Almost all the respondents (96.3%) had tertiary education. The result also revealed that 74.2% of the respondents had worked as extension agents for less than 10 years, while 25.8% had worked for above 10 years. The involvement of extension workers in the study area seems to be tailored along gender lines as more male extension officers than females were employed. Having very few women extension workers could affect agricultural educative outreach program that are female specific.

Table 2 shows that 99.2% of the respondents personally owned their mobile phones while 0.8% did not. While 67.5% used ordinary (low technology phones) 32.5% used high technology multimedia phones which enables them to send picture messages and carry other more high profile activities. Majority of them (92.5%) used their mobile phones to contact the farmers and disseminate agricultural information to them. This shows that usage of phones for extension work is a veritable tool for agricultural development and information transfer and it supports the statement by Chauhan (2006) that use of mobile phones can help facilitate the link between research and extension.

According to the result in Table 3 extension agent made use of their phones for the following types of information: notification to farmers about meeting (96.7%), updating farmers about the cost of produce (90.0%), notification of pest and disease outbreaks (82.5%), providing information on new technological approaches to farming operations (81.7%), response to the questions of the farmers on an issue bothering them (91.7%), and obtaining feedback from farmers to ascertain the level of effectiveness of the information's and solution given to them (93.3%). This result depicts that the use of mobile phone is a very useful and effective tool in the extension service delivery of agents in the study area. According to Alonge *et al* (2012) after an initial personal contact with a famer by an agent further discussions can be by phones a follow up to the personal meeting.

Table 4 showed the most used mobile application to be voice calls by 59.2% and 40% used Short Message Service (SMS) to disseminate information. About 42% of the respondents spend $\leq$ 2 minutes in calling the farmers respectively, while 50% spent more than 2 minutes. Extension agents (60.8%) spent less than N1000 every week, and 33.3% spent between N1000 and N2000 for information dissemination. The 4.2% who reported funding of their expenses for recharge card from the office are likely to be top management staff who are entitled to such allowances. Extension agents' assessment of the effectiveness of the use of mobile phones using a lickert-type scale showed high and positive rating in terms of speed (95.8%) to access information and reduction in the number of meetings (74.2%) per agent. According to Alonge *et al* (2012) mobile phones are used for follow ups thereby reducing the number of visits by extension agents.

CONCLUSION

The use of mobile phones in agricultural information and technology transfer between extension personnel and farmers is very effective. The most effective mobile phone applications used are short message service and voice calls. The use of mobile phones enhances quick access to information and reduces the number of visits to farmers without reducing the quality of service delivered. For effective utilization of mobile phones by extension workers special customized phones meant for farmers/ extension activities should be introduced and allowance for air time subscription paid by the ADP.

ABSTRACT
A 55 day feeding trial involving one hundred and eighty one day old Oba Mashall was conducted to determine the performance and economic effectiveness of broiler chicks fed dietary levels of roasted baobab seed meal (RBSM). The birds were randomly allocated to four dietary treatment groups (A, B,C and D) at the levels of 0, 4.12, 8.24 and 12.36 % respectively. The parameters considered were initial weight, final weight, body weight gain, feed intake, feed to gain ratio, feed cost per kg, feed cost per kg body weight, income above feed expenses (IAFE) and mortality rate. The result from this study revealed that all the birds on RBSM dietary treatment performed better than those on control diet. The performance improved with increased dietary levels of RBSM. The cost analysis indicated that the control diet had higher feed cost/kg, and feed cost/kg body weight gain than those on the RBSM diets. The control diet had lower IAFE than those on treatments. The lower feed cost/kg, feed cost/body weight gain and higher IAFE observed in birds fed diets containing RBSM in this study is due to low cost price of baobab seed. In conclusion, dietary inclusion of RBSM at 12.36 % both reduced cost of production and did not impair the performance of birds.

INTRODUCTION
There has been an unprecedented demand for meat and other animal products in recent times. According to FAO (2004), the increase in demand for animal products will likely be at the rate of 3.3% per year. In animal production, poultry production has the highest turnover rate and quickest returns to investment outlay (Ogundipe and Sanni, 2002), which had led to the rapid growth in poultry enterprise in Nigeria. However, the sudden decline noticed in the industry is attributed to lack of feed. Esonu *et al.* (2001) reported that about 50% of Nigeria poultry farms have been closed down and another 30% will likely reduce their production capacity due to lack of feed. While poultry producers want to maximize profit, consumers on the other hand desire quality products. The cost of producing poultry products using conventional feedstuffs that are in high competition with human is on the increase Therefore, to bridge the gap between poultry products prices and consumer purchasing power, the nutritionists and researchers have resorted to alternative feedstuffs with little or no competition between man and livestock industry (Adeosun *et al*., 2004; Adeosun *et al*., 2013; Sola-Ojo *et al*., 2013), and yet without compromising quality for low cost. Onimisi *et al.* (2009) working on quality protein maize (QPM) opined that the rapid demand in feed stuff for livestock could only be met by cereals which have potential for increasing productivity and improve nutritional value through better feed efficiency. However, these cereals are equally in demand for human consumption. As researchers therefore explore new and non-conventional crops, it is important to sort out free crops grown in such region where poultry production is situated. Baobab is a well adapted deciduous tree crops found in most part of Africa FAO (1980). These plants are indigenous in Katsina state and are in abundant supply.
The seed being rich in protein and fats will play a dual role in meeting both energy and protein requirements of broiler birds. Saka *et al.* (1994) reported that baobab seed contains 29.6% fat, 28.7 crude proteins and 7.3% crude fibre. Saulawa *et al.* (2014) worked on different methods of processing baobab seed, and reported ranges of proximate composition, as 18.68 to 28.85% CP, 2.19 to 4.41 ether extract and 8.29 to 10.78% CF. The aim of this study therefore, was to evaluate the growth performance and cost implication of feeding roasted baobab seed meal to broiler chickens.

MATERIALS AND METHODS

The experiment was carried out at Federal University Dutsinma Katsina's Livestock Research and Teaching farm. A total of one hundred and eighty one day old Oba Marshall purchased from commercial supplier was used in this study. The birds were weighed with similar average weight and allocated to four dietary treatment groups which were further divided into 3 replicates with 15 birds per replicate. The baobab seed purchased in Dutsin-Ma Local Government area of Katsina State were washed, sun-dried, roasted to golden colour and ground to a meal and then used to formulate the diets for starter and finishers phases (Table 1 and 2). The roasted baobab seed meal (RBSM) was included to four dietary treatments, A, B,C & D at levels of 0 (Control), 4.12, 8.24 and 12.36% respectively. This was done in accordance with NRC (1994) requirements. The experiment ran continuously for a period of 8 week. All necessary routine management with vaccination schedule was followed.

The parameters measured were initial weight, final weight, body weight gain, feed intake, feed to gain ratio, feed cost/kg, feed cost/kg weight gain and mortality rate. Income above feed expenses was also considered. All data collected were summarized and analysed statistically according to Steel and Torrie (1980) and significant means separated using Duncan Multiple range test (Duncan, 1955).

RESULTS AND DLSCUSSION

Table 3 shows the performance of broiler chickens fed dietary levels of RBSM. No significant ($p>0.05$) difference was observed among treatment means in final weight, body weight gain, feed intake and feed conversion ratio. Sola-Ojo *et al. (2013*) reported better performance in birds fed decorticated undefatted baobab seed meal (DUBSM) at 7.55% inclusion level. However, Ezeagu (2005) reported lowered weight gain in rats fed heat treated baobab seeds, while Hayward *et al.* (1936) reported that heat treatment enhances nutritive value of proteins by making sulfur containing amino acid readily available. It was also noticed from this study that feed cost/kg decreased as the inclusion levels of RBSM increased in the diets. The lowered feed cost/kg might be attributed to low price of baobab seeds which eventually resulted in low feed cost/kg weight gain. It is therefore concluded that inclusion of RBSM up to 12.36% in broilers diets was beneficial to growth performance of birds and also resulted in better economy of production.

CONCLUSION

In conclusion therefore, the inclusion of RBSM in the diets of broiler chickens resulted in low feed cost/kg, feed cost/kg weight gain and higher income above feed expenses; it is therefore less expensive to include RBSM in broiler diets compared with soybean meal.

ABSTRACT
A 74-day feeding trial was conducted to study the effect of yellow root cassava peel-centrosema leaf meal based diets on haematology of 36 West African Dwarf (WAD) goats. Four diets were formulated such that diets A, B, C and D contained 0%, 10%, 20% and 30% centrosema leaf meal. The diets were offered to the growing goats, which were randomly divided into 4 groups of 9 goats each, with three goats constituting a replicate in a completely randomized design. Each animal received the designated diet on 3.5% body weight basis in addition to wilted Panicum maximum. Result showed on the proximate analysis revealed that the diets were within the nutritional requirements of goats. Results showed that packed cell volume (PCV), haemoglobin (Hb), mean cell haemoglobin concentration (MCHC), mean cell volume (MCV) and white blood cell (WBC) differed (P<0.05) significantly, while red blood cell and mean cell haemoglobin were similar (P>0.05) among the groups. PCV, Hb, MCHC, MCV were improved (P<0.05) by the test diets. White blood cell (WBC) count of goats in treatment groups were significantly (p<0.05) higher and better than the control. All the haematological indices studied fell within the normal reference range reported for clinically healthy goats; an indication that of the diets had no detrimental effect on blood formation and health status of the animals.
Keywords: β-Carotene Cassava peel, centrosema Leaf meal, WAD goats, unconventional feedstuffs, blood

INTRODUCTION

Cassava is an adaptable crop that grows on marginal soils and is able to withstand disease and drought. As one of the major sources of staple food in Africa and Latin America, the need for genetic improvement became very necessary. The provitamin A (yellow root) cassava have been developed either through traditional plant-breeding or bioengineering (Sayre *et al*., 2011). Cassava with higher levels of provitamin A can help reduce vitamin A deficiency among undernourished communities that rely upon cassava for sustenance. The new yellow root cassava varieties have potential of providing up to 25% of daily Vitamin A requirements of children and women (Aniedu and Omodamiro, 2012). Yellow root cassava is very high in carotenoids. More recently, protective effects of carotenoids against serious disorders such as cancer (Donaldson, 2004), heart disease (Sesso, 2003) and degenerative eye disease (Mozaffarieh, 2003) have been recognized, and have stimulated intensive research into the role of carotenoids as antioxidants and as regulators of the immune response system. These numerous advantages has led to high demand for yellow root cassava for different human or industrial uses thereby enhancing the availability of the peels which are grossly underutilized and were hitherto discarded as waste. The yellow root cassava peels are made up of mainly polysaccharides and carotenoids; hence holds inestimable potentials as energy and vitamin A sources for goats. However, due to its crude protein deficiency, the need to supplement with readily available non competitive unconventional protein source like *Centrosema pubescens* leaf meal becomes imperative. Nworgu and Egbunike (2013) reported 23.24% CP in *Centrosema pubescens* leaf meal; hence being a potential protein source in a goat production.

Evaluation of the blood profile of animals may give some insight as to the potentials of a dietary treatment to meet the metabolic needs of the animal hence Church *et al*. (1984) noted that dietary components have measurable effects on blood constituents such that significant changes in their values can be used to draw inference on the nutritive value of feeds offered to the animals. Haematology is a good indicator of the physiological status of an animal. The assertion of Ikhimoya and Imasuen (2007) that most of the available information on haematological parameters of goats in the humid tropics is based on disease prognosis from the region. Thus, data on haematological profile of West African dwarf (WAD) goat offered agricultural by product and leaf meal from non-conventional sources are scanty.

However, the sourcing for readily and locally available feed ingredients to enhance food production stimulated this research which aimed at evaluating the efficacy of yellow root cassava peel – centrosema leaf meal based diets on the haematological parameters of West African dwarf goats.

MATERIALS AND METHODS

The experiment was carried out at the sheep and goat unit, Federal College of Agriculture, Ishiagu, Ivo L.G.A., Ebonyi state, Nigeria.

Fresh yellow root cassava peels varieties (TMS011368, TMS011412 and TMS1371) were obtained from National Root Crops Research Institute, Umudike, Abia State, Nigeria. The peels were subsequently dried to about 10% moisture content before milling and used in the formulation of yellow root cassava peel-centrosema leaf meal based diets. Fresh green *Centrosema pubescens* leaves were harvested within the College environment. The *Centrosema pubescens* were shade-dried in batches, milled and also used at different levels in the formulation of yellow root cassava peel - centrosema leaf meal based diets.

Thirty six (36) WAD goats of about 8 – 10 months of age were selected from the College herd for this experiment. The goats were randomly divided into four (4) groups of nine (9) animals each with 3 goats constituting a replicate. The groups were randomly assigned the 4 experimental diets (A, B, C and D) in a completely randomized design (CRD). The animals were housed individually in well ventilated cement floored pens equipped with feeders and drinkers. Each animal received a designated treatment diet in the morning for 74 days. Feed offered was based on 3.5% body weight per day; the animals in addition were fed 2kg wilted *Panicum maximum* later in the day. Regular access to fresh drinking water was made available.

Experimental diets designated as A, B, C and D were formulated from yellow root cassava peel, brewers dried grain, palm kernel meal, wheat offal, *Centrosema pubescens* leaf meal, bone meal, molasses and salt. Diet A served as a positive control and contained 0% of yellow root cassava peel - centrosema leaf meal based diets. Diets B, C and D contained 10%, 20% and 30% inclusion levels of centrosema leaf meal based diets respectively as illustrated in Table 1.

All feeds and test ingredients were analyzed for proximate compositions using the method of AOAC (2000) as presented in Table 2.

Blood samples (4ml) were drawn from the animals on the last day of the study. The goats were bled through the jugular vein and used for haematological studies. Mean cells haemoglobin (MCH), MCV and mean cell haemoglobin concentrations (MCHC) were calculated.

The results were analyzed using the Special Package for Social Sciences Window 17.0. One -way analysis of variance (ANOVA) was employed to determine the means and standard error. Treatment means were compared using Duncan's new multiple range test (Duncan, 1955).

RESULTS AND DISCUSSION

The chemical compositions of the experimental diets, yellow root cassava peel meal (YRPM) and *centrosema pubescens* leaf meal (CLM) used in this study is presented in Table 2. The proximate values for the yellow root cassava peel meal showed a higher crude protein (CP), ash and ether extract (EE) and lower crude fibre (CF) values compared to the reports of Ahamefule *et al*. (2005) for cassava peel meal. The differences could be attributed to the improvements that have been carried on the yellow root cassava. The proximate compositions of the *centrosema pubescens* leaf meal in this study are comparable with the findings of Nworgu and Egbunike (2013) for the same leaf meal. The dry matter levels of the test diets (B, C and D) compared favourably well with the control diet (A). The CP, ash and ether extract of the test diets were higher than the control diet and tended to increase with the increasing levels of CLM in the diets. The fibre content on the other hand is higher in the control diet and tended to decrease with increasing levels of CLM. The nitrogen free extract and gross energy did not show any specific trend among the diets.

The haematology of West African dwarf (WAD) goat fed yellow root cassava peel-centrosema leaf meal based diets is presented in Table 3. The study of the haematological parameters is in agreement with the view of WHO (1963) that blood examination is a reliable way of assessing the health status of animals as it plays a vital role in the physiological, nutritional and pathological status of animals. The packed cell volume (PCV) values (%) for the treatment groups fell within the normal range for WAD goats (21-35%), as reported by Daramola *et al*. (2005) and differed significantly ($P<0.05$) among the treatment groups. PCV is generally used as an index of toxicity and its value is influenced by breeds, age and sex. The significant increase in the concentration of PCV in the blood usually would suggest the absence of a toxic factor like haemagglutinin which had adverse effect on blood formation (Jiwuba *et al*., 2016). *Centrosema pubescens* had been reported to contain 20.01mg/kgDM iron (Nworgu and Egbunike, 2013) and yellow root cassava implicated to contain high level of vitamin A; a fat-soluble vitamin, involved in a number of physiological processes like hematopoiesis (Guimarães *et al*., 2014). It is possible that traces of iron and the vitamin A still abiding in the treatment diets may perhaps have been responsible for the improved values.

The haemoglobin (Hb) value of the treatment groups differed ($P<0.05$) significantly with diet A animals having the lowest (10.77g/dl) and diet D animals the highest value of 13.23g/dl. The Hb concentration compared

favourably with the normal range of 7-15g/dl reported by Daramola *et al*. (2005) for WAD goats. The high level of Hb of animals on diet D relative to other treatment groups may imply that the dietary protein was of higher quality, probably due to 30% fortification of the diets with *Centrosema pubescens* leaf meal. This agrees with the observation of Esonu *et al*. (2003) that one of the possible sources of cheap protein in the diets is the leaf meal of some tropical legumes. Diets containing poor quality protein would usually influence poor transportation of oxygen from the respiratory organs to the peripheral tissues (Robert *et al*., 2000).
Mean cell haemoglobin concentration (MCHC) and mean corpuscular volume (MCV) of the WAD goats fed yellow root cassava peel-centrosema leaf meal based diets differed significantly (P<0.05) while mean cell haemoglobin (MCH) values were similar (P>0.05) among the treatment groups. All the values however fell within the reference range for goats as reported by Fraser and Mays (1986). The normal range of MCV, MCHC and MCH recorded in this study for the WAD goats gave a clear indication of the absence of anaemia among the experimental groups. In humans, a close relationship between vitamin A deficiency and anemia has been long recognized (Semba and Bloem, 2002).
White blood cells differed significantly (P<0.05) among treatment groups. The values obtained in this study (8.82-11.69 ×109/l)) were within normal range of 6.8-20.1 x10/ul for WAD goats and 4–13×109/l as reported by Daramola *et al*. (2005) and Fraser and Mays (1986) respectively. WBC of the goats showed an increasing value in relation to an improvement of the immunological system. Vitamin A is has been extensively studied for its influence on immunity due to its requirement for normal functioning of the immune system. Vitamin A deficient people are more prone to more severe infections and have a higher mortality than vitamin sufficient people (Beaton et al., 1992).

CONCLUSION

In conclusion**,** yellow root cassava peel-centrosema leaf meal based diets could stimulate erythropoiesis and influence immunity of goats. It is therefore recommended to boost the blood indices of goats, since all the parameters studied were within the normal reference range for goats. The inclusion of yellow cassava peel-centrosema leaf meal at 30% produced the best performance and therefore encouraged as animal feed supplement to enhance goat production.

ABSTRACT
A feeding trial was conducted to determine the growth and organ characteristics of growing rabbits fed dietary levels of Moringa oleifera leaf meal (MOLM). A total of forty eight growing rabbits with an average initial weight of 588.05g were randomly divided into four experimental groups of twelve animals each, with four rabbits constituting a replicate. Four diets were formulated such that diets T1, T2, T3 and T4 contain MOLM at 0%, 10%, 20% and 30%, respectively and fed to the animals for 41 days. Results on average daily feed intake differed significantly (P<0.05) with rabbits on T4 diet having the highest intake of 89.84 g/day. However, average daily weight gain was different (p<0.05) across the treatments but was highest for T3 and T4 animals which were statistically (P>0.05) similar. Feed conversion ratio differed significantly (P<0.05) and was also best for T3 and T4 rabbits. Liver and kidney showed significant (P<0.05) decrease on organ weight with increasing levels of Moringa oleifera leaf meal in the diets of grower rabbits. Diets T3 and T4 promoted the best performance among the treatment diets and are therefore recommended for rabbit production.
Keywords: rabbits, ***Moringa oleifera*, performance, organ, alternative, protein resource.**

INTRODUCTION
Rabbits are highly prolific animals capable of increasing the animal protein intake among the increasing population in the developing countries like Nigeria. They are sources of cheap animal protein and mostly used in experimental research and to a lesser extent, pets and fur production in Nigeria and most other West African countries. Rabbit meat is highly nutritious, easily digestible, tender and extremely low in cholesterol and sodium hence, suitable for those with various health conditions.

Inadequate nutrition opposes rabbits in expressing their full potential. This may be due to the high cost of conventional feedstuffs and little knowledge about the efficient utilization of unconventional crude protein sources. Intensive approach to rabbit production would however entail the use of alternative nutritionally viable sources other than the conventional ones to enhance the production of meat at affordable price; hence the need for multipurpose tree species (MPTS) such as *Moringa oleifera* to improve animal performance (Jiwuba *et al*., 2016). *Moringa oleifera* is known with diverse names; miracle tree in English language and Okochi egbu in Igbo language. *Moringa oleifera* is one of the most widely cultivated species of the genius *Moringa* and serves as a nutritious vegetable tree with a variety of potential uses (Ramanchandran *et al*., 1980). Its leaves are used as vegetables by humans with good medicinal values and are rich in carotene and ascorbic acid with a good profile of amino acids, vitamins A, B and C, Ca, Fe, P (Makkar and Becker, 1996). Therefore this study was designed to determine the effects of dietary levels of *Moringa oleifera* leaf meal on growth and organ characteristics of growing rabbits.

MATERIALS AND METHODS
The research was carried out at the Rabbit Unit, Federal College of Agriculture, Ishiagu, Ivo Local Government Area of Ebonyi State, Nigeria.

Fresh leaves of *Moringa oleifera* were harvested within the College environment and air dried for some days to a moisture content of about 10%. The dried leaves were processed and milled.

Four diets, T1, T2, T3 and T4 were formulated from maize, wheat offal, soybean, fish meal, palm kernel cake, *Moringa oleifera* leaf meal, bone meal, limestone, vitamin premix, methionine, lysine and common salt. Treatment one (T1) did not contain the test ingredients, thereby serving as the positive control. The experimental diets were formulated such that *Moringa oleifera* leaf meal was included at the levels of 0%, 10%, 20% and 30% for T1, T2, T3 and T4 respectively as presented in Table 1.

Forty eight growing rabbits were randomly divided into four (4) experimental groups of twelve (12) animals each, with four (4) rabbits constituting a replicate. The four treatment groups were assigned the four experimental diets in a Completely Randomized Design. Each rabbit received an assigned diet for forty one (41) days. Regular access to fresh drinking water was made available. Feed offered and refusal was recorded on a daily basis. Initial weights of the animals were taken at the beginning of the trial and weekly subsequently. Average feed daily intake, average daily weight gain and feed conversion ratio were calculated accordingly.

At the end of the feeding trial, two rabbits per replicate were randomly selected, starved of feed for twenty four hours, weighed, stunned and bled through the jugular vein. The dressed carcass was weighed expressed as percentage of carcass weight. The organ weights were determined and expressed as the percentage of dressed weight.

All feeds and experimental materials were analyzed for proximate compositions using the standard method of (AOAC, 2000) as presented in Table 2. Metabolizable energy calculated using the formula; ME = (3.5 X Crude protein) + (8.5 x crude fat) + (3.5 x Nitrogen Free Extract) x 10.

The results were analyzed using the Special Package for Social Sciences Window 17.0. One -way analysis of variance (ANOVA) was employed to determine the means and standard error. Treatment means were compared using Duncan's new multiple range test.

RESULTS AND DISCUSSION

The proximate compositions of *Moringa oleifera* leaf meal and experimental diets are presented in Table 2. Proximate analysis of *Moringa oleifera* leaf meal and experimental diets revealed the presence of dry matter, crude protein, crude fibre, ether extract, ash, nitrogen free extract and metabolizable energy. The dry matter values of the test diets (T2, T3 and T4) compared favourably with the control diet, but however did not show a specific trend. The crude protein of the experimental diets ranged between 18.03 - 19.92% and tended to decrease with increasing levels of the test diets. The crude protein, crude fibre and energy values met the requirements for rabbits

The growth performance of grower rabbits fed diets containing *Moringa oleifera* leaf meal is presented in Table 3. The average daily weight gain differed significant ($P<0.05$) with T2, T3 and T4 having higher values than T1. The result of the present study on average daily weight gain (16.71 - 21.90g) comparable to the range of values (15.68 – 25.36g) for rabbits fed sorghum offal-based diets as reported Ogunsipe *et al*. (2014) respectively. The result of the present study on weight gain is in agreement with the results of Nuhu (2010) for weaner rabbits fed *Moringa* leaf meal diets showing significant ($P<0.05$) increase in daily weight gain over the control diet. The increase in body weights of the rabbits on test diets may be attributed to the high biological values of protein of *Moringa oleifera* leaves. The proteins of *Moringa oleifera* have very high biological values and all the essential amino acids present in Moringa are in a greater concentration than that mentioned in the feed reference for soybeans (Zarkadas *et al*., 1995). Similarly, Melesse *et al*. (2011) reported that use of *Moringa* leaf meal in the diet of Rhode Island Red chicks produced significant ($P<0.05$) increase in weight gain, when compared to a control diet. The authors also related these findings to the presence of readily available protein in Moringa leaf meal, which is convenient for monogastric animals and also to the higher levels of methionine and other essential amino acids when compared to the soybean meal of a control diet. Average daily feed intake and feed conversion ratio were significantly ($P<0.05$) affected by the treatment diets, with the animals on test diets having higher values than the animals on the control diet. The progressive increase in feed intake is in agreement with the findings of Bouatene *et al*. (2011) for young post-weaning rabbits fed *Moringa oleifera* leaves. The significant ($P<0.05$) increase in feed intake among the test diets could be attributed to the biological function of *Moringa oleifera* leaf meal that have been essential for vitality and health of the animals. The leaves of *Moringa oleifera* are rich in minerals (C, Ca, Fe and P), vitamins such as A, B, C and E and balanced protein with good profile of essential amino acids (Makkar and Becker 1996; Fahey, 2005). These high biological values could explain the improvement in body weight, feed intake and feed conversion ratio of rabbits fed the diet containing MOLM. The feed conversion ratio (FCR) values in this study are a true reflection of how the diets were utilized for growth as evidenced in their increased weight gain in T3 and T4.

The organ characteristics of grower rabbits fed dietary levels of *Moringa oleifera* leaf meal is presented in table 4. The slaughter weight, carcass weight and dressing percentage were significantly ($P<0.05$) influenced by the treatment diets. Rabbits fed the diet containing *Moringa oleifera* leaf meal had higher ($p<0.05$) slaughter and carcass weight than the rabbits fed the control diet. Carcass weight is a very important parameter of carcass characteristics hence the higher the carcass weight the higher the degree of meatiness and economic value of that carcass. Animals on T3 and T4 diets were similar ($P>0.05$) but significantly ($P<0.05$) different from T1 and T2 which were ($P>0.05$) similar for dressing percentage. The dressing percentage ranged between 52.69 to 62.16% with the highest in T4 (30% MOLM) animals (62.16%) and lowest in T1 (0%MOLM) animals (52.69%). The observed significant ($P<0.05$) difference may be due to differences in the body weight of the rabbits at slaughter The high dressing percentage observed in this study may also be related to the high meatiness and fat values recorded with the carcass. This finding is in agreement with the report of Fielding (1991), who stated that the dressing percentage of rabbits normally ranges from 50 to 56% and tends to be greater if the rabbits are fully grown and have some fat. In a feeding trial, the weight of some internal organs especially liver and kidneys are commonly used to determine the effect of toxicity on the animals. Bone (1979) reported that if there is any toxic element in the feed, abnormalities in weights of liver and kidney would be observed. This abnormal increase in weight could be as a result of increased metabolic rate of the organ in attempt to reduce these toxic elements or anti-nutritional factors to non-toxic metabolites. The significant (P<0.05) lower values of liver and kidney values of the rabbits on the test diets (*Moringa oleifera* leaf meal) over the control rabbits suggest that the test diets did not contain any appreciable toxin and thus supported the normal metabolic and physiological function of the animals; a view corroborated by Fahey (2005). However, the values for the spleen, lungs and heart were not significantly (p>0.05) affected by the dietary treatments, which suggests the safety of the *Moringa oleifera* leaf meal as a non-conventional feedstuff capable maintaining the normal metabolic function and reducing cost of production in rabbit.

CONCLUSION

From the results, it could be concluded that rabbits fed diets containing *Moringa oleifera* leaf meal recorded the best weight gain, feed intake, conversion ratio and organ weight. Therefore, *Moringa oleifera* leaf meal could be used as a cheaper protein source to enhance rabbit production without any detrimental effects on performance and carcass characteristics of rabbits.

EFFECTS OF GRADED LEVELS OF GINGER (*Zingiber Officinale*) ON HAEMATOLOGY OF BROILER CHICKENS

S. I. Imasuen, I.B. Amaza, E.E. Adomeh & C. E. Isidahomen

Department of Animal Science, Ambrose Alli University, P. M. B. 14, Ekpoma, Edo State
ebicley2k@gmail.com

ABSTRACT
A total of 120 Broiler chickens were used in an experiment to determine the effect of haematology of broiler chickens fed diets supplemented with ginger (Zingiber officinale) in a complete randomized design which lasted for eight weeks. Diet 1 (Control) contained no ginger, diets, 2, 3, 4 and 5 contained 0.5%, 1.0% ,1.5% and 2.0% ginger respectively. Blood samples were collected and analyzed for Hematological attributes Results on the hematological values obtained from the experimental birds showed significant (P<0.05) dietary treatments effect. Notably, the birds consuming 1.5% ginger had the highest values for PCV (27.57±0.49 , 27.75±1.56, 26.58±0.58, 20.77 ± 0.69 and 20.03±2.79 %) and Hb (9.52±0.13 ,9.35±0.29 ,9.32±0.30 ,8.35± 0.42 and 7.23±0.96 g/dl). It can be concluded that the inclusion of ginger (Zingiber officinale) to the broiler diet enhances the health statue. The chickens can tolerate ginger root powder up to 1.5%.
Keywords: Ginger, Broilers, Haematology

INTRODUCTION
Feed additive are added in animal feed to improve their nutritive value, boost animal performance by increasing their growth rate, better feed conversion efficiency, greater livability and lowered mortality in poultry birds (Zomrawi *et al.*,2013). Ginger (*Zingiber officinle*) has been widely used as a condiment and as a herbal medicine to treat a wide range of disorders (Ali *et al,* 2008). Recently Ahn *et al*, (2002) showed that, use of plants extracts as natural antioxidants has gained increasing interest because of the global trend of restriction in the use of synthetic substances (Zhang *et al*, (2009). These preparations have been shown to activate digestion, strengthen the immune system and have antibacterial properties. Medicinal plants are used as primary health care aid among eighty percent of the world's population in the form of plant extracts or their active component (WHO, 2008). The objective of the study is to evaluate the response of ginger, (*Zingber officinale*) diets on the physiology of birds in the humid zone of southern Nigeria.

MATERIALS AND METHOD
Design, Experimental Birds and Experimental Diets
A total of 120 Anak broilers were used for the experiment. Twenty four (24) birds were randomly selected based on their average initial weights to each of the five treatment diets. Each treatment group contains three replicates with eight (8) birds per replicate and they were assigned to the five treatment diets in a complete randomized design (CRD).Diets T1 were formulated to contain 0% (control diet), diets T2 contain 0.5% ginger, diet T_3contain1.0% ginger,T4 1.5% ginger and T_5 contain 2.0% ginger respectively.
Blood sample collection
Blood sample was collected before and after the end of the experiment. The birds were fasted over night and blood was collected from the Jugular veins. Specimen for haematological studies were collected separately in a bottle containing dipotassium salts of ethylene diamine tetra-acetic acid (EDTA) as anticoagulant while, anticoagulant free tubes were used for collecting blood samples for biochemical analyses. The blood samples were analysed using routinely available clinical methods. These include packed cell volume (PCV) or haematocrit, red blood cell (RBC) count and white blood cell (WBC) count and haemoglobin concentration (Hb), using Witrob's micro-haematocrit, improved Neubaur haemocytometer and cyanomethaemoglobin methods, respectively. The erythrocyte indices, mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCHC) were computed according to Jain (1986).
Experimental design and statistical analyses
All data obtained were subjected to analysis of variance to investigate the effect of treatment on serum biochemistry and lipid profile, using the General Linear Model of SAS (1999). Duncan's Multiple Range Test was used to separate the means that are significantly difference (Gomez and Gomez, 1984).

RESULTS AND DISCUSSION
Blood parameters results are presented in Table 1.Parameters includes hemoglobin concentration (Hb), packed cell volume (PCV)%, erythrocytes (RBC), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC)% were significantly (p<0.05) affected by dietary treatments. Results in the current study observed higher values of PCV and Hb values for birds fed 1.5%

ginger root powder did not agree with the findings of Al-Homidan (2005) and Ademola *et al*. (2009) who found a significant decrease in blood parametrs when feeding chicks up to 6% ginger. However, the results of the present study were consistent with the results of Al- Kassie, (2009), who found that the group fed with cinnamon and thyme oils had significantly higher (PVC) counts compared with the control group.

ABSTRACT
One strategy for inducing novel genetic variation in both sexually and in apomictic species is mutagenesis. In this study, dry maize seeds were exposed to different doses of gamm-rays (75-600 Gy) to determine the optimum radiation dose for mutation induction. M_1 generation was raised and studied with respect to different morphological parameters such as germination, growth, survival and seedling height. The developed seedlings response were dose dependent compared to the control. The calculated LD_{50} value based on survival percentage may serve as a baseline for mutation induction and for the specie improvement programme.
Keywords: Mutation, Breeding, Robust, Adjunct

INTRODUCTION
Since the turn of the 21st century, the successes and recognition of mutation technologies was unprecedented due to a rapid and better understanding of the technique. Retrospectively, the term "mutation breeding" was first described by Freisleben and Lein (1944) as a deliberate induction and development of mutant lines for crop improvement, although the technique was originally defined in a series of articles by de Vries (1901, 1903 and 1905) as a sudden heritable change in the genetic material of an organism. Through all these years, the technology has played a significant role in increasing and improving food production and quality. It could and have induced new agronomic traits in crop plants that either may not be found in nature or have been lost during evaluation. In nature, a mutant normally occurs as errors during DNA replication, but the frequency of genetic variation is rather minimal, necessitating the need for mutation induction. To achieve genetic variability in plants through conventional breeding; hybridization, crosses and recurrent selection techniques are used by breeders to recombine and integrate favourable gene combinations into elite genotypes. However, conventional breeding often fails to achieve desirable results, necessitating additional approaches such as genetic engineering and mutation breeding.

Amongst the two methods of mutagenesis (physical and chemical), chemical mutagenesis is acclaimed to be more effective and an important strategy in creating genetic variability in crop plants. Presently, gamma-rays and alkylating agents (ethyl methane sulphonate (EMS), -1-methyl-nitrosourea (MNU) and -1-ethyl-nitrosourea (ENU)) are the prime choice of mutagens, however, x-rays and ion-beams are now contending agents. Currently, mutation breeding has produced over 3,220 mutant cultivars in over 220 crop species (http://mvd.iaea.org). However, the interest placed on gamma-ray mutagenesis for the past ninety five years has been on its ability to generate large populations of mutant cultivars of which over 60% has been released.

Crop yield is of prime importance to farmers and some of the challenges facing food security globally are the continuous increase in human population and changing climatic conditions. Changes in climatic conditions are associated with increased risk of crop failure and uncertainties in the form of storms, flooding, extreme temperatures, drought and salinity. Such changes in weather condition trigger new incidences of pests and diseases. To circumvent this development, mutation induction comes to the rescue. This becomes a possibility because mutation induction is rapid and could create new crop varieties with diseases and drought resistance etc. Compared to spontaneous mutations that is severely limited by their low frequency and rare occurrence in nature, induced mutations can be increased greatly by treatments with mutagens to produce 10^3 times more mutants compared to spontaneous mutations (van Harten, 1998).

METHIODOLOGY
Seeds of local cultivar of maize (*Zea Mays*) were used for the experiment. The healthy seeds were equilibrated in a vacuum desiccator over glycerol (60%) and left at room temperature for 5 days in order to lower the seed moisture content to 12-14%.

Twenty seeds each were exposed to 75, 150, 300, 450, and 600 Gy doses of gamma rays from a cobalt 60 gamma radiator. The corresponding exposure time was 38, 79, 161, 243 and 325 seconds respectively. Seeds were sown in a prepared seed bed at the green house in the Seibersdorf research laboratory, Vienna, Austria in three replicates. Unirradiated seeds were also planted in the experiment as control. Germination, seedling height and survival percentages against different doses of gamma irradiation were recorded after 2 and 4 weeks of sowing.

RESULTS AND DISCUSSION

The schematic representation of the protocol is as presented in Fig. 1. Result shows that the growth parameters were dose dependent and that the decrease was proportional to the increase in dosage (Fig. 2). In plant experimental mutagenesis, seedlings are exceptionally sensitive to mutagenic agents and provides an easy means of assessing treatment effects (Kodym et al., 2011) and is usually used as an index in determining the biological effects of various physical and chemical mutagens in M_1 population (Cheema and Atta, 2003; Harding et al., 2012). In this experiment, seedling height decreased with the increase of the mutagen dosage (Fig. 2). Physical mutagen (gamma-rays) can directly cause double stranded-DNA breaks (DNA DsBs) thereby inducing physiological damage in the growth parameters of the M_1 generation. The observed response is associated with variation in auxin level, changes in the specific activity of several enzymes and physiological injury in the seeds and seedlings as a result of the exposure to gamma-rays (Reddy et al., 1992).

The percent growth and seedling height curves using a simple linear regression (Excel 2007) for different doses of gamma irradiation are as shown in Figs 2A and B. LD_{50} value was calculated as 348. LD_{50} usually produces maximum variability with minimum numbers of undesirable mutants. Defined as the dose at which 50% of the irradiated biological objects die after irradiation, it is also considered as a dose at which highest frequency of mutation occurs. The calculated LD_{50} value based on survival percentage may therefore serve as a baseline for mutation induction and for the specie improvement programme.

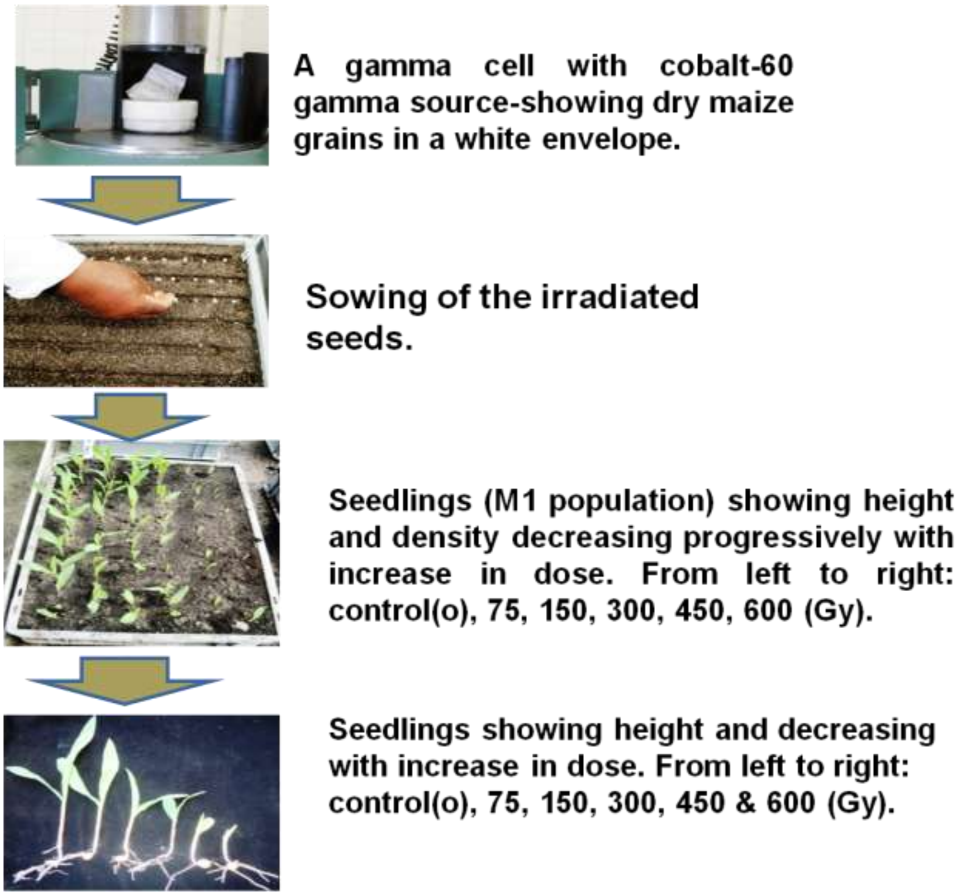

Fig. 1: Scheme for irradiation, sowing and development of seedlings for mutation breeding programme

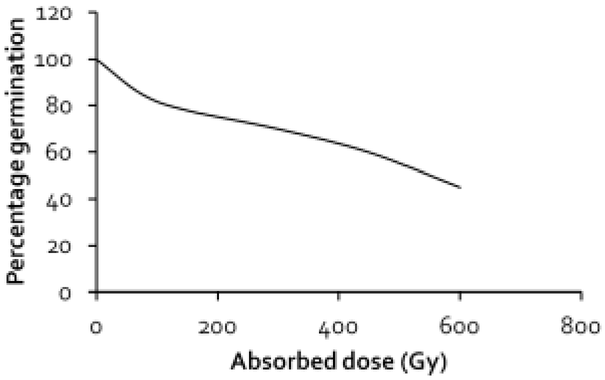

Fig. 2A: Effect of gamma irradiation on germination of white maize variety at 7 days after planting.

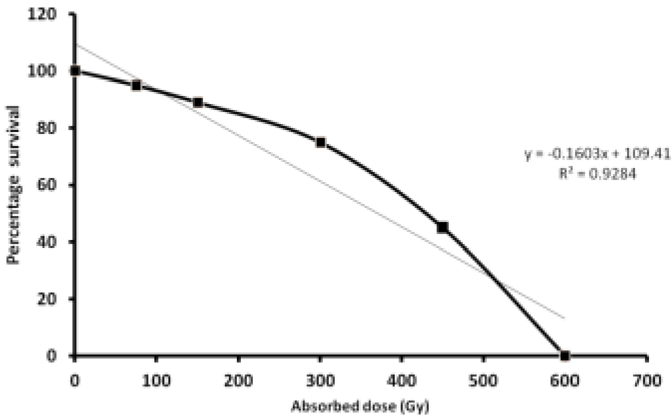

Fig. 2B: Effect of gamma irradiation on the seedlings survival at 14 days after planting

CONCLUSION

The technique has already developed "sustainable" crops that are resistant to drought, insect diseases and salinity making it an irresistible adjunct technique to classical breeding. We therefore conclude that a major advantage of mutation breeding is speed and this is becoming increasingly important with respect to responding to rapid changes in agriculture brought about by changing climatic conditions.

ABSTRACT
Solenostemon rotundifolius (*Lamiacea*) is a tuber crop in Nigeria consumed as supplementary energy food and the leaf is used in ethnomedicine for the treatment of dysentery and diarrhoea; however this claim is yet to be validated by suitable experimental model. *In vivo* antidiarrhoeal activity of ethanol extract of *Solenostemon rotundifolius* leaves was investigated on castor oil induced diarrhoea model in albino rats against , diarrhoea frequency Preliminary acute toxicity test of the leaf extract was conducted on albino rats, The plant leaf extract was administered orally to rats at dose rate of 300, 500 and 1000mg/kg. Loperamide (a standard drug) given orally at 2 and 3mg/kg was used as the positive control. The results over 4h showed significant ($p<0.05$) reduction in frequency of defecation, watery texture of faeces and cumulative wet faecal mass in rats treated with ethanol extract of *Solenostemon rotundifolius*. The plant extract significantly ($p<0.05$) reduced the weight of intestinal content and prolonged the latent time for diarrhoea induction in rats. The purging indices and faecal frequencies decreased with increase in dose up to 500mg/kg. Preliminary acute toxicity studies revealed no sign of toxicity and no death up to dose of 5000mg/kg suggesting relative safety of the plant extract at high doses. These results showed that leaves of *S. rotundifolius* possess anti-diarrheal properties which substantiate the use in the treatment of diarrhoea in traditional medicine.
Key words: *Solenostemon rotundifolius*, leaves, ethanol extract, anti-diarrhoea activity

INTRODUCTION
Diarrhoea and the associated faecal urgency and incontinence result from an imbalance between the absorptive and secretory mechanisms in the intestinal tract accompanied by hypermotility. This results in excess loss of fluid and electrolytes in faeces. (Ezenwali *et al,* 2009) Among the disease causing death in children under the age of five, diarrhoea is the second leading cause of death in developing countries (Saralaya *et al.* 2010). The World health Organization has encouraged studies into traditional medicine practices and prevention approaches with the aim of improving the management of diarrhoea (Md. Khalilur, 2013). Hence there is the need to identify and evaluate commonly available traditional drugs for their anti diarrhoea potential.
Solenostemon rotundifolius (Poir) J. K. Morton (Synonyms: *Plectranthus rotundifolius* Poir, *Coleus rotundifolius)* is of the mint family *Lamiatae* and is being reported under the genera *Coleus,Plectranthus and Solenostemon.* Its common names include Hausa potato, Frafra potato, Sudan potato, Zulu round potato, Coleus potato, Chinese potato; and the leaves are used in ethnomedicine for the treatment of dysentery, blood in urine and eye disorder (Enyiukwu *et al.*, 2014).
This study seeks to evaluate the effectiveness of the acclaimed anti diarrhoea potential of this plant using appropriate scientific model in furtherance of our search for potent medicinal agent from plant.

MATERIALS AND METHOD
Drugs: Loperamide (Square pharmaceuticals Ltd., Bangladesh), Castor oil
Chemicals: All chemicals and reagents were of analytical grade and were mainly products of Sigma-Aldrich.
Plant material: Fresh leaves of *S. rotundifolius* were collected in the month of October, 2014 from the demonstration farm of National Root Crop Research Institute Umudike and identified by experts in the Institute. The leaves were dried under room temperature, milled into powder and extracted with ethanol by continuous extraction using Soxhlet apparatus. The extract was evaporated at room temperature and gave a yield of 2% of a semi solid ethanol extract.
Animal:
Male albino rats (65-120g) obtained from the animal facility of the Faculty of Biological Sciences, University of Nigeria, Nsukka were acclimatized to normal laboratory conditions for two weeks, fed with standard rodent pellet and water *ad libitum*. All animal experiments were in accordance with the National Institute of Health Guide for Care and Use of Laboratory Animal (Pub No. 85-23 revised 1985).
Acute toxicity test:
Acute toxicity of ethanolic extract of *S. rotundifolius* was determined in albino rats using the method described by Ezenwali *et al*. (2009) with slight modification. The test was divided into two stages. In stage one, nine

randomly selected rats were divided into 3 groups (n = 3) and received 100, 200 and 300 mg/kg of the extract respectively and observed for number of deaths in 24 h. After 24 h, based on a record of zero death in the stage one test, a fresh batch of animals were divided into 3 groups (n = 3) and received 1000, 3000 and 5000 mg/kg of the extract. The animals were also observed for 24 h for deaths. No death was observed in all doses.

Castor oil-induced diarrhoea test

The effect of *S. rotundifolius* on diarrhoea was evaluated in rats using the castor oil-induced diarrhoea method (Ezenwali *et al.,* 2009 and Salaya *et al.,* 2010). The parameters observed included the latent period (the time between castor oil administration and the appearance of first diarrhoea drop) , the number of both wet and dry stools and weight of the wet stools. All these were noted every 1h and the paper changed after each evaluation. The percentage of rats that responded to diarrhoea in each group was calculated; the mean of the stools passed by the treated groups were compared with that of the control and the mean number of diarrhoea faeces pooled by the control group was considered as 100%.

The percentage inhibition of wet faeces and frequency of stool caused by ethanol extract of *S. rotundifolius* were calculated relative to the control using the relation:

Inhibition of defecation (%) = $[(NFe_C - NFe_T)/NFe_C] \times 100$

Where: NFe_C = mean number of faeces of control group

NFe_T = mean number of faeces of treated group.

The level of reduction (%) in defecation of watery faeces was calculated using the relation:

Inhibition of diarrheic faeces (%) = $[(NDF_C - NDF_T)/NDF_C] \times 100$;

Where: NDF_C = mean number of diarrhoea faeces of control group;

NDF_T = mean number of diarrhoeic faeces of treated group.

The purging index (PI) was calculated using the formula (Teke *et al*, 2010):

$$PI = \frac{\text{\% respondent x average number of stool}}{\text{Average latent period}}$$

RESULTS

Diarrhoea may be defined in terms of stool frequency, consistency, volume, or weight (Thomas *et al*, 2003). Evaluation of the effect of ethanol extract of leaves of *Solonestemon rotundifolius* on diarrhoea experimentally induced by castor oil in rodents showed significant (P<0.05) reduction in the weight, number, wetness of diarrhoea stools and in frequency of defecation. Castor oil is a suitable model of diarrhoea in rats since it allows the observation of measurable changes. After oral ingestion of castor oil, ricinoleic acid is released by lipases in the intestinal lumen. The freed ricinoleic acid irritates the intestinal mucosa causing inflammation and release of inflammatory mediators, such as prostaglandins and nitric oxide, which in turn stimulate gastrointestinal secretion, motility, epithelial permeability and oedema of the intestinal mucosa thereby preventing the re-absorption of Na^+, K^+ and water (Ammon *et a*l., 1974; Mahesh *et al.*2010) Active intestinal secretion is driven predominantly by net secretion of chloride or bicarbonate, inhibition of net sodium absorption, or increase in luminal osmotically active molecules (osmotic pressure) (Shah 2004). The extract at various doses reduced the purging index, the degree of wetness of the stool and significantly increased the latent period of diarrhoea which is suggestive of inhibition of hyper gastrointestinal secretion.

The acute toxicity test of the extract on albino rats established high LD_{50} suggesting the plant to be relatively safe at high dose.

CONCLUSION

The leaves of *Solenostemon rotundifulius* may have potential to reduce the diarrhoea in rats, therefore may contain bioactive principle that can be explored for the management of diarrhoea

Acute toxicity test: No death was observed up to dose of 5000mg/kg body weightTable 1: Effect of *S. rotundifolius* at various doses on castor oil-induced diarrhoea in experimental rats

Treatment group	Dose	Respondent to diarrhoea (%)	Latent period of diarrhoea onset (hr)	None diarrhoea faeces

ABSTRACT
This study was designed to determine the effect of Ebola Virus Disease outbreak in Nigeria on bush meat enterprise in Nsukka agricultural zone of Enugu state. The specific objectives was to determine the effects of the disease outbreak on mean level of sales and consumption of bush meat before, during and after the outbreak Random sampling technique was used in the selection of respondents. Data were collected using structured questionnaire from 40 sellers and 60 consumers of bush meat. Data were analyzed using descriptive statistics like frequency, means and t-test. The t- test for both sales and consumption were significances at 5% probability level, which made the null hypothesis to be rejected, indicating a drop in the levels of sales and consumption and consequent loss in income among sellers due to the outbreak. In view of these findings, there is a need for stakeholders to put in place agencies and relevant sensitization mechanism to educate the people on the necessary Ebola disease preventive measures and precautionary behaviours to adopt to still enjoy their bush meat in case of any future outbreaks.
Keywords: Ebola, bushmeat enterprise, agricultural zone, effect.

INTRODUCTION
In West Africa, consumption of bush meat is an ancient food tradition that is essential for supplying the necessary nutrition because of the low traditional the livestock production capacity of the people. Bush meat is eaten as a major source of protein and sustenance, especially in the rural areas, while major towns and cities treated bush meat as a luxurious delicacy in their diets (Hogenboom, 2014).
The term bush meat is commonly used for meat of terrestrial wild or feral mammals, killed for sustenance or commercial purposes throughout the humid tropics of the Americas, Asia, and Africa; in West Africa, primarily Ghana, Ivory coast and Nigeria (Nasi et. al., 2008). However, bush meat is a vector of some serious tropical diseases spread to human (Karesh and Noble 2009; Subramanian, 2012), for instance Ebola Virus Disease (EVD). The Ebola virus, for which the primary host has been identified as fruit bats, is a major concern in bush meat consumption and public health. Primates which have been suspected to be an intermediate host may carry the disease, after contracting the disease from bat droppings or remnants of fruits eaten by the bats.
According to Bausch (2014), the 2014 West Africa Ebola outbreak was the largest of its kind since the discovery of Ebola Virus Disease epidemic (EVD) in West Africa. The outbreak began in the Republic of Guinea in February of 2014. Since its initial outbreaks, the virus has already spread to the republic of Liberia, the Sierra Leone and then Nigeria. Though there was no recorded case of Ebola disease in most parts of Nigeria like Nukka area, there was a massive decline in the consumption of bush meat around the country, [and particularly in Nsukka area that notably have a robust marker and consumers,] making the bush meat enterprise to suffer major setback in sales (Ajayi, 2014). It was on this premise that this work was set out to study the effects of the disease outbreak on bush meat enterprise in Nsukka area of Nigeria. The following research hypothesis guided the study:
H_O: The outbreak had no significant effect on bush meat enterprise in Nsukka agricultural zone.
H_a: The outbreak had a significant effect on bush meat enterprise in Nsukka agricultural zone.

METHODOLOGY
Nsukka agricultural zone is one of the six agricultural zones in Enugu state. It is made up of three local government areas (LGAs) namely: Nsukka, Igboetiti and UzoUwani Local Government Areas (ENADEP, 2012). Rainfall distribution is between 168mm - 1700mm. The area has tropical climates marked by two distinct seasons. The vegetation is of derived savannah and people in this area are predominately farmers; farming constitutes their major economic activity. However, some of the urban areas like Nsukka town have more civil servants and petty traders. Their predominant crops include cassava, maize, cocoyam, yam, vegetables and economic fruits. Nsukka Agricultural Zone has a robust bush meat market, with many bars and restaurant where different varieties of bush meat are sold.
Out of the three local governments in the zone, two local governments, Nsukka and Igboetiti Local Government Areas were randomly selected for this study. From each of the local governments, 20 sellers were randomly

selected from the list of sellers from the bush meat trade union and 30 consumers were also randomly selected from the different bars from those present at the time of administering the questionnaire. This gave a sample of 40 sellers and 60 consumers.
Primary data sources were used for the data collection. Primary data for the study was collected through personal interview conducted with the use of well structured questionnaires. Two set of questionnaires were structured for both the sellers and the consumers. The questionnaire contained information on the level of sales and consumption before, during and after the Ebola outbreak for the sellers and consumers respectively. Data was analyzed using descriptive statistics; frequencies, means and t-test.

Model Specification
The t-test is an analytical tool employed to compare the periods before after the ebola disease outbreak in Nigeria. It is given as follows:

$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{S_1^2}{n_1} - \frac{S_2^2}{n_2}}} \qquad n1 + n2 + 2 \text{ degree of freedom}$$

Where:
t = t- test statistic.
$\bar{x}_1$ = Mean sale/consumption before the disease outbreak
$\bar{x}_2$ = Mean sale/consumption after the disease outbreak
S_1^2 = variance of sale/consumption before the disease outbreak
S_2^2 = variance of sale/consumption after the disease outbreak
n_1 = number of respondents before the period
n_2 = number of respondents after the period
The t-test was used to test the stated hypothesis

RESULTS
Levels of Sales and Consumption of Bushmeat Before, During and After the Outbreak
The results as presented in table 1 indicate that the sale of bush meat was booming before the outbreak and so was the rate of consumption. However, during the Ebola outbreak, some of the sellers and consumers recorded zero sales and consumption respectively. It also show that even after the outbreak, some sellers and consumers did not recover from the shock of the outbreak as they still recorded zero sales and consumption. The results show that bush meat sales and consumption in the study area highest before the outbreak, with means of 1762.5 plates (0.5kg per plate) and a mean consumption frequency of 12 times per month. Sales and consumption were lowest during the outbreak; even some sellers stopped sales, while some consumers stopped eating bush meat during the outbreak. However, the enterprise picked up again after the country has been declared Ebola disease free, but not as much as it was before the outbreak, thus, indicating a likely impact by the outbreak on the enterprise. This result is in line with the findings of Akani et al. (2015) and may be related to the ban on bush meat and the incessant awareness by the government on the risks associated with the consumption of bush meat.
Surprisingly, results show that consumption recorded a highest frequency of 60 during the outbreak. This could possibly be due to the fact that there were some consumers who actually ignored the 'bush meat cause Ebola' nuances and went ahead to have enjoy bush meat during the outbreak. These people consumed more due to the reduction in price during the outbreak regardless of the consequence. These could be the poor in the society who may be, could not afford the delicacy while the price was high before the outbreak.
To test the hypothesis of the study, t-test of the difference of two means was used to test for any any significant difference between the mean sales and consumption before and after the Ebola disease outbreak. The results of the test are as presented in Tables 2 and 3.
The results in table 2 and 3 showed that there was a statistical difference in sales an consumption before and after the outbreak. This is in line with findings of Akani et al (2015), Ndem et al. (2015), Agbo et al. (2014), United Nations Development Programme (2014), Mutasad (2015) and African Development Bank Group (2016) which pointed out that the levels of consumption and sales of bush meat in different parts of West Africa were affected by the Ebola disease outbreak. This points out to the effect of the outbreak on both sales and consumption in the study area.

CONCLUSION
The research work has evaluated the effect of the Ebola Virus Disease outbreak in Nigeria on bush meat enterprise in Nsukka agricultural zone of Enugu State. It is apparent that although there was no Ebola case in the study area, the bush meat enterprise there suffered some set back due to the outbreak in the country, as there was

a statistically significant reduction in both levels of sales and customers' patronage. Based on the findings of this study, it is recommended that information and communication department should be embedded in the Ministries of Agriculture and Health and they should be active in dispatching useful and timely information on such outbreaks to sensitize the people on the right preventive measures to take. Government should create more awareness in rural areas through the mass media that Nigeria is free of Ebola Virus Disease and that bush meat is now safe for public consumption. This would help to bring back the bush meat enterprise

Table 1: Mean monthly sales and consumption before, during and after the Ebola outbreak

	SALES (no of plates (0.5kg) of bushmeat sold in a month)			**CONSUMPTION (frequency of consumption in a month)**		
	Minimum	Maximum	Mean	Minimum	Maximum	Mean
Before Ebola Outbreak	150	6000	1762.50	2.0	50.0	12.283
During Ebola outbreak	0	4500	868.50	0.0	60.0	8.233
After Ebola outbreak	0	5100	1631.00	0.0	50.0	11.833

ABSTRACT
One hundred and eight African catfish fingerlings, obtained from a private fish hatchery, were used to assess the effect of environment and dietary protein levels on growth performance of Clarias gariepinus using 3x2 factorial in a completely randomized design (CRD) experiment. Three diets were formulated to contain different protein levels (32%, 35% and 45%) but similar energy (3800MJ/Kg), phosphorus (1.2%) and calcium levels (1.5%) and fed to fish in ponds located outside or inside a building at 36 fingerlings (averaging 70g bodyweight) per treatment. Each treatment was replicated into two at 18 fingerlings per replicate. The trial lasted fifty-nine days with twice daily feeding regime. Data collected were subjected to analysis of variance in 3x2 factorial in CRD and Least Significant Difference used to separate significant means There were significant (P<0.05) differences in protein level (PL) main effect. Clarias gariepinus had similar (P>0.05) average final weight (AFW) (2015g and 1687.5g) on PL45% and PL35% diets respectively but lower (P<0.05) value (1352.5g) on PL32% diet. The %specific growth rate (SGR) (5.668 and 5.283) on PL45% and PL35% diets were similar (P>0.05), but higher (P<0.05) on PL32% diet (4.953). Mean weight gain (MWG) was highest (P<0.05) for fish fed PL45% diet (1945g), followed by fish on PL35% diet (1617.5g) and lowest for fish on PL32% diet (1282.5g). The %relative feed intake (RFI) (2.710 and 2.668) and feed conversion ratio (FCR) (0.898 and 0.858)) of fish on PL32% and PL35% diets were similar (P>0.05) but higher (P<0.05) than RFI (1.970) and FCR (0.623) of fish on PL45% diet. There were significant (P<0.05) differences in environment (En) main effect. Outdoor (EnO) fish had higher (P<0.05) AFW (1953g), MWG (1883g) and SGR (5.622) than indoor (EnI) fish with AFW (1417g), MGW (1347g) and SGR (5.049). EnI fish had higher cost of production than EnO fish (₦220.60 versus ₦188.84).
There were significant (P<0.05) PLxEn interactions. AFW (2305g) and MWG (2234g) of EnOxPL45% were similar (P>0.05) to those (1850g and 1780g) of EnOxPL35% but higher (P<0.05) than those (1705g and 1635g) of EnOxPL32%. EnOxPL32% and EnOxPL45% had higher (P<0.05) AFW (1705g, 2305g) and MWG (1635g, 2234g) than EnIxPL32% (930g) and EnIxPL45% (1655g). SGR followed similar trend as AFW and MWG in all considerations. EnIxPL32% and EnIxPL35% were higher (P<0.05) in RFI (2.875, 3.010) and FCR (0.975, 0.975) than EnIxPL45% (0.625) and EnOxPL45% (0.620). EnIxPL32% and EnIxPL35% had higher cost of production (₦239.01 and ₦227.00) than EnOxPL32% and EnOxPL35% (₦181.40 and ₦190.91).

INTRODUCTION
Aquaculture is growing in Nigeria and becoming an increasingly important source of fish available for human consumption due to the quality protein content. Nutrition and feeding play a central role in sustainable aquaculture and therefore, feed resources as well as costs continue to dominate aquaculture needs (Bahnasawy, 2009). Development of nutritious and cost effective diets is dependent on the knowledge of basic nutritional requirement of organisms. It is also important to meet these requirements with balanced feed formulation and appropriate feeding practices (Tucker, 1998). Protein is an important factor in fish nutrition. Protein provides essential amino acids which are used for tissue repair and growth of the fish. However, maximum utilization of dietary protein for growth depends on the quality of the protein source. Dietary protein has significant importance in aquaculture system because it represents considerable economic investment and a central factor that determines fish growth so long as other physiological requirements needed for growth are fulfilled (De Silva *et al*, 1989; Buttle *et al*, 1995). Also, protein is an expensive nutrient and feed represents the single largest cost input in fish culture (80-85%). The impact of aquatic environment to the growth of fish cannot be overemphasized, and it gives birth for further reduction on protein level. Cold water experienced in Europe might increase the protein requirement of catfish but not in a place like Nigeria or Africa as a whole. The African catfish is recognized as an ideal species for aquaculture due to its continued reproductive performance, ability to efficiently utilize commercial feedstuffs and the capacity to use atmospheric oxygen (Haylor, 1989). Earlier reports on protein requirement for various fishes had been with varying results. Fatuorti *et al*. (1986)

reported the requirement of 40% CP for the growth of *Clarias lazera*. Similarly, Eyo and Falayi (1999) noted the need of 35% CP for *Heterobranchus Iongifilis x C. anguillaris* fingerlings to sub-adult, 37.5% CP for *C. gariepinus* fingerlings (Faturoti & Akinbote, 1986) and 40% CP for *C. anguillaris* fry to fingerlings (Madu and Olurebi, 1987). This study was therefore, aimed at reassessing the protein requirement and environment where *Clarias gariepinus* fingerlings are raised as it affects its growth performance.

MATERIALS AND METHOIDS

One hundred and eight (108) African catfish fingerlings were allocated to three dietary treatments in ponds located outside or inside a building at 36 fingerlings per treatment in a 3x2 factorial in a completely randomized design (CRD) experiment. The fingerlings had average body weight of 70g per treatment. Each treatment was replicated into two at 18 fingerlings per replicate. The fish were obtained from a private fish hatchery, transported in aerated plastic rubber of acclimatized aquatic nature. Twelve plastic tanks (each representing a replicate and containing 18 fingerlings) were used for this trial. Three diets were formulated to contain different protein levels but similar energy(ME= 3800MJ/Kg), phosphorus (1.2%) and calcium (1.5%) levels and designated T32 (CP=32%), T35 (CP=35%), T45 (CP=45%) as shown in Table 1. A total of 1.5kg of each diet was weighed out into a 4-litre rubber and hung on their respective tanks for feeding the fish throughout the period of trial. The trial lasted fifty-nine days and feeding pattern was two times daily and leftover feeds were equally recorded across the diets. The data collected were the initial weight of the fingerlings and its final weight obtained at the end of the trial. After all the arithmetical computations, it was then subjected to analysis of variance (ANOVA) in a 3x2 factorial in CRD. The Least Significant Difference (LSD) was used to separate means, where significant.

RESULTS AND DISCUSSION

Growth performance of *Clarias gariepinus* fingerlings fed diets with varying protein levels and reared in two environments (indoor and outdoor) is shown on Tables 2, 3 and 4. There were significant differences ($P<0.05$) in protein level (PL) main effect. Average final weight (AFW) of *Clarias gariepinus* on 45% protein diet was similar ($P>0.05$) to that of *C. gariepinus* on 35% protein diet but higher ($P<0.05$) than that of those on the 32% protein diet. However, the AFW of fish on the 35% and 32% protein diets were similar. Percent specific growth rate (SGR) of *C. gariepinus* on 45% and 35% protein diets were also similar ($P>0.05$), but higher ($P<0.05$) than that of fish on 32% protein diet. Mean weight gain (MWG) of fish fed the 45% protein diet was the highest ($P<0.05$), followed by that of fish on the 35% protein diet while that of those on the 32% protein diet was the lowest ($P<0.05$). Percent relative feed intake (RFI) and feed conversion ratio (FCR) of fish on the 32% and 35% protein diets were similar ($P>0.05$) but higher ($P<0.05$) than that of fish on the 45% protein diet. An observed general trend in the parameters including MFI but excluding RFI and FCR was that of increasing value as the protein inclusion levels increased while the RFI and FCR values decreased as the protein inclusion levels increased. This shows that increase in dietary protein encourages better performance in *C. gariepinus*. In this study, the 45% protein diet encouraged best performance of the fish.

There were significant ($P<0.05$) Protein level X Environment interactions for AFW, MWG, mean feed intake (MFI), SGR, RFI and FCR as shown in Table 4. Among the fish reared outdoors (EnO), the AFW and MWG of fingerlings fed 45% protein diet (PL45%) were similar ($P>0.05$) to the AFW and MWG of fish fed 35% protein diet (PL35%), but higher ($P<0.05$) than those of fish fed the 32% protein diet (PL32%). Compared on protein level basis, fish reared outdoor at 32% (EnOxPL32%) and 45% (EnOxPL45%) protein levels had higher ($P<0.05$) AFW and MWG than those reared indoor (EnI), while at the PL35% the AFW and MWG were similar ($P>0.05$) for the EnI and EnO fish. On indoor basis only, EnIxPL45% fish had the highest ($P<0.05$) AFW and MWG, followed by EnIx35% fish, while EnIxPL32% fish had the lowest ($P<0.05$) AFW and MWG. SGR followed similar trend as AFW and MWG in all considerations, the only exception being that SGR of fish fed PL45% diet were similar ($P>0.05$) for both indoor and outdoor. Fish fed the PL32%, PL35% and PL45% diets had similar ($P>0.05$) MFI, RFI and FCR for EnI and EnO fish. The MFI of EnIxPL35% fish was higher ($P<0.05$) than only the MFI of EnIxPL32% fish. The RFI and FCR of EnIxPL32% and EnIxPL35% fish were higher ($P<0.05$) than only the RFI and FCR of both EnIxPL45% and EnOxPL45% fish

On economics of production, level of protein inclusion did not elicit noticeable differences in the cost of feed per unit weight gained, but the differences occasioned by reason of environment (outdoor or indoor) in which the effects were highly noticeable. This showed in the interactions such that all the fish in the indoor environment at both 32% and 35% protein levels had higher cost of production than the fish in the outdoor environment, except at the 45% protein level where the differences were not noticeable. The reason of some natural factors like sunlight making for easy dissolution of oxygen and the growth of algae in the outdoor ponds appears logical.

In all the parameters considered a general trend was established. Performance of fish at all levels of protein inclusion was better in all parameters for the outdoor environment than for the indoor environment. This may be a strong confirmation of the earlier adduced reason of some natural factors playing a role. In the outdoor environment sunlight was unimpeded; oxygen was in abundance and could be easily dissolved in the presence of sufficient sunlight; there was no obstruction in aeration and air movement; and the environment was ripe for the development and growth of algae which is natural food for the and modifier of the environment for the fish. The in-house ponds lack access to all these natural factors which usually support fish life and make for their enhanced performance.

Another important trend observed was that the parameters that give strong indication of nutrient utilization (specific growth rate and feed conversion ratio) as well as cost factor that has profit implication (cost/WG) did not differ between the performances of the outdoor fish at both the 35% and 45% dietary protein levels.

Several Authors have carried out similar studies on reassessing protein level requirement of African Catfish. Keremah and Beregha (2014) did same work and their result equally conformed to the finding of the present study. The performance gap in the measured parameters of the lower protein diet (35%) and the higher protein diet (45%), including the cost implication, does not justify going for the higher protein level.

CONCLUSION

For sustainability of fish farming in Nigeria, cost of feed as a major determinant becomes an imperative for unlocking the potentials of nutrients and availability to human consumption. Thus, the need to achieve a cost effective aquaculture system is to have optimum dietary protein level of catfish, avoid wastages and pollution of water by excess crude protein. These potentials could serve as an innovative framework and agribusiness value addition to relief cost to farmers. Therefore, the 35% dietary protein level could be recommended as more economical for the agribusiness firms in livestock industry.

Table 1: Percentage Composition of Clariasgariepinus Fingerling Diets at different protein levels

	Dietary Protein Levels (%)		
Ingredient	*32*	*35*	*45*
Salt	1.3	1.3	1.1

Values with different superscripts within each row are significantly different at p<0.05.

Table 3: Growth Performance of African Catfish as affected by the environment in which they were reared

	Environment (Inside or Outside)		
Parameters	***Outside***	***Inside***	***SEM***
Average Initial Weight (g)	70	70	-
Average Final Weight (g)	1953^{a}	1417^{b}	80.485*
Mean Weight Gain (g)	1883^{a}	1347^{b}	80.485*
Mean Feed Intake (g)	1335	1123	73.739
%Specific Growth Rate	5.622^{a}	5.049^{b}	0.080*
% Relative Feed Intake	2.283	2.615	0.132
Feed Conversion Ratio	0.727	0.858	0.043
Cost of Feed (N/Kg)	263.73	263.73	
Cost/KgWG (N)	188.84	220.60	

Values with different superscripts within each row are significantly different at p<0.05.

There were significant (P<0.05) differences in environment (En) main effect. The fish in the outside ponds (O) had higher (P<0.05) AFW, MWG and SGR than fish in the in-house ponds (I). The explanation to this situation could lie in the accessibility of the fish in the outside pond to natural and good quality light as well as better aeration.

ABSTRACT
Cassava peels were collected from some farms in Umunneochi and were analyzed for copper (Cu) and iron (fe). The average values for the elements were found to be CU (0.92 mg/kg), and Fe (850mg/kg) using Atomic absorption spectrophotometer. Iron and copper are essential trace elements and therefore are needed in formulation of livestock feeds. Cassava peels are therefore recommended as a good source of dietary iron for livestock feeds.

INTRODUCTION
The current pattern of industrial activity alters the natural flow of materials and introduces novel chemicals into the environment. The rate at which effluents are discharged into the environment especially water bodies have been on the increase as a result of urbanization. Most of these effluents contain toxic substances especially heavy metals such as chromium, iron, zinc, copper, etc. metals like arsenic, mercury, lead, chromium, phosphorus, and antimony are introduced into the environment by use of chemical like pesticides, herbicides and fertilizers (Frink, 1993).
Furthermore, very many of the metallic elements are however likely to be involved at potentially hazardous concentrations in food, largely due to their increasing exploitation by man. Very many of these elements are known to be essential for healthy growth in plant, animals and man at low concentrations and only become hazardous when certain threshold concentrations are exceeded. This study was aimed at assessing the concentrations of iron and copper in cassava peels from Umunneochi and know the implication for livestock feeds production.

MATERIALS AND METHODS
Source of Materials: The samples were collected from some farms in Umunneochi Local Government Area of Abia State.

Sample Preparation
The cassava peels were first sun dried and later oven – dried to reduce the moisture content prior to extraction of the mineral elements.

Methods
Extraction of Copper from the Peels
The method used in extraction and quantitative determination of copper was that described by Pearson (1976).

Determination of Iron
The sample was analyzed using the dry ash method, in which the sample was ashed in a muffle furnace and the cooled ash dissolved with 50cm^3 at 6m HNO_3 and boiled for about 15mins on a hot plate. The resulting filtrate was analyzed using Atomic absorption spectrophotometer.

RESULTS AND DISCUSSION
Table 1 shows the concentration of iron and copper in cassava peels. The iron content was 850mg/kg while the copper content was 0.920mg/kg. The result obtained showed that cassava peels is rich in iron and poor in copper. According to Wagman and Pergrsion (1982) iron is necessary for the formation of hemoglobin in the red blood cells. The recommended daily need of iron for man is 15mg/kg per day according to Lucas (1975).
The level of copper as seen in table 1 is low when compared to iron. The recommended daily need of copper is 2 to 3mg per day. According to Bowen (1979) copper content of normal plant tissues varies according to species but it is usually within the range of 1-250mg/kg dry matter. According to Walsh (1971) copper is toxic to man at concentration of 250mg/kg per day.
The iron content of normal plant tissues varies according to species but it is usually within the range of 20-200mg/kg dry matter. According to Bowen (1979) copper and iron fall within the group essential nutritive - trace elements.

CONCLUSION

Based on the result of the study, cassava peels are rich in iron but poor in copper content. The iron content of 850mg/kg is far above the daily dietary need of livestock such as goats and pigs which is supposed to be 15mg/kg per day. The copper content of 0.920mg/kg is low when compared to the iron content. Iron is a major component of hemoglobin in red blood cells and it is deficiency in animals could result to anaemia. The iron content of normal plant tissues varies between 20 to 200 mg/kg according to Lucas (1979). It falls within the essential trace element group. According to Lucas (1979), the copper content of normal plant tissues varies between 1-25.0mg/kg. Copper is an essential trace elements needed by the animals body in low concentration.

Table 1: Iron and copper concentrations of cassava peels

Minerals Element	ABS	QTY in MG/KG
Iron	0.365	850mg/kg
Copper	0.025	0.920mg/kg

ABSTRACT

The study was conducted at Hadejia Central Abattoir, Jigawa State, Nigeria. Hadejia lies approximately between 10º.10'E Longitude and between 12º.25N and 12º.30'N Latitude. Fifty four (54) copies of structural questionnaires were administered to different butchers to obtain information about their socio-economic background and perception on abattoir management and environment. The data collected were analyzed using simple descriptive statistics. Results showed that all the butchers were male, majority of them were youth, have secondary school leaving certificates and married. Most of the butchers have 3 to 5 years of experience, their main source of water was bore hole, respondents were satisfied with the sanitary condition of the abattoir and commended government effort in the overall management of the abattoir. It is recommended that similar study should be conducted in the north-west and south-south of the state so as to come up with the general trend within in the state.

Keywords: Butchers, abattor management, background, Nigeria

INTRODUCTION

A Butcher is a person who slaughters animals, dresses their flesh, sells their meat or do any combination of these tasks. A butcher may be self-employed, employed by supermarkets, grocery stores, butcher shops or slaughter houses, (Salakoni, 2002).

An abattoir is a composite unit or structure in which animals are slaughter, prepared and made ready for distribution to general public i.e. the meat retails. Different activities are carried out in fully mechanized line. The workers were assigned to specific work station and the carcasses move on a conveyor system, from station to station until slaughter process is completed.

In slaughter line operation, clean and unclean operations are physically separated and individual adhered to avoid contamination of carcasses and edible by products. The unclean operations include stunning, bleeding and skinning (ruminants). The clean operations include evisceration, carcasses splitting and carcasses dressing. In rural setting, slaughtering can be done on basic small-scale facilities. Before building slaughtering facilities a number of factors must be consider such as environmental impact, the availability of a work force and the linkage to the meat markets (Osinero, 2007).Closeness to livestock market, frequent water supply, location away from residential areas, adequate supply of power, good ventilation, ease of cleaning are some of the factors tobe considered in siting an abattoir (Anonymous, 2012).

Mason (2005) classified abattoir as good, poor or fair depending on the facilities available, units and operational sections. The abattoir management system is made up ofa number of independent yet integrated modules confined to the slaughtered processes. Within the abattoir management system it is possible to identify the supplies, date of slaughtered and all relevant classification details, grading information of the byproducts and sale information of any kind that has been captured into the system. The software modules handles data input of the entire processes starting from livestock at the abattoir and ending with the dispatch of the carcasses (Bello and Oyedemi, 2009).

A standard abattoir should consists of lairage, slaughtering/dressing unit, unit for hanging meat and editable offal's for inspection, cooling and chilling room, guttery and trippery section,isolation block for emergency and causality slaughter, laboratory for microscopic examination, detained meat room, offices for meat inspectors,staff toilets, vehicles among others (FAO, 2001). The following equipment are found in an abattoir: Restraint Ropes, Halters, Stunners, Dressing knives and axes, containers for blood collection, Overhead rails for line movement of carcasses during dressing, tables for placing meat, Hooks for hanging dress meat, Scalding vats (pig haring), Refrigerating facilities, cold rooms and Vehicles.

MATERIALS AND METHODS

The study was conducted at Hadejia central abattoir in Hadejia Local Government Area of Jigawa State, Nigeria. Hadejia town is the capital of Hadejia and is located in the central part of the emirate. Hadejia lies approximately between 10º.10'E Longitude and between 12º.25N and 12º.30'N Latitude. The town is served by federal trunk roads linking it to Nguru on the east, Kano on the north -west, Katagum on the south and Dutse (the capital city of Jigawa) on the south-west. The old town is walled with newer physical development having extended outside the walls; it is bounded at the northern sector of the town and through Mallam-Madori.

Hadejia has an average annual rainfall of 75 mm accompanied by heavy wind, the annual temperature ranges between 30 to 40ºC. The area experiences two seasons in a year, it has about 6-8 months of dry season and harmattan is experienced between December to February. The area has a population of 105,628 (NPC, 2006). Majority of the inhabitant are farmers.

Fifty four (54) copies of structural questionnaires were administered to different butchers to obtain information about their socio-economic background and perception on abattoir management and environment. The data collected were analyzed using simple descriptive statistics.

The objective of the study was to analyse Butchers Background and Abattoir Management in North-Eastern Part of Jigawa State.

RESULTS AND DISCUSSION

Table 1 showed the Socio-Economic Background of Butchers. All (100.00%) the butchers in the study area were male that means female do not participant in butchering activity, this may not be unconnected with the socio-cultural background of the area. Majority (38.89%) of the butchers were within the ages of 21 to 30 years which implies that youth dominated the meat trading activity. Most (55.50%) of the butchers have secondary schools leaving certificates, hence the butchers can easily been trained and can accept modern technology, this is in agreement with the work of Umunna *et al.* (2011).It could be interfered, therefore that the respondents were literate. For the purpose of adopting new technology, education is an important factor, which if lacking can have adverse impact on meat trading and processing.The high level of literacy can provide scope for an information interface between animal producers, extension workers, researchers and development agents. Most (55.46%) of the respondents were married, this shows that butchering activities is done mostly by responsible members of the society. Majority (31.48%) of the butchers have weekly income ranging from ₦ 10,000.00k to₦ 14, 999.00k, which may mean that the occupation is rewarding.

Information on Abattoir Environment and its Management is presented on Table 2. The results showed that majority (42.59%) of the butchers have 3 to 5 years of experience in the abattoir.

Most (75.92%) of the butchers in the abattoir used borehole water as their primary source of water. This indicated that the butchers have good and clean source of water.All (100.00%) the respondents were satisfied with the sanitary up keep of the abattoir. Responds (64.89%) from the butchers indicated that the abattoir is cleaned on daily basis that may be the more reason that the butchers were contended with the sanitary condition of the abattoir. This indicated that butchers in the study area carryout regular sanitation exercise. All (100.00%) the butchers are happy with government involvement with regards to abattoir maintenance. This indicated that the abattoir is regularly maintained. Majority (66.67%) of the butchers are satisfied with the facilities in the abattoir. This indicated the facilities in the abattoir are adequate. Most (53.70%) of butchers perceived the condition of the abattoir to be very good. This indicated that the abattoir and its environment are kept well clean.

CONCLUSION

The study concluded that all the butchers in the study area were male, majority of them were youth and have Secondary School Leaving Certificate. Majority of the butchers were satisfied with the sanitary condition of the abattoir as well as acknowledged government intervention in the up keep of the abattoir.

ADOPTION OF AGRO-FORESTRY PRACTICES AMONG SMALLHOLDER FARMERS IN MAI'ADUA, KATSINA STATE, NIGERIA

G.Y. Jamala

Federal University, Dutsin-Ma, Katsina State, Nigeria
gjamala@gmail.com

ABSTRACT
The study was carried out in Mai'Adua metropolis of Katsina State, Nigeria, situated in the dry-land region of the State. Data were collected with pre-tested questionnaires administered to 100 farmers-household heads. Data were analyzed using descriptive statistics and t-test statistics. The t-test result shows a significant difference with respect to the type of agroforestry practices among the respondents. The deliberate retaining of trees on farmland was the most common agroforestry practice in the study area as indicated. The farmers maintained that tree species are retained to provide various uses such as Wind break (8%), Fodder (16%), Fuel wood (6%), Staking material (4%), Source of Income (14%), Soil improvement (28%), Medicinal herbs (10%), Shade (6%) and constructional materials (8%). The result of the t-test shows a significant difference (p< 0.01) in the proportion of those aware of agroforestry practices and those not aware. About 82% maintained that they are aware of the potentials of agroforestry while 18% claimed not to be aware. About 76% of the respondents indicated that they were willing to retained/plant trees on their farm land. Farmers' responses to questions on some reasons for unwillingness to practice agro-forestry technologies were different. Generally none of the reasons provided in the survey could be considered to greatly influence agro-forestry practice. The result indicated that lack of knowledge and lack of seed/planting materials influence the adoption of agro-forestry more than other factors do. Generally, level of awareness is high. Therefore lack of awareness was not one of the main reasons preventing farmers from adopting agroforestry. Since lack of knowledge and lack of seed were said to influence agroforestry practice more than would lack of awareness, limited land, and lack of interest, they perhaps deserve particular attention when planning and implementing agroforestry development.
Keywords: Adoption, Willingness, Agroforestry, Taungya, Smallholder and Farmers

INTRODUCTION

About 70 percent of Nigeria's population live in the rural areas and the majority of these people depend on agriculture for improving livelihoods (Odurukwe 2004). However smallholder agriculture faces many challenges including low productivity, high dependence on rain-fed agriculture, insecurity of the traditional land tenure system and environmental degradation due to unsustainable agricultural practices. As a result of these challenges, smallholder agriculture remains at low productivity and this has led to high incidence of poverty among rural smallholder farmers (Opio, 2001). Part of the solution to address low land productivity is the development of new agroforestry technologies. In Nigeria, agroforestry technologies have been trialled at research stations since 1980 and also on farms since 1984 in collaboration with farmers (Franzel et al., 2002). Nair (1993) pointed out that the presence of woody perennials in agroforestry systems may affect several bio physical and bio-chemical processes that determine the health of the soil substrate. Puri and Bangarawa, (1992) pointed out that the choice of tree species is the most important factor to be considered in agroforestry practices. On the other hand Foroughbackhch (1992) stated that the choice of tree species be made after careful consideration of their adaptability for growth and benefit for rural populace. According to Rogers (2003), adoption occurs when one has decided to make full use of the new technology as a best course of action for addressing a need. Adoption is determined by several factors including socioeconomic, environmental, and mental processes that are governed by a set of intervening variables such as individual needs, knowledge about the technology and individual perceptions about methods used to achieve those needs (Thangata & Alavalapati, 2003). In Nigeria, natural fallows have been a common practice among smallholder farmers for restoring soil fertility. However with rapid population increase and land use pressure, these fallows have been reduced to below the minimum threshold required for the system to sustain itself. As a response to declining land productivity, farmers open up forests to expand to new areas and this has led to loss of extensive forests and subsequent land degradation. As findings on factors that influence adoption of agroforestry vary between studies, it is necessary to further probe the adoption process so as to understand what actually influences adoption of agroforestry as these would be instrumental in furthering their effective promotion and accelerating their equitable uptake. Literature suggests that successful adoption depends on favourable convergence of technical, economic, institutional and policy factors (Feder *et al*., 1985; Rogers, 2003).

MATERIALS AND METHODS

The study was carried out in Mai'Adua local government area of Katsina State. The local government lies between Latitude 13°11′26″N and 8°12′42″E. The area falls within the dry-land region of Katsina State, defined roughly as one of the area lying north of 12^0N latitude in the State. It has a land mass of 228 km^2 (204 sq ml) and a population of 201,178 (NPC, 2006). The method used for this study is survey research method. The survey method was adopted due to the nature of the research, which involves practical issues. The questionnaire was designed to find out views concerning factors influencing the adoption of agro-forestry among smallholder farmers in Mai'Adua Local Government area, Katsina State. The questionnaires were randomly administered to a total of 100 farmers in the study area. Data obtained were analyzed using descriptive statistics that include the use of frequency distributions, means and percentages. Student t-test was used to verify the presence of significant differences between respondents' gender, proportion of those aware of agroforestry practices and those who are not aware using (SPSS version 18) statistical package.

RESULTS AND DISCUSSION

Adoption of agroforestry systems by respondents is presented in Table 1. The t-test result shows a significant difference with respect to the type of agroforestry practices among the respondents. The deliberate retaining of trees on farmland was the most common agroforestry practice in the study area as indicated. The farmers maintained that these species are retained to provide various uses such as Wind break (8%), Fodder (16%), Fuel wood (6%), Staking material (4%), Source of Income (14%), Soil improvement (28%), Medicinal herbs (10%), Shade (6%) and constructional materials (8%). Table 1 shows the level of awareness of agroforestry practices. 82% maintained that they are aware of the potential of agroforestry while 18% claimed not to be aware. The results of the t-test show a significant difference ($p< 0.01$) in the proportion of those aware of agroforestry practices and those not aware. About 76% of the respondents were willing to retain/plant trees. The species retained include *Tamarindus indica* L., *Parkia biglobosa* (Jacq), *Mangifera indica, Prosopis Africana, Acacia senegal* L., *Azadiracta indica* Adr. Juss, *Moringa oleifera* Lam., *Adamsonia digitata* and *Jatrofa Carcus.* The result revealed that 82% of the respondents are aware of the agroforestry as a farming system. This indicates that agroforestry is not a new system of agricultural practice to the farmers in the study area. The responses of farmers show that majority of the farmers (38%) retained trees on their farmlands and the remaining farmers practice various forms of agroforestry such as alley cropping, mulching with tree species and approved Tungya system of land use. Majority of the respondents (76%) maintained that they are willing to plant trees in their farm land and at the same time retained some valuable species of trees. The remaining indicate unwillingness, this may be either due to lack of ownership of land or are not aware of the importance of agroforestry. The study revealed that the respondents either plant trees for additional income, food, firewood, staking materials, constructional materials, soil improvement, fodder, shade, or medicinal herbs. This is in consonance with Adewusi (2006) who stated that farmers plant or retain trees on their farm land, both for food, income, soil improvement, environmental amelioration and for shade during the harsh weather period. The result shows that various tree species ranging from leguminous and non-leguminous, medicinal plants; tree crops and economic trees were either retained or planted by the farmers in their farm lands. Farmers' responses to questions on some reasons for unwillingness to practice agro-forestry technologies were different (Table 2). Generally none of the reasons provided in the survey could be considered to greatly influence agro-forestry practice. Table 2 indicates that lack of knowledge and lack of seed/planting materials influence the adoption of agro-forestry more than other factors. Generally, level of awareness is high. Therefore lack of awareness was not one of the main reasons preventing farmers from adopting agroforestry. Since lack of knowledge and lack of seed were said to influence agroforestry practice more than would lack of awareness, limited land, and lack of interest, they perhaps deserve particular attention when planning and implementing agroforestry development.

CONCLUSION

This study examined the adoption of agroforestry practices in MaiAdua fringe of Katsina State, Nigeria. To effectively in improve rural living standards, agroforestry should form part of an integrated rural development programme and thereby meet more of the farmers basic needs than it presently does. Technical assistance is needed to facilitate the spread of agroforestry practices. More so, adequate information is required to keep farmers abreast of current trends and development in the practices of agroforestry. Provision of economic incentives by the forestry department to farmers participating in agroforestry practices should be considered. Farmers in the rural areas should be encouraged to go into agroforestry by the relevant government agencies so that they can benefit from yield of the crops and additional income from the sales of the tree products such as fruits, oils, staking materials, constructional materials, medicinal herbs soup condiments, wood and other unquantifiable benefits.

TAUNGYA: AN ECONOMIC LAND USE SYSTEM FOR TROPICAL FOREST RESTORATION

U.F. Akpan, F.S. Akpan, E.E. Eric & G. Otiwa

Forestry Research Institute of Nigeria, Ibadan
udemeakpe@gmail.com

ABSTRACT
Nigeria has experienced a remarkable degradation and depletion of its forest resources over the years. This process has undermined the socio-economic and socio-cultural importance of the forests for millions of rural people who depend on the resource to support their livelihood. This has exacerbated landlessness, land conflict and rural poverty. Forests can be restored in a wide range of circumstances; it aims to achieve the best possible compromise between meeting both conservation goals and the needs of rural communities. As human pressure on landscapes increases, forest restoration must commonly be practiced as a form of forest management to meet the economic needs of local people. Weed invasion is one of the main challenges in tropical forest restoration project which attribute to high cost of the project (Brancalion et al 2012). However, instead of spending money on herbicides or mechanical weeding, it is possible to save and earn money early in a restoration project by introducing and producing annual crops in a forest restoration system known as "taungya".
Keywords: Forest, Degradation, Restoration, Economic and Taungya.

INTRODUCTION
Forest restoration is action to re-instate ecological processes, which accelerate recovery of forest structure, ecological functioning and biodiversity levels. It is a specialized form of reforestation, but it differs from conventional tree plantations in that its primary goals are biodiversity recovery and environmental protection. Forest restoration may include simply protecting remnant vegetation or more active interventions to accelerate natural regeneration, as well as meeting economic needs of the local dwellers (UNEP 2012). Tree species planted (or encouraged to establish) are those that are typical of, or provide a critical ecological function in the targeted ecosystem. However, wherever people live in or near restoration sites, restoration projects often include economic species amongst the planted trees, to yield subsistence or cash-generating products (Brancalion *et al* 2012). Many restoration projects are now being implemented under the umbrella of "forest landscape restoration" (FLR). This is defined as a process of forest restoration that aims to regain ecological integrity and enhance human wellbeing in degraded forest landscapes (Lamb 2012). FLR recognizes that forest restoration has social and economic functions. It deals with the integrated management of large forest systems. As habitat to an estimated 80 percent of the world's biodiversity, forests provide genetic material important for crop and livestock improvement and are home to many pollinator species (FAO 2012). Forests and trees help to mitigate climate change by absorbing carbon dioxide and storing carbon. They can also help to reduce the vulnerability of people to climate change by providing food, income and other ecosystem services during critical periods of climate driven food shortages (UNEP 2015; Matta and Meins 2012). Its goal is to both regain ecological integrity and enhance human wellbeing. Achieving this objective requires equitable negotiations amongst all concerned stakeholders on: maximum gains in biodiversity protection, catchment protection and provision of economic resources to local communities. The key part of this process is the selection of appropriate criteria, which comprises tools and procedures to integrate site-level forest restoration actions with desirable landscape-level objectives (Lamb 2012), and delivery of a range of utilitarian benefits to local communities. This may including a reliable supply of clean water, environmental protection particularly watershed services (e.g. reduced soil erosion, lower landslide risk, flood/drought mitigation etc.), a sustainable supply of a diverse range of forest products including foods, medicines, firewood etc., monetary income from various sources (Brancalion *et al* 2012). One of the main challenges in restoration plantings in the tropics is the effective control of fodder grasses which can dramatically reduce trees growth. As usual, trees take at least three years to shade the understorey and out-complete weeds, instead of spending money on herbicides or mechanical weeding, it is possible to save and earn money early in a restoration project by producing annual crops such as cowpea, corn, cassava, soybean, okra, and pumpkin, among others, in a forest restoration system known as "taungya".

Taungya Landuse Technique
Depending on local environmental and socioeconomic factors, TAUNGYA: forests trees on farms agroforestry system involves restoration and management of forests, that they made gains in food crops yields and income generation (Brancalion *et al* 2012) , which reduced poverty considerably as compared with non-taungya .
The word "taungya" is a Burmese word coined in Burma, Taung = hill, ya= cultivation. The taungya method spread from Burma to other parts of the world. While the trees are small and widely spaced, the free space

between the newly planted trees can accommodate a seasonal crop. Instead of costly weeding, the underutilized area provides an additional output and income as taungya technique use the between-tree space for a series of crops. The crops become more shade resistant as the tree canopies grow and the amount of sunlight reaching the soil surface declines. If a plantation is thinned in the latter stages, this opens further the between-tree cropping opportunities. This is a modified form of shifting cultivation in which the labour is permitted to raise crops in an area but only side with the forest species planted to it. This labour is responsible for the upkeep of a plantation. The practices consist of land preparation, tree planting, growing agricultural crops for 1-3 years, until shade become too dense for crop production. In some cases crop may be grown one year before the trees are planted. Furthermore, it has needs to develop farm-level analyses of potential economic costs, benefits, associated with agroforestry practices. The technique is a vital prerequisite to the objective comparison of both production-and conservation-driven agroforestry practices with alternative land use options. Research on tree-crop-environment interactions are pursued to provide a scientific basis for optimizing agroforestry designs.

Economic Benefits of Taungya

Economic indices of success include the value of forest products and ecological services generated (e.g. watershed protection, carbon storage etc.), which ultimately contribute towards poverty reduction (Clewell *et al*. 2000), and forest products can provide strong incentives for local people. Forest restoration is appropriate wherever both biodiversity recoveries (wildlife conservation, environmental protection, eco-tourism) and the supply of a wide variety of economic forest products to local communities is the main goals of reforestation.
The key characteristics of the approach are;

- The complementary relations between the different components of landscape mosaics and not just on the management unit.
- It involves all stakeholders in equitable negotiations over outcomes.
- Allows for maximum production in specialized management areas that allowed other benefits to be managed at a larger scale.
- Reduce the opportunity costs of very extensive single use approaches such as large-scale industrial plantations or very extensive protected areas.
- Often yield higher biodiversity pay-offs than further investment in protecting the remote residual forests on poor soils that are often the focus of conservation initiatives.
- It can bring multi-functional forests to areas of high human population density and thus serve a valuable educational and awareness raising function as well as directly contributing to the quality of life of people in densely populated and degraded areas.
- Mitigation of environmental problems as it renders ecological service to the ecosystem through shading of soil surfaces against erosion, floods etc.

CONCLUSION

Taungya is an acceptable, agroforestry practice that offers much income potential, without significantly greater risk, unlike other market-driven land uses it has a better prospects for solving a particular conservation problem compared to other practices. There are many ways in which forests, trees on farms contributed to the survival of forest-dwellers, particularly many indigenous peoples, more so, it an important providers of ecosystem services, including maintaining or restoring soil fertility, protecting watersheds and water courses. Therefore, Institutions which promote rural development should incorporate awareness of taungya system into developmental agenda to enable rural households improve upon their livelihood and know-how of the system (Lamb 2012). Thus, Taungya as a forest restoration technique should be deem economical and sustainable management approach in tropical country like Nigeria.

DIFFERENT METHODS OF BREAKING SEED DORMANCY IN TWO INDIGENOUS TREE CROPS (*Afzelia africana* and *Monodora myistica*) IN OWERRI, NIGERIA

C. A. Peter-Onoh, A. A. Ngwuta & J. C. Obiefuna

Department of Crop Science and Technology, Federal University of Technology, Owerri
chidinmaonoh@ymail.com

ABSTRACT

Afzelia africana *and Monodora myristica are two important indigenous fruit tree crops known for their medicinal, domestic and industrial uses in Southeast Nigeria. This experiment was conducted in the Screen house of the School of Agriculture and Agricultural Technology Owerri Nigeria for 4 and 8 weeks, respectively to investigate the different methods of breaking seed dormancy in two indigenous fruit tree crops. Five pre-sowing treatments: hot water (3, 6, 9, 12 min), Sodium chloride (NaCl) (5, 10, 15 min), 70^{C} Oven temperature (3, 6, 9, 12 min) 98% Sulfuric acid (98% H_2S0_4) (5, 10, 20, 30) and untreated seeds (control) for A. africana and 3 treatments cold water (12, 24 min), 98% H_2S0_4 (5, 10, 15) and control (0) for M. myristica were laid out in a complete randomized design (CRD) with three replications. Data were collected on percentage germination (PG), germination index (GI), mean germination time (MGT) and coefficient velocity of germination (CVG) for A. africana and M. myristica, respectively. These were subjected to ANOVA and least significant differences were use to separate significant means. Pre-sowing treatments used are needed to facilitate germination of A. africana because untreated seed attained maximum PG but increased MGT and reduced CVG. Monodora. myristica PG was enhanced when the seeds were soaked in cold water for 24 h followed by 5 min of 98% H_2S0_4 acid but the scarifying duration of 98% H_2SO_4 should be reduced to avoid damaging of the embryo by the chemical for both the tree crops. The investigation suggests that the type of dormancy exhibited by the two crops is physical dormancy since the treatments could effectively break the hard seed coats.*

INTRODUCTION

Afzelia Africana commonly known as Lucky–bean tree (Akparata–Igbo) belongs to the family Leguminosae. Evergreen, small to fairly large tree up to 40 m tall, bole branches of up to 20 m, usually straight and cyliderical, up to 150-200 m in diameter. Fruit is oblong, flattened pod, dark-brown to black that contains up to 10-seeds; seeds are ellipsoid or oblong-ellipsoid, black with cup-cup and orange aril at base. *Afzelia africana* is useful in varying ways; timber for furniture, fodder plants, leaves as vegetable. The seeds are used in the eastern parts of the country as soup condiments and is rich in oil and used as thickening agent. *Monodora myristica Dunal*-commonly known as African nutmeg. Ehuru (Igbo), belongs to the family *Annonaceae*. The *M. myristica* tree can reach a height of 35m and 2m in diameter at breast height (DBH). It has a clear trunk and branches horizontally. The fruit is a berry of 20cm diameter and is smooth, green and spherical and becomes woody at maturity. Inside the fruit the numerous oblongoid, pale brown, 1.5cm long seeds are surrounded by a whitish fragrant pulp. The odour and taste of the *M. myristica* seed is similar to nutmeg and it is used as a popular spice in the West African cuisine (Louise, 2002). The fruits from these tree crops are collected from volunteered fruit trees in the wild. Seed dormancy is a physiological phenomenon in wild and crop plants, and is more common in wild plants than the crop plants (Farahani *et al*., 2011). Several studies on seed germination and seed emergence revealed the beneficial effects of seed priming by several ways including heat, smoke, soaking, leaching, temperature, scarification and NaCl salinity (Ahmed *et al.*, 2005). The main problem encountered in propagating seedlings of most indigenous tree for afforestation programmes are dormant seeds. The dormancy must be broken before germination can occur (Bewley, 1997). Lack of seed germination at certain times and suitable conditions are a big problem for seed researchers, botanists, and farmers. Therefore, this study investigated different methods of breaking seed dormancy in two indigenous tree crops of Southeastern Nigeria.

MATERIALS AND METHODS

Germination experiments of *Afzelia africana* and *Monodora myristica* were carried out in the Screen House of the School of Agriculture and Agricultural Technology, of the Federal University of Technology Owerri, Nigeria for 4 and 8 weeks, respectively. The seeds were sourced from the wild in Ivo Local Government Area of Ebonyi and Umuahia South Local Government of Abia states respectively. *Afeliaz africana* seeds were treated with five treatments; (98% sulphuric acid ($H_2S0_{4)}$ (5, 10, 20, 30 minutes), Hot water at boiling point (3, 6, 9, 12 minutes), 70^{0}C Oven temperature (3, 6, 9, 12 minutes), Sodium chloride (NaCl) (5, 10 and 15 min) and untreated intact seeds as control. *Monodora myristica* were subjected to three treatments; 98% sulphuric acid (5, 10 minutes), Cold water soaking (12, 24 h) and untreated intact seeds (control). Apart from cold water and untreated intact seeds in both experiments, the seeds were thoroughly washed with tap running water and soaked with distill water for 24 h before sowing in germinating trays, using sawdust as the germinating medium and watered two times in a week.. The seeds were laid out in a complete randomized design with three replications according to specifications. Data collected were percentage germination (PG)

$$\text{Percentage germination (\%)} = \frac{\text{Number of seeds emerged} \times 100}{\text{Number of seeds planted}}$$

Germination index (GI) according to the equation of Kader and Jutzi (2004).

GI= Σ(TiNi). Ti: number of day after sowing and Ni: number of germinated seeds in the day.

Mean emergence time (MGT)

This was calculated based on Ellis and Roberts (1981).

$$MGT = \frac{\sum ni\ di}{\sum ni}$$

ni and di are respectively number of germinated seeds and the number of days from the beginning of germination of the experiment.

and

Coefficient velocity of emergence (CVG)

This was calculated according to Ranal and Santana (2006) and Obiefuna *et al.*, (2012)

$$CVG = \frac{fi}{fixi} \text{ X } 100$$

where fi is number of seeds newly germinating on day i; xi is number of days from the beginning of germination experiment, and k is the last day of germination.

All data collected were subjected to Genstat 2007 model and least significance difference (LSD) was used for separation of significantly different means.

RESULTS AND DISCUSSION

All the germination parameters measured (PG, GI, MGT and CVG) showed significant differences in the treatments (Hot water, NaCl, 70^{C}Oven temperature, 98% H_2SO_4 acid and untreated seeds) evaluated. Seeds soaked in 98% H_2S0_4 acid for 30 minutes recorded significantly the least PG (25%) compared with other treatments that recorded 75%-100% except 98% H_2S0_4 acid for 20 min (50%). Meanwhile, the highest CVG (10.5) was recorded in 5 min H_2S0_4 acid, followed by NaCl for 5 min (9.1), hot water 9 and 12 min (8.2), respectively and MGT of 9.5 days, 11.0 days, 12 days and 11.4 days respectively, compared with control (0) treatment with reduced CVG (3.9) and increased MGT of 20.2 days significantly ($P<0.05$). All the germination parameters measured (PG, GI, MGT and CVG) showed significant differences in the treatments (Cold water, H_2S0_4 acid and untreated seeds) evaluated. Seeds soaked for 24 h in cold water significantly produced 70% seedlings at a reduced MGT (37.7days) with increased CVG (2.6) followed by 98% H_2SO_4 acid at 5 min which produced 60 PG within 43.7 days (MGT) at CVG of 2.6 but 98% H_2SO_4 acid for 10 and 20 min, respectively recorded 30 PG each. Increased number of MGT (54.2 days) was significantly recorded by untreated seeds (control) in the production of 50 PG at CVG of 1.4 and a higher G.I of 271.0. Seed germination starts with the uptake of water by the quiescent dry seed, ending up with the elongation of the embryonic axis (Holdsworth *et al.*, 2008). Most of the treatments attained the maximum PG of 100 even untreated seeds (control) but untreated seeds recorded more MGT and lower CVG, respectively than other treatments used in *A. africana*. Seed dormancy, a seemingly inactive or resting condition of the seed, slows down or stops seed germination of seeds over long time periods. In *M. myristica*, 24 h hydroprimed seeds and 5 min in 98% H_2S0_4 acid increased germination to 70% and 60% respectively more than in untreated seed (control) (50%). This is in line with Peter-Onoh, *et al* (2014) reported that *Measo barteri* seed emergence was improved by several pre-sowing methods and durations. Prolonged duration of 98% H_2S0_4 acid gave low PG, reduced CVG and increased MGT in both tested crop seeds. Lower PG recorded in 98% H_2S0_4 acid on *A. africana* (20 and 30 min) and *M. myristica* (10 and 15 min) could be due to the damage caused to the embryo by the chemical. This is in conformity with the findings of Likoswe (2008). Early germination of pretreated seeds over untreated seeds is probably due to water and gases entering the embryo early through the cracks and causing a series of enzymatic breakdown and resulted in the transformation of the embryo into a seeding early enough than other seed treatments (Odunfa, 1989). Seed dormancy is a physiological phenomenon in wild and crop plants, and is more common in wild plants than the crop plants (Farahani, *et al.*, 2011).

CONCLUSION

Afzelia africana and *Monodora myristica* need pre-sowing treatments to hasten germination. All the pretreatment methods and duration evaluated enhanced germination except 98% H_2S0_4 acid at 20 and 30 min for *A. africana* and 98% H_2S0_4 at 10 and 15min for*M. myristica* recorded poor PG, this could be due to damage caused by the prolonged duration used. Since the treatments used could effectively break the seed coat, it can be concluded that the seed coat was the barrier to germination. The results drawn from this research suggest that the type of dormancy exhibited by *Afzelia africana* and *Monodora myristica* is physical dormancy which is entirely imposed the seed coat.

ABSTRACT
Problems and prospects of private forest plantation in Oyo State were investigated. Multistage sampling techniques were employed for this study. Data analyzed were through the use of descriptive statistics. The results show that respondents were males (98.33%) and females (1.67%). The level literacy is high total 96.67%. The predominant age group was in the range of 31-40 years (48.33%) while 55% of the respondents source for fund through their personal savings. The results also revealed that respondents (75%) were more involved in Tectona grandis plantation which contributes widely in timber production, pole production, and pulp production. Based on these findings, private plantation owners should be more encouraged through provision of loan with lesser interest rate, favourable government policy and provision of quality seedlings. This only assures the future prospect of forest plantation which includes high income, provision of employment, provision of plank wood, fuel wood, and protection of environment.

INTRODUCTION

Nigeria (the most populous country in Africa) faces extremely mounting pressures on biodiversity and tropical forests. Wildlife, trees, and many other plants are over-harvested and poached, and the natural environment faces increased degradation from expanding unsustainable agriculture, water pollution, air pollution, and a variety of other anthropogenic factors (David, 2008). Nearly 1,000 forest reserves areas are included in the International Union for Conservation of Nature (IUCN) World Database on Protected Areas (FAO, 2005). Oyo State had 18 out of 78 forest reserves areas in Southwest State of Nigeria (FORMECU, 1990). Many of these have no forests left, and most are highly degraded due to unsustainable extraction of timber, fuel wood, economically important plants, bush meat, and other resources. Nigeria's tropical forests are particularly hard hit. According to the United Nations Food and Agriculture Organisation, the country has the highest deforestation rate in the World (FAO, 2005). Between 2000 and 2005, Nigeria lost 55.7 per cent of its primary forests due to logging, agricultural expansion, and fuel wood collection (FAO, 2005). Forest reserves are areas designated by State governments for the protection of timber and other forest resources. Constitutionally, all lands are owned in trust by the Governor of each State. But the lands outside forest reserves, called "free areas", are claimed by traditional communities, local governments and elite families and individuals. Nigeria does not have land titling and registration systems like those common in western countries. A forest resources study (Beak Consultants, 1998) estimated that the closed forest remaining in the "free areas" totaled 905 000 hectares in 1995. The problem of poor management and inadequate funding of these forest plantation calls for private practice involvement in forest plantation activities. A private forest plantation program attracts most individuals but in developing countries there are usually no encouragements or provision of adequate facility by government that makes it convenient to engage in. The global area of plantations in 2000 was 187million ha, a significant increase over the 124 million ha in 1995 (FAO 2001). These plantation forests accounted for less than 5% of global forest cover, and for less than 22% of global round wood supplies to industry. The greatest threat to forests industry is the conversion of forests into other land uses due to increasing pressure from human populations and aspirations for higher standards of living, without due concern to sustainability of resources underpinning such developments, heighten concerns in this regard (Oduntan, 2009). Increased need for wood products, pressure for converting better forest lands to agriculture, destruction of indigenous forests by shifting agriculture and indiscriminate logging, increased areas being set aside for conservation or other purposes, and the difficulty in managing tropical hardwoods in fragile ecosystems, have all led to a realisation among responsible observers that proper use of private forest plantation is the only way to complement government effort and combat treat to our environment. This study is therefore justifies by the need to ensure continue availability of forest product to the ever increasing human population. Thus, this paper examined the problem and prospect of private forest plantation in Oyo State Southwest, Nigeria. Different types of existing private forest plantation as well as purpose of establishing the plantation in the State were also identified.

METHODOLOGY

The empirical setting for this study is Oyo State, Southwest Nigeria. The state is a fast developing state created in 13th February 1976 with its administrative headquarters in Ibadan, a reputable city known to be the largest in West Africa and the second largest in the Africa after Cairo of Egypt (Wikipedia, 2014). It lies within the latitude of 7.85^0N and longitude of 3.93^0E. It covers a total area of land size of 27,848 square kilometers out of which 6.09% is government forest reserves (FORMECU, 1990). The state has a population of 5,591,589 representing 4% of the country population (NPC, 2006). It is bounded in the south by Ogun state and in the north by Kwara state, while in the west by the republic of Benin. The state is a homogenous state comprises of Oyos, Ibadan and Ibarapas, all belongings to the Yorubas family and speaking same Yoruba dialect, people from within and outside the country trade and settle in the state. The climatic condition is the usual tropical pattern with dry and wet seasons with relatively high humidity. The two identifiable seasons are the rainy season which begins from late March to October and dry season stretching from November to early March. The mean annual temperature varies between 21.1^0 C and 31.1^0 C. The annual rainfall is within the range of 800mm in the derived eco-zone to 1500mm in the rainforest belt. The rainfall is bimodal with its peak in July and September (Faleyimu and Agbeja, 2004). Agriculture is the main occupation of the people of the state. The state soil and climate favours the cultivation of crops like cassava, yam, cereals (maize, millet) grains (rice), cocoa, palm tree, cashew as well as many forest tree plantations. Forestry activities in the state is been administered by forestry department of Ministry of Agriculture & Natural Resources (MANR) of the state on a zoning basis which are Ibadan, Saki, Oyo and Ogbomosho zone. A multistage sampling technique was used to select respondents for this study. In the first stage, following Forestry Department, Ministry of Agriculture and Natural Resources (MANR) Oyo state zoning basis, Oyo state is divided into four (4) zone of Ibadan, Saki, Oyo and Ogbomosho. In the second stage, 15 respondents per zone were randomly selected from the list of registered private forest plantation in the forestry department, making a total of 60 respondents for this study. Primary data were collected using a well-structured questionnaires and interview schedule were personally arranged with the targeted respondents (private forest owners/ farmer) in the various forest zones of the State. Data collected were analyzed using descriptive analyses such as mean, frequency and percentage.

RESULTS AND DISCUSSION

Socio-demographic Characteristics of the Respondents in the Study Area

Table 1 shows that 98.33% of the respondents were male. This might be attributed to the fact that private forest plantation were usually the role of men in the socio-cultural setting of the people under study. Age distribution of the respondents revealed that 48.33% of the farmers in the study area were between 31 – 40 years of age, being within the youthful ages, it is also an indication that they may be amenable to changes and education according to (Fakoya *et al.,* 2007). Maritally, 71.67% of the respondents were married and 25% were single. The level literacy is high, about 50% of the respondents had Secondary School education, followed by 30% of the respondents that had tertiary education. Low level of education had relative adverse effect on man, this high level of literacy therefore enhance good communication and understanding in agricultural practices (Adams, 1982). The respondents were majorly Muslims (56.7%) while (43.3%) were Christian. Majority of the respondents' source for fund to established the private forest plantation through their personal savings (55%), while 33.33% source for finance through Cooperative society's loan. This shows the most nagging problems facing forestry development in Nigeria is paucity of funds. Funding forestry program and projects is capital-intensive. Much money is required for tree planting and forest restoration.

Distribution of Respondents Based on Types of Forest Plantation and Purpose of Establishment in the Study Area

Table 2 shows that majority of the farmers are involved in different forestry plantation, Saki zone *Gmelina arborea* (13.33%) and *Tectona grandis* (86.67%), Ibadan zone *Gmelina arborea* (33.33%) and *Tectona grandis* (66.67%), Oyo zone *Gmelina arborea* (33.33%) and *Tectona grandis* (66.67%) and Ogbomosho zone *Gmelina arborea* (20.0%) and *Tectona grandis* (80%). In total, 75.0% of the respondents involved in *Tectona grandis* plantation and 25.0% involved in *Gmelina arborea* plantation. The Table also shows that majority (86.673%) of the respondents established the plantation for timber production purposes; while 78.33% established the plantation for pole production purpose and 81.67% established the plantation for all purpose. These results also show the multipurpose aspects of species used by inhabitants around the plantation. These trees species planted for timber purposes were used all over the globe for construction of houses, bridges, boats and furniture (Ogunwusi, 2013). These purposes for establishing these plantations directly enhance the respondents' better income, crate employment, provision of plank wood and fuel wood and protection of environment.

Distribution of Respondents Based on Constraints Faced on the Establishment and Maintenance of the Private Forest Plantation in the Study Area

Figure 1 shows that an establishment of private forest plantation faces various constraints. Hundred per cent of the respondents faces the problem of fire outbreak in the plantation, 98.33% faces the problem of inadequate fund, followed by 93.33% that faces the problem of Government Policy, 61.67% had disease outbreak problem. In Nigeria, various factors are obstructing the effective implementation of conservation policies. There is the problem of lack of adequate data on the status of biodiversity and the extent of degradation of the forest in the country (USAID/Nigeria 2008).

CONCLUSION

Based on the findings, the result has shown that the farmers were more involved in *Tectona grandis* forest plantation than *Gmelina arborea* plantation. The plantation tree species serves widely in use as timber production, pole production and all other purposes. Also, findings reveal that, future prospect of forest plantation include provision of employment, provision of plank wood, fuel wood, and protection of environment. Thus, it is therefore recommends that Government should ensure availability of quality seeds even at subsidized rates. The extension agents should encourage farmers to plant forest trees along their agricultural farming activities. Plan must be in place for acquisition of more lands and funds availability for private forest plantation while a public enlightenment campaign encourages mass participation in tree planting.

ABSTRACT
The study examined the adoption of improved agroforestry technologies among farming households in Jos South LGA of Plateau State. Well-structured questionnaire were designed and administered to ninety farmers who were selected using a multistage random sampling technique. Data collected were analyzed using Tobit regression analysis and descriptive statistics. Findings shows that the main determinants of the adoption were farmers' age (P<0.05), educational level (P<0.1), household size (P<0.1), farming experience (P<0.1), farm size (P<0.05), income (P<0.05), access to credit (P<0.01) and extension contact (P<0.01) and this variables were all significant. Apart from age of the farmers which was negatively related to adoption of agroforestry technologies all other variables mentioned affected the adoption rate of agroforestry technologies positively. Also, the agroforestry technologies practiced in the study area had many benefits including; Wood fuel/Firewood (97%), boundary marks/ Live fence (88%), Food/Fruits (64%), Wind breaks (50%), income (56%), fodder for animals (33%), soil conservation (28%), shade (24%), aesthetic (17%), and herbal medicine (31%). Based on the findings of this study, it was strongly recommended that farmers be provided with loans at concessionary interest rates to solve their financial problem of adopting innovations, planting stocks (inputs) should be subsidized for the farmers. Furthermore there is need to increase extension contact with the farming households in the study area.
Keywords: Agroforestry Technology, Adoption, Determinants and Benefits

INTRODUCTION

Adoption is a decision made by an individual or group to use an innovation in a continuous manner (Akubuilo *et al*., 2007). Technology is the systematic application of scientific or other organized body of knowledge to practical purposes (Akubuilo *et al*., 2007). This includes new ideas, inventions, innovations, techniques, methods and materials. Agroforestry is an agricultural approach of using the interactive benefits from combining trees and shrubs with crops and/or livestock (enwikipedia.org/wiki/agroforestry). It combines agriculture and forestry technology to create more integrated, diverse, productive, profitable, healthy and sustainable land use system. It incorporates several plant species into a given land area and creates a complex habitat that can support a wider variety of birds, insects and other animals. Agroforestry is an aspect of farm forestry that encourages the deliberate integration of woody perennials with agricultural crops and/or animals on the same management unit, with the aim of enhancing soil fertility and increasing farmers' income through the use of economic trees (Akinbili *et al*., 2007). Agroforestry addresses many of the global challenges such as deforestation, unsustainable cropping practices and hunger, poverty and malnutrition (Udofia, 2001).The agroforestry technologies prevalent in the study area are; snail rearing, apiculture, mushroom production, Woodlots, Tree planting on the homestead, Home gardens, Hedge planting and Boundary marking however, the adoption of these technologies over the years has not been encouraging. The reason for the increasing concern of stakeholders on the adoption of agroforestry technologies is due largely on the interactive benefits of agroforestry and other farming activities (Adekoya *et al*.,). Agroforestry is widely recognized as a branch of agricultural science that is rapidly becoming a science in its own right and many studies have been conducted in this area, most of which has been from the biophysical perspective, research on the determinants of adoption of agroforestry technologies have been inadequate, this has caused a void in research. Previous studies on the adoption of agroforestry technologies (Ajayi et al., 2006) focused more on the linkage between research organizations and extension, with neglect to the linkage between extension and farmers, and farmers are central to adoption of innovations as they are the supposed users of the technologies (Aboh and Akpabio, 2008). According to them, ineffective linkage between extension and farmers is responsible for low adoption of agroforestry technologies by farmers. It is against this background that the study addressed the following research questions; i. What are the factors affecting the adoption of agroforestry technologies by farmers in the area? ii. What are the benefits of adopting agro-forestry technologies among the respondents?

MATERIALS AND METHODS

This study was conducted in Jos-South Local Government Area of Plateau state. The site lies on latitude of 80 43'N and Longitude 80 46'E with an altitude of 1293.2m above sea level. Jos-South Local government area(LGA) is one of the seventeen Local government areas in Plateau state of Nigeria. It is made of four districts; these include Vwang, Du, Gyel and Kuru. The Local government has an average land area of 1, 037km2. Rainfall from April to August constitutes the rainy season in the study area with an average temperature of 27^0C. The multistage random sampling technique was adopted for this study. In the first stage, Jos south LGA was purposively selected due to the prevalence of farmers who adopted agroforestry practices. In the second stage two districts were randomly selected. Finally, ninety farmers were randomly selected at a constant proportion of 0.10, from a compiled list of nine hundred farmers who had adopted any of the various forms of agroforestry technology by the local extension agents in the selected districts. Data for the study was analyzed using Tobit regression analysis and descriptive statistics. The Empirical Tobit Model is expressed as: $Y_{ij}= \beta_{ij}x_{ij} +u_i$

Where; Y_i=agro forestry technologies adopted, X_i = vector of the explanatory variable, β_i = vector of the coefficient, u_i = random error term .The explicit model of the regression is as follows: Y = f(X_1, X_2, X_3, X_4, X_5, X_6,X_7,X_8,e).

Where; Y= Agroforestry Technologies (Woodlots, Tree planting on the homestead, Home gardens, Hedge planting and Boundary marking), X1= Farmers Age (years), X2= Farmers Educational level (years), X3= Household Size of Farmers (Number of Persons), X4= Farming Experience of Farmers (Years), X5= Farm Size of Farmers (Hectares), X6= farmer income (₦), X7= Farmers access to credit (Dummy variable, Yes =1, No = 0), X8= Farmers contact with extension agents (Dummy variable, Yes =1, No = 0), E= Error term.

RESULTS AND DISCUSSION

Factors influencing the adoption of agro forestry technology

From the results of the Tobit regression analysis the log likelihood was 79.10 indicating that the independent variables (X_1, X_2… X_8) jointly explained 79.1% of the variation in the dependent variable (Y). Consequently the interpretation of the regression result indicates the following: Farmers' age (X_1) is negatively related to adoption of agroforestry technologies, meaning that younger farmers adopted the technologies more than the older farmers. This relationship is significant at the 5% level of probability. Farmers' educational level (X_2) has a positive relationship with adoption of agroforestry technologies implying that the more educated farmers had higher tendencies to adopt agroforestry technologies. Farmers' household size (X_3) is positively related to the adoption of agroforestry technologies indicating that farmers having larger households adopted the technologies more efficiently due to increased farm labour supply. This relationship is significant at the 10% level of probability. Farmers' experience (X_4) has a positive effect on the adoption of agroforestry technologies showing that the more experienced farming households adopted the packages more than the less experienced farming households. This relationship is significant at the 10% level of probability. Farm size of farmers (X_5) is positively related to adoption of agroforestry technologies implying that as the farmers' farm sizes increase they adopt more of agroforestry technologies, and vice versa. This effect is however significant at the 5% level of probability. Farmers' income (X_6) is positively related to adoption of agroforestry technologies meaning that farming households with higher remunerative income adopted the technologies more than the farming households with low remunerative income. The effect is significant at the 5% level of probability. Farmers' access to credit (X_7) has a positive effect on adoption of agroforestry technologies indicating that farmers with access to credit adopted the technologies more than those without access to credit. This effect is statistically significant at the 1% level of probability. Farmers' contact with extension agents (X_8) is positively related to the adoption rate of agroforestry technologies showing that farming households with higher number of contacts with extension agents adopted the agroforestry technologies more than farmers with less contact with extension agents. This relationship is statistically significant at the 1% level of probability.

Benefits of adopting agro forestry technology

The results (Table 2) shows the benefits the respondents derive from adopting the various agro forestry technologies in the study area. The agroforestry technologies practiced in the study area had many benefits including; Wood fuel/Firewood (97%), boundary marks/ Live fence (88%), Food/Fruits (64%), Wind breaks (50%), income (56%), fodder for animals (33%), soil conservation (28%), shade (24%), aesthetic (17%), and herbal medicine (31%).

CONCLUSION

The major aim of the study was to analyze the determinants of adoption of agroforestry technologies in the study area. The research study concluded that: Agro forestry technology adoption in the study area was relatively high and there were a variety of Agro forestry technologies that have been adopted. The major factors influencing agroforestry adoption in the study area were age, educational level, household size, experience, farm size, income, access to credit, and extension contact. The agroforestry technologies practiced in the study area had many benefits including; wood fuel/Firewood, boundary marks/ live fence, Food/Fruits, Wind breaks, income, fodder for animals, soil conservation, shade, aesthetic, and herbal medicine. Based on the findings of this study it is recommended that there is need for further studies on the specific economic benefits from each of the Agro forestry technology adopted. Also, farming households should be provided with low interest agricultural loans to solve the problem of inadequate finance. Furthermore, Inputs like planting and starting stocks should be subsidized so that the poor rural farmers will easily adopt the technologies by affording to buy the inputs. In addition, extension activities should be intensified to sensitize and motivate farmers to adopt agro-forestry technologies.

Table 1: Factors influencing adoption of agro forestry technology

ABSTRACT
The study was carried in Ikwuano to compare honey produced by Bee honey hunters and bee keepers (Traditional and modern beekeeping method). A total sample size of 60 respondents (30 bee hunters and 30beekeepers were used for the study. Information was collected from the respondent with the use of structural questionnaire. Data were analyzed using cost and return analysis. Result showed that profit from bee hunting/traditional beekeeping is 26.67. While that of the beekeepers (modern) is 66.67. The result shows that modern beekeeping is more profitable than traditional bee hunting. The result called for policies that will encourage establishment of hives by farmers in the rural areas since honey is a free gift by nature.
Keywords: Beekeeping, comparative assessment, traditional, modern

INTRODUCTION
Beekeeping is practiced all over the world it is maintenance of honey bee commonly in hive by human. A colony is made up of three caste, workers, the queen and drones. A beekeeper or Apiarist Keeps bees in order to collect honey and other bee products such as beeswax, propolis, pollen and royal jelly (Bradbear, 2003). There are two categories of bee-farmers in Nigeria, the modern beekeepers and the traditional honey bee hunters (Anyaegbunam *et al.*, 2006). Modern beekeepers are organized bee-farmers that use scientific and improved method of beekeeping in which hives are constructed for the bees to inhabit, produce honey and other bee products. This method involves the use of movable comb hives ranging from top-bar hive to frame hive, on the other hand the traditional bee farmers (honey hunters) harvest the honey by cutting down and burning the whole or part of the tree where the honey is produced. This often results to the physical destruction of the nest location (Spore, 2007). The honey produced through traditional beekeeping method is often of low quality when compared to honey produced through modern beekeeping method and this affects the curative and nutritional quantity of the honey (Anyaegbunam, 2006)

METHODOLOGY
The study was conducted at Ikwuano L.G.A in Abia State, the respondent comprised of traditional and modern beekeepers in Ikwuano. The sample size was sixty respondents made up of thirty members of beekeepers and honey hunters. Information was collected from the respondents with the aid of structural questionnaire. The analytical frame work incorporated the concept of gross margin analysis and complete costing as described by Reddy *et al.,* (2004). There is a direct relationship between cost and outputs. All the accounting cost element such as direct labor, material and expenses are embodies in the products, the gross margin analysis will deduct the variable cost of production from the revenue generated per litre.

GM = TR – TVC
Where
GM = Gross margin
TVC = Total variable cost
TR = Total revenue

Complete costing valuates the profitability of beekeeping production.

RESULTS AND DISCUSSION
The study has shown that the annual bee honey produced by modern beekeepers total revenue and profit generated were 66.67 greater than those produced by the traditional honey hunters which is 26.67 modern beekeeping method is more profitable and variable than traditional beekeeping method, this is consistent with Farinde *et al.,* (2005) who reported that bee honey production was a viable and highly profitable enterprise. Table one (1) shows that modern beekeepers harvested a mean yield of 66.67 litres of bee honey valued at N800 per litre while the traditional beekeeper had a mean yield of 26.67 valued at N500 per litre. It also shows that both traditional and modern beekeepers harvest at least three times per season. The traditional beekeepers has been into beekeeping business for seven years on the average while the modern beekeepers has been in the business for five years. Table 2 shows that modern beekeepers has mean yield of 66.67 litres of bee honey valued at N800 per litre while the traditional beekeepers had a mean yield of 26.67 litres valued at N500 per

litre this confirmed the fact that modern beekeeping is an organized enterprise unlike the traditional beekeeping which is a game of chance (Anyaegbunam, 2006).

CONCLUSION

The comparative study revealed that modern beekeeping is a high income generating enterprise compare to traditional method of beekeeping. To improve the living standard of the people, modern beekeeping should be encouraged and the government should as a matter of urgency introduce modern beekeeping method to the rural farmers which will be sustained taken into account the abundance of bee plants in the locality.

Table 1: Average annual output of honey produced by modern beekeepers and traditional beekeepers

Items	Modern Beekeepers (mean value)	Traditional beekeeper (mean value)

ABSTRACT
Bamboo is a valuable non-timber forest product yet to be fully explored in Nigeria. In this regard, this study evaluated the socio-economic potentials of bamboo processing in Ekiti state, Nigeria. A three-stage sampling techniques was used to elicit information from 120 bamboo processors in Ekiti State, Nigeria. Descriptive statistics, costs and returns, multivariate regression and Kendall's coefficient of concordance were used for data analysis. The results of the study show that 83.3% were males while 16.7% were females. Average age of the respondents was 43years. About 76.7% of the respondents were married, 6.7% were single. The study further revealed that, most bamboo processors were men who utilize improved method of processing. They rely heavily on cooperatives and local money lenders as their source of credit and they utilize family labour. The major profitability determinants of bamboo processing in the study area include quantity and cost of bamboo processed, labour and fuel at P=0.01 level of significance. The net returns to bamboo processing were estimated at ₦345,485.84 ($1919.366) per year. The major challenges to bamboo processing include inadequate bamboo culms, labour shortage and non-availability of credit among others. The study recommends that research institutes should develop higher yielding varieties which will be made available to bamboo processors at affordable costs. Cooperation among bamboo processors should be encouraged to enable them acquire improved tools and equipment needed for bamboo processing so as to enhance ease of processing and enhance productivity.
Keywords: Bamboo, Potentials, Processing, Socio-economic, Nigeria

INTRODUCTION

Bamboo (*Bambusa vulgaris*) is a group of perennial evergreens in the true grass family *Poaceae* and includes the largest members of the grass family. There are more than 70 genera of bamboo divided into about 1,450 species, of which only around 50 species are routinely cultivated (Hunter, 2003). Native bamboo grows in many parts of the world, including East Asia, Sub-Saharan Africa and the Americas. Bamboo is not limited to tropical climates, with some species able to withstand frost and survive in Northern Europe (Hunter, 2003).

Bamboo is an ancient woody grass widely distributed in tropical, subtropical and mild temperate zones. Traditionally seen as the "poor man's tree", in recent years bamboo has risen to a high-tech, industrial raw material and substitute for wood. Although the commercialization of planted bamboo has been slow, bamboo is becoming an increasingly important economic asset in poverty eradication, economic and environmental development (FAO, 2005).

Bamboo is an extremely fast growing plant, with some species obtaining growth surges of 100cm per 24 hour period. Most bamboo species grow to their full height within a single growing season. Over the following seasons the walls of each culm (or stem) dry and harden, reaching maturity within 3 to 5 years. After a maximum life, which varies by species and climate, the individual bamboo culm will collapse and decay, although the plant itself may survive. Furthermore bamboo tolerates poor soils, which makes it useful for planting on degraded land (Hunter, 2003).

In spite of the numerous uses of Bamboo and its low investment uptake, there is a gross dearth of investment on Bamboo development and processing in Nigeria. In addition, the potentials of Bamboo as raw materials for industries, generation of employment and poverty alleviation are yet to be fully explored. These issues necessitated this study by evaluating the socio-economic potentials of Bamboo processing in Nigeria.

MATERIALS AND METHOD

The study was carried out in Ekiti state, Nigeria. The state is in Southwest Nigeria. The state has a total land area of 6,353 square kilometres with a population of 2,737,186. Agriculture is the main occupation of the people of Ekiti, and it is the major source of income and employment for more than 75% of the population of Ekiti state. The land is buoyant in agricultural resources with cocoa as its leading cash crop. The land is also known for its forest resources, notably bamboo and timber. Because of the favourable climatic conditions, the land enjoys luxuriant vegetation it has abundant resources of different species of timber (Ekiti State Government, 2008; NPC, 2007). Ekiti, State is one of the four states of Nigeria that have indicated interests in bamboo cultivation (RMRDC, 2011). A three-stage sampling technique was used for this study to select 120

Bamboo processors. Data were collected with the aid of a structured questionnaires administered to respondents at the Bamboo processing sites in the study area.

Data collected were analysed using descriptive statistics such as frequency, mean, mode average and percentages. Net Returns to Processing equals Gross margin –Average Total fixed Costs-------------Eq 1

Gross margin analysis estimated as:

Gross margin= Average Total Revenue (ATR) – Average Total Variable Cost (ATVC)--Eq 2 Average total revenue includes the returns from bamboo and all other products. Average total variable cost (ATVC) includes costs of variable inputs such as cost of bamboo culms, fuel, labour and costs of other variable inputs.

Multivariate Regression Model was also used for analysis with the implicit and explicit models used for this analysis are given as follows:

The implicit model Y_1:

$Y_1 = \beta X_1 + e$--------------------------Eq 3

Where:

Y_1 = Net farm income (₦),
β = Coefficient to be used for the model,
X_1 = Age of the respondents (years), and
e = Error term.

The explicit model Y_2:

$Y_2 = \beta X_1 + \beta X_2 + \beta X_3 + \beta X_4 + \beta X_5 + e$-------Eq 4

Where: Y_2 = Net farm income (₦),
β = Coefficient to be used for the model,
X_1 = Cost of bamboo (₦),
X_2 = Cost of labour (man-day),
X_3 = Quantity of bamboo processed (kg/cm^3),
X_4 = Quantity of fuel (litres),
X_5 = Depreciated cost of land (₦), and
e = Error term.

The Kendall's Coefficient of Concordance

The Kendall's Coefficient of concordance was used to rank the challenges faced by bamboo processors as estimated below:

W = $12S/P^2\,(n^3 - n) - P^T$--------------------------------Eq5

Where:

S = Sum of squares,
P = Number of predictor variables,
n = Number of respondents,
T = Correction factor.

RESULTS AND DISCUSSION

Cost and Return Analysis

The costs and returns to bamboo processing per year are presented in Table 1. For the analysis, the average total fixed cost was ₦405,051.63 per year include costs of land, cutlass, chainsaw, slicer machine, generator and vehicle while the average total variable cost was ₦1,406,360.51 per year include labour, fuel, electricity and bamboo processed. The average total revenue ₦2,156,897.98 was gotten from the summation of all the prices of bamboo products processed. The net returns (net profit) of ₦345,485.84 ($1919.366) per year calculated as Gross margin minus average total fixed cost. The result indicates the Bamboo processing is profitable. This will result in an average monthly net returns of₦28,790.49 to a processor.

Therefore, from the results presented so far, it may be inferred that bamboo processing is a profitable venture. Bamboo processing though largely un-developed has been described to be profitable providing income to rural households. The findings from this study corroborated earlier studies (IFAD, 2013a,b; Sythud, Zhang, and Mukete 2015; INBAR, 2015a and b).For example, in Tanzania, studies have shown that bamboo has improved the lives of several thousand people and is also being used by these communities to reverse land degradation(IFAD, 2013a; INBAR 2015a). These activities have created new income streams in several rural areas, where communities produce crafts and desks for local schools. Charcoal briquette production and selling that generate income and slow deforestation employs over 5000 women, many of them single mothers, who now have stable incomes (INBAR, 2015a;b) . In Ecuador, bamboo grants have sparked a number of public-private partnerships that make furniture, flooring, crafts and construction products. IFAD, 2013a, INBAR, 2015a and b). These models have now also been shared with neighboring regions in Northern Peru, with some 2000 people now employed. These value chains and enterprises, produce affordable and earthquake and flood resistant housing which reduces risks to climate change and transforms coastal and peri-urban areas with better quality homes for low-income communities IFAD, 2013a and INBAR 2015a).

In order to know the major determinants of the profitability of bamboo processing, multivariate regression analysis was carried out. As shown in the table, cost of bamboo (X_1) has significant influence on the profitability of bamboo processing, this implies that the higher the cost of bamboo, the lower the profit. Cost of labour (X_2) also has a significant influence on the profitability of bamboo processing, which implies that, as the cost of labour increases, it will amount to decrease in profitability of bamboo processed.

The quantity of bamboo processed (X_3) is one of the major determinants of the profitability of bamboo processing, in the sense that, the higher the quantity of bamboo processed, the higher the profit incurred from bamboo processing. Also, the quantity of fuel (X_4) has a major influence on the profitability of bamboo processing. The lower the quantity of fuel consumed by the various machines and generator, the higher the profitability of bamboo processing. The depreciated cost of land (X_5) is also a major determinant of the profitability of bamboo processing because the lower the cost of land, the higher the profitability of bamboo processing.

The other determinants of the profitability of bamboo processing are: quantity of labour (man-day), depreciated cost of generator (kg/cm^3), and tertiary education. They also have influence on the profitability of bamboo processing. The quantity of labour (man-day) determines the profitability because the higher the efficiency of labour, the higher the profitability of bamboo processing.

The R^2 value of 0.47 determines the variation in profitability of bamboo processing, which is explained by the explanatory variables or the determinants of profitability of bamboo processing that have been mentioned above. The F-value is 80.1.

Proportion Estimation Of Bamboo Products Processed

These are the proportion estimation of bamboo products processed by the various respondents in their communities. The major bamboo products processed are bamboo scaffold, bamboo stakes and bamboo fencing planks (and also ply bamboo). They are produced in large quantities than other bamboo products. The remaining bamboo products processed by the respondents in the study area are; bamboo pots for inputs, bamboo benches for sitting in farm houses, bamboo window blinds, bamboo chairs, ornamentals, medicinal leaves, bamboo floor tiles, bamboo tables, bamboo flower vase, bamboo bed, bamboo stool and firewood but most times, the unprocessed bamboos are used for firewood. These products were line with earlier identified bamboo products from previous studies (Mekonnen et al 2014; Sythud, Zhang and Mukete 2015).

CONCLUSION AND RECOMMENDATIONS

This study shows that bamboo processing is a profitable business. Its production is affected mainly by quantity and cost of bamboo culms availability, labour shortage and fuel inputs. There is however a number of constraints limiting the processing of bamboo products in the area inadequate bamboo culms, labour hiring problem and non-availability of credit. Based on the findings of this study, for the productivity of bamboo processing to increase, the bamboo processors should have a way of coming together as cooperative society in order to acquire improved tools and equipment needed for bamboo processing so as to enhance ease of processing and increase productivity.

Table 1: Analysis of Costs and Returns

Items	Average quantity(q)	Average cost/unit (₦) (c)	Total value of q*c
Fixed Items			
Land (Rent)	-	10, 260.50	10, 260.50

ABSTRACT
Rising trends in Non-performing loans (NPLs) adversely affected availability of credit to economic agents in the Nigerian economy specifically agricultural sector thereby constraining financial intermediation and economic activities. The study sought to investigate the effects of NPLs in the Nigerian banking system on the performance of the forestry sub-sector of the economy from 1981-2015. Time series data were collected from annual statistical bulletin of the Central Bank of Nigeria. Results from the trend analyses substantiated by graphical presentation indicated that NPL and forestry performance showed an average downward trend with undulated fluctuations and distinct crests and troughs throughout the period of study. The exponential growth rates in NPLs and performance of the forestry sub-sector were -6.11% and -3.39% respectively. The Pearson correlation coefficient and analysis of bilateral Granger causality revealed insignificant relationship between NPLs and forestry's performance in Nigeria. The results of auto-regressive estimates also indicated that, non-performing loans in the Nigerian banking system had insignificant negative relationship with the performance of the forestry sub sector in Nigeria. Policy on increased participation of specialized financial institutions to increase volume of loans while insurance companies could intensify de-risking investments in forestry sub-sector should be introduced and enforced by CBN.

Keywords: Loans, Nigerian banking, forestry, economy

INTRODUCTION

Various studies have pointed to the key roles which the banking system plays in any economy. These crucial roles predominantly include among others; the provision of loans and advances to the different economic agents in the various sectors namely: agriculture, industry, services and others. Agricultural sector consists of crops, livestock, forestry, fishery and agro processing. (CBN, 2014). Loans and advances from the banking system are granted to the various economic agents in these Sub-sectors in order to expand scale of operations or initiate new agro-economic activities which will add values to agricultural growth over time in the country.

In Nigeria, forestry sub-sector has high employment opportunities, foreign earnings via exported timbers and other investment windows (FAO, 2001; Faleyimu, 2013). Yet in 2003, forestry sub-sector contributed only 0.6% to the gross domestic product (GDP). Nigerian forests provide a huge quantum of forage and fodder which are not only vital to the country's livestock production but a sufficient boost toward enhanced agricultural growth. Woods obtained from the forests are not only used for domestic purposes but for commercial. These woods are used as fuel wood and charcoal. The different commercial uses of forest wood include saw wood, paper products, furniture making and electrical, marine transportation and others. Faleyimu, (2013), in a study on the declining contributions of forestry to the gross domestic product of Nigeria: cause and cure noted that there was a declining role of export of forest products in Nigeria. In another study, Yusuf, Rufai and Komolafe (2013), evaluated externalities linked in the Nigerian forests. The result indicated the value of some positive externalities worth N 265,833 billion.

Bank loan constituted a major source of business capital and its availability may increase production efficiency whiles its inadequacy or non -availability can hamper productivity (Umoren, 2008). The performance of the forestry sub- sector of agricultural sector is crucial to the growth and development process of the economy and seemed to have been influenced by the availability of loans and advances from the banking system. The dismal performances of the sub-sector may be linked with high default rate associated with agricultural activities and poor health of the banking system resulting in high prevalent of Non Performing Loans (NPLs) (Elegbe, 2013). The non- repayments of loans over a prolong period of time ranging from 90 days and beyond constitutes non-performing loans (NPLs) (Badar and Javid, 2013, CBN, 1991). Some of the major causes of NPLs include: excessive credits creation by the banks, insider abusive, relaxed credit condition and poor loan recovery strategies, business cycles, volatility in macroeconomic and bank specific factors which are gross domestic products, inflation, interest rate and liquidity of the banks. The existence of NPLs affects lending to various economic agents in agriculture and other sectors. This seems to contribute to the problem of declining agricultural activities (CBN, 2003) which persisted in economies of many Subs –Saharan countries including Nigeria in the 1990s (Fofack, 2005). Following the importance of forestry sub- sector to Nigerian economy, this study investigates the effects of Non-performing loans in the Nigerian banking system on the performance of the forestry sub-sector.

MATERIALS AND METHODS

Study Area, Data Source and Analytical Technique: The study was conducted in Nigeria; a country situated on the Gulf of Guinea in the sub- Saharan Africa. Nigeria lies between 4^0 and 14^0 North of the Equator and between longitude 3^0 and 15^0 east of the Greenwich. The country has a total land area of about 923,769km^2 (or about 98.3 million hectares) with 853km of coastline along the northern edge of the Gulf of Guinea and a population of over 140 million people (National Population Commission, 2006). Secondary data used in the study were collected from the statistical bulletins of the Central Bank of Nigeria (CBN). The study employed trend analysis, Granger causality test and simple regression model to explore the relationship between the non-performing loans and performance of forestry sub- sector in Nigeria from 1981 to 2015.

The trend Analysis of Non-performing loans and Forestry performance Sub-sector's Performance in Nigeria (1981 – 2015)

The study investigated the nature of relationship, movement and growth rate in Non-performing loans and Forestry Sub- sector's performance in Nigeria. An exponential trend equation was specified as thus:

$log_e FOR_t = b_0 + b_1 T + U_t \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$

Where 'T' is the time expressed in year; FOR_t is the forestry sub sector performance proxy by the percentage share of forestry sub sector GDP in total agricultural GDP in Nigeria. The exponential growth rate in forestry Sub-sector (FOR) is given as:

(r) $=(e^{b1} - 1) * 100 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$

Note, the trend equation was estimated for the non-performing loans ($NPLs_t$) likewise

Bilateral Granger Causality Test on Non-performing loans and Forestry Sub- sector's performance in Nigeria

The primary model in Vector Autoregressive Regression forms are represented as thus:

$$\left\{\begin{aligned} \Delta \boldsymbol{LnFOR_t} &= \boldsymbol{\beta_0} + \boldsymbol{\beta_1}\sum_{i=1}^{n} \Delta \boldsymbol{LnFOR_{t-1}} + \boldsymbol{\beta_2}\sum_{i=1}^{n} \Delta \boldsymbol{LnNPL_{t-1}} + \boldsymbol{\varepsilon_{1t}} \ldots .(3) \\ \Delta \boldsymbol{LnNPL_t} &= \boldsymbol{\delta_0} + \boldsymbol{\delta_1}\sum_{i=1}^{n} \Delta \boldsymbol{LnNPL_{t-1}} + \boldsymbol{\delta_2}\sum_{i=1}^{n} \Delta \boldsymbol{LnFOR_{t-1}} + \boldsymbol{\varepsilon_{2t}} \ldots .(4) \end{aligned}\right\}$$

From the specification, there is bilateral granger causality from NPLs to forestry sub- sector's performance, if $\beta_2 \neq 0$ and $\boldsymbol{\delta_2} = 0$. Similarly, there is granger causality from the crop Sub sector Productivity to NPL if $\boldsymbol{\beta_2} = 0$ and $\boldsymbol{\delta_2} \neq 0$. The causality is considered as bidirectional if $\beta_2 \neq 0$ and $\boldsymbol{\delta_2} \neq 0$. Finally, there is no link between forestry sub sector performance and NPL if $\beta_2 = 0$ and $\boldsymbol{\delta_2} = 0$. (Guranti and Sangeetha, 2007)

RESULTS AND DISCUSSION

Augmented Dickey Fuller Unit Root Test Result

The stationarity of series was examined by the Augmented Dickey Fuller (ADF) unit root tests. The results are presented in Table 1.

The result showed that NPLs and forestry sub- sector's performance are non-stationary at levels but stationary (at 1% significance level) at first difference for the ADF equation that contains constant and constant and trend equations. The result implies that data for forestry sub- sector performance and non-performing loan cannot be specified at their levels without the risk of obtaining spurious regression. Also, the result indicates that, there is need to difference the variables before they are used in the model specified, so as to ensure stability.

Exponential Trend Analysis of Non-performing loans and Forestry sub- Sector's Performance in Nigeria (1981 to 2015)

The exponential trend equations for Non-Performing Loans and forestry sub- sector performance specified in equation 1 is presented in Table 2. The regression estimates for each of the variables is followed by the calculated exponential growth rate derived from the respective long run exponential trend equation. The results reveal that trend in NPLs show negative significant association with time in Nigeria. This implies that a change in NPLs is negatively influenced by time. NPLs have average exponential growth rates of -3.39%. This means that the growth in NPLs reduces over time in Nigeria. Similarly, the forestry sub-sector exhibits negative significant relationship with time. This indicates that the forestry sub- sector's performance decreases over time in Nigeria.

To further verify the previous assertions graphically; the linear trend in FOR and NPLs is showed in figure 1. Movements in both graphs are in consonant with the trend equations. However, the pattern of fluctuations in the two variables were remarkably different over time. It is suggested that, fluctuations in both variables are consistent with various policies and intervention programmes implemented in the country. For instance, the banking sector consolidation and other reforms helped shaped the undulated nature of NPLs in Nigeria. Also, the agricultural policies and programmes determined the orientation in the trend of forestry performance Nigeria.

Since these variables are highly dispersed and do not showed significance level of coherence, it is suggested that, there may be no significant relationship between the NPLs and Forestry sub-Sector's Performance in Nigeria. Fluctuations were undulated in NPLs with distinct crests and troughs in the trend. On the part of forestry sub-Sector performance, the trend assumes a progressive decline till 2005 when growth was stagnated.

The linear and symmetric relationship between Non-performing loans and Forestry sub- sector performance in Nigeria was tested using Pearson correlation coefficient. The results reveal that the correlation coefficient of 0.275 (not significant at conventional levels, 2-tailed test). This implies that NPLs has a weak linear and positive relationship with forestry sub- sector performance in Nigeria. In other words, the movement in forestry sub sector's performance is not significantly detected or correlated by NPLs in Nigeria.

Bilateral Granger Causality Test for Non-performing loan and Forestry sub-Sector's Performance in Nigeria

The Granger causality relationship between Non-performing loans and performance of the forestry sub- Sector in Nigeria is shown in Table 3.

The results presented indicate that there is no evidence of Granger causality between the two variables. Hence, the null hypothesis is accepted for the two proposed relationships. To further test the relationship between the NPLs and the forestry sub sector's performance in Nigeria, a simple log linear autoregressive model was estimated at the first difference of variables. The result is presented in Table 4. Though the diagnostic tests do not show reliable estimates, yet the preliminary results reveal insignificant negative relationship between NPLs and forestry sub –sector's performance in Nigeria.

The result indicated that, NPLs and the performance of forestry sub- sector do not have significant causation relationship in Nigeria. Precisely, the Non-performing loans in the Nigeria's banking system have insignificant negative relationship with the performance of the forestry sub sector in Nigeria. The results support previous results as earlier reported using correlation, trends and bilateral Granger causality analyses. Hence, increase in the NPLs in the Nigeria banking system does not significantly increase activities in the forestry sub sector in Nigeria. The result has several implications. Firstly, it suggests that most of the loans disbursed to various economic agents in the economy were not given to the agricultural sector. Secondly, it is likely that activities in agricultural sector and the sector's performance were not significantly influenced by the level of default or NPLs. Thirdly, it could be that, other sectors accounted for the large percentage of NPLs in the country; as such its effect was not significantly felt in the agricultural sector. Another possible reason for this result which is also prominent in the literature is the fact that, more than 90% of agricultural activities in the country are anchored by resource poor farmers who do not have collaterals and access to credit facilities. Hence, the issue of NPLs which is affiliated to formal banking system does not practically apply to them. However, the results has revealed that the performance of forestry sub sector is invariant with the NPLs in the Nigeria's banking system.

Conclusion and Recommendations: There was no significant effect of NPLs on the performance of forestry sub-sector in Nigeria during the period of the study. NPLs and Forestry sub-sector's performance exhibited an average negative trend during the study period. The Pearson correlation analysis, bivariate Granger causality and simple regression estimation, all pointed to a weak and non-significant relationship between the NPLs and performance of the forestry sub-sector in Nigeria. This result might suggest that banks' loans and advances to the Forestry sub-sector were inadequate probably due to none or insufficient collateral requirement needed as one of the pre-conditions to access such facilities. Banks might have been more adverse to grant loans to the economic agents in the sub-sector because of increased risk of defaults among other reasons. Policy on increased participation of specialized financial institutions to increase volume of loans while insurance companies could intensify de-risking investments in forestry sub-sector should be introduced and enforced by CBN.

ABSTRACT
Quarrying activity is a necessity that provides much of the materials used in traditional hard flooring. However, nothing is gained without some costs to individuals and the environment. Rock quarrying and stone crushing is a global phenomenon, and has been the cause of concern everywhere in the world, including advanced countries. Therefore, an assessment of the environmental impact of quarrying activities on the inhabitants of ishiagu in Ebonyi State, South Eastern Nigeria was carried out using questionnaire administration and physical count. Additional information was also obtained from a major health facility in the community. Indices studied centered on socio-economic characteristics of respondents, social negative effects of quarrying operations on the community, health problems associated with quarrying activities and the environmental impact of quarrying. Results of questionnaire administration indicated the existence of a strong relationship between the influx of people into Ishiagu, obviously in search of better job opportunities offered by the quarry industry and increased crime rate and teenage pregnancies. Results revealed that the prevalent health problems associated, with quarrying operations were catarrh, hearing problems, respiratory diseases, and heart problems. Similarly, the devastating environmental effects of quarrying included road destruction, industrial pollution, agricultural land degradation, noise pollution, contamination of water sources and cracking of buildings. Considering the various health risks associated with inhalation of particulate matter, environmental impact assessment should be made mandatory for all quarries. Although quarrying is an age-long economic activity, evidence of its negative impacts should influence more comprehensive policies and strict enforcement of such policies within the areas of operations of quarry sites. Quarry industries should be compelled to adopt modern techniques of dust strapping such that a negligible quantity of dust escapes from the various operations at quarry site. Particulates released can be controlled with scrubbers, precipitators, and filters, which can be retrofitted to dust stacks for pollutant removal from emissions.

Keywords: Quarry activities, environmental cost, communities

INTRODUCTION
Quarrying is the process of obtaining quarry resources, usually rocks, found on or below the land surface (Banez *et al*; 2010). On the other hand, quarrying is an open or surface excavation for the extraction of building stone, ore, coal, gravel or mineral deposits from the earth's crust (Brucce, 1989). Quarrying industries are therefore, those industries that are generally referred to as extractive industries which undertake the extraction of construction materials such as crushed rock aggregates, road bases, sands, clays and dimension stones. The search for granites in Ishiagu started in 1970 (Aja, 1998), but it was not until 1972 that commercial quarrying activities began. The exploration for more granite deposits between 1977 and 1978 led to the discovery of large granite deposit at Ugwu-Chime which comprises of three villages of Ngwogwo, Amokwe and Okue, all in the larger Ishiagu Community. Since then, granite has been discovered by different quarrying industries in Ishiagu with Crushed Rock being the major operator. Others include Crushed Stone, MCC, Biwa Dams, Fougerole, Marble Stone, Geominox and Macgrek line. Their products include dimension stone, granite, lead and zinc.
One of the biggest negative impacts of quarrying on the environment is the damage to biodiversity (Anand, 2006). Biodiversity essentially refers to the range of living species, including fish, insects, invertebrates, reptiles, birds, mammals, plants, fungi and even micro-organisms. Odiete (1999) reported that quarrying activities with excessive blasting operations cause cracking of buildings and equally affects human beings. Quarrying carries the potential of destroying habitats and the species they support (Mabogunje, 1980). Even if the habitats are not directly removed by excavation, they can be indirectly affected and damaged by environmental impacts – such as changes to ground water or surface water that causes some habitats to dry out or others to become flooded. Even noise pollution can have a significant impact on some species and effect their successful reproduction.
Increasing attention is being paid to the impacts of dust on human health, as finer particles can be inhaled and breathed into the lungs and cause harm. Particulates are tiny solid or liquid particles that are suspended in air and which are usually individually invisible to the naked eyes (Baird, 1992). Particulates include soot, smoke,

ash from fuel (mainly coal) combustion, dust released during industrial processes like quarrying and other solids from accidental and deliberate burning of vegetation (Montgomery, 1992). Particulate matter(dust) inhaled penetrate deeply into the lungs and are capable of making their way to the air sacs deep within the lungs where they may be deposited and cause respiratory problems (Zheng *et al*; 2011). Air pollutants such as dust are unhealthy particles (solids, liquid gas mixtures) that are liable to harm both living and nonliving things (Ward *et al*; 1993). Fine rock and mineral dust of many kinds have been shown to be carcinogenic when inhaled (Montgomry, 1992). According to Banez *et al*, (2010) inhalation of dusts can cause "pneumoconiosis" which is a term that refers to a group of lung diseases. After several decades of quarrying operations in Ishiagu with the attendant environmental hazards occasioned by dust emission, there has been little empirical information (as no previous study has been documented) on the effects of this activity on the physical and socio-economic environments and the health of the people living in the community. It is envisaged that the results of this study will help to audit the environmental implications of this project for scientific use and policy formulation. In this study, we assess the environmental impacts of quarrying activities in Ishiagu, Ebonyi State, Nigeria.

METHODOLOGY

The study area is within 2kilometer (km) radius of the quarry site in Ishiagu, Ivo Local Government Area of Ebonyi State, South East Nigeria. The town is about 10km from the Ishiagu junction of Enugu – Port Harcourt Express way. An area of moderate relief with an average height of about 300m above sea level; in a derived savanna of south east agro-ecology with characteristic sparse vegetation. The community lies within latitude 5^0 and 6^1 N and longitude 7^0 and 8^1 E with annual rainfall in the range of about 1,200-1,600mm and mean temperature range of 27^0C – 33^0C. Nine villages of Ishiagu viz Amaokwe, Okue, Ngwogwo, Ihietutu, Amaeze, Amata, Amonye, Ihie and Ogwor, which are nearest to the point sources of the perceived impact, were purposively selected as target population for the study. Thus, ten (10) respondents from each village were selected at random and interviewed by questionnaire administration. A total of ninety (90) respondents formed the sample size for this research. The respondents were interviewed (using questionnaire) to obtain primarly information on the socio-economic impact of quarrying in the study area. Physical count of the number of pot holes on devastated roads was also undertaken.

The data collected from the survey were analyzed using descriptive statistics. The major constraint in this study was the distribution of questionnaire, which involved a lot of movement and expenditure.

RESULTS AND DISCUSSION

Social characteristics of respondents

Results of responses show that questionnaire administration cut across every strata of the population for a determination of the socio-economic impact of quarrying in Ishiagu with Table I indicating that the total population of respondents consisted of 60% (54) males and 40% (36) females.

Table 2 revealed that the highest proportions of respondents were in the age bracket of 18 – 30 years constituting 36.67% of the population, followed by the age group of 31 – 40 (30%). Only 22.22% of the studied populations were of the age bracket of between 41-50 years. People in this category are known to shoulder great family responsibilities. The least population (50 years and above) constituted only 11.11% of the entire population. From this result, it is therefore, apparent that the sampled population is a very active one with great majority of the respondents less than 40 years.

The distribution of respondents based on their educational attainments (Table 3) showed that 14.44% (13) had no formal education. Those who dropped out of primary school were only 3 (3.33%) while 8.89% obtained primary education. Among the respondents, 28.89% and 44.44% acquired secondary and tertiary education respectively. This result indicates a high literacy rate in the study population.

Social negative effects of quarrying operations on community life

An assessment of the influx of people into Ishiagu as a result of the activities of the quarry industry is shown in Table 4. Eighteen (18) respondents representing 20% of the sampled population rated very high the contributions of quarrying operations to the influx of people into Ishiagu, while 30% (27) and 43.33%(39) scored as high and moderate respectively the influence of quarrying industries on human movement into the community. Only very low population 4.44% shared contrary opinion. That is therefore, a confirmation of overwhelming contributions of the industry to the influx of people into the community.

In Table 5 are presented the negative social effects with regards to crime rate resulting from the presence of quarrying activities in Ishiagu. In the opinion of 10% of the studied population, the presence of quarry industry has engendered very high crime rate. A reasonable percentage (21.11%) of respondents were of high opinions concerning the contributions of quarrying operations to increased crime rate, 24.44% were moderates, while 34.44% were of low opinion and 10% scored crime rate as very low in the community due to quarry industries.

Table 6 indicates that 24 representing 26.67% of the sampled population rated teenage pregnancy as very high 23 (25.56%) scored it as high due to the negative social influence of quarry industry, while 20% held moderate opinion. Only a lowly 12 (13.33%) and 13 (14.44%) of the population rated teenage pregnancy in the study area low and very low respectively. By this result, the prevalence of the high rate of teenage pregnancies is a cause for worry.

The results of the negative social effects of quarrying on community life were just stating the obvious. Considering the scope of quarrying activities by the Crushed Rock Industries in Ishiagu, it is expected that a high volume of employment will be generated by way of direct employment to different categories of workers and indirect employment opportunities offered to the haulage industry, loaders, agents, contractors etc with the attendant influx of people. It is only normal for people to migrate from different places in search of such employment opportunities with the consequent increase in such negative social vices as increased crime rate and teenage pregnancies. Current results suggest the existence of a strong relationship between the influx of people into the community in search of better opportunities and increased crime rate and teenage pregnancies. Current findings may corroborate the evidence of Odiete (1999) that quarrying activities have adverse impact on land use, physical and biological environment and the socio-economic life of the people. He went further to suggest on inter-relationship between quarrying, social economic and technological advancement. Furthermore, NEST (1991) reported that environmental problems associated with quarrying have drastically affected the socio-economic welfare of the rural people.

Health problems associated with quarrying activities

Health problems associated with quarrying industries are illustrated in Table 7. It is apparent that the most prevalent health problem associated with quarrying was catarrh, which drew the attention of 30% of the respondents. Industrial acadents accounted for 27.78%, 18.89% of the studied population had respiratory diseases, while 14.44% and 8.89% population of the study area encountered hearing and heart problems respectively. Similarly, from the hospital records obtained from the General Hospital Ishiagu, the following were the health problems or ill health effects associated with quarrying in the last 5 years; serious cough and catarrh – 185 cases, respiratory diseases – 141 cases, heart problems/chest pain – 130 cases, and industrial hazards/accidents – 18 cases.

The results of the study from respondents were similar and substantiated by the records obtained from the General Hospital (secondary sources) the high prevalence of catarrh and respiratory diseases may not be unconnected with particulate dusts generated by quarrying operations in the study area. Oyegun (1998) reported a case of death arising from complications that began with catarrh and respiratory problems allegedly resulting from unrestrained inhalation of quarry particulate dust. Dusts from quarry sites is a major source of air pollution, which is not, only a nuisance (in terms of deposition on surfaces) but also its possible effects on health, in particular for those with respiratory problems (Guach, 2001). Similarly Zheng *et al*; (2001) stated that particulate matter (dust) inhaled penetrate deeply into the lungs and are capable of making their way to the air sacs deep within the lungs where they may be deposited and cause respiratory problems.

Environmental impacts of quarrying activities

Table 8 indicates that 17.78% of the studied population were for industrial pollution, 15.56% were for road destruction/devastation, 13.33% of the population scored for noise pollution, 8.89% responses for agricultural land degradation, 11.11% rated water sources contamination, while the highest percentage population (33.33%) of the study area were for cracking of buildings.

With regard to road destruction, an additional independent data was obtained. A distance of 2kilometers covered in each section and the result indicates that from the crushed rock junction to Ivo river, 4 pot holes were recorded whereas from the same junction to the Railway line (towards Enugu – Port Harcourt Expressway) 23 pot holes were observed.

Cracked buildings are common sites in the community and may be a consequence of explosives (dynamites) used in quarry operations (Odiete, 1999). He consequently cautioned that ignorance or inadequate attention to such quarrying destructions can lead to high accumulation of solid wastes, production of unpleasant odours, contamination of ground water for industrial and domestic use, noise pollution, soil erosion, and destruction of wild life, farm structures, and cracking of buildings, loss of aesthetic landscapes, poverty and ecological imbalance. The sections of the road more frequently used by quarry trucks are comparatively more devastated than the other sections. Support could be found in the previous work of Mayer and Maghum (1994) in South Africa who reported that the blasting and crushing areas and the surrounding lands have been rendered useless to other land uses including agriculture as a result of quarrying and heavy vehicular movements and activities. Like many other man-made activities (anthropogenic factors), quarrying activities cause significant impact on the environment (Okafor, 2006). The quarry industry, unfortunately discharge dust that settles not only on land, plants and trees but also on surface waters used for drinking and other domestic chores by the community (Osha, 2006).

CONCLUSION

It is evident that quarrying industries have contributed to the development of Ishiagu. Indeed, quarrying has brought about both benefits and costs to the community. The benefits include employment creation, infrastructural development and revenue generation for Local Authorities. A major socio-economic problem in Nigeria, which is unemployment, has been reduced substantially in the community with the advent of quarrying operations, with the attendant influx of people and the consequent increase in social vices like crime rate and teenage pregnancies. The devastating negative environmental effects of quarrying include road destruction, industrial pollution, and agricultural land degradation, noise pollution contamination of water sources and cracking of buildings. Inhalation of dust resulting in respiratory diseases, catarrh, heart problems and other health effects or hazards also add to the list of the negative effects of quarrying in Ishiagu. Health data has also supported the deadly effects of quarrying activities on the people in the study area. Although, quarrying industries may have contributed to the socio-economic wellbeing and rural development of the community, it may be necessary to establish better industry – community relationship including hazard mitigation strategies. In addition, dust suppression measures especially during the dry season must be effectively implemented. All these will enhance or foster proper and sustainable development of Ishiagu and consequently stem the tide of riots and demonstrations carried out by the natives against the quarry industry.

Table1: Distribution of respondents according to gender

Gender	Frequency	Percentage(%)
Male	54	60.00
Female	36	40.00

MORPHOLOGICAL VARIATION OF FOUR *TILAPIA GUINEENSIS* POPULATION IN SELECTED COASTA RIVERS IN SOUT-WEST, NIGERIA

***E. A.Ukenye, O. R. Oguntade & S. Njoku**

Department of Biotechnology, Nigerian Institute for Oceanography and Marine Research, Victoria Island, Lagos, Nigeria

**E-mail:* eekwelem@yahoo.com

ABSTRACT

Multivariate analysis was used to morphologically differentiate four populations of Tilapia guineensis from Epe, Badagry, Igbokoda and Ilaje in Lagos and Ondo states of Nigeria using 13 morphometric and 5 meristic characters. Principal component analysis (PCA) revealed two principal components (PC- I and PC- II) that accounted for 65.3% of observed variation in morphometric and 59.3% in meristic attributes respectively. Dendrogram revealed two clusters for morphometric and two clusters for meristic variables which indicate variability among the studied populations which could be attributed to either genetic differences or environmental factors. The observed morphometric differences came from the dorsal, caudal and pectorial fin rays. The morphometric and meristic study has differentiated T. guineensis from the four populations into two morphological groups indicating phenotypic heterogeneity among the populations.

Keywords: *Tilapia guineensis*, morphometrics, meristics, principal component analysis.

INTRODUCTION

Species identification and population discrimination are important in the conservation of biodiversity, natural resources and fisheries management. Determination of population structure of exploited species is an essential component in successful management of fisheries. Purely environmental, genetic characters or those that may reflect both genetic and environmental variation can be used to identify fish stocks (Swain *et al*., 2005). Morphometrics and meristics are the two types of morphological characters that have been most frequently used to delineate stocks of a variety of exploited fish species (Turan, 2004).

Tilapia guineensis, an important Cichlid species is a valued food fish in many tropical and sub-tropical countries. It provides one of the most important sources of animal protein and income throughout the world (Sosa *et al*., 2005). The species is usually found in creeks, lagoons, adjoining rivers and other coastal waters of West Africa (Philippart and Ruwet, 1982). Lagos and Ondo are among the coastal states in Nigeria where *T. guineensis* has continued to contribute immensely to the nutritional needs, economic growth, and development of the populace. Despite the wide acceptance of this fish due to it's nutritional and economic importance, It is still facing identification problem especially when found in mixed of other tilapia species. The need to identify and differentiate different populations of *T. guineensis* from South west part of the coastal regions in Nigeria for fisheries management necessitated this study.

MATERIALS AND METHODS

A total of 200 samples of both male and female *Tilapia guineensis* fish weighing 20-357g were randomly collected from four selected coastal rivers in two coastal states of Nigeria. Their geographical location in terms of longitude and latitude is shown in Table 1. Fifty fish samples from each location were obtained from the respective locations through the help of fishermen at the landing sites and were first frozen and transported to the Biotechnology Laboratory of Nigerian Institute for Oceanography and Marine Research, Lagos, in ice and were identified by a fish taxonomist from the Institute then stored at -20^{o}C until used for detailed analyses. A total of 18 morphological characters were measured which included 13 morphometric variables and five meristic characters which were directly counted and measured to the nearest 0.1 cm using a thread and measuring board. Measurements of body parts were made with the head of fish pointing left. However, to avoid possible biases produced by size effects on the morphometric variables, all morphometric characters were standardized by dividing the measurement by the standard length of each fish to minimize the effect of fish size (Allendorf *et al*, 1987).

Statistical Analysis

Analysis was carried out separately for morphometric and meristic characters using statistical tool for Agricultural Research (STAR) version 2.0. The body shape data were subjected to principal components analysis (PCA) in order to reduce the variables to principal component that can explain most of the variation observed in the data.

RESULTS AND DISCUSSION

Morphometric Analysis

Analysis of morphometric data showed that the first principal component (PC-I) accounted for 56.61% while the second (PC-II) accounted for 8.66% giving a total of 65.28% of the variations in morphometric measurements data and were used to explain the variations (Table 2). Principal component analysis showed that samples are on separate quadrants from one another reflecting morphological difference among the populations. Cluster analysis illustrated by the dendrogram in figure 1 revealed two major clusters also indicating variability among the populations. The variation might be attributed to distinct genetic structure and environmental conditions. Since Munasinghe, 2014 reported that distinct genetic and environmental structures have been deemed responsible for morphological variability among different geographical populations. Thus, species with same morphometric characters are often believed to constitute same stock. This idea has found wide usefulness in stock identification or differentiation in fisheries. This result is in accordance with the report of Ramakrishnan *et al*., 2013 that observed two distinct groups of estuarine stocks in his morphometric study. Erguden *et al*. (2009) made similar observation in a morphometric and meristic analyses of chub mackerel, *Scomber japonicas* throughout the Black, Marmara, Aegean and northeastern Mediterranean Seas.

Meristic Analysis

Two components explained 59.27% of the variability (PC-I= 30.82%, PC-II= 28.45%) (Table 3). The dendrogram for meristic characters (Figure 2) showed three populations (Epe, Igbokoda and Badagry) clustered together reflecting low variability in meristic characters compared to morphometric characters. This is in agreement with the result of Samaradivakara *et al*, (2012) that showed the existence of low variability in meristic characters compared to morphometric characters in tilapia populations from Sri Lanka. Murta, 2000 made similar observation in studies on meristic characters of horse mackerel, Munasinghe and Thushari, 2010 also reported that in shrimp, meristic traits were less informative, when compared with the morphometric ones. Because of the observed morphological (morphometric and meristic) variation that exist in this study, the four populations may be considered as two distinct stocks. The PCA loadings (Table 4) showed that dorsal fin (DFC), caudal fin (CFC) and pectorial fin rays were found to be important discriminating characters that differentiate *T. guineensis* populations in the study. This is consistent with the report of Yakubu and Okunsebor (2011) that identified three discriminating variables that differentiate two fish species (*Oreochromis niloticus and Lates niloticus*).

CONCLUSION

From the current study, it could be deduced that morphometric characters differentiate the *T. guineensis* populations from south-west, Nigeria more than the meristic attributes. This indicates that the observed variation among the populations probably reflects environmental factors rather than genetic. Also, the studied populations could be considered as two distinct morphological stocks.

ABSTRACT
This study examined operational requirements, mode and investment pattern in trawling vessels. Random sampling techniques were used to select 60 trawling vessels classified according to ownership- Nigerian- Owned Companies, Foreign-owned companies registered in Nigeria, Vessels Chartered by Nigerian Owned companies, Vessels chartered by Foreign-owned companies registered in Nigeria. Data were collected with aid of a questionnaire and personal interview with the captains of vessels. The study revealed that for vessels to operate in Nigeria, they should be licensed by Federal Department of Fisheries (FDF), registered by Nigerian Maritime Administration and Safety Agency (NIMASA), call for inspection by FDF at expected time of arrival, landing of all catches in Nigerian ports, maintenance of catch data and membership of Nigerian Trawler Owners Association(NITOA). Vessels operate as Nigerian flagged registered vessels fishing in Nigeria's waters, Nigerian flagged registered vessels fishing in foreign waters, Foreign flagged registered vessels chartered by Nigerians fishing in Nigeria's waters and Foreign flagged registered vessels chartered by Nigerians fishing in foreign waters but all landings in Nigerian ports. The study further revealed that ownership and investment in trawl fisheries is dominated by the private sector with government only playing a regulatory role. To prevent the maritime sector from being dominated by foreigners. This study recommended the urgent implementation of the Cabotage Vessel Fund whereby Nigerians can access loans to buy their own distant water vessels at a single digit interest rate, amongst other things..
Keywords: Trawling, Fishing , Shrimping, Vessels, Maritime

INTRODUCTION
Trawling vessels are specialized ships designed for fish capture. Before the advent of trawlers, the exploitation of marine fish stocks was carried out by artisanal fishermen in their dug-out canoes. This method of fishing was characterized by drudgery, low volumes of catch per man, sea accidents and limitation of fishing distance. Trawling therefore emerged as a technologically efficient method in the exploitation of the marine fishery resource relative to artisanal fisheries. The emergence of trawling has helped in no small way in increasing domestic fish production in Nigeria. Today, fish supplies in Nigeria comes from both the artisanal sub-sector comprising coastal and brackish water, inland rivers and lakes and fish farms (aquaculture), industrial trawlers as well as imports (NBS,2005).
According to (NBS,2005), Nigeria is still unable to produce at least 60% of her annual fish demand presently estimated at 2.66 million metric tonnes. The country is at present producing about only one third of the quantity of fish she requires to feed her citizens. The shortfall in domestic fish production is augmented through importation. Massive importation of fish puts Nigeria in an unfavourable balance of trade position. It is believed that massive investment in trawling can go a long way in boosting fish supplies thereby reducing reliance on fish imports. This study examines ownership/investment pattern in trawling vessels and the implication for domestic fish production. A study of this nature is expected to provide a lee way for facilitating meaningful investment decisions which could stimulate increased investment in the marine capture fishery sub-sector and hence make possible the realization of the objectives of national fisheries policy.

METHODOLOGY
The study area is located within Nigeria's territorial (marine) waters and the Exclusive Economic Zone (EEZ) - the operational base of trawling vessels. Nigeria has territorial marine waters of thirty (30) nautical miles which come into operation in 1967. The EEZ extends from the extreme limits of the territorial waters of Nigeria up to a distance of 200 nautical miles from the baseline from which the breadth of the territorial waters of Nigeria is measured. Nigeria has a coastline of about 853 kilometres bordering the Gulf of Guinea in the Atlantic Ocean. It also has territorial (fresh) waters in Lake Chad. Most of the vessels have their operational base at Apapa Port where they do berth and land their catches.
A multi-stage sampling procedure was used in selecting the sample for the study. First, the list of licensed vessels operating in Nigeria was obtained from the Federal Department of Fisheries (FDF) from which 60 vessels were randomly selected. The second stage involved the use of stratified sampling where the vessels were classified according to ownership viz Nigerian- Owned Companies, Foreign-owned companies registered in Nigeria,

Vessels Chartered by Nigerian Owned companies, Vessels chartered by Foreign-owned companies registered in Nigeria. The third stage involved the random selection of 15 vessels from each of the ownership categories. A total of 60 copies of questionnaire was administered to captains of the trawling vessels using the above criteria. Relevant information for this study was gathered through a combination of personal informal interviews, discussions and interview with a questionnaire. Secondary data for the study was obtained from Federal Department of Fisheries (FDF), Nigerian Trawler Owners Association (NITOA) and Nigerian Maritime Administration and Safety Agency (NIMASA).

RESULTS AND DISCUSSIONS

Table 1 shows the operational requirements for vessels in Nigeria . Vessels are expected to be licensed by the Federal Department of Fisheries (FDF). Before this is done, prospective owners of fishing vessels are expected to first check with FDF and get a written assurance that the vessel will be given a fishing license before arrangements for the purchase of the vessel is concluded.

For vessels to operate for fishing in Nigeria's territorial waters, it should not be longer than 25.3 meters length overall (LOA) and of gross registered tonnage (GRT) not more than 150. And if it is to operate for shrimping, it should ideally not be above 76 ft LOA with a GRT not exceeding 100.However, vessels of greater GRT are permitted to fish in the Exclusive Economic Zone. All the vessels surveyed (60) were observed to possess an operational license. This implies that there is a strong inspectorate unit in place that ensures vessels do not operate illegally. A vessel may be granted license to fish in Nigerian territorial waters and the EEZ or it may be granted license as a distant water fishing vessel. Out of the 60 vessels surveyed only 40 registered with (NIMASA). This shows that the enforcement of the Cabotage Act which specifies registration for all classes of vessels including trawlers is weak. While most of the foreign owned vessels are registered, a proportion of unregistered vessels with NIMASA were mainly Nigerian owned.

All vessels surveyed call for inspection on their expected time of arrival (ETA). Areas of inspection includes fishing gear to ensure compliance with laid down regulations on mesh size, undersized fish, tonnage caught, installation of by-catch reduction devices (BRD), turtle exclusion devices, facilities for processing and storage of fish etc. with this type of arrangement. It is possible for vessels to delay calling for inspection until things that would make them FAIL inspection is removed. All the vessels belonged to the Nigerian Trawler Owners Association (NITOA) where their common interest and goal is being pursued. This association parleys with government in the formulation of policies affecting the industrial fishery sub-sector. They also collaborate with relevant stakeholders in the industry to ensure a conducive environment for their activities. Even though membership of NITOA is not compulsory, virtually all the vessels were members.

Table 1 further revealed that there was full compliance by all the vessels in landing of all catches in Nigerian ports. This implies that none of the vessels surveyed exported nor shipped away their catches from Nigeria at sea. This provision is difficult to monitor nor enforce by the inspectorate unit of the FDF as vessels land their catches in different jetties in Lagos instead of a central dedicated fishery harbor. Similarly, all the vessels surveyed maintained accurate record of catch data on all fishing activities which is usually required by FDF for planning purposes.

Table 2 shows that Nigerian flagged registered vessels fishing in foreign waters where Nigeria has bilateral agreement but landing all its catches in Nigerian ports constitute the highest with 33.3 percent. This followed by Nigerian flagged registered vessels fishing in Nigerian waters and foreign flagged registered vessels chartered by Nigerians fishing in foreign waters but landing all catches in Nigerian ports which constitute 25 percent. According to the sea fisheries Act 1971, for a vessel to be Nigerian flag registered, it must have a clean bill of sales to a Nigerian corporate body registered to the prevailing rules and regulations of Nigeria and must be registered with the Federal Ministry of Transport. Similarly, any vessel fishing in the high seas, or any vessel on charter carrying frozen fish by straight importation into the country is considered as a distant water fishing vessel. Such vessels can be licensed without being Nigerian flagged registered (FDF, 1982). The least (16.7) percent are foreign flagged registered vessels chartered by Nigerians fishing in Nigeria's waters (the Exclusive Economy Zone). FDF classifies all fish landings by distant water fishing vessels as imports (those fishing in foreign waters). These vessels were observed to occasionally involve in direct importation of frozen fish into the country. Fish landing by vessels fishing inshore and in the Exclusive Economic Zone is considered as domestic production.

Presently, total fish demand in Nigeria is 2.66 million metric tonnes while domestic production is only 0.62 metric tonnes. This leaves a wide supply gap of about 2.04 million metric tonnes to be filled by imports. In 2007, total fish amounted to 0.74 million metric tonnes. The huge import bill relative to exports account for a wide balance

of payment deficit. The decline in domestic fish production in the industrial fishing sub-sector according to FDF (2008) can be attributed to the following factors.
(i) Illegal exploitation of the marine fisheries resources particularly by foreign vessels. (ii)Piracy at sea and incessant harassment of fishing trawlers by militants thereby warranting vessel owners to withdraw their vessels. (iii)Monitoring, control and surveillance mechanism not fully developed. (iv)Poor management and non-effective utilization of most of Nigeria's numerous water bodies.
The Table 3 shows ownership and investment pattern of trawler vessels operating in Nigeria. Among the vessels surveyed there was no government owned vessel whether Nigerian or foreign .Rather all the category of vessels surveyed was privately owned. This result shows that globally trawling business is dominated by the private sector in view of their immense capacity for efficient management of resources. Most vessels owned by the Nigerian government in the past were grounded on account of poor management. That all the foreign owned and chartered vessels are owned by the private sector reveals that globally, the private sector is playing a leading role in investment in industrial marine capture fisheries. Government's role is to provide an enabling environment for businesses to thrive. Chartered vessels are vessels that are placed on charter arrangement for companies who do not own distant water vessels. Investment in trawling vessels is capital intensive. Funds are needed not only to cover the cost of the vessels, gear and equipment but also for the developing of the essential supporting shore based infrastructures such as cold rooms, ice plants, landing jetty and marine workshop (Essien, 1982). This may be responsible for the limited number of Nigerian investors. The Cabotage Act came into effect in 2005 and is an attempt by government to encourage increased participation of Nigerians in marine business. This is meant to discourage the maritime sub-sector from being dominated by foreigners as is presently the case. According to Amire (2009), investment profile in industrial fisheries sub-sector which is private sector driven is in the neighbourhood of N30 billion and directly employs over 5000 Nigerians. However, it should be appreciated that entry into open access fishery in Nigeria is limited not by resource scarcity but more by the dearth of investment funds (FDF 1989). This fact may have been responsible for establishing the Cabotage Vessel Fund to provide investment fund to Nigerian entrepreneurs to be able to acquire vessels at a single digit interest rate. The Cabotage Act specifies that where a Nigerian goes into partnership with a foreigner, Nigerians should own not less than 60 percent equity share. Similarly, all crew members of vessels operating in Nigeria should be Nigerians except for the position where no Nigerian is available or qualified for the position. To further ease the burden of investors, there are some government established fishing terminals and other shore-based facilities for the fishery industry.

CONCLUSION AND RECOMMENDATIONS

In an attempt to diversify the Nigerian economy in the light of dwindling oil revenue, investment in trawling vessels could be a viable option in view of its capability to contribute to food security, employment and income generation, foreign exchange as well as raw materials for livestock and feed industry This study recommends the urgent implementation of the Cabotage Vessel Fund whereby Nigerians can access loans to buy their own distant water vessels at a single digit interest rate. This will prevent the maritime sector from being dominated by foreigners. This can also serve to replace old vessels with frequent breakdowns and attendant high repair and maintenance cost.

The incidence of piracy constitutes a serious bottleneck to investors in industrial fishery sub-sector and could be responsible for dwindling investment in the sector. The Navy, Air Force and Marine Police should be fully equipped to combat this anomaly. There is need to provide more platforms for security agencies. The Navy should establish Forward Operational Bases along the Nigerian coastline to monitor the activities of fishing and shrimping vessels.

Vessels only call for inspection on their expected time of arrival date. Presently most fishing and shrimping vessels operate out of private jetties at different locations in Lagos. This makes co-ordination of fishing activities difficult. This calls for the establishment of a modern centralized fishery terminal at Lagos. Moreover, the operation of private jetties have serious security implications such as importation of illegal drugs, arms and ammunition as well as smuggling of contraband goods.

ABSTRACT
This study investigated tanks fish culture methods and information sources among fish farmers in Obio/Akpor Local Government Area of Rivers State, Nigeria. Data for the study was obtained through the administration of questionnaire and scheduled interview to 120 sampled fish farmers randomly selected from the study area. Data obtained were analyzed through the use of descriptive statistics which are percentages and means. The results showed that 39.2% of the fish farmers were aware of pen, earthen pond and tanks as fish culture methods. Fish farmers were very conversant with the black plastic fish tank (95%) with a mean score of 2.92 which was above the pooled mean score of 2.0. Majority of the fish farmers (62.5%) got to known about fish tanks from other fish farmers. It is therefore recommended that fish farmers should not depend on themselves alone for information about a newly developed technology but should try and pay attention to the media such as radio or television, posters and bill boards to get information.
Key words: Earthen pond, fish culture, fish farmer, information, tank

INTRODUCTION

The rapid increase in world population has resulted in a huge increase in the need for animal protein and other nutritional requirements. This is particularly crucial in developing countries like Nigeria where there is widening gap between supply and demand of fish leading to the large scale fish importation (Ogunremi and Oladele, 2012). Fish provides roughly 40% of the protein intake for nearly 2/3 of the world's human population (Oyetoro and Akinboye 2010). Fish production from aquaculture is seen as the only way of solving the problem of over fishing of the natural water bodies as capture from the wild kept reducing because rate of recruitment is lower than exploitation of the resource while the human population is on the increase every year. Also, the need to solve over fishing of wild fish stocks is a very strong premise for fish farming (Akinrotimi *et al*, 2011). Nigeria has a high potential of developing fish culture to meet up with its burgeoning fish demand that is costing the nation at least $400 million annually in foreign exchange (Onoja and Achike, 2011). Aquaculture is the fastest growing food-producing sector in the world, with an average growth rate of 8.9% since 1970, compared to only 1.2% for capture fisheries and 2.8% for terrestrial farmed meat production systems over the same period (Dauda *et al*, 2015). Inyang (2001) observed that the concept of fish farming is perceived as a foreign technology by the small scale resource poor farmers, most especially in Sub-Saharan Africa and it is seen as a donor driven development. For developing countries like Nigeria where in emphasis is on oil, fish farming can generate significant employment, enhance the socio-economic status of the farmer as well generate foreign exchange (Oluwasola and Ajayi, 2013).

In agriculture, the role of information in enhancing agricultural development cannot be over emphasized. Information is vital for increasing production and improving marketing and distribution strategies (Oladele, 2006). Information also opens windows of sharing experiences, best practices, sources of financial aids and new markets (Ugboma, 2010). Information is an indispensable factor in the practice of farming and it is the basis of extension service delivery. It is defined as data that have been put into a meaningful and useful context which is communicated to recipient who uses it to make decision (Adereti *et al*, 2006). Fish farming information can be considered as all published or unpublished knowledge in all aspects of culture fish production. Land for aquaculture is highly competitive among many other intending users, also access to necessary information on available culture systems is expected to improve fish production and enhance better standard of living among the fish farmers. The study therefore examined fish tank culture and information sources among fish farmers in Obio/Akpor Local Government Area of Rivers State, Nigeria. The specific objectives of the study include are: (i) identify culture systems among fish farmers

(ii) investigate various tanks fish farmers are conversant with

(iii) identify various sources of information on tank usage among fish farmers.

METHODOLOGY

The study was carried out in Obio/Akpa Local Government Area (LGA), Rivers State of Nigeria. The study area belongs to the South-South region of Nigeria or otherwise known as Niger Delta region. Obio/Akpor being one of the 23 LGA of the state has its headquarters at Rumuodumaya with a total land mass of approximately

311.7/sq.km.. The council area shares boundaries with Emohua, Ikwerre, Etche Oyigbo, Eleme, Okrika and Port-Harcourt Local Government Areas of Rivers State. It is mainly constituted by the people of Ikwerre ethnic nationality but due to its urban status and the hospitality of the people, there is influx of other nationalities to the local government area. The major occupation of the people is farming, fishing and trading. The vegetation found in this area includes Raffia palm, thick mangrove forest and light rain forest.

The sampling frame for this study was obtained from Rivers State Agricultural Development programme (RISADEP) which contained the list and addresses of 300 fish farmers registered in the study area.

Simple random sampling technique was used to select 40% (120) of the fish farmers in the study area. This number of respondents was selected because of the time frame for the research since it will be practically impossible to sample all the fish farmers in the study area in a short period of time. The simple random sampling technique was used to ensure that every fish farmer in the study area was given equal chances of being selected and to avoid bias. A structured questionnaire was used for primary data collection alongside with interview scheduled.

The data obtained in this research was analyzed using descriptive statistics such as frequency, mean and percentages.

RESULTS AND DISCUSSION

From the results presented in Table 1 and it shows that the fish culture methods prominent in the study area include the use of pen, earthen pond and tank culture, having the highest percentage of 39.2%. Earthen Pond culture method had the lowest percentage (8.3%), implying that the respondents in the study area are not so much used to earthen pond culture method. This could be because earthen pond culture sometimes is regarded as an old system of culturing fish. With the advent of new culture methods such as the concrete tanks, most fish farmers have left the use of earthen pond and adopted the new culture methods.

Three out of the four tank types identified by fish farmers had a mean score above 2.0 (Table 2), wooden tank (x=2.28), black plastic tank (x=2.92) and white plastic tank (x=2.26) which suggested that most fish farmers were familiar with these tanks. The mean score of the fiber tank (x=1.83) did not reach the cutoff point (x=2.0). This indicates that most of the fish farmers are not familiar with the fiber tank which could be because it is expensive compare to other tanks. Black plastic tank had the highest mean score of 2.92 and 95.0% indicating that many of the fish farmers were conversant with black plastic tanks for fish culture. This could be because of the fact that black plastics absorb heat and warm the water to suit culturing condition of fish. Despite the high level of awareness of the black plastic tank among the fish farmers, 2.5% of the fish farmers do not know about it. Extension agents could therefore ensure that in all their demonstrations of a new technology, every material that needed to be used for the demonstration is provided so that fish farmers can be familiar which will eventually make adoption process easy.

The result shown in Table 3 reveals that majority of the respondent (62.5%) became aware of fish tanks through other fish farmers. In a similar study, Ufuoku *et al*, (2008) reported high information source among other farmers Only 20% of the fish farmers got information from the Extension Agents. This may imply that fish farmers might be into some form of groups' of cooperative societies where they interact and share ideas as a method of improving their production. An extension agent (20.0%) as source of information is low properly because of the low ratio of extension agents to fish farmers. It is quite evident that when the support from extension service is not adequate, the small-scale operator has to depend upon external sources for information Radio/Television has 4.2% each indicating that the farmers pay less attention to them as information sources probably because of their personal engagements or tight schedules. This may be the reason why fish farmers look out to other fish farmers for information. Internet, as one of the sources, had none of the farmers agreeing to it as a source through which they got the information about fish tank. In a similar study, Ugboma (2010) reported that internet access is not common among fish farmers. The reason could be that the farmers may not have the knowledge of internet accessibility or quite expensive for them to afford. Giving farming to a variety of information sources, which are accessible, affordable, relevant and reliable is the ultimate aim of providing agricultural information services. Harma *et al,* (2015) reported that with the advent of information technologies which has succeeded in eliminating bottle necks in information dissemination constraints to access to information is still a problem. The difficulty encountered in accessing vital fisheries information specially from printed and electronic media sources which would have created a more convenient platform for improved and increased fish yield which by extension translates into higher profit and more job opportunities should be addressed by the government at all levels and non-governmental organizations.

CONCLUSION

Fish farmers are conversant with various types of fish tanks apart from the conventional earthen pond culture systems. Also, major information source on tank as culture method is predominantly from other fish farmers. It is recommended that other information sources among fish farmers should be strengthened as it will encourage many other potential individuals and corporate organizations to invest in fish culture which will reduce the huge amount of money spent on importation of fish into the country.

ABSTRACT
This *study analyses the pattern of calorie consumption and the factors determining the intake of calorie of small-scale farmers in the northern guinea savannah of Nigeria. Data were obtained from 244 small-scale farmers with the aid of structured questionnaire. Data were analyzed using descriptive statistics and multiple regression analysis. The results showed that the average household size of the respondents was 7.5 as the average cultivated farm size was found to be 2.05 hectares. The average total crop output was found to be 2147.61kg between the range 412.5kg to 7915.5kg. The daily calorie intake skewed towards starchy foods as the calorie proportion of meats, fish, fruits and vegetables were found to be very low, with wide variation even among farmers. The results further revealed that total crop production, household size, dependency ratio, total farm income, the age and education level of household heads significantly determine the daily per capita calorie intake. The study therefore recommends that policy interventions should include measures that get farmers increase their level of education, enlighten them about family planning and the provision of nutrition education as all factors that could lead to increasing production and productivity should also be pursued.*
Keywords: Calorie intake, small-scale farmers, northern guinea savannah.

INTRODUCTION

Eating well is essential and vital for a healthy and active life. People in virtually all countries of the world who do not eat well have basically poverty to blame as it has been noted that calorie intake have a strong linkage with both human health and productivity. The human body needs dietary calorie energy to maintain normal body metabolic function and engage in activity related to good health and hygiene. In addition, calorie intake is the main determinant of under nutrition and malnutrition among the people. It is needed for growth and assimilation of micronutrients among children. Inadequate supply of calorie lowers productivity, hinders learning and increases the risk of diseases (Aromolaran, 2004). Aromolaran (2004) further argued that the level of calorie intake (both stock and flow) by an individual should be adequate to sustain his functions and activities over his expected lifetime. When this lifetime calorie consumption pattern falls short of a minimum threshold, the individual is at a health risk. Secondly whenever there is a persistent short fall in the flow of calorie intake relative to the amount required for optimal productive activity, the inflow of other nutrient intakes is likely to be affected since the resources required to acquire these nutrients is obtained from productive work. This situation is especially true in populations where the major income earning asset is human labor efforts, that is, populations made up of poor farm households where non-earned income forms an insignificant component of full income. In such populations, increased calorie intake may imply increased productivity, increased income and thus improved overall nutrition (Strauss, 1986). Increased nutrition is associated with sustained increments in productivity and thus sustained access to food energy intake.

In Nigeria however, there is an overwhelmingly large proportion of Nigerians who are hungry. Recent estimates put the number of hungry people in the country at over 53 million, which is about 30% of the country's total population of roughly 150 million; and 52% live under the poverty line (Ajayeoba, 2010). The proportion of the hungered are spread across both rural and urban settings in Nigeria, though most are in rural areas and among the farming population who produce about 90% of the total agricultural product of the country (Government of the FRN, 2006). This fact is further corroborated by Famine Early Warning System Network, FEWS NET (2007). It is to be noted still that food consumption pattern in the country had undergone remarkable changes over the years. There has been an increase in the consumption of starchy foods like rice, maize, cassava and yams, and some decrease in the consumption of protein based food items such as fish and meats (Oloyede 2005). The daily per capita calorie supply as a proportion of requirement was 90% in 1988-1990 and 85% in the period 1992-1996 (FOS, 1996), and in the last decade, the average protein intake by Nigerians was found to be only at the threshold of adequacy as aggregate protein consumption was 61.1g per capita per day in 2002 (FAOSTAT 2004). These protein consumption figures fall short of the critical human body requirement which was put at 70g per capita per day by Food and Agriculture Organization (FAOSTAT 2004). Food consumption plays an important role in the economic growth and development of both developed and developing nations

(Abdulahi, 1999). It has a considerable impact on the circular flows of income in the economy, meaning that, it has a significant effect on the economic activities of a country.
Furthermore, as Iyangbe and Orewa (2009) put it, there are basically two types of hunger: undernourishment (i.e. a situation where an individual's food intake falls short of the minimum calorie (energy) requirement and malnourishment (when the calorie (energy) intake is sufficient but the protein and other essential nutrient intakes are inadequate). Both types of hunger are present the world over but the incidence is said to be more in developing countries. One out of five persons in the developing countries is unable to meet his or her basic daily needs of life (Lupien and Menza, 2004).
Developing policies and interventions to reduce hunger and malnutrition, and increase food security requires an understanding of factors that determine calorie intake, their inter-relationships and their relevance to particular groups of people (FAO, 2004) and in this case the majority poor small-scale farmers. It therefore becomes very imperative to determine quantitatively, the current level of calorie intake and pattern of calorie consumption in diet of farmers in Nigeria, vis-à-vis the increasing incidence of under nutrition, malnutrition and food insecurity. The matter must be accorded the necessary priority as Bliss and Stern (1978) have observed that small increases in food consumption can bring about substantial improvement in productivity and consequently, improved standard of living. This study is regarded relevant for targeting assistance and for the formulation of policies and measures to cushion the effects of hunger and under nutrition among the Nigerian faming populace.

MATERIALS AND METHODS

This study was conducted in Nigeria's Kaduna state, situated between latitude 11^0 32' and $09^0$2' North of the equator and $80^0$50' and $06^0$15' East of the meridian. Kaduna state is located at the centre of Northern Nigeria and lies within the Northern Guinea Savanna region with tropical climate. It has a political significance as the former administrative headquarters of the North during the colonial era. The state has 23 local government councils. Agriculture is the main stay of the economy of the many tribes of the northern people with over 80% of the people actively engaged in farming. Food crops that are cultivated and produced include: Maize, Groundnut, Cowpea, Guinea Corn, Millet, Rice and Cassava, while cash crops include Gum Arabic, Cotton and Ginger. The people also rear animals like cattle, goats and sheep.
Multi-stage sampling techniques were used for this study. The first stage involved the random sample of four Local Government Areas in the state namely Giwa, Ikara, Zango Kataf and Kachia and equally two randomly sampled communities within the LGAs making a total of eight (8) communities. A 10% sample sizes of the farm households in these villages were then randomly sampled for questionnaires administration, making a total of 244 respondents.
Descriptive statistic was used for this study to describe the socio-economic characteristics of the respondents and the calorie consumption pattern as the tools involved the use of measures of central tendency such as mean, mode, percentages, use of bar and pie charts, while a multiple regression analysis was used to obtain the determinants of per capita daily calorie intake. The Regression model is specified below:

$$\gamma_i = \acute{\alpha}_o + \Psi_1 x_1 + \Psi_2 x_2 + \Psi_3 x_3 + \Psi_4 x_4 + \Psi_5 x_5 + \Psi_6 x_6 + \Psi_7 x_7 + \Psi_8 x_8 + \Psi_9 x_9 + \tilde{u}$$

Where,

γ_i = *Per capita calorie intake*
X_1 =*Age of household head in years*
X_2 = *Education level of household head*
X_3 = *Adjusted household size*
X_4 = *Total cultivated land size in hectares*
X_5 = *Total farm income in naira*
X_6 = *Non-farm income in naira*
X_7 = *Consumer credit in naira*
X_8 = *Total crop production in grain equivalence*
X_9 = *Dependency ratio*
$\acute{\alpha}_o$ = *Constant term*
$\Psi_1 - \Psi_9$ = *Coefficients for the respective variables in the regression model*
$\tilde{u}$ = *Error term*

RESULTS AND DISCUSSION

The mean age of the respondents as presented in Table 1 is 39.1 years showing a virile and agile average farmers' age with the consequent capability of doing a lot of farm work if given proper incentives. Also, about 88% of the respondents are male as the average household size was observed to be 7.5 within the range 1- 27. The household size means the number of people in the house, which includes wives, children and dependents who reside within the family and eat from the "same pot". Education in agricultural production will enhance farmer's ability to make informed and accurate decisions on the management of the farm. This also could be a source of additional income. The level of literacy among farmers in the study area as measured by ability to read or write in Arabic or Hausa languages was high. It was found that only 10.25% of farmers have no formal education. About 24% have Quranic (Arabic) education while 7.38% have adult education. About 24.18, 27.87% and 6.56% have primary, secondary and post-secondary education level respectively. The average farm size was found to be 2.05 hectares while the average total crop production in grain equivalent was found to be 2,147.61kg between the range 412.50kg to7,915.50kg. It is expected that with increasing or high total crop production, farmers will have more access to food, with the consequent positive influence on daily calorie intake of members of the households.

Daily calorie consumption patterns among sampled farm households

Following the identification and aggregation procedure, the daily per capita consumption pattern results was computed. The result is as presented in Table 2. Calories from cereals products form the bulk of the food consumed by the households. The average daily calorie value for cereals was found to be 1386.7kcal per capita, followed by legumes at 460.59kcal per head per day. Root and tubers food products were found to have 248.74kcal while fat and oil products closely followed with 424.11kcal. These groups of food products comprise the bulk of calorie intake of the farm households and except for the leguminous food products, the bulk of the calorie intake as shown from the result are starchy foods. It is to be noted further that the coefficient of variation of leguminous food consumed is high, close to 1, at 0.845 but those of cereals and fat and oil were observed to be low (0.445 and 0.404 respectively). This suggests that there is a high variation in the consumption of legumes among the sampled population. The result further shows that daily calorie intake per capita from proteinous food products were very low and the coefficient of variation, which essentially provides a measure of variation that is corrected for the size of mean, were found to be high, suggesting the inappropriateness of the average to represent the population. Average daily calorie intake from meat products was found to be 178.18kcal (1.019 coefficient of variation), fish products had 49.21kcal (0.898) while other animal protein sources like eggs and milk products was observed to be 43.72kcal (1.655) per capita per day.

Fruits and vegetables proportions of the average daily calorie intake were equally observed to be low at 0.96kcal and 33.51kcal respectively. More worrisome is however, the observation that, even at this low daily per capita proportion level, the measure of variation in consumption within the population were observed to be very high. The coefficient of variation for fruits calorie intake was found to be 1.896 while that of vegetable products daily intake, 1.670. The quantity and quality of calorie intake is important as it has been noted that a short fall in quality lead to malnutrition.

Determinants of daily per capita calorie intake

Cobb-Douglas regression form was found as best fit for the multiple regression that was run. It has multiple R of 79%, R Square was found to be 63%, adjusted R Square 61%, standard error is 0.21, and the F value obtained is 44.01, found to be significance at 1% level. The signs on the coefficients of independent variables also fit *a priori* expectations except for the total farm income coefficient which carries a negative sign. Owing to the fact that the average farm size was found to be 2.05 hectares (low) and a high average household size of 7.5, increasing sale of farm produce to earn income for some other household responsibility could actually decrease the stock left for household consumption. The result is however presented in Table 3. It was found that adjusted household size, total farm income, total crop production in grain equivalent and dependency ratio were found to be significant at 1% level.

The education level of the household head, whose responsibility is to feed his household, was also found to be significant at 5% level, while the age of the household head measured in years was also found to be significant, though at 10% level. The significant result of age of the household head and dependency ratio is similar to a study on the determinants of daily calorie intake among rural and urban low-income households in Edo state, south-west, Nigeria by Orewa and Iyangbe (2009), and Babatunde *et al.*, (2013) similarly observed that the age of household head, his level of education, the household size and crop output were the determinants of calorie intake among farming households in rural Nigeria.

CONCLUSION AND RECOMMENDATIONS

It is indicative from this study that though the average per capita daily calorie intake in the study area was found to be about 2840.46 kilocalories, it only suggests that the area is at the verge of adequacy to the recommended level of 2500 kilocalories per capita per day as a wide variation in consumption from the population was observed. It was further observed that daily calorie intake proportion skews towards starchy food with low intake proportion of proteinous food, fruits and vegetables whose nutritive values included essential amino acids, vitamins and minerals for healthy and productive living. So by disaggregating calorie intake by pattern and proportions, the calorie consumption of the farmers was observed to tend towards malnutrition. It was further observed that total crop production, household size, dependency ratio, and the education level of the household head were found to be the determinants of daily per calorie intake per capita. We therefore suggest that policy interventions should include measures that get farmers increase their level of education, enlighten them about family planning and the provision of nutrition education among rural small scale farmers should be accorded the necessary priority. By the positive influence of total crop output (production), all factors that could lead to increasing production and productivity should also be pursued.

PRODUCTION OF GLUCOSE SYRUP FROM SELECTED YAM LANDRACES USING ENZYME PRODUCED BY MICROORGANISM

P.O. Nwankwo & J.U. Ukpabi

National Root Crops Research Institute, Umudike. Abia State. Nigeria.
Corresponding e-mail address: pastornwankwo@yahoo.com

ABSTRACT
Glucose syrup production from selected yam landraces (Okpani, Hemba, Ogoja, Dorban and Ameh) stored for three months in the barn of National Root Crops Research Institute, Umudike, was investigated. The proximate and mineral compositions of the samples were also determined. The proximate composition showed that Ogoja had the highest moisture content (48.78[a]) significantly different (P=0.05) from that of the other samples, with Hemba having the least moisture content (47.41[e]). Crude protein was moderately high in all the samples studied with Ameh (3.81[a]) having the highest value. Ash, crude fiber and crude fat were not so high in all samples with Hemba (1.37[a]), Ameh (1.74[a]) and Okpani (1.03[a]) having the highest contents of ash, crude fiber and crude fat respectively. The carbohydrate contents of all selected landraces were high with Hemba (45.13[a]) having the highest value and significantly different at (P=0.05), from the other samples. The mineral composition of the selected yam landraces investigated showed that all samples were very rich in the macro- and micro- elements evaluated which include potassium, phosphorus, magnesium, calcium, iron, zinc and sodium. Okpani was found to have the highest contents of almost all the elements under investigation. Heavy metals such as copper, cadmium and lead were present in minute quantities in all the samples, and no lead was detected in Ameh. The rate of glucose syrup production from the starches of the selected yam landraces was highest in Okpani (60%) at 24 hours reaction time, followed by Hemba and Ameh (55.0%) respectively, then Dorban (50.0%) and Ogoja (48.0%). Okpani, Hemba, Ameh, Dorban and Ogoja exhibited good potentials as substrates for glucose syrup production.

Keywords:Glucose syrup, amyloglucosidase, yam landraces, starch hydrolysis, proximate/mineral compositions.

INTRODUCTION
Root tubers which are widely cultivated produce abundantly in most developing countries of the tropics such as Nigeria, but due to poor storage facilities, these tubers deteriorate overtime. Despite their importance as one of the staple foods of the people, a large proportion of these tubers are lost yearly. However, these loses can be avoided if these tubers are harnessed into other various useful products such as glucose syrup, maltodextrins, maltose syrup, etc. Starch pastes of all types are susceptible to hydrolysis by amylolytic enzymes resulting in shorter polymer chain lengths and sharply reduced viscosities (Bello-Perez *et al.*, 2002). A diastatic enzyme (alpha-amylase) that rapidly hydrolyzes starch to short, water soluble fragments was used. The starch slurry was adjusted to the desired pH, α-amylase added and a programmed heat cycle set in operation, after which a saccharification enzyme was applied to produce glucose syrup (Omemu *et al.*, 2004). Glucose syrup is a concentrated aqueous solution of glucose maltose and other nutritive saccharides from edible starch (Van der Venn *et al.,* 2005). Glucose syrup is used in large quantities in fruits, liquors, bakery products, pharmaceuticals and brewery products as well as in cosmetics industries
This study is aimed at the production of glucose syrup by the enzyme hydrolysis of the starches obtained from the selected yam landraces.

MATERIALS AND METHODS
Sources of Materials
Chemical: All Chemicals used were of analytical grade.

Yam Species: Yam landraces were obtained from the yam barn of NRCRI, Umudike three months after storage

Enzymes: Alpha-amylase was procured commercially from Agar-Technical (Oxoid).
Amyloglucosidase was isolated from the liquid in which the fungus *Aspergillus niger* AM07 was grown.

Methods:

Proximate The proximate composition (moisture, ash,

Analysis crude fiber, crude protein, crude fat and carbohydrate) were determined using the standard method of AOAC, 2003

Mineral Analysis: The mineral composition of samples was determined according to the methods of AOAC, 2003.

Production of glucose syrup:

Glucose syrup production from various yam species was sub-divided into the following processes according to the method reported by Ji *et al,* 2004.

- **Liquefaction**
- **Saccharification**
- **Purification**
- **Liquefaction:** A starch slurry made with 35% dry solids, pH 6.0 – 6.4 had Calcium added to it in form of Calcium hydroxide to stabilize the enzyme. Alpha amylase was mixed with the slurry and the mixture heated to 100°C for 10 minutes, then cooled to 90°C for 2 hours to further hydrolyze the starch to form dextrin molecules.
- **Saccharification:** After liquefaction, the pH was reduced to 4.0-4.5 and solution cooled to 60°C. Glucoamylase enzymes were added and the mixture was incubated for 24-48 hours based on the concentrations of enzymes used. Glucoamylase released glucose syrup from the dextrin molecules. The formation of glucose was monitored using the glucose oxidase method at different times.
- **Purification:** The resulting glucose syrup was purified by ion exchange chromatography and then concentrated by evaporation under reduced pressure.

Statistical analysis:

The results are expressed as mean ± standard deviation. A one-way analysis of variance (ANOVA) was used to analyze data. A *P- value* of 0.05 was considered as statistically significant. Where a significant difference was observed, data were further analyzed using Turkey's significant different test.

RESULTS AND DISCUSSION

The result of the proximate composition of flour samples of the selected yam landraces are depicted in Table 1. Ogoja (48.78^a) had the highest moisture content, then Dorban (48.68^b). Generally, the moisture content of all the samples was high indicating that the samples are prone to microbial attack in the course of storage. The slightly high ash content exhibited by the samples with Hemba (1.36^a) having the highest value, is an indication that the samples could be rich sources of mineral having nutritional importance. Crude Protein was moderately high in all samples with Ameh (3.81^a) having the highest value. Proteins are polymers of amino acids and are required for the building and repair of damaged tissues (Mac William, 2005). The high fiber content in all samples studies with Ameh (1.74^a) having the highest value showed that the selected yam landraces could be useful as sources of fiber and may play a useful role in providing roughage that aids digestion (Chiarelli *et al.,* 2000). All samples had high contents of carbohydrate as well as high energy values, and thus could be used as rich sources of energy.

The results of the mineral composition of the selected yam landraces are shown in Table 2. All samples were very rich in their macro-elements content, such as potassium with Okpani (900.15^a) having the highest value, phosphorus with Okpani (269.32^a) topping the list, calcium with Okpani (91.36^a) having the highest value and magnesium with Okpani (57.39^a) having the highest value. Sodium was very high in all samples studies. Iron and Zinc were moderately, high in all samples under investigation.

These mineral elements are essential for proper functioning of cellular activities, proper formation of bones and teeth, formation and regulation of blood cells and when properly combined together regulated the blood pressure (Heaney, 2000). However, the samples studied had little or no quantities of the heavy metals (Copper, Cadmium and Lead) and thus regarded as safe for consumption.

The result of the hydrolysis of the gelatinized yam starches with amyloglucosidase from *Aspergillus niger* are presented in Figure I. For the selected yam landraces investigated, the optimum starch hydrolysis (glucose syrup production) was obtained at 24 hours of the reaction time. The glucose concentration increased significantly (P=0.05) at the 24 hours reaction time compared to the values obtained at 4-12 hours of the reaction time. The result also showed that after the maximum production at 24 hours of the reaction time, no significant difference in glucose syrup production was observed at the 36-48 hours of the reaction time. This finding is in contrast to that reported by Zainab *et al,* (2011), that after the optimum production of glucose syrup using starches from selected cereals, the production of glucose syrup dropped or decreased with increase in reaction time.

CONCLUSION

Okpani, which is yellow in colour and highly affected by browning reaction and often not the choice variety for consumption was found in this investigation to be good in nutritional composition as well as in the production of glucose syrup, thus may be recommended for glucose syrup production to avoid waste.

The hydrolysis of the gelatinized starch from the selected yam landraces with amyloglucosidase isolated from *Aspergillus niger* showed an optimal glucose concentration within 24 hours of the reaction time in all samples, and there was no significant increase in the glucose syrup produced with increase in reaction time. It suggested that starch hydrolysis by the enzymes used may be limited to a time range of 4-24 hours

Furthermore, the technologies used for glucose syrup production using the starches from the selected yam landraces and enzymes produced by the microorganism *Aspergillus niger* was successful and can be up-scaled for industrial purposes.

E-mail:helenokudu@yahoo.com

ABSTRACT
The objective of this study was to compare the nutrient composition of "moi-moi" prepared from cowpea (Vigina uniguculata) and that of pigeon pea (Cajanus cajan). "Moi-moi" was prepared using a standard method. The proximate and vitamin content of the samples were determined using standard AOAC methods. Mineral elements were determined using wet-acid digestion method for multiple nutrients determination. All tests were carried out in duplicates and the data generated were analysed using standard methods. Crude protein (23.4%), crude fiber (2.5%), ash ((2.4%) and CHO (44.4%) were significantly (p<0.05) higher in cowpea "moi-moi" while crude fat (11.0%), and energy were significantly higher in pigeon pea. Pigeon pea was a better source of the B-vitamins, vitamin C and zinc. The results show that pigeon pea "moi-moi" can be used as an alternative for cowpea moi-moi.
Keywords: Cajanus cajan, Vigina uniguculata, "moi-moi", B-vitamins, Vitamin C

INTRODUCTION

Legumes are a major source of plant protein in the developing countries; they are the next invaluable food crop after cereal (Uzoechina, 2009). Apart from been a good source of plant protein, consumption of legume is associated with the control and prevention of metabolic diseases (Simpson *et al*., 1981; Oloyo, 2004). Cowpea (*Vigna unguiculata*) a member of *phaseolease* and a tribe of the *leguminosae*, is one of the most commonly consumed legume in Nigeria. The economic down turn and resultant inflation in the country is however taking a negative toll on the consumption of cowpea. It has therefore become imperative for researchers to seek for alternative measure that can be used to sustain protein intake in individuals.
Pigeon Pea *(Cajanus cajan)* belongs to the family of *leguminosae* (Ghadge *et al.*, 2008). Among the Igbos In Nigeria, it is commonly called "foi-foi" or "Agbugbu" among the Igbos (Ene-Obong, 1984). Pigeon pea (*Cajanus cajan*) is a legume with nutritional and medicinal potentials that is yet to be fully exploited (Balogun *et al*., 2011). Pigeon pea produced in Nigeria is either consumed alone or consumed with starchy staple food (Ene-Obong, 2002). The hard - to - cook nature of pigeon pea has however been identified as a limiting factor in its consumption in Nigeria. Diversifying the use of pigeon pea by developing it into steam pudding (moi-moi) may enhance its consumption (which in the long run may mitigate the problem of malnutrition in individuals). This work was therefore designed to produce and compare the nutrients composition of moi-moi produced from pigeon pea and cowpea.

MATERIALS AND METHODS

Source and cleaning of materials

Seeds of pigeon pea *(Cajanus cajan)*, cream coloured specie and Cowpea *(Vigna unguiculata)* (Ife brown) were both purchased from *Ose Okwudu* Market, *Onitsha* in Anambra State. The pigeon pea seeds were sorted and cleaned by removing unwanted materials and unhealthy seeds. The pigeon pea was soaked in hot water (70-80^{0}C) for 30 minutes while the cowpea was soaked in potable tap water for 15 minutes. Dehulling of the seeds was done manually by rubbing the soaked seeds in between the palms until every hull was be completely removed.

Preparation of *moi-moi* from pigeon pea and cowpea seeds

Moi-moi was prepared using the recommended standard method described by Enwere (1998).The dehulled beans (500g) were grinded separately using 750ml of water for each. Ingredients ; crayfish (50g), onions (15g), red pepper (15g), maggi star (5g), salt (5g) were added to the paste and mixed manually with the aid of a wooden pestle until homogeneous slurry was obtained. The paste was scooped into aluminum foils and steamed for 60 minutes under moderate heat using a cooking stove.

Chemical analyses

Proximate composition of the sample was determined using standard AOAC (2006) methods. Carbohydrate was obtained by difference, while energy was calculated using the Atwater Conversion factors in KJ and Kcal (17KJ/4Kcal, 17KJ/4Kcal, and 37KJ/9Kcal) for protein, carbohydrate and lipid respectively.

Mineral elements were determined using wet-acid digestion method for multiple nutrients determination as described by the method of AOAC. (2006). The digest was used for the determinations of calcium (Ca) and magnesium (Mg) by the ethylamine ditetra acetic acid (EDTA) Versanate Complexiometric titration method. Potassium (K) and sodium (Na) were evaluated by flame photometry method and phosphorus (P) by the Vanadomolybdate method using the spectrophotometer. The trace metals (Zn, Fe) were determined using the atomic absorption spectrophotometer 969 instrument. The vitamin A, riboflavin, niacin and thiamin of the products were determined spectrophotometrically as described by AOAC (2006), while ascorbic acid was determined as described by AOAC (2006) using titration method.

Statistical analysis

All determinations were done in duplicates. The data generated were analyzed using Statistical Software for Social Sciences (SPSS version 18.0). Means and standard deviation obtained from the chemical analysis were calculated. Studentized T- Test was used to compare the means (P =0.05).

RESULTS AND DISCUSSION

The energy and proximate composition of the products is shown on Table 1. The moisture composition of the products ranged between 23.9-25.1%. *Moi-moi* prepared from cowpea had the highest moisture value (23.9%) while that of pigeon pea had the lowest moisture value (23.9%). The higher moisture obtained in cowpea moi-moi could be attributable to the fact that cowpea may have a greater affinity for absorption/retention of moisture (Eddy *et al*., 2007). Crude protein (23.4%), crude fiber (2.5%), ash ((2.4%) and CHO (44.4%) were significantly ($p<0.05$) higher in moi-moi prepared from cowpea while crude fat (11.0%) and energy value were significantly higher in moi-moi prepared from pigeon pea.Higher values of crude protein and fiber in moi-moi prepared from cowpea confirms with the report of Hall *et al*., (2003)

The result of the mineral composition of the products on Table 2 showed that the Ca (1.6mg/100g), Na (81.2mg/100g) Mg (3.9mg/100g) P(129.6mg/100g), K(181.6mg/100g) and Fe(1.8mg/100g) compositions of cowpea moi-moi were significantly higher than those of pigeon pea. Though pigeon pea moi-moi had lower Ca, Na, Mg K, and Fe compared to cowpea moi-moi, the consumption of pigeon pea moi- moi alongside other food sources will increase intake. The zinc obtained for pigeon pea moi-moi (2.4mg/100g) was significantly ($p<0.05$) higher than that of cowpea moi-moi (1.6mg/100g). Zinc is an important micronutrient in human diet. It is needed for catalysis, stabilization of cell membranes and regulation of gene expression (Black, 2003).

The vitamin A and E obtained for cowpea moi-moi were 16.1µg/100g and 0.34mg/100g respectively while those obtained for pigeon pea moi-moi were 6.6µg/100g and 0.30mg/100g respectively. Vitamin A plays an important role in vision, growth and development of tissue and it enhances immunity (FNB. 2001), while vitamin E is known for its role as an antioxidant (FNB 2000). Vitamin B_2 (0.30mg/100g) B_3 (2.6mg/100g), and vitamin C (20.2mg/100g) composition of pigeon pea moi-moi were significantly higher than those of cowpea moi-moi. The B-vitamins in food or taken as supplements enhances carbohydrate metabolism while vitamin C helps to convert plant iron into absorbable form in-vivo.

CONCLUSION

The study shows that *moi-moi* prepared from cowpea was a richer source of protein, fiber, Magnesium Phosphorus Potassium, vitamin A, and Iron. *Moi-moi* prepared from pigeon pea is a better source of fat, energy, Zinc, vitamins B_2, B_3 and C. The study shows that moi-moi prepared from pigeon pea can serve as an alternative to cowpea.

E-mail: mcojinnaka@yahoo.co.uk

ABSTRACT
The effect of modification on the proximate and functional properties of tiger nut starch was studied. The results obtained from the proximate composition shows that fat and protein were not detected in the 1.0%HCl and 1ml glucoamylase treated starch samples. The native starch sample had fat content of 0.57% with a protein content of 1.92%. The moisture content of the starch samples were within the range of 8.13 – 8.69%. Their carbohydrate values were high as expected being devoid of many other nutrients. Observations on the functional properties showed that the modified tiger nut starches exhibited higher bulk densities than the native starch sample. The bulk density values were in the range of 0.68 – 0.72g/ml while the wettability values had 3.38sec for 1ml glucoamylase treated starch sample and 3.24secs for 1.0%HCl treated sample. There were significant difference in the foaming capacity of the starch samples with the native starch sample having 2.29% higher than the modified starch samples (1.10 -1.50%). The foaming capacity of all the starch samples can be rated as low since they do not contain considerably high amounts of proteins.
Keywords: starch, modification, tiger nut

INTRODUCTION

Tiger nut (*Cyperus esculentus* L.) is an edible perennial grass-like plant native to the Old World, and is a lesser-known vegetable that produces sweet nut-like tubers known as "earth almonds" (Cos¸kuner *et al*., 2002). It is also known as yellow nut sedge, earth or ground almonds, "*souchet*" in French, "*ermandeln*" in German and "*chufa*" in Spanish (TTSL, 2005). Tigernut is found wild and cultivated in Africa, South America, Europe and Asia. Tigernuts grow in the wild, along rivers and are cultivated on a small scale by rural farmers mostly in the northern states of Nigeria. It is locally called "*aya*" in Hausa; "*aki awusa*" in Igbo; "*ofio*" in Yoruba and "*isipaccara*" in Effik. *C. esculentus* had been reported to be a "health" food, since its consumption can help prevent heart disease and thrombosis and is said to activate blood circulation (Chukwuma *et al*., 2010). The tuber is rich in energy content (starch, fat, sugar, and protein), minerals (mainly phosphorus and potassium), and vitamins E and C (Belewu and Belewu 2007).

Wurzburg (1989) gave insight into the physical properties of native starch, which limits its usefulness in many commercial applications and defined a modified starch as a product in which the chemical and (or) the physical properties of the native starch may have been altered. Food consumers are primarily influenced by the sensory properties of the food while the manufacturers are interested in the technological and functional properties of which starchy foods are linked closely to their rheological behavior. This study however tries to investigate the effect of tiger nut starch modification on their nutrient and functional properties.

MATERIALS AND METHODS

Source of material

The tiger nut used for this research work was purchased from Ubani market in Umuahia Abia State. Starch was extracted from tiger nuts by the modified method of Umerie *et al*. (1997). The acid and enzyme modification treatments of tiger nut (*Cyperus esculentus* L.) starch were performed using the method of Asinobi *et al*. (1988).

Nutrient and Functional Properties Analysis - The samples were analyzed for moisture, ash, protein and fat contents according to the method of AOAC (2000). The carbohydrate content was determined by difference.

Functional Properties - The Bulk density, viscosity, wettabiity and solubility index of the tiger nut starch samples were determined using the method described by Onwuka (2005). The swelling index determination was done by the method described by Ukpabi and Ndumele (1990). The method described by Abbey and Ibeh (1998) was used for water absorption capacity determination. The foaming capacity and stability of the starch samples were studied according to the methods described by Abbey and Ibeh (1988). The emulsion capacity was determined according to A.O.A.C (1990).

Statistical Analysis - Data obtained were subjected to statistical analysis using the statistical package for social services (SPSS).

RESULTS AND DISCUSSION

Table 1 shows that there were significant difference in the fat and protein contents of the starch samples. The native starch obtained from tiger nut starch had 0.57% fat and 1.92% protein respectively. The was significant difference in the moisture content of the starch samples. The native starch from tiger nut had higher moisture content of 8.69% compared to the 8.13% and 8.26% obtained by the 1.0% HCl modified starch and 1.0ml glucoamylase modified starch from tiger nut. Salwa *et al*., (2010) in their study of the physicochemical properties of starch extracted from different sources and their application in pudding and white sauce reported moisture content of 9.18% for native starch of tiger nut and 8.36% for corn. The moisture content of the starch samples were relatively low. The samples all had high carbohydrate values. This is to be expected as starch extract is devoid of other nutritional components.

Table 2 shows that bulk density values of the samples were higher for the 1%HCl treated starch (0.72g/ml), closely followed by 1ml glucoamylase treated starch (0.68g/ml) and the native starch (0.68g/ml). Higher bulk density is desirable for greater ease of dispersibility and reduction of paste thickness (Okezie and Bello, 1988). The swelling index of the native and modified starch samples were in the range 2.91 – 3.38%. The swelling power of starch is negatively affected by the presence of fat and protein in the sample (Udensi and Eke,2000). The modified starch samples had lower wettability values of 13.42 and 13.48 secs respectively. The native starch sample had wettability value of 17.82 secs. This could be due to its low protein content. It has been reported that the lower the level of denatured protein present, the slower it takes to get wetted or imbibe water (Oti and Akobundu, 2008). The native starch from the tiger nut had foaming capacity of 2.29% higher than those of the acid and enzyme treated starches. The foaming capacity of all the starch samples can be rated low (1.10 – 2.29%) since they do not contain considerably high amounts of proteins, a good foaming agent (Ayele and Nip, 1994). The native starch also had higher solubility in water index (17.82) compared to those of the treated starches. Bremiller (1993) also reported that modification of starches could bring about increased solubility of the starches.

The gelatinization temperature were in the range of 71.17 – 75.33^{o}C.The least gelation concentration for the starch samples were 9.33% for the native starch sample while the modified starches were 14.67 and 14.00% respectively. Gelatinization affects digestibility and texture of starch containing foods, It is also observed that gel forming capacity increased with increase in concentration of the starch samples (Lawal *et al.*, 2004). It has been reported that acid hydrolysis may make starch to lose its ability to gel (Sester, 1993).

CONCLUSION

It could be concluded from the study that native and modified tiger nut starches using 1% Hydrochloric acid and 1ml glucoamylase could be used in industrial food processing as well as thickening agents in food production.

Table 1: Proximate composition (%) of native and modified tigernut starches

Sample	Crude Fat	Moisture content	Crude Protein	Ash	Crude Fibre	Carbohyd-rate
Native starch	$0.57^{b}\pm0.08$	$8.69^{b}\pm0.03$	$1.92^{b}\pm0.87$	$2.19^{c}\pm0.06$	$0.32^{b}\pm0.03$	$86.30^{a}\pm0.85$
1.0% HCl treated starch	$0.00^{a}\pm0.00$	$8.13^{a}\pm0.15$	$0.00^{a}\pm0.00$	$1.15^{a}\pm0.16$	$0.01^{a}\pm0.01$	$90.65^{b}\pm0.30$
1ml Glucoamylase treated starch	$0.00^{a}\pm0.00$	$8.26^{a}\pm0.02$	$0.00^{a}\pm0.00$	$1.35^{b}\pm0.01$	$0.09^{a}\pm0.02$	$90.26^{b}\pm0.00$

ABSTRACT
Pineapple and banana flavored Instant Zobo Drinks spiced with ginger were produced from local Hibiscus sabdariffa and packaged in tea bags (Thermoplastic packaging material). The drinks were coded as sample (A) pineapple flavored, (B) banana flavored and (C) the control. Proximate, physico-chemical and microbiological analysis of the infusion were carried out on the drinks. Sensory evaluation was conducted to determine the acceptability of the drinks using nine point hedonic scale and 20 panelists who assessed taste, color, flavor, texture and the overall acceptability. The proximate percentage composition of the drinks showed that moisture, protein, fat, ash, crude fiber and carbohydrates ranged between 13.10 - 13.20; 2.70 - 3.11; 3.40 - 3.60; 6.08 - 6.60; 12.30 - 13.40; and 61.12 - 62.60 respectively. In addition, the energy values recorded were between 86.70 - 289.85 Kcal. The physico-chemical analysis of the infusion revealed that pine apple flavored drink had the highest value of vitamin C, total soluble solid, total solid and specific gravity. While the banana flavored drink and the control recorded the highest pH and total titratable acidity respectively. In addition, the results of microbiological analysis revealed low counts of $<1.0x10^2$ CFU/g. The sensory evaluation results indicated no significant (5%) difference for taste, color and overall acceptability but statistically significant (5%) differences were observed for flavor and texture. It was concluded that a well packaged, spiced and flavored instant Zobo drink that is microbiologically safe, nutritious and generally acceptable and is convenient to handle and easy to prepare can be made from Hibiscus sabdariffa calyces.
Keywords: Zobo, drink, functional and sensory, characteristics

INTRODUCTION
Zobo drink (sorrel, Zoborodo) is a non – alcoholic local beverage made from dried petals, acid – succulent calyces of the flower - *Hibiscus sabdariffa* by boiling and filtration of the aqueous extracts of the calyces. The drink is gaining wide acceptance, being consumed by several millions of people from different socio – economic classes and background in the West Africa sub – region, especially amongst the youths, who see Zobo drink as an alternative source of cheap and relaxing non – alcoholic drink in social gathering (Ogiehor and Nwafor, 2004). In addition, Zobo drink is used as a substitute to carbonated drinks in Nigeria and indeed Africa due to its beneficial effect in the prevention of hypertension, urinary tract infection, low sperm count (infertility in men), antidiuretic and diabetes mellitus and lowering of cholesterol in the blood (Adesokan, *et al*., 2013).
Zobo drink is a highly nutritious food drink rich in vitamins, minerals, fibre and other antioxidants in addition to its content of macronutrients such as carbohydrate, protein and fat (Osutogun and Aboaba, 2004). It is believed to help cure ailments such as diarrhoea and pneumonia, and is recommended for people with vitamin C deficiency diseases, hypertension and urinary tract infection (Ojokoh, *et al*., 2002). The flowers of *H. sabdariffa* are rich in vitamins and other antioxidants (Kochlar, 1991).The proximate composition of Zobo drink shows that it has 90% water, 0.7%protein, 8% carbohydrate, 1.4%, fiber and 1.1 fat with iron, niacin, riboflavin, thiamine, Betacarotene, phosphorous and calcium also present in various proportions (Fasoyiro et al., 2005). The medicinal value of the zobo plant has been claimed to include antihypertensive, antiseptic, astringent, diuretic, purgative activities, remedy for cancer, abscesses, cough, debility, scurvy and fever (Ogbo, 2002).
The flavour of food is important to its enjoyment and it is not surprising that flavours are added to food to increase its acceptability. Herbs and spices are used in cooking to improve the taste of food and bring out its natural flavor. Spices (e.g. ginger, glove and black pepper) added to Zobo drink enhance its organoleptic properties, flavour, aroma and taste. Spices have been known and used for ages especially for their aroma and to some extent for their preservative qualities (Dziezak, 1989). Garlic, Cinnamon and cloves have also been shown to inhibit bacterial and mould growth (Paster *et al*., 1995). The use of cheap, readily available and largely underutilized local spices as additive in Zobo drink will have a dual effect of improving the taste as well as prolonging the shelf life. Therefore the objective of this study was to produce and evaluate the production processes of flavoured instant Zobo drink with an improved shelf life.

MATERIALS AND METHODS

Row Material Collection and Preparation

Hibiscus sabdariffa dried calyces, ginger rhizomes, cloves pods, black pepper seeds and flavors (pineapple, banana) were purchased from a local market in Kaduna metropolis. The raw materials were then properly sorted, cleaned, washed in cold water and weighed with a weighing balance. The materials were later dried in the cabinet drier at 50 ^{0}C for 3 hours, milled using harmer mill and sieved to obtain fine powder of about 20um.

Production of Instant Flavored Zobo drink

The materials for the production of the Zobo drinks including, Hibiscus sabdariffa calyces - sorrel flowers processed to Zobo powder - (700g); ginger powder (100g); cloves powder (50g); black pepper powder (50g) and flavors - pineapple or banana - (100g each) were thoroughly mixed and blended together to a homogeneous mixture in a bowl and used to formulate the three different Zobo flavors A (pineapple), B (banana) and C (control). Five grams of each of the product was then packaged in thermoplastic packaging material and sealed using electric impulse sealing machine to protect against moisture uptake and microbial contamination as instant Zobo drink. The flow chats for the processing operations for the production of instant flavored Zobo is shown figure 1.

Proximate Analysis

The proximate composition (moisture, protein, fat, ash, crude fibre, carbohydrate and energy value) of the flavored Zobo drink were determined following the methods described by the Association of Official Analytical Chemists (AOAC, 2000).

Physico-Chemical Analysis

The functional properties of the instant flavored Zobo drink were determined by assessing the total titratable acidity (TTA), vitamin C, total soluble solid, total solid, and specific gravity. Similarly, the pH of the various Zobo samples was determined at 24 h interval as described by Adesokan *et al.*, (2008) using a digital pH meter. The titratable acid (TA) of Zobo samples was also analyzed at the same time interval by titrating 0.1M NaOH solution and phenolphthalein as end point indicator. The titer volume of each homogenate was multiplied by 0.09 to give the percentage TA as lactic acid (Olubamiwa and Kolapo, 2008).

Microbiological Screening

For the microbial analysis the following bacteria's were enumerated:

a. Mesophilic bacteria using standard plate count method (WHO/FAO , 2006).
b. Yeasts and moulds using standard plate count method according to WHO/FAO, (2006).
c. Coliform bacteria using standard plate count method (WHO/FAO, 2006)
d. Gram staining as described by WHO/FAO (2006).

Sensory Evaluation

Sensory evaluation was carried out using 20 panelists who assessed the various drinks for differences in taste, color, flavor, and over all acceptability, using 9 point hedonic scale. A sachet of each flavored Zobo drink was infused into 200ml of hot water in a transparent plastic cup by dipping continuously for a few minutes to complete the extraction. 2 cubes of sugar equivalent to 10g was added and mixed to dissolve complexly to a degree brix of between 10.1 to 10.6%. The samples were then presented to the panelists in the department of food technology sensory evaluation room.

Statistical Analysis

The data collected from the organoleptic assessment were statistically analyzed using ANOVA (Analysis of variance) to determine whether significant differences exist among the samples.

RESULTS

Proximate Analysis

The result of the proximate analysis conducted on the instant Zobo drink mixed with different flavors and spices is presented in Table 1. The data indicated that compared to the pineapple flavored Zobo Drink and the control, the banana flavored Zobo drink re-coded the highest percentage of protein, fat, and ash being 3.11, 3.60 and 6.60 percent respectively. The moisture and crude fiber content of the unflavored Zobo sample was higher than pineapple and banana flavored Zobo products. It was observed from the result that the carbohydrate composition of the pineapple drink (61.60%) was higher than that of the banana flavored instant Zobo and the control with 61.23 and 61.12 percent respectively. In terms of Energy, the highest value of 289.85 Kcal was recorded by the banana flavored instant drink as against the energy contained by the pineapple flavored Zobo (289.44) and the control (286.78).

Physico-chemical Analysis

The physicochemical attributes of the Zobo drinks that include the pH, total titratable acid, vitamin C, total soluble solid, total solid and specific gravity as affected by the addition of flavor and spice is presented in Tale 2. The pH of the instant Zobo drinks ranges from 4.58 to 4.62 with the banana flavored Zobo drink having the highest. The none-flavored Zobo sample recoded the highest total titratable acidity (0.086%) which is comparable to those of the pineapple and banana flavored Zobo products having 0.084 and 0.083 percent respectively. The pineapple flavored Zobo drink was observed to have the highest content of vitamin C, total soluble solids, total solids and specific gravity among the three instant Zobo drinks with 48 mg/100 ml, 10.4%, 17.58% and 1.012 respectively.

Microbiological Analysis

The result of the microbial count of the instant Zobo drink is presented in Table 3. The data indicated a very low microbial growth for all the three samples. The microbial counts results also showed very few growth of mesophilic bacteria **($<1.ox10^2$ CFU/g)** and the Gram staining of the isolated organism reveals bacillus species (a spore former).

Sensory Evaluation

The mean sensory evaluation scores of the instant Zobo drink in terms of taste, color, flavor, texture and overall acceptability as examined by 20 member panelists is presented in Table 4. The organoleptic test data indicated that the flavored drinks (samples A and B) performed significantly better than the control in terms of all the parameters evaluated. The data further demonstrates that the pineapple flavored Zobo drink had the highest acceptability (8.35), followed by the banana flavored instant Zobo with an acceptability rating of 7.70, while the flavor free Zobo Product (control) had the least overall acceptability rating of 7.40 . The panelist showed higher preference for the pineapple flavored Zobo product, followed by the banana flavored instant Zobo with respect to taste, color, flavor and texture. In addition the result showed least preference for control in terms of the variable listed.

DISCUSSION

Beverages, as part of food, are among the important requirements for life sustenance for both plants and animals. These beverages are sometimes referred to as non-alcoholic drinks. They are obtained mainly from local sources such as plant sources. Their methods of preparation and preservation still depend on local technologies and due to microbial contamination their storage and long shelf life is not guaranteed (Osuntogun and Aboabe, 2004).

The proximate composition of Zobo-drink mixed with deferent flavor and spices (Table 1) indicated a moisture content ranging from 13.10% to 13.20%. Adedokun, *et al*., (2015) reported a high moisture content of Zobo-drink ranging from 85.21% to 86.49% that was attributed to a desirable, refreshing and thirst-quenching attribute. The low moisture content observed in this trial was as a result of the dry state of the Zobo product. The protein content of the pineapple (03.10%) and banana (03.11%) flavored Zobo product was higher than that of the control sample without flavor (02.70%). The variation and increase of protein could be due to difference in chemical composition of raw materials used *Hibiscus sabdariffa L*. and spices or other plant flavoring materials. Total carbohydrate composition of the Zobo samples showed a slight variation with the pineapple flavored drink having the highest (61.6%) and the control having the least (61.12%). These values represent the mineral elements present in the drink. The ash content of the banana flavored Zobo product was fairly higher than that of the other two samples indicating the high mineral value. Rao, (1996) recorded that roselle generally contain high amount of ash which indicates that the plant provides appreciable quantity of minerals required by the body.

The data on the physicochemical properties of instant Zobo drink (Table 2) indicates that the products contain some reasonable amount of vitamin C in which pineapple flavored drink had the highest. Duke (1985) had earlier reported that vitamin C in Zobo drink raises human immunity. The pH value of the instant Zobo drink which ranges from 4.58 to 4.62 (Table. 2) imply that it belongs to a class of food referred to as high acid foods (Frazier and Westhoff, 1988). Similarly, Wong *et al*., (2002) has observed Zobo drinks to be a naturally acidic fruit rich in organic acids: Oxalic, tartaric, malic and succinic. An advantage of an acid food is that it does not support the survival of many pathogenic organisms Jay (1996). The total soluble solid described as ^{0}Brix content of instant flavoured Zobo-drink ranged between 09.10 - 3.410 for the three sample with the control having the list. The titrable acidity (%) is a measure of acidity level present in a food. The percentage found was between 0.083 – 0.086 percent. The findings on the properties of Zobo-drink shows that combination of Roselle extract with spice bioactive extract tends to improve the proximate composition and chemical properties of non-alcoholic drink.

The microbial counts of the instant Zobo drinks presented in Table 3 indicated very low microbial growth. The low population of microbes in these products could be attributed to the low moisture content or the preservative effect of the spices added to the drinks. This may have been because the active component of these spices may have interacted synergistically with other factors to increase its preservative effect. The preservative effect of

these spices is due to their chemical composition especially the essential oil fractions which are inhibitory to microbial growth. Furthermore it has been documented that the volatile oil in spices are responsible for their aroma, flavor and taste as well as their antimicrobial properties (Zaika, 1998).
The data generated from the sensory evaluation result in this study indicated that the flavored drinks (samples A and B) performed significantly better than the control in terms of all the parameters evaluated. As was expected superior acceptability of these drinks over the control was due to the addition of flavor (pine apple and banana). Overall acceptability is the product of color, taste and flavor. Conversely, there was least preference for control in terms of taste and overall acceptability. It could be concluded that fortification of Zobo samples with additives to a certain level resulted in organoleptically more acceptable samples than the control as reported by Abulude *et al.,* (2006) who observed that fortification of Kunun Zaki resulted in increased acceptability over the control.

CONCLUSION

It can be concluded from this study that a generally acceptable, microbiologically safe and nutritious flavored instant Zobo drink packaged in tea bags (thermoplastic packaging material) can be produced from *Hibiscus sabdariffa* (Zobo) calyces. The results of this research also show that addition of flavors (pineapple and banana) and local spices (ginger, cloves, black pepper) had significantly improved the taste and acceptability of Zobo drinks. The findings on the properties of Zobo-drink showed that combination of roselle extract, Zobo-drink" with spice bioactive extracts tend to improve the proximate composition and chemical properties of non-alcoholic Zobo-drink and improve its shelf life.

ABSTRACT
The morphology of an area determines its land-use suitability. The study was carried out on three toposequences of dissimilar lithologies namely Coastal plain sand, Imo clay shales and Falsebedded sandstone all in Imo State, with the aim of studying the morphological properties of the soils for optimal management and utilization. A transect survey technique was used to align three profile pits on each of the toposequence at an inter-pedal distance of about 100 m. The profile pits were sited on each physiographic position consisting of the summit, midslope and toeslope. Soil samples were described using FAO soil description approach. The textural class of the toposequences generally appears more sandy in composition with a fewer clay and loamy concentration. All the horizons were well drained, except for the horizons that had common boundary with the high water table at the toeslope of coastal plain sand toposequence. The soils varied among the toposequences due to their geological and morphological properties. Therefore, agro-environmental practitioners should consider these soil attributes in order to maintain and sustain soil utilization.
Key words: morphology, horizon, lithology, physiographic position, toposequence

INTRODUCTION
The nature of soil is determined by the material from which it has been developed and the environment to which it has been subjected. Variations in the environment give rise to variations in soils, since the processes responsible for soil development are controlled by the environment. The toposequence concept emanated as slope soil evolutionary processes. Soils along a toposequence can be with or without uniform lithology (Brady and Weil, 1999). The distribution of individual soil series on a toposequence and the spatial distribution of the toposequecne itself have considerable influence on the land use pattern of an area. It also results in morphological changes and horizonation thus relating hydrology to topographic position (Odenerho, 1980). Soil properties along a toposequence vary from summit to toeslope due to micro climate, pathogenesis and geologic processes which result to a considerable influence on the land (Nuga *et al.,* 2008). The variation along a toposequence can be as a result of parent materials and slope aspect which implies that different soil lithologies give rise to different soil formations. It is very important to understand the nature, behaviour and distribution of various soils along a toposequence and the various parent materials that constituted the soils, but this can only be possible if these soils are studied. It is important to study the geomorphology of an area for proper management and precision decision. Hence, this study was aimed to describe the morphological properties of soils of toposequences underlain by dissimilar lithology.

MATERIALS AND METHODS
Study Area
The study was carried out at three (3) different locations namely, Inyishi in Ikeduru Local Government Area (L.G.A), Isiebu in Isiala Mbano L.G.A., and Ihube in Okigwe L.G.A. all in Imo State, South-east Nigeria. The study areas lie between latitude 5° 52' 07.83'' N and 7° 22' 05.03'' E for Ihube site, 5° 45' 02.44'' N and 7°10' 36.33'' E for Isiebu site, while 5° 33' 59.23''N and 7° 10' 30.75'' E for Inyishi site.
The geological (lithology) materials from which the soils of the study areas developed are Coastal Plain Sand (Benin formation) for Ikeduru study site, Falsebedded Sandstone (Ajalli formation) for Okigwe study site and Imo Clay Shales (Imo formation) for Isiala Mbano study site. The study areas are generally denominated by plains and lowlands (Ofomata, 1987).
The area lies under the tropical rainforest zone of the South-east Nigeria with a humid tropical rainfall range of 1500 mm to 2200 mm. The average annual atmospheric temperature above 20 °C creates an annual relative humidity of 75 % while during the rainy season humidity reaches 90 %. The areas have a typical rainforest with sparse vegetation at Okigwe and densely vegetated rainforest at Ikeduru and Isiala Mbano.

Field Sampling
A reconnaissance study was carried out on the study areas. Subsequently, transect survey technique was used to sunk three (3) soil profile pits along each toposequences with respect to physiographic positions namely summit, midslope and toeslope. The profile pits were described following the guideline of FAO, (2006) soil description approach.

RESULTS AND DISCUSSION
The result of the soil morphological properties of the studied sites as indicated in Tables 1, 2, and 3 showed that all the horizons were well drained except for the Bt-horizons that had common boundary with the high water table at the toeslope of Coastal Plain Sand (CPS) toposequence. The surface soils were loose at all physiographic land units except for the summit and midslope of falsebedded sandstone (FBS) toposequence while the subsurface horizons were mostly firm. The loose nature of the soil may be as a result of runoff and downward migration of finer particles. The roots sizes and quantity was as a result of the type and age of plants in the study sites. Also, the land-use types suggest root sizes and quantity. Soil of the CPS recorded more roots in terms of quantity and size over soil of other lithologies.

Soils formed over the coastal plain sand toposequence indicated that across the horizons the soil colour ranged from dark red (10R 3/6) moist, very dark reddish brown (2.5YR 3/3) moist to dull reddish brown (5YR 4/3) moist at the summit and dark red (10R 3/4; 10R 3/6; 2.5YR 3/4) moist, reddish brown (5YR 4/5) moist to dark reddish brown (2.5YR 3/4; 2.5YR 3/2) moist at the midslope while, very dark reddish brown (2.5YK 2/4) moist, dark reddish brown (10R 3/6; 2.5YR 3/4) moist to brown (7.5YR 4/6) moist was recorded at the toeslope. The soils of Falsebedded Sandstone had colour matrix ranged from red (10R 4/8) moist, dark red (10R 3/6) moist to dark reddish brown (2.5YR 3/6; 5YR 3/3) moist at the summit and dark red (10R 3/6; 10R 3/4) moist to dark reddish brown (5YR 3/4) moist at the midslope while, dark reddish brown (10R 3/3; 5YR 3/3) moist to very dark reddish brown (2.5YR 2/4; 5YR 2/3) moist was indicated at the toeslope. However, it was also observed that soil horizons at Imo Clay Shale (ICS) toposequence showed colour matrix ranged from dull reddish brown (2.5YR 3/4; 5YR 5/4; 2.5YR 4/3) moist, bright reddish brown (5Y 5/6) moist to reddish brown (2.5YR 4/6) moist at the summit and dull orange (2.5YR 6/4; 5YR 6/4) moist, bright brown (7.5YR 5/6) moist to dark brown (7.5YR 3/4) moist at the midslope while, the toeslope had bright brown (2.5YR 5/6; 7.5YR 5/6;) moist, bright reddish brown (5YR 3/6) moist to brown (7.5YR 4/6) moist. Generally the surface horizons of each physiographic position has a colour matrix range of dark red (10R 3/6) to very dark reddish brown (5YR 2/3) moist at the coastal plain sand toposequence while, the surface horizons of falsebedded sandstone toposeqence showed colour ranged from red (10R 4/8), dark red (10R 3/6) to dark reddish brown (10R 3/3) moist. However, surface horizons of Imo clay shales toposequence indicated soil colour matrix range of dull reddish brown (2.5YR 4/4), dull orange (2.5YR 6/4) to bright brown (2.5YR 5/6) moist at the surface horizon of each physiographic position respectively. The drainage condition and physiographic position may have influenced the observable change in the soil colour matrix in the horizons which agrees with the works of Gerrard, (1981) and Esu *et al.*, (2008). The parent materials and environmental factors (rainfall, humidity and temperature) may have contributed to the soil colour variation of each horizon. Also, the amount of eluviations and/or illuviations that has occurred within these toposequences may equally contribute to the soil colour matrix on each topographic unit. The red colours are due to the presence of ferrous (Fe^{2+}) compound and indicate that the soils are well aerated. According to Nuhu (1983) the brownish tinges in most of the horizons of the profile were due to the presence of organic matter which is the main colouring agent in surface soil.

Furthermore, the textural class of the toposequence generally appears sandy in composition with fewer clay and loamy concentration. The coastal plain sand toposequence had textural range of loamy sand (LS) at the Ap and A-horizons while sandy clay loam (SCL) was observed at the other horizons for the summit. The midslope had range of sandy loam at the Ap and Bt_3-horizons while other horizons was observed as sandy clay loam (SCL). The toeslope recorded a textural range of loamy sand (LS) at the Ap and Bt_2 horizons while A-horizon had sandy clay loam (SCL) texture. TheBt_1 and Bt_3 horizons were observed to be sandy loam (SL) in texture. Falsebedded sandstone toposequence recorded textural range of sandy loam at A-horizon while other horizons were observed as sandy clay texture at the summit. The midslope had sandy loam at A-horizon and sandy clay loam at E and Bt-horizon. Furthermore, the toeslope had it's A, E and B_t-horizon as sandy loam in texture while Bt_2, was observed as sandy clay loam in texture. However, the textural range of Imo clay shale toposequence showed that at the summit it was sandy clay loam in texture across the horizons. Its midslope showed loamy sand texture at the Ap horizon, sandy clay texture at the Bt_3 horizon while others had sandy clay loam texture. The toeslope of the ICS toposequence was observed to have, sand, loamy sand, sandy clay loam and sandy clay down its horizon. However, the textural classes of the toposequences agrees with the findings of Tomer and Anderson (1995) who attributed difference in soil texture to the variation in parent materials and to the topography. Also, the result is in conformity with the findings of Brady and Weil, (2007) that attributed difference in soil texture to soil formation factors.

The study sites had crumb or granular structure in all the surface horizons of the toposequences and dominating the subsurface horizons are subangular blocky structure. The crumb structure could be as a result of eluviation of mostly clay particles and runoff effect on the soil surface.

CONCLUSION

Significant morphological differences were observed in the horizons of the study sites which varied physiographically and among the toposequences. This is an indication that the soil under different toposequence has possessed different characteristics. However, land users are encouraged to adopt agro friendly practices while exploring the toposequences due to land pressure that is on the increase within the studied areas. The use of conservation tillage, application of organic manure into the soils, adequate ground cover will encourage soil sustainability in the area.

EFFECTS OF NITROGEN SOURCES ON SOME SOIL PHYSICAL PROPERTIES UNDER MAIZE–COWPEA ROTATION SYSTEM IN UMUDIKE, SOUTHEASTERN NIGERIA

N. R., Njoku, C.C., Nwokocha & R. M. Omodamiro
National Root Crops Research Institute Umudike, PMB 7006 Umuahia, Abia State, Nigeria
nwanyiezernjoku@yahoo.com

ABSTRACT
The effects of organic and inorganic nitrogen fertilizer applications on soil physical properties are important to agricultural sustainability and increased crop yield. A trial was carried out in rainforest area of Umudike to investigate the physical properties of the soil under maize-cowpea rotation system as affected by nitrogen sources in 2009 and 2010 using urea (UR), sawdust (SD), poultry dropping (PD), Cow dung (CD), brewers' spent grains (BS), pig manure (PM) and combination of the organic N sources (CB), each applied at the rate 120 kg ha^{-1}. It was observed that there were significant variations in the soil physical conditions of the location of the study area during the two years of the study. However, observed values of bulk density, soil porosity and volumetric moisture contents for the whole profile at 0 – 40 cm depth ranges from 1.42 Mg m^{-3} for SD to 1.51 Mg m^{-3} for CT and 1.41 Mg m^{-3} for SD to 1.48 Mg m^{-3} for CT respectively, from 43.4 % for CT to 63.7% for SD and 44.3% for CT to 47.0 % for SD and from 26.8 v/v, % for CT to 28.8 v/v, % for CD and 29.3 v/v,% for CT to 31.2 v/v,% for CD, PM and CB after maize and cowpea harvest respectively. Across the two cropping seasons and among the organic N sources, the sawdust treatment maintained the lowest bulk density and highest porosity values for the entire soil profile depth. The results indicated that soil physical properties with the organic nitrogen sources maintained more favorable content than fertilizer urea and control.

Key words: Nitrogen sources, soil physical properties and maize–cowpea rotation.

INTRODUCTION
The maintenance of optimum soil physical fertility is an important component of soil management that has only recently been accepted. If well managed, organic waste material can provide significant source of plant nutrient as well as improves the physical properties of the soil (Janzen, 1993; Opara – Nadi and LaI, 1987; Nottidge *et al*, 2005).

Several studies (Eghball, 2002; Whalen and Chang, 2002; Fares et al., 2008) reported that N sources might improve soil physical property by improving soil tilt, decreasing soil bulk density, increasing total porosity and saturated hydraulic conductivity. Zhong and Shangguan (2014) reported that N-applied treatments increased water consumption in different layer of soil and evapor-transpiration that were significantly higher in N-applied than in non-N treatments.

Application of nitrogenous (N) fertilizers alone adversely affected physical quality of the soil and significantly declined the system productive capacity. Hati *et al.*, (2006) studied the effects of farmyard manure on soil physical properties and reported that the combined application of inorganic fertilizer and farmyard manure resulted in the lowest bulk density and total porosity in the top soil layer compared with total porosity and bulk density of control treatment and had little effect on bulk density and saturated hydraulic conductivity in subsurface soil layer. They attributed the change to better soil structure, pore size distribution and soil water transmission in the manure amended soil. However, no study has been done on the effects of nitrogen sources on soil physical properties under maize–cowpea rotation system in Umudike. The objective of this study therefore, was to determine the effects of nitrogen sources involving organic and inorganic fertilizer on soil physical properties in Umudike, Southeastern Nigeria.

MATERIALS AND METHODS
The experiment was conducted in 2009 and 2010 cropping seasons to determine effects of nitrogen sources on soil physical properties under maize–cowpea rotation system in Umudike. The experimental design was a randomized complete block (RCBD) with three replications. The treatments were eight as follows, control (CT), urea (UR), sawdust (SD), poultry dropping (PD), cow dung (CD), brewers' spent grain (BS), Pig manure (PM) and combination of all the organic manure (CB) applied at 120 kg ha^{-1} recommended rate for maize in the area.

Undisturbed core soil samples were collected from the experimental site before establishing the experiment from 0 – 10, 10 – 20 and 20 – 40 cm depths. Another soil sample was collected from each replicate plot after maize and cowpea harvest respectively using soil cores (5 cm and 5 cm internal diameter) were used to determine the physical properties of the soil.

Bulk density was determined by using Blake and Hartge, (1986) core method:

$$Bd = \frac{Ms}{Us}$$

Where Bd is the bulk density (g cm^3), Ms is the mass of soil (g) and Us is the volume of soil (cm^3). Total porosity was determined by calculating particle density (Pd) and bulk density (Bd) values.

$$Pt = 100\left(1 - {}^{Bd}/_{Pd}\right) = 100\left(Pd - {}^{Bd}/_{Pd}\right)$$

Where Bd is the bulk density (g cm-^{3}) and Pd is the particle density (g cm-^{3}). Volumetric moisture content was determined by oven dry method:

$$Wv = Wd * {}^{Pb}/_{Pw}$$

Where Pb is the soil bulk density (g dry soil /cm3 soil) and Pw = density of water (1g water/cm3 water)
The data collected were subjected to standard statistical analysis of variance (ANOVA). Treatment means were separated using least significance difference (LSD) at 5% level of probability test.

RESULTS AND DISCUSSION

Some soil physical properties of the experimental site are shown in the Table1. Bulk density increased with depth, with values of 1.36, 1.49 and 1.59 Mg m^{-3} in the 0 – 10, 10 – 20 and 20 – 40 cm depths respectively. The lower bulk density values in the 0 – 10 cm depth for the experimental site showed that the value may be attributed to the influence of the organic matter, root and faunal activities, while the higher value in the 20 – 40 cm depth may be due to the higher clay content and reduced root and faunal activities Table1.

Effects of N sources on soil bulk density measured after maize harvest in 2009 and 2010 are shown in Table 2, while after cowpea harvest in 2009 and 2010 is in Table 3. Bulk density values averaged two years of study (for both maize and cowpea) showed that SD treatment produced the lowest value of 1.41 Mg m^{-3}, while CT treatment has the highest value of 1.51 Mg m^{-3} for the three depths. Generally, the variation in bulk density among the different N sources with the exception of the SD treatment was minimal especially in the 0 – 10 and 10 – 20 cm depths. However, the CT treatment produced significantly higher bulk density when compared with the different N sources, while the SD treatment also produced significantly lower bulk density values when compared with the other N sources and this could be due to the improved soil structure caused by the SD treatment.

Effects of addition of different N sources on mean soil total porosity after maize and cowpea harvest in 2009 and 2010 are shown in Tables 4 and 5 respectively. After the two years cropping, significant differences in total porosity were observed for the three depths among the different N sources. Data on total porosity showed that the higher porosity measured for the SD treatment indicated the lower bulk density resulting from the adjustment in soil structure form the SD materials. On the other hand, the CT treatment resulted in lowest total porosity as a result of high bulk density.

Effects of nitrogen sources on volumetric moisture content measured after maize harvest in 2009 and 2010 and also after cowpea harvest in 2009 and 2010 are shown in Tables 10 and 11 respectively. Generally, differences in volumetric moisture content measured for the three depths for the different N sources were significant. For both after maize and cowpea harvest measurements, volumetric moisture content for the N sources increased with depth. Data in Table 10 showed that mean volumetric moisture content for the three depths (average for 0 – 40 cm depth) was of the order CD > PM = CB > PD > SD > BS > UR > CT. Similarly, mean volumetric moisture content for all three depths sampled after cowpea harvest (Table 11) was of the order CD = PM = CB > BS > SD > PD > UR > CT. The high moisture content under the N sources in comparism with the control seem to indicate the improved moisture storage capacity under the nitrogen sources as a result of improved soil physical properties such as bulk density. On the other hand, the CT treatment, which gave the lowest volumetric moisture content, seems to indicate the reduced moisture storage capacity in the crop-rooting zone (0 - 40 cm depth) as a result of increased bulk density and reduced total porosity. Data in Tables 10 and 11 shows that moisture storage under cowpea was better than under maize which showed that cowpea produced greater vegetative cover than maize for the soil surface which in turn reduced evaporation from the soil

CONCLUSIONS

After two cropping season, data on bulk density, total porosity and volumetric moisture content showed that the organic nitrogen sources maintained more favourable soil physical properties than fertilizer urea and control. Among the organic N sources, the sawdust treatment maintained the lowest bulk density and highest porosity values.

Table 1: Some soil physical properties of the experimental plot before treatment application in 2009 and 2010.

Parameter	Depths		
	0-10cm	10-20cm	20-40cm

ABSTRACT
The effect of oil palm bunch ash (OPBA) as source of nutrients in okra production when used alone or combined with urea (U) or NPK fertilizer was investigated in two years on Ultisol at Ewatto in Edo State of Nigeria. There were thirteen treatments replicated three times on okra (Abelmoschus esculentus moench), in Randomized Complete Block Design. The treatments were Control, 100% U (160kg/ha), 100% OPBA (4t/ha), 75% U + 25% OPBA, 50% U + 50% OPBA, 25% U + 75% OPBA, 100% NPK (240kg/ha), 75% NPK + 25% OPBA, 50% NPK + 50% OPBA, 25% NPK + 75% OPBA, 75% OPBA, 50% OPBA and 25% OPBA. Each plot was 13.5m^2 with okra seeds planted at 60cm by 90cm at one plant per stand after thinning. Treatments were applied three weeks after planting by ring method with NPK or urea and OPBA mixed. Soil samples were collected at 0-15cm depth with soil auger before planting and ten weeks after treatment applications and analysed for pH, OM, N, P, K, Ca and Mg. Statistical analyses were performed using Statistical Analysis System (SAS) software version 9.0. Duncan multiple range test (p=0.05) was used to compare means. The soil is sandy, acidic and low in OM, P, K, Ca and CEC. OPBA increased soil OM, N, P, K, Ca and Mg, and the nutrients increased with level of OPBA. OPBA alone or combined with Urea or NPK fertilizer increased soil pH, had liming effect. The pH increased with OPBA rate. Addition of OPBA to inorganic fertilizers (Urea and NPK) increased soil and plant growth and yield components of okra. Combinations of reduced rates of OPBA and NPK or Urea fertilizer most increased okra pod weight, although the combinations with NPK had highest pod weight.
Keywords: soil nutrients, okra, performance, oil palm, inorganic fertilizers

INTRODUCTION

Okra (*Abelmoschus esculentus)* is an important vegetable that is popularly cultivated and consumed in Nigeria and other tropical countries of the world. The fresh fruits and young leaves are used in preparing soups as they are rich in vitamins and other minerals. The mature pods contain a mucilaginous substance that can be used in the pharmaceutical industry and manufacture of papers. Because of its importance in human diet and local economy, there is the need to improve the production and quality of okra plant through application of organic and inorganic fertilizers. Moyin-Jesu (2007) asserted that okra plays important role in human diet by supplying carbohydrate, protein, fats, minerals and vitamins that are usually deficient in the staple food. Despite the nutritional value of okra, its optimum yields (2-3 t/ha) and quality has not been attained in tropical countries partly because of a continued decline in soil fertility (Fatokun and Chedda, 1983; Muoneke and Aliyu, 1997). Hence research is needed on using organic and inorganic fertilizers to enhance growth and pod yield. Oil palm bunch ash is an organic waste derived from burning of empty oil palm bunch refuse. Ojeniyi and Folorunso (2005) reported that oil palm bunch ash contains P, K, Ca and Mg. It is almost impossible to meet the crop demand with inorganic fertilizers alone, hence the need for combined application of OPBA with Urea and OPBA with NPK.
With a combination of organic and inorganic fertilizers, the organic fertilizer can exhibit its long residual effect and add organic matter to the soil (Palm and Nariduwa, 1997). Sustainable crop production in the tropics is possible only with combination of organic and inorganic fertilizers. This study is to provide research information that is scarce on integrated nutrient supply, to investigate the effect of combined application of OPBA with NPK and OPBA with Urea on soil chemical composition, growth and yield, and also to determine the rate suitable for okra production.

MATERIALS AND METHODS

The work was done at Abhuru farm settlement in Ewatto, Edo State located in the southern zone of Nigeria. The site was manually cleared, heap packed and planted with Dwarf Long-45 variety of okra. The plot is 13.5m^2 and okra seeds were planted 60cm by 90cm with one plant per stand after thinning. There were thirteen treatments replicated three times using randomized complete block design. Treatments were Control, 100% U, (160kg/ha), 100% OPBA (4t/ha), 75% U + 25% OPBA, 50% U + 50% OPBA, 25% U + 75% OPBA, 100% $NPK_{15\ 15\ 15}$

(240kg/ha), 75% NPK + 25% OPBA, 50% NPK + 50% OPBA, 25% NPK + 75% OPBA, 75% OPBA, 50% OPBA and 25% OPBA. Treatments were applied three weeks after planting by ring method with NPK or Urea and OPBA mixed. Thorough weeding was done before the application and it was weeded twice after the application of treatments. Harvesting of pods was done at 4 days interval from 50 days of planting to 90 days. The experiment was repeated in the following year.

Soil Analysis

Auger soil samples collected at the site were bulked for analysis. Surface soil (0 – 15cm depth) samples collected below treatment plants in each plot 10 weeks after treatment applications were also bulked. The samples were air dried, sieved with 2mm mesh and analysed chemically. Organic matter was determined using dichromate oxidation method, total N was determined by microkjedhal method, available P was extracted using Bray-1 extract followed by molybdenum blue colorimetry, exchangeable cations were extracted using ammonium acetate, K was determined on flame photometer, while Ca and Mg were determined using EDTA titration. The pH in soil-water 1:2 medium was determined.

Data Collection

Ten plants were randomly selected and tagged for data collection which included plant height, number of leaves and weight of pods.

Statistical Analysis

Statistical analyses were performed using statistical analysis system (S.A.S) software version 9.0. Duncan multiple range test (p=0.05) was used to compare means.

RESULTS AND DISCUSSION

The soil at the site is sandy, acidic, low in OM, total N, available P, exchangeable K, Ca and Mg (table 1). In both years, Urea did not influence soil pH. It reduced it in subsequent year. Application of OPBA alone or combined with Urea or NPK increased soil pH in both years. Generally, combined application of OPBA with either urea or NPK increased soil OM, P, K, Ca and Mg compared with sole use of chemical fertilizers (tables 2 and 3). Urea alone applied at 100% gave highest value of N in both years but has low values in soil pH, OM, P, K, Ca and Mg. Its combination with OPBA increased the values. Also, NPK had higher values of soil pH, OM, N, P, K, Ca and Mg when compared with control but its combination with OPBA gave higher values in both years. However, 75% NPK + 25% OPBA and 50% NPK + 50% OPBA gave relatively high values in all the parameters. The combination of OPBA with NPK or urea increased number of leaves of okra in both years. Sole OPBA, NPK, urea and their combinations increased and had similar values of number of leaves in both years when compared with control (tables 4 and 5). Urea, OPBA, NPK and their combinations at reduced rates increased plant height. Sole OPBA gave the least plant height relative to sole NPK and urea. It indicated that urea and NPK more enhanced okra growth. Combinations of reduced rates of fertilizers with OPBA at 75% U + 25% OPBA, 50% NPK + 50% OPBA and 50% U + 50% OPBA gave highest and similar values of pod weight, although, the combinations that involved NPK gave highest pod yield. OPBA and NPK combination gave highest values of mean pod weight with 75% NPK + 25% OPBA having the highest value (table 6). The highest mean value for number of leaves for the two years was recorded at 75% U + 25% OPBA. Also, the highest mean values for pod weight in the two years were derived from 75% NPK +25% OPBA and 50% NPK + 50% OPBA (table 6). Generally, it was found that OPBA as an organic material increased soil nutrient concentration of K, Ca, Mg and pH. It was reported that plant derived ash has some base elements which could be used to supply these nutrients and lime (Adetunji, 1997). The use of mineral fertilizer alone has not been helpful under intensive agriculture because it is often associated with reduced yield, increase in soil acidity and nutrient imbalance. However, nutrients are readily released from inorganic fertilizers because organic manures undergo mineralization before nutrients are made available for crop use. To achieve meaningful increase in crop production, adequate combination of organic and inorganic fertilizers is essential (Lombin *et al*, 1991).

CONCLUSION

Yield of okra as a major stable crop in Nigeria is limited by low soil fertility and soil acidity. It responds to application of organic and inorganic fertilizers. OPBA used alone or combined at different and lower rates with urea and NPK fertilizers increased soil OM, pH, N, P, K, Ca and Mg. The combinations also increased plant number of leaves, plant height and pod weight. 75% NPK fertilizer with 25% OPBA and 50% NPK fertilizer plus 50% OPBA generally had highest soil nutrient contents and growth and yield parameters. Therefore 75% NPK + 25% OPBA or 50% NPK + 50% OPBA is recommended for okra production.

ABSTRACT
This study investigated the mineralogy of soils formed on olivine basalt (Ikom), coastal plain sands (Ekparakwa) and shale (Abakaliki) in selected areas in South-eastern Nigeria using X-ray diffraction techniques. Two profile pits each of about 150cm deep were sunk in these locations. Profile pits were delineated according to natural horizonation. Soils derived from these parent materials were randomly collected, air-dried, sieved and analysed in the laboratory. Clay mineralogical analysis was carried out using clay fractions less than two microns in size from selected B- horizons of the various profiles. Two series of specimens namely Mg- saturated and K – saturated samples were prepared. Results showed that the dominant minerals in the clay fractions were kaolinite and quartz, while vermiculite, montmorrillonite and illite occurred in Abakaliki soil. Gibbsite occurred in Ikom and Abakaliki in moderate amounts. Soil properties that are related to soil fertility status particularly organic matter concentration, exchangeable (available) potassium and pH were higher in Abakaliki soil.
Keywords: clays, Mineralogy, Parent materials, Pedogenesis

INTRODUCTION
To assess inherent soil fertility for appropriate large – scale management, it is important to understand how clay mineralogy relates to geological and weathering conditions (Tetsuhiro et al., 2006). The knowledge of mineralogy is useful for an understanding of many important characteristics related to soil nutrient status (Unamba- Oparah et al., 1989). Consideration of the characteristics of minerals found in soils, and their transformation from one form to another, is essential in understanding both the nature of soils chemical properties and the origin of its fertility (Foth, 1984). The nutrient supply by a soil, and the type of problems one is likely to encounter, often differ greatly, depending on the parent material from which the soil was formed (Asher et al.,2002). Important processes in the formation of clay minerals are the neoformation of gibbsite, kaolin minerals and smectite, and the transformation of mica. Neoformation is mainly controlled by H_4SIO_4 activity. Gibbsite forms under conditions of strong desilication, where H_4SIO_4 activity is low (Huang et al., 2002). Kaolin minerals forms under moderate H_4SIO_4 activity conditions and smectite under high activity (Reid –Soukup and Ulery, 2002). Mica which is commonly present in felsic and sedimentary rocks, weathers to vermiculite and smectite, with a decrease in the layer charge and release of alkaline metals. The increased resistance to weathering of dioctahedral mica means that dioctahedral vermiculite is more common in soils than trioctahedral vermiculite (Malla ,2002). Kaolinite formation is favoured in acidic soils low in base and montmorillonite is favoured by high magnesium in the weathering environment. Montmorillonite originates from weathering of basalt where magnesium remains in the soil (Foth, 1984).
The goal of the study was to investigate mineralogical properties of soils of the selected sites (Ikom, Abakaliki, and Ekparakwa) in south-eastern Nigeria.

MATERIALS AND METHODS
The study was conducted in Ebonyi, Cross River and Akwa Ibom States, all in South-Eastern, Nigeria.The area lies between latitudes 4^0 15^I and 7^0 20^I North, and longitudes 5^0 05^I and 9^0 30^I East. The study area covered about 75,488 km^2 and lies within the rainforest agroecology. The geology of the sampled locations namely Ikom, Abakaliki, and Ekparakwa were olivine basalt, shale and coastal plain sands, respectively. The soils were of a flat topography (0 – 1 % slope). Profile pits of about 150 cm deep were sunk in soils of these areas. The profile pits were described according to FAO (1990) soil description guidelines. Soil samples from the subsoil were collected, air dried and sieved using 2- mm aperture. The pH was determined in 0.1 mol L^{-1} KCl, and the values were read off electrometrically using the pH meter. Cation exchange capacity was determined by the method described by Rhoades (1982). Organic carbon was analysed by Walkley and Black wet digestion method as described by Nelson and Sommers (1982).
Clay mineralogical analysis was carried out using clay fractions of less than two microns (< 2 um) in size collected from the B horizon. Clay fractions were obtained by sedimentation method after decomposing the organic matter with hydrogen peroxide (H_2O_2). Two series of specimens, namely Mg-saturated and K- saturated samples were prepared. For Mg and K saturation, one mole of chloride salt each of Mg and K samples was added to the clay

suspension and centrifuged. The excess salt was washed with distilled water once, and with ethanol for three times. Further treatments were as follows: Mg – saturated and glycerol solvated; K – saturated heated at 550 ^{0}c in an electric oven for two hours. Scanning was done from 2 –34 degrees (2 theta) for all specimen (Rich and Kunze 1964).

RESULTS AND DISCUSSION

The results of the physico-chemical properties of the soils are presented in Table 1. The clay content ranged from 22.8 to 250.7 g/kg. The highest amount of clay occurred in Abakaliki. The silt content ranged from 29.2 to 185.3 g/kg. The highest amount of silt occurred in Ikom. The sand fraction dominated in the soils with a range of 599.0 to 946.5 g/kg. The highest amount of sand occurred in Ekparakwa. The pH of the soils varied from 4.41 to 6.30 indicating strongly acidic to slightly acidic reaction. Soils of Abakaliki were slightly acidic, while Ikom and Ekparakwa were strongly acidic. Organic carbon varied from 5.8 to12.1 g/kg. The highest amount of organic carbon occurred in Abakaliki and the lowest occurred in Ekparakwa. Potassium content varied from 0.03 to 0.81cmol/kg. The highest amount occurred in Abakaliki and the lowest in Ekparakwa .The diffractograms for the clay fraction (Figure 1) of the three selected soils show that the most common clay minerals identified in all the soils were kaolinite and quartz. Kaolinite was characterized by strong diffraction peaks at 7.2 A^0 and 3.5 A^0 (first and second order peak respectively) under Mg – saturated air dried treatment. The peaks however disappeared after heating for 2 hours at 550 ^{o}C confirming the presence of kaolinite (Rich and Kunze, 1964). Quartz was characterized by strong diffraction peaks at 3.34 A^0 and 4.26 A^0 in all the soils studied. Soils derived from shale in Abakaliki (pedon 02) and olivine basalt in Ikom (pedon 07) contained some amount of montmorillonite which was identified by the presence of 15 A^o peak under Mg – saturated air – dried sample which increased to 17 A^o under ethylene glycol treatment and further collapsed to 10.57 A^o when the samples were subjected to heating at 550 ^{o}C. Other clay minerals found in the samples included vermiculite in Abakaliki soil characterized by a peak at 4.76 A^o under K – saturated treatment heated at 550 ^{o}C, illite in Abakaliki soil, characterized by a peak at 5.03 A^o in Mg – saturated sample. Gibbsite in Ikom and Abakaliki, , characterized by a peak at 4.37 A^o under Mg – saturated, glycerol solvated sample in Ikom and by a peak at 2.39 A^o under Mg – saturated, glycerol solvated sample in Abakaliki. Hematite (2.68 A^o and goethite (4.19 A^o) occurred in the samples. Soils were collected from site 0 -1 % slope to homogenize the topographic factors. Again climate, time factor, vegetation were considered to be the same for all sample points hence main source of dissimilarity was the parent material. For the purpose of recognizing or mapping different types of soils, the properties of the B horizons are often paramount. Not only is this the zone of major accumulations of minerals and clays, but the layers nearer the soil surface are too quickly altered by management and soil erosion to be reliable source of information for the classification of soils.

The presence of kaolinite was corroborated by the generally low pH and ECEC of the soils studied. The dominance of quartz has the implication of bringing about low pH, low ECEC and generally low fertility status of the soils. The presence of montmorillonite in soils derived from Abakaliki and Ikom brought about higher pH and ECEC on the soils. The presence of Iron and Aluminium oxides is justified by the fact that the soils are highly weathered and the minerals generally form the last stage of weathering of tropical soils. They give rise to the typical reddish or dark reddish brown colour of such soils.

It can be deduced from the results that the mineralogy of the clay fraction of the well drained upland soils typified by Ekparkwa were generally dominated by kaolinite, quartz, and the sesquoxides whereas the mineralogy of the lowland soils typified by Abakaliki were dominated by montmorrillonite and other 2:1 lattice clay minerals. This implies that the soils of Abakaliki are consequently less leached and have the ability to retain water for long period of time thereby making it possible for dry season cultivation to be practiced on them. They can attract, retain and fix a lot of nutrients without their being washed away. They have negative charges for binding nutrients to themselves and when fertilizer is applied, they are able to retain the nutrients and will not allow them to be washed away easily.. They therefore have high agricultural potentials. Their agricultural potential is in this order Abakaliki > Ikom > Ekparakwa. Secondly, Abakaliki soils are possible sink for contaminants like divalent lead in the environment because of the presence and dominance of montmorillonite that have high cation exchange capacities (Nagy et al. 2003). They can hold or adsorb low molecular mass organic acids, which increase their adsorptive capacity for pollutants such as Cadmium and Lead by forming bridging bonds (Huang et al. 2010). Clay mineral studies carried out by Asadu et al. (1990) and Eshett et al. (1990) on soils of south-eastern Nigeria identified kaolinite as the most abundant mineral in clay fraction. An investigation of the mineralogy of the soils suggested that properties of the soil are largely dependent on the parent materials. This agrees with Allen (2001); Radoslovich (2006) and Atkinson and Waugh (2007) that parent material influenced mineralogy of the weathering products in soils.

CONCLUSION

The variations in clay mineralogy of these soils appear to depend mainly on the parent materials from which the soils are formed. Those soils developed on coastal plain sands and olivine basalts contain more kaolinite, quartz, Iron and Aluminium oxide. Those soil developed on shale contain more montmorrillonite, vermiculite and illite. It is recommended that the mineralogical properties of these soils be considered in their management for the production of crops and trees. There is need for scanning electron microscopy of soils studied for the purposes of corroboration.

Table 1 : Average values of soil properties of the soil studied

Soil property	Ikom Olivine basalt	Abakaliki shale	Ekparakwa coastal plain sands
Sand mg/kg	599	641.8	946.5
silt mg/kg	185.3	117.5	29.2
clay mg/kg	215.7	250.7	22.8
organic carbon mg/kg	10.6	12.1	5.8
pH	4.83	6.30	4.41
ECEC cmol/kg	4.85	4.58	2.88
Base saturation %	80.52	50.25	60.42
Ca cmol/kg	2.18	0.36	0.66
Mg cmol/kg	1.18	0.07	0.23
K cmol/kg	0.17	0.81	0.03
Na cmol/kg	0.96	1.05	0.81

obia.joe@gmail.com

ABSTRACT
Soil organic carbon and nitrogen status under tillage, cropping systems and nitrogen fertilizer in a Savanna Alfisol were investigated at the Research Farm of the Institute for Agricultural Research, Ahmadu Bello University, Samaru, Zaria, Nigeria, for two years (2011 and 2012). This study was set up in a split-split plot design with three replications using improved soybean variety (TGX-1448-2E) and maize (SAMMAZ 14) as the test crops. The treatments consisted of two tillage practices (reduced and conventional tillage) as main plot, four cropping systems (inoculated soybean-maize intercrop, uninoculated soybean-maize intercrop, inoculated soybean-maize rotation and uninoculated soybean-maize rotation) as sub plot and four nitrogen fertilizer rates (0, 40, 80 and 120 kg N ha^{-1}) as sub-sub plot. At harvest the second year of trial (2012) only, soil samples were taken from each of the experimental plots and used for laboratory analysis. The organic carbon and nitrogen content of the soil were consistently higher in reduced tillage (RT) (6.59 and 1.11 g/kg) than under conventional tillage (CT) (6.32 and 1.06 g/kg) respectively. With respect to the cropping systems, soil organic carbon and nitrogen content were significantly higher under inoculated soybean-maize rotation compared to other cropping systems. A significant difference was found among the effects of N rates on soil organic carbon and total nitrogen content which was consistently lower in control plots. The study demonstrated that the integration of inoculated soybean inoculated in the cropping systems under tillage practices, especially reduced tillage in combination of meaningful N fertilizer management, would improve the productivity of the soil.
Keywords: Tillage, Cropping Systems, Nitrogen fertilizer, organic carbon and nitrogen status

INTRODUCTION
Soil organic C (SOC) and total N (TN) contents play a crucial role in sustaining productivity of the soil and environmental quality (Bauer and Black, 1994; Doran and Parkin, 1994; Robinson *et al.*, 1994) due to their effects on soil physical, chemical, and biological properties, such as soil water retention, nutrient cycling, gas flux, and plant root growth (Sainju and Kalisz, 1990; Sainju and Good, 1993). Soil, as an open system, can be a net source of CO_2 released to the atmosphere due to elevated SOC mineralization as a result of disruptive agricultural practices especially during tillage operation. On the other hand, soil can function as a net sink for sequestering atmospheric CO_2 under appropriate soil tillage and crop management, and thus reducing atmospheric CO_2 (Paustian et al., 1992; Lal *et al.*, 1995). This would subsequently enhance SOC and TN status of the soil which virtually promotes the productivity of the Savanna soil.
The SOC and TN status of a soil often influences soil fertility and productivity, depending also on their forms, sources, concentration, and cultivation practices. Tillage enhances the mineralization of soil organic C and nitrogen (N) by incorporating crop residues, disrupting soil aggregates, and increasing aeration (Tangyuan *et al*. 2009). But conservation tillage is a complex, fairly flexible agricultural system that can be widely adapted to local conditions (Wall 2007) which promote slow mineralization of SOC and TN. Nitrogen fertilization improved crop production and some soil quality attributes but also increased the potential for NO3-N leaching and N2O-N emissions, especially when it was applied in excess of the crop requirements (Malhi and Lemke 2007). Also, N is one of the major reasons to support the food for increasing human population (Robertson and Vitousek 2009). However, frequent tillage and excessive nitrogen fertilizer not only reduces the crop productivity but also exacerbates soil erosion, air and water pollution (Hundera *et al.* 2001, Godfray *et al.* 2010).
Declining of SOC and TN contents in Nigerian Savanna soils due to continuous cropping under conventional tillage and total removal of plant residues after harvest is posing a threat to the sustainability of maize-based cropping systems.

MATERIALS AND METHODS
***Study Area*:** A field study was conducted at the Research Farm of the Institute for Agricultural Research, Ahmadu Bello University (IAR/ABU), Samaru, Zaria during the 2011 and 2012 cropping seasons. The research field was located within longitudes11^{o} 11' N and latitudes 007^{o} 37' E. Samaru has an average of 686m above sea level and is located in the Northern Guinea savanna of Nigeria, having a total rainfall of 1207mm2011 and 1333mm in

2012, distributed between April and October with a mono-modal rainfall pattern. The temperature data was 21.05ºC (minimum) and 33.47ºC (maximum) of the cropping season (Oluwasemire and Alabi, 2004).The mainsoil sub-group is Typic Haplustalf (Awujoola, 1979) or Chromic cambisols according to the FAO system of soil classification (FAO, 2001). The study area was dominated by fire tender and fire tolerant trees, with an understory of shrub and grasses.

Treatments and Experimental Design:

The experiment was a split-split plot arrangement in a randomized complete block design with three replicates. The treatments were two tillage practice as main plots (reduced and conventional tillage), four cropping systems as sub-plots (inoculated soybean-maize intercrop, uninoculated soybean-maize intercrop, inoculated soybean-maize rotation and uninoculated soybean-maize rotation) and four nitrogen fertilizer rates as sub-sub plots (0, 40, 80 and 120 kg N ha^{-1}). The conventional tillage (CT) was manual ridging at 0.75 m apart using hoe and remoulded at 8 weeks after sowing, while reduced tillage (RT) was planted directly without ridging at 0.75 m interval between the lines after the field was demarcated into plots. Each plot measured 6 m by 5 m (eight ridges; 5 m long) and a total of 96 plots were used for the research. The intercropping system was maize/soybean intercrop in the order of 2 rows maize to 2 rows soybean (2:2); this was maintained for both seasons. The crop rotation system was soybean–maize rotation, with soybean planted in 2011 (1:0), followed by maize in 2012 (0:1). Soybean (TGx 1448-2E) and maize (SAMMAZ 14) were used as test crops.

Soybean seed inoculation and planting:

The soybean seeds were surface sterilized, as reported by Vicent (1970), and inoculated with commercial rhizobium inoculants, Legume-fix, as directed by the producer (See 3.1.2). Both maize and soybean seeds were sown on 1st July 2011 and 16th July 2012. The maize seeds were sown manually, two seeds per hole at an intra-line or intra-row spacing of 25 cm. The seedlings were thinned to one plant per stand at two weeks after sowing to give a plant population of approximately 53,333 plants ha^{-1}. Soybean seeds were drilled on the lines or ridges and covered lightly with soil. The uninoculated soybean treatment rows were sown first in order to avoid cross contamination. The seedlings were thinned to one plant per hill at a spacing of 5cm to achieve a population of approximately 266,667 plants ha^{-1}.

Fertilizer application:

Phosphorus and potassium fertilizers were applied to all the plots planted with maize at the rate of 60 kg P_2O_5 ha^{-1} and 60 kg K_2O ha^{-1}, whereas those of soybean received 40 kg P_2O_5 ha^{-1} and 20 kg K_2O ha^{-1} at planting in both seasons, respectively. The sub plots were divided into four; only maize plots in both cropping seasons received urea fertilizer application at the rates of 0 kg N/ha, 40 kg N/ha, 80 kg N/ha and 120 kg N/ha. Nitrogen fertilizer rate was applied in two splits; first application was done at four weeks after sowing, while the remaining part was done as second application at eight weeks after sowing in the ratio of 1:2.

Soil Sampling:

Soil samples were collected systematically by dividing the field into eight sections. A total of 16 points two points per division within the field were sampled using the soil auger at 0-15 cm depth before trial establishment. The samples were bulked and thoroughly mixed and a composite sample was taken for analysis. At the end of the field experiments in 2012, four disturbed surface soil samples (0-15cm depth) were taken at alternate points from four inner ridges per plot using a soil auger. The samples were bulked to form a composite sample per plot. The composite samples taken were bagged, properly labelled, air-dried, crushed lightly and sieved through 2 mm sieves in readiness for analysis.

Laboratory Analysis:

Particle size distribution was determined by the hydrometer method, as described by Gee and Bauder (1986), using sodium hexametaphosphate as a dispersing agent. The textural classes were obtained from the USDA textural triangle. The bulk density was measured using core method (Grossman and Reinsch, 2002). The moist core soil sample was oven-dried at 105°C for 24 h, until a constant dried weight was obtained.

$$\text{Bulk density (BD Mg cm}^{-3}\text{)} = \frac{\text{Oven dry soil sample}}{\text{Volume of core cylinder}} \quad (1)$$

Bulk density (BD Mgm^{-3}) = Oven dry soil sample Volume of core cylinder (1) Soil porosity was calculated using a mathematical relationship between bulk density and particle density (Foth, 1984). Porosity (P) was computed as follows:

$$P (\%) = 1\text{-}BD/PD \times 100 \quad (2)$$

Where P= Porosity, BD=Bulk density (Mg m3) and PD=Particle density (2.65 g/cm3).

Soil pH was determined electrometrically in duplicates both in distilled water and 0.01M calcium chloride solution. A soil-solution ratio of 1:2.5 was used and read on pH meter (Hendershot*et al.*, 1993). The total nitrogen in soil was determined by micro-kjeldahl digestion method as described by Bremner and Mulvaney (1982). Organic carbon was measured using the method described by Nelson and Sommers (1982).

***Statistical analysis*:**

Data collected were subjected to analysis of variance (ANOVA) using the mixed linear model MIXED Procedure of SAS, Institute Inc., (2009). Effects of the various factors and their interactions were compared by computing least square means and standard errors of difference (SED) at 5% level of probability. Coefficient of correlation (r) analysis among some soil properties was also performed.

RESULTS AND DISCUSSION

Soil organic carbon

Data on the effect of tillage systems on soil organic carbon are presented in Table 1. Soil organic carbon (OC) was not significantly different among the tillage systems. The higher value of organic carbon found in reduced tillage could be attributed to reduced mineralization rate of soil organic matter due to less soil disturbance and less exposure of SOC fractions within soil aggregate (Al-Kaisi*et al*., 2005). However, the initial value of OC of the soil was lower than that obtained under both tillage systems, with a difference of 14.91 % for CT and 19.82 % for RT. The differences found in soil organic carbon content in response to tillage systems at surface soil of 0-15 cm depth, compared to initial value, were most likely due to the short-term implementation of the tillage, and the quantity of plant residues returned to the soil. The soil organic carbon impacted by tillage in the short-term are small, relative to the pool of soil organic carbon already present in the soil (Ellert*et al*., 2001). This implies that RT enhances redistribution of SOC closer to the soil surface than CT.

Cropping system had a significant effect on soil organic carbon (Table 1). The four cropping systems evaluated in this study revealed substantially greater OC contents than initial OC contents obtained at the same 0-15 cm depth before the commencement of the experiment. The soil under inoculated soybean-maize rotation had the highest OC content, which was significantly different from other cropping systems. The soil under uninoculated soybean-maize intercropping had the lowest OC content, and was not significantly ($P>0.05$) different from that of uninoculated soybean-maize rotation. The significantly higher OC content found under rhizobium inoculated soybean-maize rotation could be due to high maize-soybean biomass production with low C/N ratio, compared to sole maize. Other factors that can increase OC content in the cropping system are crop residues accruing from nodule mass, root and in-season fall-off leaves, as well as leftover shoot system after harvest. Plant root system may be more important than above-ground crop residues in sustaining soil organic matter (Al-Kaisi*et al*., 2005).

Data on the effect of nitrogen fertilizer rate on soil organic carbon content indicated a significant difference (Table 1). The result revealed a value greater than the initial value of 5.50 g kg^{-1} obtained from the experimental field. The plots treated with 120 kg N ha^{-1}resulted in higher OC content, followed by 80 kg N ha^{-1}. The least was found in soil under 0 kg N ha^{-1} application, which increased with increase in N fertilizer rate (Table 1).The effects of cropping system on soil C under 0 kg N ha^{-1} treatment are limited due to poor performance, which contributed to low plant residues returned to the soil in-season and after harvest. This could explain the non-significant difference observed among the plots treated with N fertilizer. However, little or no changes in SOC observed in control plots reaffirmed the low N status of the soil, which may intensify N immobilization by soil microbs (Karborzova-Saljnikov, 2004).

Soil total nitrogen (TN):

Soil tillage systems had a significant effect on TN (Table 1). The values of soil TN were low in soil under CT plots, compared to that under RT plots. The percentage contrast between RT and CT was 4.72 %, whereas the value increase in both tillage practices when compared with the initial TN of the soils before the experiment.The result suggested that CT produces more soil disturbances and exposes the soil to biotic and abiotic which result in reduction in soil N than RT. The effects of conventional tillage practices on SOC and TN dynamics depend, in part, on soil properties and environmental factors, such as soil texture, clay mineralogy, topography, and climate (Campbell *et al.,* 1999). These environmental factors may have contributed to the significant difference observed in soil total N contents in response to tillage systems at 0–15cm depth. However, greater total N contents in soil under RT may have accrued from more ground cover and slow decomposition rate due to settlement of crop residues on the soil surface and the decreased contact of crop residues with soil microorganisms (Salinas-Garcia *et al*., 1997; Schomberg and Steiner, 1999). This can also be attributed to the reduced mineralization rate of soil organic matter due to decreased soil aeration and less exposure of SOC fractions within soil aggregates with no-tillage (Al-Kaisi*et al.*, 2005). The statistically non-significant C/N ratio observed in response to tillage systems was most likely due to the short-term implementation of the tillage treatment. It implies that the quantities and quality of SOC impacted by tillage are small relative to the pool of SOC already present in the soil (Ellert*et al*., 2001).

Data on the effects of various cropping systems on total soil N at 0 to 15cm depth are presented in Table 2 The total N in inoculated soybean-maize rotation and inoculated soybean/maize intercrop was higher than those in the other two cropping systems involving soybean without inoculation. Total N in the plots previously cropped with inoculated soybean (rotation) or maize/inoculated soybean (intercrop) was 20% and 28% higher than those in rotation plots with uninoculated soybean, and intercrop with uninoculated soybean, respectively. The results showed significant differences between the cropping systems with inoculated soybean, as well as those without inoculation. Cropping systems with inoculated soybean in rotation contributed the highest amounts of N to the soil, followed by inoculated soybean intercropped with maize;thelowest amount was recorded for uninoculated soybean intercropped with maize, considering the initial TN in soil. This could be attributed to additional N_2 fixed (residual effect of rotation) due to effectiveness of rhizobium strain used in the inoculants and possibly supported by low nitrogen content and C/N ratio of the soil. Thus, a low C/N ratio suggests the release of soil nitrogen in available form to plants due to high microbial activity, while the reverse is the case for high C/N ratio. The increases in N supply in previous soybean treatments and yield of subsequent maize was probably due to additional N fixed and left in the soil for the subsequent maize crop. Study conducted by Yusuf *et al*., (2006) showed that cowpea fixed 16-34 kg N ha^{-1} and soybean fixed between 41-50 kg N ha^{-1} in the same Nigeria savannaAlfisol. Sanginga*et al.*, (2002) reported a nodulating soybean improve soil total N with an estimated net N balance input from fixation following grain harvest of 43 kg N ha^{-1}. This would be more enhanced under inoculated soybean cropping systems, suggesting higher soil productivity improvement, compared to cropping systems without inoculated soybean.

Furthermore, data on the effects of nitrogen fertilizer application on soil TN content are presented in Table 1. Total N in soil was significantly affected by N fertilizer rates at probability level of 5 %. The value was higher in soil with 120 kg N ha^{-1}, followed by 80 kg N ha^{-1}. The least was obtained for plots without N fertilizer. The result revealed that TN in soil increases with an increase in N fertilizer rate. The values of TN ranged from 1.04 to 1.14 g kg^{-1} across the N fertilizer rates. Thus, soil TN content indicated a consistent increase with corresponding N fertilizer application rate, with a significant difference between 120 kg N $ha^{-1}$and other treatments, but at par with 80 kg N ha^{-1}. The same trend was observed at 40 kg N ha^{-1} and 0 kg N ha^{-1} application rates as well as C/N ratio. The implication is that N fertilizer application improves N status of the soil. This can partly be explained by the changes in composition of SOM; suggesting that addition of inorganic N reversed immobilization of mineral N by microorganisms (Karborzova-Saljnikov, 2004) due to a reduction in C/N ratio. It is an indication that the N mineralization process exceeded immobilization process, which raises N in the study soil. This may be supported by low C/N ratio obtained in soil under N treatments that reflected the increase in microbes (bacteria) activity due to N application, which invariably enhanced decomposition and mineralization.

CONCLUSION

The study revealed that reduced tillage promotes carbon and nitrogen content in the soil than conventional tillage. Results also showed that values of OC and TN content of the soil were improved under inoculated soybean-maize rotation by 49.48 % for OC, 57.97 % for TN, higher than under uninoculated soybean-maize rotation. This implies that integration of inoculated soybean with rhizobium in the maize-based cropping systems would improve the productivity of the soil.

ACKNOWLEDGEMENT

The financial support that enables me to carry out the project by the Ahmadu Bello University Zaria, Nigeria, as a staff in training is greatly appreciated. The field, inputs and laboratory facilities needed for the research were made available by the Institute for Agriculture Research, Ahmadu Bello University, Zaria, Nigeria. Your contribution is also highly appreciated.

ABSTRACT
Pot trial was conducted in the screen-house of University of Calabar Teaching and Research Farm, Calabar, Cross River State, Nigeria to determine the influence of varied ratios of cassava peels and pig manure based compost on soil properties, growth and yield of okra. The eight (8) treatments comprised of the absolute control, cassava peels alone (CP), pig manure alone (PM), three parts of cassava peels to one part of pig manure (3 CP + 1 PM, 3:1 ratio), two parts of cassava peels to one part of pig manure (2 CP + 1 PM, 2:1 ratio), one part of cassava peels to one part of pig manure (1 CP + 1 PM,1:1 ratio), one part of cassava peels to two parts of pig manure (1 CP + 2 PM, 1:2 ratio) and one part of cassava peels to three parts of pig manure (1 CP + 3 PM, 1:3 ratio) each applied at the rate of 20 t/ha The experiment was laid out in a completely randomized design (CRD) with three replications. The results obtained showed that the treatments applied brought about significant (P < 0.05) improvement in soil properties relative to control. The growth parameters of okra were significantly increased in all treated soil, especially the 2:1 and 1:1 ratios, relative to control. The highest fruit weight of okra (5200 kg/ha) was obtained from the 2: 1 ratio and is therefore recommended for sustainable production of okra as well as in promoting environmental safety.
Keywords: cassava peels, okra, pig manure, soil

INTRODUCTION

Okra (*Abelmoschus esculentus (L) Moench*), is a widely cultivated vegetable crop and very important in the diet of Africans (Omotoso and Shittu, 2008). Okra thrives naturally in the low land rainforest soils, high in moisture and temperature. However, owing to continuous cultivation devoid of adequate soil management practices, soil nutrient depletion, soil structure degradation, reduced water infiltration and run off erosion, non-profitability of okra production is on the increase. Researches into organic wastes that are cheap, readily available and environmentally friendly that could be used as fertilizers is of great necessity. This is due to the capability of organic waste in conserving soil physical, chemical and biological properties with implications on nutrient cycling, reducing erodibility, enhancing water storage, boosting plant vigor and the overall soil productivity (John *et al.*, 2013 and Iren *et al*., 2015).

Cassava peels are commonly found in farm locations and processing sites as heaps that are generally perceived as hazard to the environment. These materials, however, could be utilized more effectively and sustainably through recycling. Cassava peels like many organic waste materials are potential source of organic matter and plant nutrients. Management of cassava peels includes direct incorporation into the soil, feeding them to livestock, burning or processing them into a more stable organic fertilizer called compost. Composting cassava peels eliminate the problem of waste disposal and increase the manurial value of the materials (Akanbi e*t al.*, 2007; Iren *et al*., 2015). The abundance, as well as cheapness of cassava peels and pig manure had necessitated a research into their use by composting either solely or in combination for soil fertility trials and for okra production.

MATERIALS AND METHODS

Description of experimental site: The experiment was conducted at the screen house of the Teaching and Research Farm of the University of Calabar, Calabar (latitude 5º 32' and 4º 27' N and longitude 7º 15' and 9º 28' E). The total rainfall ranges from 2000- 3500 mm annually while the mean temperature ranges from 23 -33 ºC. The mean relative humidity is 60- 90%.

Collection and preparation of materials: Plastic buckets (10 Litre capacity) were perforated at the bottom to allow for easy drainage and facilitate aeration. Cassava peels and pig manure were composted on dry weight basis based on specified ratio for 12 weeks using the heap method. Top soil (0-15cm) used for the experiment was collected from the Teaching and Research Farm of the University of Calabar.

Experimental design and treatments/ Rate of manure application: Eight (8) treatments, including the control were laid down in a completely randomized design (CRD) and replicated three times. To each experimental bucket containing 10 kg of soil, the various treatments were applied, based on the calculated rate of application of 20 t/ha with each bucket receiving 100 g of specified manure. The treatments were thoroughly mixed with the soil except the absolute control pots, watered to field capacity for a period of seven days before planting.

Planting and crop management/ Data collection: Four (4) okra seeds were planted in each pot and were later thinned down to two plants per pot two weeks after planting (WAP). Watering was done every other day after planting using one litre of water per bucket. The growth parameters measured after one month of planting were number of leaves per plant, stem girth, plant height, number of fruits and fruits weight and these continued at a monthly interval.

Soil sampling/Laboratory analyses: One composite soil sample was taken before experiment and at the end of the experiment; soil in each pot was sampled for analysis. The soil samples were air dried, ground and sieved with 2 mm size sieve and physicochemical properties analyzed following standard procedures as outlined by Udo *et al*. (2009). The properties analyzed include particle size distribution, Soil pH (H_2O), organic carbon, total nitrogen, available phosphorus, exchangeable bases and exchangeable acidity. Effective cation exchange capacity and base saturation were calculated.

RESULTS AND DISCUSSION

Soil properties before experiment and nutrient contents of pig manure and cassava peels before composting: The physicochemical analysis of the soil at the onset of the experiment is presented in Table 1. The soil texture was sandy loam and strongly acid (pH = 5.5) in reaction, low in organic carbon, total nitrogen but high in available P. Results of the analysis of pig manure and cassava peels are also presented in Table 1.

Influence of cassava peels and pig manure based compost on soil properties: Table 2 presents the influence of cassava peels and pig manure based compost on soil properties. Soil pH was significantly ($P < 0.05$) increased across the various treatments when compared with the initial pH of 5.5 and the absolute control (5.2). The highest pH value of 7.2 was obtained from the 1:1 ratio (1CP + 1PM). Generally, it was observed that the cassava peels and pig manure based compost buffered the soil pH, increase organic carbon, available P, calcium and potassium contents in the soil when compared to the initial status of the soil and control. The results agree with previous reports which asserted that organic compost helps in maintaining the nutrient content of the soil while improving other soil condition (Alarisi and Ogunkeyede 1999; John *et al.*, 2013; Iren *et al*.,2014; Iren *et al*., 2015)

Influence of cassava peels and pig manure based compost on growth parameters of okra plant: The number of leaves per okra plant at one month after planting (MAP) and at 2 MAP was significantly increased by all the treatments with the highest number obtained from soil treated with 1:1ratio (1CP + 1PM) (Table 3) whereas at 3 MAP the highest number of leaves was obtained from soil treated with 2:1 ratio (2CP + 1PM) compost. Generally, the cassava peels and poultry manure based compost improved the number okra leaf more than when either of them was applied singly. Increase in the number of okra leaves as a result of organic based fertilizer application has been reported by Olatunji and Oboh (2012).The same trend was observed for the leaf area of okra plant. This is in agreement with the findings of Iren *et al*. (2015) who observed higher increase in leaf area of waterleaf from cassava and poultry manure based compost treatments than their sole application.

The influence of cassava peels and pig manure based compost on stem girth and height of okra plant are shown in Table 4. Generally, all the treatments significantly ($P < 0.05$) increased the stem girth of okra plant across all the growth stages when compared with the control. There was significant increase in plant height of okra at different growth stages as shown in Table 4. At 1 and 2 MAP, tallest plants were obtained from 1: 2 ratio (1CP + 2PM) treatment followed by 1: 1 ratio (1CP + 1PM) treatment while the shortest plants were from control. At 3 MAP, the 1: 1 ratio (1CP + 1PM) treated plants were taller than the other treated plants. Generally, the untreated plants were shorter than the treated plants at all the growth stages. This agrees with the findings of Odiete *et al*. (1999) who reported increase in okra plant height by the application of goat manure.

Influence of cassava peels and pig manure based compost on the number of fruits and weight of okra: The influence of cassava peels and pig manure based compost on number of fruits and weight of okra was significant (Table 5) with the highest number of fruits (12.6) and fruit weight (5200 kg/ha) of okra obtained from the application of 2:1 ratio (2CP + 1CP), followed by cassava peels. All the treatments differ significantly from one another. This is similar to the findings of Olatunji and Oboh (2012) who reported response of okra plant to applied manures. The increase in fruit weight of okra was in the order 2CP + 1PM > CP > 3CP + 1PM = 1CP + 3PM > 1CP + 2PM > 1CP + 1PM > PM > control. Similar trend was obtained for number of okra fruits.

Conclusion: The addition of pig manure and cassava peels solely or in combination improved soil chemical properties as well as growth performance of okra when compared with control. Growth parameters were increased mostly by the combined application of cassava peels and pig manure treatments than the single applications. The cassava peels and pig manure based compost when used effectively will help reduce the hazard caused by indiscriminate dumping of these materials for a safer environment.

BIO-FERTILIZERS AS AN INNOVATIVE TOOL FOR SOIL FERTILITY AND CROP PRODUCTIVITY: A REVIEW

O.P. Onyiba*, O.N. Edeh, U.V. Udealor & J. C. Udemezue

*National Root Crop Research Institute, Umudike, Abia state.
princewillogugua@yahoo.com

ABSTRACT
The continuous application of synthetic fertilizers enhance proper growth and crop yield but these fertilizers endanger ecosystem, soils, plants, human and animal lives. Alternative to chemical fertilizers is required to reduce environmental pollution, depletion of soil health status and d risk to human lives. Bio-fertilizers are one such technique, which can be used in a scientific way to avoid environmental pollution, and to increase soil fertility and crop productivity. Bio-fertilizers not only keep the crops healthy, will change micro environment of the soil and increase beneficiary microbial fauna.
Keywords: bio-fertilizers, soil, crop productivity, innovative

INTRODUCTION
With the introduction of green revolution technologies, the modern agriculture is getting more and more dependent upon the steady supply of synthetic inputs. Intensive agriculture with the use of chemical fertilizers in large quantity has resulted in manifold increase in the productivity of farm commodities but the adverse effect of these chemicals are clearly visible on soil properties leading to depletion of water holding capacity of the soil, soil fertility, micro flora, quality of water, and disparity in soil nutrients (Mohapatra et al,2013). Hence, the need to develop some low cost effective and eco-friendly fertilizers which would work without disturbing the nature arise. At this critical juncture, bio-fertilizers as an alternative become useful supplement to chemical fertilizers.
Bio-fertilizers are natural and organic fertilizer that helps to keep in the soil with all the nutrients and live microorganisms required for the benefits of the plants. It is used in organic farming, sustainable agriculture, green farming and non pollution farming. It is also one of the important components of integrated nutrient management, as they are cost effective and renewable source of plant nutrients to supplement the chemical fertilizers for sustainable agriculture.(Mishra et. al,2013). Scientists have developed the way of organic farming by use of "Bio-fertilizers" to prevent chemical pollution in farm lands. Bio-fertilizer contains microorganisms which promote the adequate supply of nutrients to the host plants and ensure their proper development of growth and regulation in their physiology. Living microorganisms are used in the preparation of Bio-fertilizers which have specific functions to enhance plant growth and reproduction. Bio-fertilizers being essential components of organic farming play vital role in maintaining long term soil fertility, crop productivity and sustainability (Venkatashwarlu, 2008). The aim of bio-fertilizers is to complement and, where appropriate, replace conventional chemical fertilizers so that their use can be reduced with the resulting economic and environmental benefits.

What are Bio-fertilizers?
A **Bio-fertilizer** is a substance which contains living microorganisms(bacteria, fungi, and algae) which, when applied to seeds, plant surfaces, or soil, colonizes the rhizosphere or the interior of the plant and promotes growth by increasing the supply or availability of primary nutrients to the host plant (Vessey,2003).In addition, a live formulation of micro-organisms are used for fertilization of farm lands in the aspect of fixation of N2, solubilisation and mobilization of phosphorus, increasing organic carbon content, balanced C/N ratio, plant growth promotion by increasing nutrient absorption, antagonistic activity against plant pathogens, production of hormones etc that are beneficial for agriculture. Bio-fertilizers were promoted through integrated plant nutrient systems (IPNS) that involved combining fertilizers, organic/green manures and bio-fertilizers to sustain crop production, maintaining soil productivity, health and diversity.(Mohaptra, et. al 2013).

Why Biofertilizers?
Since a bio-fertilizer is technically living, it can symbiotically associate with plant roots. Involved microorganisms could readily and safely convert complex organic material in simple compounds, so that plants can easily take it up. Microorganism function is in long duration, causing improvement of the soil fertility. It maintains the natural habitat of the soil(Chen,2016). It can also provide protection against drought and some soil-borne diseases are sufficient for growth and multiplication of organisms in subsequent years. They improve soil texture, pH, water holding capacity and other properties of soil. They have lower manufacturing costs. As a safe alternative to chemical fertilizer, it minimizes the ecological disturbance and are cost effective, eco-friendly and when they are required in bulk can be generated at the farm itself. They increase crop yield up to 10-40% and fix nitrogen up to 40-50 Kg and parental inoculums especially regarding nitrogen and phosphorus use. They produce

plant growth promoting substances IAA, amino acids, vitamins etc. Bio-fertilizers contained 3.5% - 4% nitrogen, 2% - 2.5% phosphorus and 1.5% potassium. In terms of N: P: K, it was found to be superior to farmyard manure and other type of manure (Mishra,et al.,2014).

Types of Bio-fertilizers

The various types of bio-fertilizers which help the plant to grow at different levels of its growth are:

1. **Nitrogen fixing bio-fertilizers** (Azotobacter, Nostoc, Rhizobium, Azospirillum) increase soil nitrogen level (ii). Fixes the atmospheric nitrogen in the soil and make it available to the plants.

2.**Phosphate bio-fertilizers** (a). Phosphorous solubilizing bio-fertilizers (Species of Bacillus, Pseudomonas, Penicillium, Aspergillus) solubilize the insoluble phosphate from organic and inorganic phosphate sources, releases insoluble phosphorus in soil and fix in clay minerals, secrete organic acids and lower the pH to dissolve bound phosphates in soil. (b). Phosphorus mobilizing biofertilizers (Arbuscular Mycorrhiza, AM fungi) fungus penetrates the cortical cells of the roots, increase surface area of roots, displace of absorption equilibrium of phosphate ions which increases the transfer of P ions, stimulate metabolic processes, Arbuscles absorb these nutrients into the root system

3.**Bio-fertilizers for micro-nutrients** (Bacillus sp.) bacterial species are Silicate and Zinc solubilizers, degrade silicates and aluminum silicates in soil, help in silicate weathering

4**. Plant growth promoting Rhizobacteria** (Pseudomonas sp., Bacillus sp.) act as both bio-fertilizer and bio-pesticides, promote growth by improved nutrient availability (bio-fertilizers), suppression of plant disease (bioprotectants), phytohormones production (biostimulants)

5. **Compost** (Cellulolytic fungi, Azotobacter) utilize animal dung to enrich soil with microorganisms, eco-friendly organic fertilizer, consists of nitrogen, phosphate solubilizing bacteria and various decomposing fungi, microorganisms breaks down organic matter (dead plants, farm yard waste, cattle waste).

These microbes (Table. 1) are effective in inducing plant growth, enhance seed germination and root and shoot growth, decomposition of organic materials and enrichment of compost.(Mishra,et al.,2014)

Biofertilizers for Different crop plants

Bio-fertilizers provide eco-friendly organic agro-input and are more cost-effective than chemical fertilizers. Bio-fertilizers such as Rhizobium, Azotobacter, Azospirilium and blue green algae (BGA) have been in use a long time. Rhizobiuminoculant is used for leguminous crops. Azotobacter can be used with crops like wheat, maize, mustard, cotton, potato and other vegetable crops. Azospirillum inoculations are recommended mainly for sorghum, millets, maize, sugarcane and wheat. Blue green algae belonging to a general cyanobacteria genus, *Nostoc* or *Anabaena* or *Tolypothrix* or *Aulosira*, fix atmospheric nitrogen and are used as inoculations for paddy crop grown both under upland and low-land conditions. *Anabaena* in association with water fern Azolla contributes nitrogen up to 60 kg/ha/season and also enriches soils with organic matter.

Other types of bacteria, so-called phosphate-solubilizing bacteria, such as Pantoea agglomerans strain P5 or Pseudomonas putida strain P13, are able to solubilize the insoluble phosphate from organic and inorganic phosphate sources. In fact, due to immobilization of phosphate by mineral ions such as Fe, Al and Ca or organic acids, the rate of available phosphate (P_i) in soil is well below plant needs. In addition, chemical P_i fertilizers are also immobilized in the soil, immediately, so that less than 20 percent of added fertilizer is absorbed by plants. Therefore, reduction in P_i resources, on one hand, and environmental pollutions resulting from both production and applications of chemical P_i fertilizer, on the other hand, have already demanded the use of new generation of phosphate fertilizers globally known as phosphate-solubilizing bacteria or phosphate bio-fertilizers.

Role of Bio-fertilizers in soil fertility and Agriculture

Some of the important functions or roles of Bio-fertilizers in agriculture are:

1.They supplement chemical fertilizers for meeting the integrated nutrient demand of the crops.

2. They can add 20-200 kg N/ha year *(eg. Rhizobium sp* 50-100 kg N/ha year ; *Azospirillum , Azotobacter* : 20-40 kg N/ha /yr; Azolla : 40-80 kg N/ha; BGA :20-30 kg N/ha) under optimum soil conditions and thereby increases 15-25 percent of total crop yield.

3.They can at best minimize the use of chemical fertilizers not exceeding 40-50 kg N/ha under ideal agronomic and pest-free conditions.

4. Application of Biofertilizers results in increased mineral and water uptake, root development, vegetative growth and nitrogen fixation.

5. Some Biofertilizers *(eg, Rhizobium, BGA, Azotobacter* sp) stimulate production of growth promoting substance like vitamin-B complex, Indole acetic acid (IAA) and Gibberellic acids etc.

6. Phosphate mobilizing or phosphorus solubilizing Biofertilizers / microorganisms (bacteria, fungi, mycorrhiza etc.) converts insoluble soil phosphate into soluble forms by secreting several organic acids and under optimum conditions they can solubilize / mobilize about 30-50 kg P2O5/ha due to which crop yield may increase by 10 to 20%.

7. Mycorrhiza or VA-mycorrhiza (VAM fungi) when used as Biofertilizers enhance uptake of P, Zn, S and water, leading to uniform crop growth and increased yield and also enhance resistance to root diseases and improve hardiness of transplant stock.

Application of Bio -fertilizers

Seed treatment : One packet of the inoculants (200 g) is mixed with 200 ml of rice kanji to make slurry. The seeds required for an acre are mixed in the slurry so as to have a uniform coating of the inoculant over the seeds and then shade dried for 30 minutes. The shade dried seeds should be sown within 24 hours. One packet of the inoculant (200 g) is sufficient to treat 10 kg of seeds**.**

Seedling root Dip: It has better application for transplanted crops. Two packets of the inoculant is mixed in 40 liters of water. The root portion of the seedlings required for an acre is dipped in the mixture for 5 to 10 minutes and then transplanted.

Main field application: 1kg of the inoculant is mixed with 20 kg of dried and powdered farm yard manure and then broadcasted in one acre of main field just before transplanting.

Mass Production of Bio-fertilizers :

The mass production of Bio-fertilizers involves three stages:

1 : Culturing of microorganisms

2: Processing of carrier material

3: Mixing the carrier and the broth culture and packing

Bio-fertilizers are carrier based preparations containing efficient strain of nitrogen fixing or phosphate solubilising microorganism prepared in suitable medium and mass produced in fermentor with proper aeration, temperature, growth conditions and without any undesired microbial contaminations. Bio-fertilizers are formulated usually as carrier based inoculants. The organic carrier materials are more effective for the preparation of bacterial inoculants. Peat soil, lignite, vermiculite, charcoal, press mud, farmyard manure and soil mixture can be used as carrier materials. The neutralized peat soil/lignite are found to be better carrier materials for bio- fertilizer production which is cheaper, locally available, inert, having high WHC and organic content. The bacterial culture drawn from the fermentor is added to the sterilized carrier and mixed well by manual (by wearing sterile gloves) or by mechanical mixer then sealed at room temperature (Mohapatra et al,2013**).**

CONCLUSION

Bio-fertilizers being essential components of organic farming play vital role in maintaining long term soil fertility and sustainability by fixing atmospheric di-nitrogen (N=N), mobilizing fixed macro and micro nutrients or convert insoluble P in the soil into forms available to plants, there by increases their efficiency and availability. Currently there is a gap of ten million tonnes of plant nutrients between removal of crops and supply through chemical fertilizers. In context of both the cost and environmental impact of chemical fertilizers, excessive reliance on the chemical fertilizers is not viable strategy in long run because of the cost, both in domestic resources and foreign exchange, involved in setting up of fertilizer plants and sustaining the production. In this context, organic manures (bio- fertilizers) would be the viable option for farmers to increase productivity per unit area.

Table. 1. Microbes used as Biofertilizers

Groups	Examples
1. N2 Fixing Biofertilizers	
❖ Free Living	Berijerinkia,Azotobacter,Anabaena, Nostoc
	Rhizobium,Frankia,Anabaena,Azolla
	Azospirillum
❖ Symbiotic	
	Bacillus Megaterium,B.subtilis,
❖ Associative Symbiotic	B.Circulans,Pseudomonas Striata
2. P Solubilizing Biofertilizers	
❖ Bacteria	Penicillium spp, Aspergillusawamori
❖ Fungi	Glomus spp.,Gigaspora spp., Acaulospora spp.
	Laccaria spp.,Pislithus sp.,Boletus sp.,Amanita spp.,
3. P Mobilizing Biofertilizers	Pezizellaericae
❖ Arbuscular Mycorrhiza	
	Rhizoctonia solani
❖ Ectomycorrhiza	
❖ Ericoid mycorrhizae	Bacillus spp.
❖ Orchid Mycorrhiza	
4. Biofertilizers for Micronutrients	Pseudomonas fluorescens
❖ Silicate and Zinc solubilizers	
5. Plant Growth Promoting Rhizobacteria	
❖ Pseudomonas

Table 2. Micro organisms as Biofertilizers for different Crops

Micro organisms	Nutrient fixed (kg/ha/year)	Host crops for which used
Actinorrhizae (frankia spp)	150 kg N/ha	For certaain non-legumes mainly trees and shrubs
Algae	25kg N/ha	Rice
Azolla	900kg N/ha	Rice
Azospirilllum	50 to 300kg N/ha	Non-legumes like Maizee, barley, oats, sorghum, Millets, rice, Sugarcane
Rhizobium	0.026 to 20kg N/ha	Legumes like pulses, peas, Groundnut, soyabeans, beans and clover
Azotobacter	10-20kg N/ha	Cereals, millets, cotton, vegetables
Mycorrhizae (VAM)	Solubilize food phosphorus (60%)	Many trees species, wheat, sorghum, ornamentals
Phosphate Solubilizing Bacteria and fungi	Solubilize about 50%-60% of them fixed phosphorus in the soil	Soil application for all crops

ABSTRACT
The study investigated distribution of selected soil properties in aggregate sizes under different geologic formations in south eastern Nigeria. The experiment was analysed using ANOVA suitable for RCBD. ***.*** *Bulk density ranged from 1.2 gcm-^{3} in Obinze to 1.4gcm-^{3} in Umuna. Soil organic matter content ranged from 1.13 % in Obinze to 2.49 % in Umuna respectively. The stability of aggregates using percentage water stable aggregates greater 0.25 mm (WSA > 0.25) was significantly higher in soils under Umuna (59.18%) and least at soils of Obinze (26.27 %) under coastal plain sand. Soil properties significantly p(< 0.05) varied with sieve sizes. Soil organic matter ranged from 2.12 % in aggregate diameter of 2 mm to 2.74% in 0.3mm, 1.39 % in 0.3mm diameter to 3.21% in < 0.3mm in Obinze, 2.03% in 2mm sieve to 3.02% in < 0.3mm and from 1.45% in sieve of 0.3mm to 2.73% in < 0.3mm sieve size in Uzoakoli. In all cases however, organic matter were low and occurred majorly in less than 3 mm aggregates sizes.*
Keywords: Geologic formation, aggregate sizes, soil properties, southeast Nigeria, organic matter

INTRODUCTION

Soil aggregation is a soil quality indicator that provides information on the soil's ability to function as a basic component of the ecosystem and influences the transportation of liquids , gases and heat as well as physical process such as infiltration and aeration (Nimmo 1997).

Land forms (lithology and morphology) permits an understanding of differences in soil formation, evolution, soil analysis and soil aggregate depends on site-specific characteristics of the morpho-edaphological unit. The growing population leading to land use increase, the non adoption of modern technologies amidst inappropriate management practices such as continuous cropping, burning, deforestation, tillage (Mbagwu and Obi 2003) has led to soil disintegration of soil aggregates thus leading to soil erosion, which according to Brady and Weil (1999). There is a death of information on the relationship between aggregate sizes and properties of soils of the south eastern Nigeria. Scantiness of such information could be responsible for the increasing spate of soil structural breakdown and development of a variety of rills and gullies on a once beautiful landscape, leading to soil loss, displacement of homes, loss of farmlands, poor nutrient reserve and declining yield of crops Osuji and Onweremadu (2007). Based on the above, the major objective of the study was to determine the distribution of selected soil properties in aggregate sizes under different geologic formations in south eastern Nigeria. Specifically the studies determined the soil physical and chemical properties, the distribution of selected soil properties in soil aggregate sizes.

MATERIALS AND METHODS

The study was conducted at Ishiagu in Ebonyi State located on latitude 5^{0} 27'11"N and longitude 7^{0} 31'50.04' E, Umunah in Okigwe, Imo state on Latitude 5^{0}42'N, Longitude 7^{0}10'E, Uzoakoli in Abia State on latitude 5^{0}38'10.2" E and longitude 7^{0}33'32.1" N and Obinze in Owerri Imo State on Latitude 5^{0} 22'23.3"N and longitude 7^{0} 9'34"E, representing four parent materials namely Asu River group, false bedded sand, Bende Ameki and coastal plain sand respectively (FEDLAR 1990). The study areas belong to the humid tropical climate which is warm all the year round (Anyadike 2002). Mean annual rainfall ranged from 1205 mm in Ebonyi - 2700 mm in Imo State, NIMET (Nigerian Meteorological Agency), Nigeria, (2012) while annual temperatures and humidity range from 26-29^{o}C and 80 %- 90 % respectively (NIMET, 2012). The major vegetation is tropical forest (Anyadike 2002), which has been tampered by anthropogenic activities. There also exists forest savanna vegetations and fresh water swamp around Afikpo, Akeze, Abakiliki, and Okigwe and within the Riverine areas. Farming is a major socio-economic activity of the area.

Soil samples were collected randomly at a depth of 0-15 cm from the four locations in three replicates. Samples were air dried, crushed and sieved using 2 mm mesh, properly labelled and was taken to laboratory for analysis. Samples for aggregate stability were not crushed after air drying. Core samplers were also used to collect samples for bulk density determination.

Experimental design. The experiment was arranged in randomized complete block design (RCBD). The parent material and the aggregate sizes constitute the treatments.

Laboratory analyses. Particle size determination was determined in calgon and water by bouyoucos hydrometer method (Gee and Or 2002).Bulk density was measured by core method (Grossman and Reinsch 2002). Soil aggregate stability (WSA) was estimated by wet-sieving techniques (Kemper and Rosenau 1986). Aggregates sizes were separated with nest of sieves having diameters of 4.75mm, 2.0mm, 1.mm, 0.5mm, 0.25mm stacked together and shaken. Soil pH was determined potentiometrically in soil-water ratio of 1:2.5 as described by Hendershot *et al.* (1993). Soil organic carbon was measured by wet digestion (Nelson and Sommers, 1996). Available phosphorus was measured by Olsen method (Emteryd, 1989). Effective cation exchange capacity will be determined by summation method.

Data Analyses. Data were analysed using analysis of variance ANOVA. Significant means were separated using least significant difference (LSD) at 5% probability.

RESULTS AND DISCUSSION

The results of the physical and chemical properties of the studied soils are presented in Table 1. Sand fraction ranged from 552.90 to 840.00 gkg^{-1} and is significantly higher ($p<0.05$) in Uzoakoli. Clay fraction ranged from 110.00gkg^{-1} to 323.30gkg^{-1}, while silt ranged from 40.00gkg^{-1} to 123.80 kg^{-1}.These values were typical of soils of south eastern Nigeria (Igwe, 1995). Texturally, soils of Ishiagu was sandy clay loam, Obinze, sandy, Umuna and Uzoakoli were sandy loam and loamy sand respectively. The classification was in line with Esheth (1995), Akamigbo and Asadu (1993) who documented similar textures for surface horizon soils of humid tropics. Bulk density ranged from 1.2 $gcm\text{-}^{3}$ in Obinze to 1.4$gcm\text{-}^{3}$ in Umuna. Soils whose bulk densities were low related to high porosity, lesser compaction and easier penetration of roots and movement of micro fauna in them. Soil pH in water though not significantly differed ($p<0.05$) among parent materials ranged from 5.37 to 5.75. Moderate acidic condition of the soils was attributed to constant leaching by rainfall in the area which leaves the soil saturated with more aluminium and hydrogen (Landon 1991). Soil organic matter content ranged from 1.13% in Obinze to 2.49% in Umuna respectively Table 1. These values have been rated as low and are typical of tropical soils a factor that predisposes the soils to dispersion making it prone to erosion menace. The stability of aggregates using percentage water stable aggregates greater 0.25 mm (WSA > 0.25) was significantly higher in soils under Umuna (59.18%) and least at soils of Obinze (26.27 %) under coastal plain sand. The trend of the stability with respect to studied parent material was FBS > ARG>BAG> CPS. This trend is attributed to texture, type of clay (USDA 1996), organic matter which acts as a bonding agent between mineral soil particles (Tisdall and Oades 1982; Hayness and Swift 1990; USDA 1996) and their interactions (Le-Bissonnaise 1996), exchangeable sodium percentage (Kazman *et al.* 1983), soil management (Iraj 2009). Kay and Angers (1999) stated that aggregate stability declines rapidly as organic carbon decreases from 1.5- 1.2%. Among the list of other factors that affect structural stability include sesquioxides (Le-Bissonnaise and Singer 1993).

The result of soil organic carbon presented in Table 1 significantly differed ($p<0.05$) with parent material and followed similar trend with that of aggregate stability (FBS > ARG>BAG> CPS). SOC ranged from ranged from 9.60 in Obinze soil - 14.80 gkg^{-1} in soils under Umunna. Generally, the result of soil organic matter are rated low (Landon 1991; Igwe and Stahr 2004, Opara - Nadi (1988).

The distribution of selected soil properties in aggregate sizes of studied soil

The distribution of selected soil properties in aggregate sizes of studied soils are presented in Table 2. Soil organic carbon ranged from 12.3 % in aggregate diameter of 2 mm to 15.9 % in 0.3mm, 8.10 % in 0.5 mm diameter to 18.60 % in < 0.25mm in Obinze, 11.80 % in 2mm sieve to 17.50 % in 0.25 mm and from 8.40 % in sieve of 0.50 mm to 15.80 % in 0.25 mm sieve size in Uzoakoli respectively. In all cases however organic matter were low and occurred majorly in 0.25 mm aggregates sizes. The high values of soil organic matter at this level of aggregation is attributed to slaking which occurs when higher aggregates are not able or strong enough to withstand internal stresses caused by rapid water uptake or tillage thus releasing heat which makes the aggregate to collapse. Igwe (2003) observed that soils whose aggregates occur more on the < 0.25 mm sizes correlates with inter rill and rill erosion in the field. Le Bissoinnaise (1996) posited that aggregates at these sizes are very unstable and undesirable. This implies that the organic matter contained in the above soils are very much prone to erosion loses. The relationship between micro aggregate stability and organic matter concentration in tropical soils has been reported to be positively significant (Mbagwu *et al.*1993, Obi 1982). Effective cation exchange capacity ECEC ranged from 5.77 to 9.03 $cmolkg^{-1}$ in sieves of 2mm and 1mm in Ishiagu, from 2.20 to 2.93$cmol^{-1}$ in sieves of 0.25 mm and 1mm, Obinze ; from 5.22 to 12.13 $cmolkg^{-1}$ in sieves of 2mm and 0.5 mm in Umuna and from 3.04 to 3.44 $cmolkg^{-1}$ in sieves of 0.25 mm and 2 mm in Uzoakoli respectively. ECEC like soil organic carbon in all soils are low. These values are below the critical limits for soils of Southeasthern Nigeria (Enwezor *et al.* 1990), suggesting poor fertility status of the soil (Igwe 2000). Ojanuga and Awojuola (1981) attributed low ECEC to the nature of clay minerals dominant in the study area. Available phosphorus was significantly ($p<0.05$) higher in aggregates size of 1mm in all studied soils. It ranged from 2.90 – 5.70 in sieve size 2 and 1mm in Ishiagu, 3.84 -6.64 in 0.5 and 2 mm sieves in Obinze, 6.60 -9.60 in sieve size of 0.25 and 2mm in Umuna and 0.10 to 9.40 mgkg^{-1} in aggregates sizes of 0.5 and 0.25mm in Uzoakoli respectively. The values were low (Landon 1991) and typical of soils of the area. Uzoho and Oti (2005) recorded similar trend in similar soil. Low phosphorus availability in tropical soil is attributed to intense weathering and partly due to the low availability of phosphorus in the aluminum and iron combination which were the dominant sources in these soils (Brady and Weil 1999). It has also been documented that low phosphorus values inhibit effective nodulation and leads to biological nitrogen fixation process of leguminous plants (Brady and Weil 1999).

CONCLUSION AND RECOMMENDATIONS

The study investigated distribution of selected soil properties in aggregate sizes under different geologic formations in south eastern Nigeria. Standard methods were used in soil sampling and analyses. The experiment was analysed using ANOVA suitable for RCBD**.** Results showed that soils of Ishiagu was sandy clay loam, Obinze, sandy Umuna and Uzoakoli were sandy loam and loamy sand respectively. Bulk density ranged from 1.2 gcm-^{3} in Obinze to 1.4gcm-^{3} in Umuna. Soil organic matter content ranged from 1.13 % in Obinze to 2.49 % in Umuna respectively. The stability of aggregates using percentage water stable aggregates greater 0.25 mm (WSA > 0.25) was significantly higher in soils under Umuna (59.18%) and least at soils of Obinze (26.27 %) under coastal plain sand. Soil properties varied with sieve sizes. Soil organic matter ranged from 2.12 % in aggregate diameter of 2 mm to 2.74% in 0.3mm, 1.39 % in 0.3mm diameter to 3.21% in < 0.3mm in Obinze, 2.03% in 2mm sieve to 3.02% in < 0.3mm and from 1.45% in sieve of 0.3mm to 2.73% in < 0.3mm sieve size in Uzoakoli. In all cases however, organic matter were low and occurred majorly in less than 3 mm aggregates sizes.

Based on the findings of the study, it is recommended that practices including cover cropping, mulching application of organic amendment etc that improve organic matter content of the soil should be adopted. Since soil erosion is a function of rainfall, measures such as afforestation mulching etc that will dissipate the kinetic energy of falling rain drops before it strikes the soil surface are recommended.

ABSTRACT
The study was conducted at the eastern farm land of NRCRI, Umudike in 2014 and 2015. Land preparations: slashing, ploughing, harrowing and ridging were carried out. 0.2 ha area of land was marked for the study at 20m² per plot, after which pre-planting soil sample was collected. The experiment was laid out in 5x4 factorial arrangements in a randomized complete block design with three replications. 30g minisett size of land race white yam (Dioscorea rotundata) (Ame) was planted at a space of 0.25x1m. The treatment combinations comprise of four rates of NPK 20:10:10 fertilizer at 0kg/ha, 200kg/ha, 300kg/ha and 400kg/ha and five rates of agrolyzer at 0kg/ha, 10kg/ha, 15kg/ha, 20kg/ha and 25kg/ha were applied on 7th week after planting. Data were collected on following growth parameters: Vine length, number of secondary tillaries, canopy cover, leaf area and stem girth at 4, 5 and 6 months after planting(MAP), yield parameters such as: stand count, number of seed and ware yams, net gross tuber yield, tuber shape index(TSI) and percentage available yield (PAY) were determined at harvest. Application of NPK fertilizer and Agrolyzer at the rate of 400kgNPK/ha+20kgAg/ha led to yield increase of 5.98t/ha when compared to zero application (control) and 3.28t/ha relative to standard check (400kgNPK/ha + 0kgAg/ha). F3A3 when compared to F0A0 (control) and F3A0 (recommended NPK fertilizer rate) showed 9.31% and 8.05% higher percentage available yield respectively.
Keywords: optimum rate, seed yam, NPK, agroyzer

INTRODUCTION

The intensive cropping system under reduced fallow period has led to decline in crop yield and soil fertility, such that a state of over exploitation of the soil natural fertility has been reached in many parts of the Nigeria, thus application of recommended rate of macro inorganic fertilizer has not been giving expected yield output (Ano, *et al.*, 2005; Asiedu, 2007). In addition to over exploitation of soil natural fertility due to reduced fallow period, is the low emphasis on the importance of micro nutrients fertilizer by Nigeria soil fertilization policy frame work, which lays all emphasis on the replenishment of soil with macro nutrients fertilizer to total exclusion of micro nutrients fertilizer. This leaves the attainment of optimum agricultural productivity at a nutritional disadvantage. Eke Okoro *et al*., (2005) and Mortvedr (1985) reported micro nutrients increased root crops yield. Amanze *et al*., (2010) also report that combination of agrolyzer and gibberelic acid induced flowering and fruiting in non-flowering yam variety (Nwopoko) and increased yield of both ware and seed yam.

Agrolyzer belongs to a group of essential elements that are classified as micro nutrients fertilizer, because they are required in smaller quantity compare to those classified as macro elements fertilizer (Akoroda and Okechukwu, 2007). May be the fact that they are required in small quantity has been mistaken to be that they are less important. But on the contrary, these essential elements which include; boron (B), copper(Cu) iron (Fe) chloride (Cl), Manganese (Mn), Molybdenum (Mo) and zinc (Zn) play important roles in plants physiological and reproductive developmental processes; such as root metabolism and protein utilization by copper, whole plant metabolism by Chloride, chlorophyll formation by iron, carbohydrates breakdown and nitrogen metabolic enzymes synthesis by Manganese, nitrogen utilization by Molybdenum and carbohydrate transformation and growth regulation by Zinc. Therefore considering the delicate sett size used in seed yam production by minisett technique, it is very important that these important fertilizer elements are made available in right proportion for maximum yield output.

It is well established that one of the greatest challenges in yam production is the scarcity of planting material (seed yam) (Ikeorgu and Nwokocha 2001). This is because yam is not like most of other root and tuber food crops that are propagated either by botanical seed or non-edible portion such as stem, instead yam is propagated through its edible tuber and so most of what is produced is consumed due to high demand for yam food. It has become a difficult challenge to combat the perennial problem of scarcity of planting material. Although, considerable progress has been made towards development of rapid seed yam production techniques such as; mini tuber, minisett, peel sett and vine cutting (Mazza, *et al.*, 2012; Ikeorgu, *et al.*, 2010). Optimum nutrient requirement for these noble innovations has not been determined. FAO stat.(2006) reported that in Nigeria average yields of yam have been steadily declining over the last 8-10 years as result of declining in soil fertility due to shorter fallow periods and more use of marginal lands for yam production. Therefore it has become imperative that a robust and sustainable fertilization technique that plays emphasis on right combination of micro and macro nutrients fertilizers is developed in order to reverse the declining trend of the average yields of yam in Nigeria. Hence the objective is to determine the optimum rate of agrolyzer and NPK combination for seed yam production using minisett technique in Southeastern Nigeria.

MATRIALS AND METHODS

The study was conducted in rainforest agro ecological zone of Nigeria at the eastern farm land of NRCRI, Umudike in 2014 and 2015. Land preparations: slashing, ploughing, harrowing and ridging were carried out. 0.2 ha area of land was marked for the study at 20m^2 per plot, after which pre-planting soil sample was collected. The experiment was laid out in 5x4 factorial arrangements in a randomized complete block design with three replications. 30g minisett size of land race white yam (*Dioscorea rotundata)* (Ame) was planted at a space of 0.25x1m. The treatment combinations comprise of four rates of NPK 20:10:10 fertilizer at 0kg/ha, 200kg/ha, 300kg/ha and 400kg/ha and five rates of agrolyzer which contains Zn, CU, B, Mn and Fe at 0kg/ha, 10kg/ha, 15kg/ha, 20kg/ha and 25kg/ha were applied on 7th week after planting. Data were collected on following growth parameters: Vine length, number of secondary tillaries, canopy cover, leaf area and stem girth at 4, 5 and 6 months after planting(MAP), yield parameters such as: stand count, number of seed and ware yams, net gross tuber yield, tuber shape index(TSI) and percentage available yield (PAY) were determined at harvest. Postharvest soil samples were collected from each plot. The soil samples were analysed for macro and micro nutrient elements and other soil fertility factors.

Data generated were subjected statistical analysis using Excel and SPSS software, while Dunca multiple ratio test (DMRT) was used to separate the means.

Treatments were combined in the following order with the corresponding codes:

[F0A0= control, F0A1= 0 kg NPK + 10 kg Ag, F0A2 = 0 kg NPK + 15 kg Ag, F0A3= 0 kg NPK + 20 kg Ag, F0A4= 0 kg NPk + 25 kg Ag, F1A0= 200 kg NPK + 0 kg Ag, F1A1 = 200 kg NPK + 10 kg Ag, F1A2 = 200 kg NPK + 15 kg Ag, F1A3 = 200 kg NPK + 20 kg Ag, F1A4 = 200 kg NPK + 25 kg Ag, F2A0 = 300 kg NPK + 0 kg Ag, F2A1 = 300 kg NPK + 10 kg Ag, F2A2 = 300 kg NPK + 15 kg Ag, F2A3 = 300 kg NPK + 20 kg Ag, F2A4 = 300 kg NPK + 25 kg Ag, F3A0 = 400 kg NPK + 0kg Ag, F3A1 = 400 kg NPK + 10 kg Ag, F3A2 = 400 kg NPK + 15 kg Ag, F3A3 = 400 kg NPK + 20 kg Ag and F3A4 = 400 kg NPK + 25 kg Ag.]

RESULTS AND DISCUSSION

Parameters presented are only those that significant differences were observed among the treatments combinations.

Treatments combinations showed significant (P=0.05) difference with regard to vine length at four months after planting (4MAP) (figure 1). The vine length ranges from 56.33 to 63.45cm. F1A4 which recorded the longest vine length of 63.45cm, and was significantly higher than the vine length of F0A0 (control) which has the shortest vine length of 56.33cm, F1A2, F2A2 and F3A1, but it was not significantly higher than F3A0 which is the recommended NPK fertilizer rate. It appears that combination of 200kg/ha of NPK and 25kg/ha encouraged vine enlongation more than other combination rates. There were significant (P=0.05) differences among some of the treatment combinations for leaf area at six after planting (6MAP) (figure 2). The leaf area ranges from 45.57cm^2 to 82cm^2. F2A4 recorded largest leaf area, while F2A1 had the smallest leaf area. F2A4 equally showed significantly higher leaf area than F3A0 (recommended NPK fertilizer rate), but it was not significantly higher than F0A0 (control). Again 300kg/ha NPK and 25kg/ha Agrolyzer produced high leave area which indicates that 25kg/ha Agrolzer could be responsible increased vegetative development and not NPK fertilizer rate. Figure 3 shows that there were significant (P=0.05) among the treatment combinations for yield in t/ha equivalent. The yield in t/ha ranges from 12.08 to 18.06 t/ha. F3A3 recorded the highest yield of 18.06 t/ha, while F0A3 had the lowest yield of 12.08t/ha. F3A3 also showed significantly higher yield than F0A0 (control) and F3A0 (recommended NPK fertilizer rate). Figure 4 indicates that there were differences among the treatment combinations for percentage available yield (PAY). The percentage available yield for the treatment combinations ranges from 64.75 to 74.87%. F3A3 recorded highest percentage available yield, while F0A3 had lowest percentage available yield. F3A3 when compared to F0A0 (control) and F3A0 (recommended NPK fertilizer rate) showed 9.31% and 8.05% higher percentage available yield respectively. It does appear that while 100kg/ha, 200kg/ha NPK fertilizer and 25kg/ha Agrolyzer increased vegetative development, it does translate to yield output, instead, 400kg/ha NPK fertilizer and 20kg/ha Agrolyzer led to increased yield output and subsequently increased also the percentage available yield (PAY), which is the profitability of applying the treatments more than other treatment combinations. May be the vigorous vegetative growth at 100kg/ha NPK, 200kg/ha NPK and 25kg/ha Agrolyzer combinations reduced the bulking rate of tuber and hence could translate to complementary yield output.

CONCLUSION

Application of NPK fertilizer and Agrolyzer at the rate of 400kgNPK/ha+20kgAg/ha gave the highest seed yam yield in t/ha and percentage available yield from minisett technique. Application of this rate of combination of NPK and Agrolyzer led to yield increase of 5.98t/ha when compared to zero application (control) and 3.28t/ha relative to standard check (400kgNPK/ha + 0kgAg/ha). F3A3 when compared to F0A0 (control) and F3A0 (recommended NPK fertilizer rate) showed 9.31% and 8.05% higher percentage available yield respectively. Therefore, it could be recommended that farmers should apply combination of NPK and Agrolyzer at this rate for increased seed yam production through minisett technique.

RECAPITALIZATION OF SOIL FERTILITY: A PANACEA FOR SUSTAINABLE FOOD SECURITY IN NIGERIA

E.N. Nwaogu
National Root Crops Research Institute Nyanya Sub-Station, Abuja, Nigeria
Email: eddynwaogu2012@yahoo.com

ABSTRACT
Soil recapitalization is the replenishment of soil fertility as nutrients are added to the soil (inflows) to replace nutrients removed from the soil (outflows) by harvests, erosion, runoff, leaching, N volatilization, and de-nitrification. The reverse of recapitalization is soil mining, which occurs when nutrient outflows exceed in flows the study explores the recapitalization of soil fertility as away to sustain food security in Nigeria.
Keywords: recapitalization, soil fertility, food security

INTRODUCTION
Human population pressure has a major impact on land utilization and land degradation. Population pressure leads to the exhaustion of fertile agricultural lands and the progressive utilization of environmentally fragile marginal areas. In the Nigerian context, environmental degradation as a result of deforestation, overgrazing and cultivation of marginal lands is already a serious problem closely associated with population growth. In an effort to meet the food needs of the growing population of Nigeria, one major challenge is how to increase food production on lands already under cultivation without bringing marginal land into production. Among other things, such a challenge requires making sure that the soil is able to adequately provide the nutrients required to sustain the needed increased crop yields. Current agricultural practices in Nigeria are extractive in nature, taking out more than what is put back into the soil. In addition, since all productive agriculture results in removal of nutrients at harvest, careful management of soil resources is considered imperative in order to prevent unnecessary wastage and improve the efficiency of nutrient recycling. In this regard, soil nutrient levels must, nonetheless, be maintained above a critical threshold through replacement of the nutrients removed at harvest in order to sustain production. This critical threshold will vary for nutrients, yield goals and soil types. The objectives of this review paper are: (1) To highlight the causes and main effects of soil degradation; (2) To review some available technologies for soil fertility recapitalization in Nigeria with a view to highlighting major obstacles associated with their implementation and to suggest cost-effective ways of overcoming these obstacles.

The Nigerian Environment
Nigeria is located within latitude 4^0 – 14^0 N and longitude 2^0 -14^0 E. The country has an estimated land surface area of 923,768 km^2 equivalent to 924 million ha. Out of this figure, only 79 million ha are cultivable while 32 million ha are actually cultivated (Akoroda, 2010). Nigeria is the most populous country in Africa with an estimated population of 131,859,731 inhabitants (July 2006 estimate, World Factbook). The average annual growth rate according to the 2006 estimate was 2.38 %.

The Nigerian Soils
The soils of Nigeria are generally mostly light-textured and low in CEC with clay content ranging from 9 – 43 % in more than 60 % of the area (Agboola, 1986). Average clay content is less than 15 %. Organic matter ranges from 1.0 – 2.55 % while CEC ranges from 2.40 – 9.55 meq/100 g soil, the value being less than 5.0 meq/100g soil in 75 % of the area (Agboola, 1986). In terms of classification using the productivity rating index, Agboola (1986) reported that 94.51 % of the Nigerian soils fall within medium, low and very low productivity classes (Table 1)

Continuous cultivation of soils with such fertility credentials as indicated above without proper management and conservation measures has resulted in accelerated rate of degradation of the natural soil resources culminating in continuous low crop yields and poverty and hence, the need for re-capitalization.

Soil Fertility Re-capitalization: What is it?
Soil recapitalization is the replenishment of soil fertility as nutrients are added to the soil (inflows) to replace nutrients removed from the soil (outflows) by harvests, erosion, runoff, leaching, N volatilization, and de-nitrification. The reverse of recapitalization is soil mining, which occurs when nutrient outflows exceed inflows. The concept of recapitalization views Soil fertility as a form of renewable natural capital with service flows (crop production, food security) that increase when proper technical nutrient-saving measures aimed at protecting soil resource base from future degradation are put in place. The objective of recapitalization is not to build up maximum stocks of nutrient capital, but appropriate stocks of nutrient capital which can provide sustainable levels of nutrients to crops.

What is Food Security?

Food and nutrition security is said to exist when "all people at all times have physical, social and economic access to food, which is consumed in sufficient quantity and quality to meet their dietary needs and food preferences, and is supported by an environment of adequate sanitation, health services and care, allowing for a healthy and active life" (FAO, 2002). In this context, Recapitalization of soil fertility for sustainable food security therefore means "replacement of soil resources (either used by crop for physiological functions or removed out of the soil system through crop harvest, erosion, leaching, de-nitrification etc.) in a manner that guarantees adequate quantity and quality for future food production and environmental protection.

The alternative route to food security in Nigeria is to ensure that the economic means to purchase food exist, and that the food can be purchased at affordable prices. One important prerequisite is access to land, as more people need to produce their food supplies and make a living from the land. Traditional land management systems are dependent on the availability of sufficient land to allow long fallow periods to maintain soil fertility. When there is no more access to new land, the fallow land has to be used and soil fertility falls. The expansion of agriculture over the past three decades involved the cultivation of marginal areas, or clearance of important natural habitats such as forests and wetlands. Such conversion is a major driving force behind land degradation. More intensive use of land also implies that it becomes more prone to soil erosion. To maintain and raise its productivity, new sustainable management measures have to be introduced and policies changed.

Why Recapitalize Soil Fertility in Nigeria?

As populations continue to grow, competition for use of agricultural land increases, and arable land reserves become increasingly marginal as they are put into continuous cultivation (often times without nutrient-saving measures) resulting in over exploitation of available soil resources. The consequences of over exploitation of soil resources include but not limited to:

(i) Degradation of soil structure and loss of other soil physical qualities.
(ii) Decline in organic matter and soil biological activity.
(iii) Reduction in availability of major nutrients (N, P, K) and micro-nutrients.
(iv) Increase in toxicity, due to acidification or pollution.
(v) Continuous Soil fertility decline resulting in low crop yield and food insecurity and increasing level of unemployment.
(vi) Increased rural poverty.

Soil Fertility Parameters for Recapitalization

Soil fertility is not a static feature. On the contrary, it changes constantly and its direction (accumulation or depletion) is determined by the interplay between physical, chemical, biological, and anthropogenic processes.

Consequently, all soil properties which are amenable to change through investment and which affect long term crop productivity may be regarded as **assets which can be recapitalized.** In this regard, soil properties such as **organic matter, total N, available P, exchangeable K and pH,** are critical soil fertility indices requiring recapitalization.

However, particular properties may be more limiting than others and returns on investment may differ between strategies aimed at different soil properties. Based on this, soil organic matter has an over bearing influence on other fertility parameters and its proper management is important for sustainable food production.

Functions of Soil Organic Matter

Soil organic matter is known to play a wide number of roles in agricultural crop production through its effects on soils. These roles were summarized by Mbagwu (2000) to include:

Nutrient Cycling

(i) Organic matter increases nutrient holding capacity of soils
(ii) It serves as a pool of nutrients for plants.
(iii) It binds nutrients, preventing them from becoming unavailable.

Water Dynamics:

(i) Organic matter improves water infiltration
(ii) It decreases evapotranspiration
(iii) It also increases water Holding Capacity of soils

Soil structure modification:

(i) Improves aggregation, preventing erosion
(ii) Prevents compaction
(iii) Encourages root development.

Review of Various Strategies Adopted by Farmers for Soil Fertility Recapitalization in Nigeria
A number of strategies are potentially available for soil fertility recapitalization in Nigeria. These technologies, some of which are already adopted by small scale farmers in Nigeria, are summarized in Table 4

Recapitalizing Soil for Organic Matter
This refers to those strategies/technologies which are specific for increasing the level of soil organic matter in agricultural crop production. Examples of such technologies include:

(i) Use of animal Manures (poultry manure, cow dung, pig waste, cattle dung etc).
(ii) Residue mulching (using crop residues).
(iii) Kitchen waste
(iv) Legume cropping
(v) Zero tillage
(vi) Organic mulching

Such technologies, their setbacks and suggestions on how to circumvent their setbacks are summarized in the Table 1

Soil Recapitalization for P
Soil P recapitalization takes advantage of the comparative immobility of P in soil. Losses of P through leaching are small, except on sandy textured soils with limited P sorption capacity. However, the immobility of P in soil may render added P susceptible to loss through erosion and surface run-off. Incorporation of P within the rooting depth of the crops reduces losses by erosion and increases reactions with the soil, which is of particular benefit for rock P sources.The available technologies for soil P recapitalization include use of inorganic fertilizers such as urea, NPK fertilizers, rock phosphate, and organic manures.
K and Mg are not good candidates for recapitalization of acid upland soils as their chemical and physical properties may result in large losses by leaching and erosion due to poor retention. However, there must be balanced additions of these and other nutrients so they do not become major limiting factors as productivity increases with soil recapitalization.

Obstacles in Soil Fertility Recapitalization in Nigeria
Number of obstacles are involved in soil fertility recapitalization in Nigeria. These obstacles may be classified as technical, economic or political.

Technical Obstacles in Soil Fertility Recapitalization
Organic matter is vulnerable to high rates of decomposition in marginal soils. Since the rate of decomposition is a major factor in determining the rate at which nutrients are released to the soil, a better understanding of the dynamics of organic matter in a soil is important to significantly enhance its ability to increase yields and improve soil quality simultaneously.
There is not enough organic matter in Nigeria to recapitalize all the degraded soils under cultivation. This poses a big problem in the effort to recapitalize soil fertility in Nigeria.
Sole application of inorganic or organic fertilizers cannot make much fertility impact for sustainable crop production.
Fertilizer makes very little (if any) direct contribution to soil macrostructure, increased water-holding capacity, improved infiltration and erosion control, prevention of soil hardening or improved nutrient holding capacity.
Use of inorganic fertilizers acidifies the soil thereby distorting eco-balance.

Economic Obstacles in Soil Fertility Recapitalization
Inorganic fertilizers are costly and unavailable and much cost is involved transporting huge amounts of organic manures. The high rate of poverty amongst smallholder farmers in Nigeria makes it very difficult for them to be able to afford the cost of fertilizers resulting in their sub-optimal application. In addition, many small scale farmers do not have enough technical knowledge about the working and dynamics of fertilizer usage.
The decision to recapitalize soils is generally a private one made by individual farmers on the basis of perceived accruable financial returns. Farmers tend to focus more on short-run benefits of recommended technologies (e.g., the immediate returns to fertilizer) than on the long-term benefit technologies. This disposition affects the rate at which developed fertility recapitalization technologies are adopted by farmers.
Lack of Government Incentives There is lack of well-adapted technologies and also lack of economic incentives for farmers to adopt soil fertility management technologies developed. This is in addition to poor agricultural credit system which does not encourage farmers to obtain loan for implementation of certain fertility recapitalization strategies.

RECOMMENDATIONS ON THE WAY FORWARD

Government should reduce direct and indirect taxes on fertilizer imports to reduce the cost and encourage efficient use of fertilizers by smallholder farmers in Nigeria. Government should develop, implement and enforce policies intended to:

(i) Minimize land degradation due to erosion and/or organic matter depletion.

(ii) Promote integrated soil fertility management (ISFM) interventions to prevent nutrient depletion through erosion. The strategy is to minimize soil erosion, create positive SOC and N budgets, enhance activity and species diversity of soil biota (micro, meso, and macro), and improve structural stability and pore geometry

(iii) Promote fertilizer use-efficiency by fine-tuning recommendations aimed at strengthening the capacity of the extension systems for better service delivery.

Table 1. Classification of Nigerian Soils Using their Productivity Rating Indices.

S/N	Productivity Classification	Area Covered (Km^2)	Percentage of Total Area
1.	Very High Productivity	Nil	0
2.	High Productivity	8,802.82	5.49
3.	Medium Productivity	50,741.45	31.75
4.	Low Productivity	73,318.00	46.45
5.	Very Low Productivity	28,098.55	16.31

Table 3. Over view of Different Technologies Available for Soil Fertility Recapitalization in Nigeria.

S/N	Technology	Limitation for Use	References
1.	Bush Fallow	Practiced where land is not limiting	Van Reuler and Prins (1993)
2.	Crop Rotation/Intercropping	(i) Crop combinations and planting arrangements are variable; (ii) Extracts more nutrients from the soil than sole crops and may cause more rapid decline in soil fertility	Eke-Okoro et al., 1998; Ijoyah et al., 2012a
3.	Green Manuring	Adoption by farmers is low due to tedium of land preparation and economics of the practice	Liu et al 2006;Nilza et al., 2015.
4.	Organic Manuring	Large quantity of material needed to give equal crop yield response with mineral fertilizers; Long time is needed for mineralization to occur.	FAO, (2000)
5.	Soil Amendment with Rock Phosphate	Lack of immediate agronomic response on non-acid soils; Handling and transportation challenge	World bank, (1994)
6.	Use of mineral fertilizers	High cost and sporadic availability coupled with acidulation tendencies	Abdul-Galil et al., (2003).
7.	Integrated nutrient management (combined use of organic and inorganic fertilizers	Ideal combination does not exist. Optimum combinations depends on target and farm perculiarity.	Gruhn et al., (2003); Tarfa et al., (2001).
8.	Legume-based cropping	Variability in N-fixing capacity of legumes	Nwaogu et al., (2013)

Table 5. Available Technologies for Soil Organic Matter Recapitalization, their Setbacks and Suggested ways of overcoming their Constraints.

S/N	Technology	Setback	Suggestion on the Way Forward
1.	Use of organic Manures such as cow dung, poultry manure, rice mill waste, kitchen waste, etc.	Large amount of material needed to give equal crop yield response with mineral fertilizers due to low nutrient content; Nutrient mineralization depends on rate of organic matter	Complement with inorganic fertilizers.
2.	Use of mineral fertilizers	Acidulation tendency	Apply with cautious lime use
3.	Legume cropping	Variability in N-fixing capacity of legumes	Use legumes with high N-fixing capacity

STUDIES ON EFFECT OF NEEM BASED FERTILIZER ON PERFORMANCE OF CASSAVA ON SOILS DERIVED FROM SHALE PARENT MATERIAL IN SOUTHEASTERN NIGERIA

I.N. Onyekwere, L.I. Chukwu, J Adiele, M. S. Ejalonibu & M. H. Tokula

National Root Crops Research Institute Umudike
innonyeoma@gmail.com

ABSTRACT
A study was conducted to investigate the effect of neem based fertilizer on the performance of cassava grown on soils derived from Shale parent material at the National Root Crops Research Institute Igbariam Substation Anambra State experimental field, during the 2012/2013 and 2013/2014 cropping seasons. Prior to trial establishment soil samples from the experimental sites were collected at 0 to 20 cm depth and analyzed in Soil Science Laboratory alongside the neem based fertilizer. Result revealed that the soil was moderately acidic (pH 5.5), had moderate total N (0.16 %), moderate available P (10.50 mgkg^{-1}), low exchangeable K (0.18 cmolkg^{-1}), moderate organic Carbon (2.50 %) and Sandy clay loam texture. The neem fertilizer contains 3 % N, 6 % P, 3 % K and 20 to 30% organic Carbon by composition. Based on the nutrient requirement of cassava and the analytical result, 6 treatment combinations were made and applied 8 weeks after planting of cassava (TME 419) and the experimental design was randomized complete block design replicated three times. The yield result showed that neem based fertilizer and N P K fertilizer mixture at the rate of 2,250 kg neem and 187.5 kg N P K 12: 12: 17 + 2 gave significantly ($P < 0.05$) higher fresh root yield in both years than any other treatment, and is therefore recommended for sustainable cassava production in the soils studied.
Keywords: neem based fertilizers, soil, cassava, shale

INTRODUCTION
Most Nigeria soils are highly susceptible to degradation as a result of leaching, low soil reaction (pH), low organic matter content and exchange cations. Ojeniyi and Adejobi (2002).
Consequently, for productivity to be improved in these soils the use of organic fertilizer is essential. According to Agboola and Omueti (1982), the inherently poor fertility characteristics of tropical soils have fertility and nutrient availability in them to be largely controlled by soil organic matter content. Therefore, neem based fertilizer a new organic fertilizer may go a long way for this purpose, but its effectiveness for cassava production is not yet known. The objective of this study was to determine the effectiveness and the optimum rate of neem based fertilizer for performance and fresh root yield of cassava grown on soils derived from shale parent material in southeastern Nigeria.

MATERIALS AND METHODS
The experiment was conducted at the Igbariam substation, Anambra State of National Root Crops Research Institute (NRCRI) Umudike, south east agro ecological zone of Nigeria, during the 2012/2013 and 2013/2014 cropping seasons. The geology of the location is Shale. Pre planting soil samples were collected, prepared and analyzed in the Soil Science Laboratory using the methods outlined by Udo *et al*, (2010). The fields were fallowed for two years in each season, after which they were slashed ploughed harrowed and ridged and planted cassava stakes on the crest of the ridges, laid out in 6 m x 6 m plot size with a planting space of 1m x 1m, and variety of cassava planted was TME 419. The experimental design was Randomized Complete Block Design (RCBD) replicated three times, with six treatments that were applied 8 WAP. The plots were weeded 6 and 20 WAP then under brushed 32 WAP. Data were collected on plant height, girth size, number of leaves and fresh root (t/ha) yield harvested 12 MAP. Data were analyzed statistically using SAS (2002) computer package and means were separated using LSD at 5 % probability

RESULTS AND DISCUSSION
Soil and neem composition
The mean values of the physico chemical properties of the soils of the experimental sites for the two year study are as follows: Texture Sandy clay loam, pH 5.5, organic Carbon 2.50 % , Available P 10.50 mg /kg ,exchangeable K 0.18 cmol / kg, exchangeable Ca 3.32 cmol / kg , exchangeable Mg 2.20 cmol / kg , exchangeable Na 0.08 cmol / kg, Effective Cation Exchange capacity 7.48 cmol/kg total nitrogen 0.16% and exchangeable acidity 1.50 cmol /kg, while neem based fertilizer had the following composition organic Carbon 25 – 30%, Available P 6% and total N 3%. The results indicated that the soil texture is suitable for cassava production consequently, the soil had the following characteristics, low exchangeable K, moderate total

N and available P, moderate organic Carbon and moderately acidic. For sustainable cassava production to be achieved in this soil, these parameters, which are major soil indicators for cassava production, need to be improved.

Performance and yield of cassava

Table 1 shows effect of treatments on plant height, number of leaves, girth size and fresh root yield of cassava. The results showed that the highest plant height of 2.10 m and 2.30 m was obtained with treatment 2 (0kg neem + 750kg NPK 12:12:17+2/ha) in 2012/2013 and 2013/2014 respectively and both values were not significantly (P<0.05) different from values obtained from control and other treatments apart from treatment 3 (750kg neem + 562kg NPK 12:12:17+2/ha) .Treatment 5 (2,2500kg neem + 187.5kg NPK 12:12:17+2/ha) gave the highest girth size (7.49) in 2012/2013 but was significantly (P<0.05) different from values obtained from control and other treatments, apart from treatment 2 (750kg neem +562kg NPK(12:12:17+2/ha). In 2013/2014 treatment 6 (3,000 kg neem + 0 kg NPK 12:12:17+2/ha) had the highest girth size with a value of 8.6 cm , but was significantly different from value obtained from control only. Treatment 5 (2,250kg neem +187kg NPK 12:12:17+2/h), also had the highest number of leaves in both 2012/2013 and 2013/2014 having leave number of 56 and 59 respectively but in 2012/2013 it was significantly (P<0.05) different from the values obtained from control and other treatments apart from treatment 3 (750kg neem +562kg NPK 12:12:17+2/ha), while in 2013//2014 it was not significantly different from values obtained from control and other treatments . In terms of fresh root yield, treatment 5 (2,2500kg neem + 187.5 kg NPK 12:12:17 + 2/ha) gave the highest fresh root yield of 44.71 t/ha in 2012/2013 and 42 .35 t/ha in 2013/2014 but the yield values were significantly (P<o.05) different from the yield values obtained from control and other treatments apart from that of treatment 2 (0kg neem +750kg NPK 12:12:17+2/ha) in both years.

CONCLUSION/RECOMMENDATIONS

From the study, it can be affirmed that neem based fertilizer alone cannot be used for cassava production. Instead the combination of 2,250kg neem + 187.5kg NPK 12:12:17 + 2, which is equivalent to 2,250 kg neem + 150 kg NPK 15:15:15 or 2,250 kg neem+112.5 NPK 20:10:10 or 2,250 kg neem+83.34 kg NPk 27:13:13 is more suitable and therefore is recommended for cassava production in soils derived from Shale in southeastern Nigeria.

ABSTRACT
Cow dung fertilizer is widely accepted as the approach to sustain crop production and maintain soil fertility in urban and peri-urban vegetable production system in northern Nigeria. Because of its availability and accessibility in terms of costs, farmers prefer to use it in sustaining production than to go for inorganic fertilizer with high cost especially in vegetable systems. The effects of cowdung application rates and placement methods on fresh yield of cabbage was evaluated at the peri-urban garden of Bomo,northern Nigeria.The manure was applied at four rates 7.5,15.22.5 and 30t/ha and three placement methods of broadcasting, spot and banding application.The experiment involve factorial combination of these manure rates and the placement methods laid down in randomized complete block design (RCBD) and replicated 3 times. Records of fresh weight of cabbage where taken at full maturity (13 weeks).The result showed that application of 22.5t/ha gave highest fresh weight of cabbage (55.67 t/ha), while the broadcasting and spot placement methods gave the highest fresh weight (50.20 and 49.0 t/ha) of cabbage yield respectively. The response of cabbage yield does not only depend on farmers' management practises, but also on the rates and methods of cow dung application.
Keywords: cow dung rates, application methods, cabbage yield

INTRODUCTION

Urban and peri- urban garden systems are characterized by high nutrient input mainly from the organic sources such as manure, wastewater and municipal waste (Drechsel and Dongus, 2010), and often associated with environmental challenges although a corresponding increase in yield and economic return is obtained (Abdu, 2010; Abdulkadir *et al.*, 2015). Soils of the Nigerian savanna are characterized with weak structure and poor soil fertility (Jone and Wild, 1975; Lawal and Girei, 2013) and crop production depends on the application of fertilizer from organic and inorganic sources. Integrated nutrient management has been shown to have a positive impact in sustainable crop production. Fertilizer management such as application of different rates of organic fertilizer such as cow dung and its placement method have significant influences on improving soil fertility, crop yields and nutrient use efficiency (Chavez, et al 2014).

Cabbage (*Brassica oleraceae* L.) is a cool season crop belongs to the family Brassicaceae (Best, 2000) and a very important vegetable for household nutrition security. It is consumed raw or cooked with other vegetables and mostly grown as a commercial crop by most farmers and income. In Nigeria, there is an increasing demand for the cultivation of cabbage to meet the need of urban markets. Cow dung is an efficient organic fertilizer that is readily available for cabbage cultivation in northern guinea savanna (NGS) agroecological zone of Nigeria. However there are limited studies on the effect of cow dung rates and application method on the production of cabbage in Zaria, NGS of Nigeria.This objective of this study is to see the effect of different rates of cow dung and its placement methods on the yield of cabbage in Zaria, NGS of Nigeria.

MATERIALS AND METHOD

The experiment was conducted in a cabbage garden in Bomo village (Latitude. 11'11.255°, Longitude. 7'37.597 °) in the Northern Guinea Savanna ecology of Nigeria. A garden of 1375m^2 size was selected for the experiment and laid in a randomized complete block design (RCBD). The experiment involved two treatments which are manure and placement methods. The manure was applied at four levels, (7.5, 15, 22.5 and 30 t/ha) and three placement methods that is, Broadcasting (PM1), Spot application (PM2) and banding application (PM3).The cabbage was sown in the nursery for a period of 4 weeks, there after it was transplanted to the field,hoe weeding was carried out 3 times and irrigation was applied at 3 days interval. The crop (cabbage) was monitored to maturity(13 weeks) before harvestingg The final yield (fresh weight) was recorded and the result obtained where compared base on the application methods and the rates of applied manure using a simple statistical package SAS.and DMRT for mean separations.

RESULTS AND DISCUSSION

The properties of soil determine its suitability for agriculture and other uses. Organic carbon, total N and available P content of soils in the study area fall within the range of low fertility class, a typical characteristic of soils of Northern Nigeria (Jones and Wild, 1975)

While the textural classes of surface soils in study area (0-30cm) were sandy loams. This indicates that soils of this region are suitable for agriculture, as most crops thrive best on loam textured soils (Chude *et al.*, 2012).

Effects of Manure Rates on Yield of Cabbage

This study shows highest fresh yield weight of cabbage from application of 22.5 tons ha^{-1} manure. This result agree with a similar investigation of Talekar (2000), who reported that highest head weight per plant and best yields were obtained with application of 20 tons ha^{-1} of decomposed poultry manure. Generally, there was increase in fresh weight of the cabbage with a corresponding increase in rates of manure application although not beyond 22 tons ha^{-1}. These also support the findings of Muhammad *et al*. (2007) who reported that yield and nutritional quality of cabbage was increased with increase in fertilization. This was further corroborated with observations of Choudhary *et al*. (2005) that increase in cabbage vegetable parameters corresponded with increase in levels of nitrogen application and stated that vegetative parameters of cabbage increased considerably with increasing nitrogen rates. This implies that increased in cow dung supply may boost the growth and yield of cabbage as was observed in this study.

Effects of Manure Placement Methods on the Yield of Cabbage

The three different manure application methods (broadcasting, spot and banding) where compared on the basis of the final weight of the cabbage. There was no significant difference between the methods (Table 1). However broadcasting and spot application methods gave best yield of cabbage than banding application. This is an indication that in the two methods, plants effectively utilized the applied nutrients due to proximity to rooting depths, leading to higher yield than it is in banding methods, where plant roots were unable to utilize applied fertilizer at early vegetative growth. This has supported the findings of Akanni *et al*. (2011) that broadcasting of organic fertilizer was more effective in increasing soil nutrient content and yield of vegetable than spot and band applications. In Ghana it was also reported that broadcasting of cow dung manure increased maize yield compared to spot application, which was attributed to overall improvement of soil physical, chemical and microbiological properties (Abunyewa *et al.*, 2006).

CONCLUSION

The highest fresh yield of cabbage will be obtained from application of 22.5tones/ha of cow dung manure, while the broadcasting and spot application of manure increase yield of cabbage than the banding application in a peri urban garden of northern Nigeria savanna.

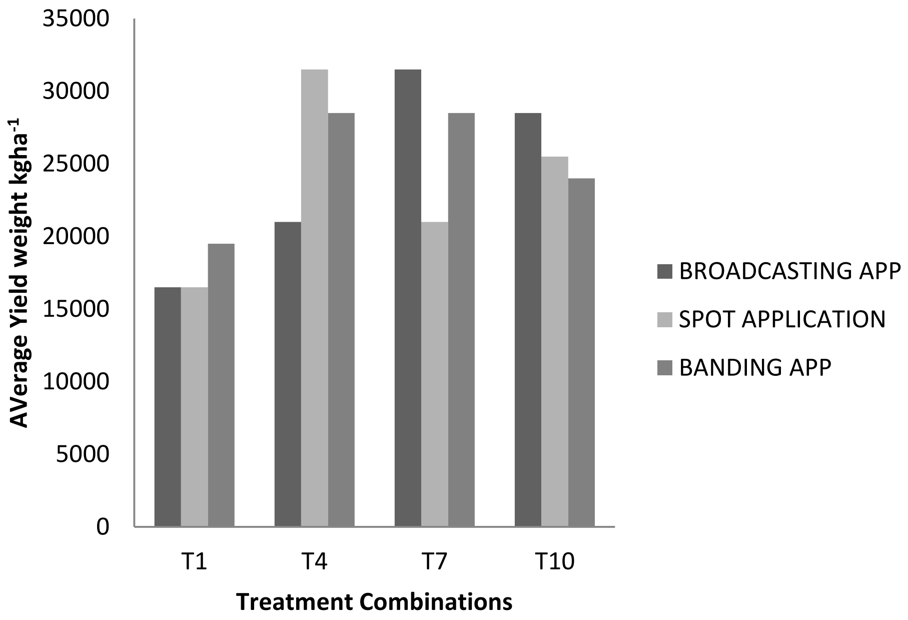

Figure1. Average yield (fresh weight) of Cabbage at three different methods of manure application in a UPA garden of Bomo, Zaria

SOIL FERTILITY AND CONSERVATION MANAGEMENT PRACTICES IN ABIA STATE: EXAMINING THE ROLE OF SYSTEM-RELATED AND SOCIO-ECONOMIC VARIABLES

R.N. Echebiri & K. Ikeabuaku

Department of Agricultural Economics, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
danielchinedu32@gmail.com

ABSTRACT
Accelerated soil erosion and declining soil fertility are among major constraints to agricultural production. The study identified organic manure application, inorganic fertilizers and liming as the commonest practices adopted. The coefficient of labour was positively signed and related to adoption of soil fertility and conservation management practices at 10% level, indicating that the more labourers available to a farmer, the higher likelihood event of adoption. The negative coefficient of conservation cost which is significant at 5% implies that if this cost is high, farmers will not adopt these practices. Non-availability of markets to sell products, farm labour constraints, high cost of soil fertility management materials and lack of credit to boost capital were the most influential challenges affecting the full adoption of soil conservation practices. The findings of this study reinforce the fact that in order to achieve sustainable soil fertility and conservation management, institutional and economic factors should be given special attention. In line with this, considering the positive effect of a farm's size and the negative effects of conservation costs on adoption, encouraging peasant farmers to cooperate, consolidating farms, setting agricultural cooperatives and stock farming could be a proper way to encourage conservation methods. Farming systems and extension education courses with relevant content may increase awareness about the effects and consequences of sustainable soil conservation practices among farmers.
Keywords: soil fertility, conservation, management

INTRODUCTION
In recent years, there has been a sharp rise in environment-related problems as a result of the declining climate condition giving rise to unfavourable climate changes of which soil erosion and degradation has been identified the most economical. A group of studies conducted by world bodies on environment-related issues have it that soil erosion is a major global concern as it leads to topsoil removal and to loss of both applied and native plant nutrients (WRI, UNEP, UNDP and WB, 1996). This has been the cause of reduced agricultural productivity per unit area and high costs of production due to the rehabilitation of farmlands. In Africa, the problem of soil erosion is estimated to cause a damage of $26 billion annually to productive soils of the continent (Lal, 2001). Soil erosion results in crop production decrease and gradual decline in fertility of ten million hectares of rain-fed lands of the country (Mahboobi, 2004). Loss of arable land due to soil erosion causes poverty and underdevelopment in the rural communities and it raises migration rate of villagers to surrounding cities, which is followed by social problems in the cities and non-sustainability in the rural areas.
The fertility of soil can be considered in different ways, depending on land use. Deressa *et al*. (2009) identify soil conservation as one of the major strategies farmers in developing countries employ towards the threats of climate change. In addition, Difalco and Bulte (2012) argue that adoption of certain farm management strategies reduces exposure to such shocks, given that agriculture is most exposed to climate change. According to Alimi (2000) and Ologbon *et al*. (2011), resources must be available and efficiently used in order to achieve optimum food crop production level hence, the mission of increasing agricultural productivity to sustain food requirement could be facilitated through efficient management of productive resources and practices, such as soil fertility improvement, proper land preparation, timely cultivation, use of good quality varieties, weed control and use of integrated pest management techniques to check the problems as soil erosion, yield losses and low productivity. Winter *et al* (2004) noted that these practices are for restoring, replenishing, conserving and maintaining the quality of agriculture land in order to increase farmer yield and income levels under the prevailing rate of population growth.
In Nigeria, a number of conservation practices are currently applied by farmers including: terracing, mulching, cover crops between independent variables and adoption of integrated cropping and timely use of fertilizers, to name only a few. Although several soil conservation technologies had been developed and promoted through past decades, the adoption of many recommended measures still minimal. This problem necessitates the urgency to study the level of use of these practices in Abia state.

METHODOLOGY

The area of coverage is Bende Local Government Area of Abia State, South Eastern Nigeria with a population of about 176,565 people based on the 1991 population census; and it is located in the northern part of Abia State. Abia State occupies the area lying between coordinates 6º5' and 4º50'N and between 7º08' and 8º00'E. The major occupation of the people of the area is farming, and rice farming is predominant. Other crops produced include cassava, maize, and beans. Their high level of agricultural practice makes it suitable to study their level of soil fertility and conservation management practices' adoption. A two stage sampling technique was used to select three (3) communities (first stage) and twenty (20) farmers from the three communities (second stage) to make a total of sixty (60) farmers. Well-structured questionnaires were used to elicit data from the farmers. Data were analyzed using simple descriptive statistics and inferential statistics like probit regression. Furthermore, a probit regression model was estimated to capture effects of factors on adoption of soil fertility and conservation practices by the farmers. The model was explicitly specified as:

$$Y^*_i = \alpha + \beta X_i + \mathcal{E}_i \qquad (1)$$

Y_i^* = Y for all farmers who have adopted soil management practice

Y_i^* = an underlying latent variable that indexes the level farmers adoption of soil fertility and conservation practice.

Y = soil fertility management index of the farmer (ratio of soil fertility management practices adopted by the farmer to the listed soil fertility management practices used in the study area); β = vector of estimated parameters; $\mathcal{E}_i$=error term; a=intercept of the function; X_i=set of independent variables, captured as:X_1=Area of land conserved; X_2=Availability of labour (number of adult labourers); X_3=Access to credit (1 = yes, 0 = otherwise); X_4=Cost of conservation (Naira); X_5=Access to extension services (1 = yes, 0 = otherwise)

RESULTS AND DISCUSSION

Socioeconomic Characteristics of the Farmers

The socio-economic characteristics of the farmers are presented in Table 1.

The result indicates that there were more female farmers (51%) in the area than men, although the difference is relatively little. Traditionally, in the eastern part of the country, women who are divorced by the husbands do not own lands. In line with argument, soil management and conservation practices' adoption may be limited. The result also showed that a majority of the farmers (about 72%) had no formal education. With the alarming rate of rural illiteracy, it must be noted that the ability of a farmer to adopt any farming technology, including soil fertility management techniques, is expected to be improved by attainment of formal education. The income generated from farming activities by the farmers is relatively low, with more than 72% of them earning at most N30,000 per annum. This is expected giving the high rate of illiteracy in the area which could be traced to the poor soil fertility management and conservation practices in the area.

Soil Fertility and Conservation Practices

A list of these practices is identified in Table 2. As shown in the table, use of organic manure as a technique for managing and conserving soil fertility was mostly adopted, as 38.74% of the farmers use it. The farmers who used this method spent on the average, N3,833.33 per farming season. Mulching and fertilizer application were equally used by same proportion of farmers. Mulching which involves the use leaves or green plant residues to protect the soil from excessive heat after planting is an age-long practice in many farming communities in Nigeria. About 19% of the farmers interviewed used mulching as a soil conservation technique. On the average, N4,300.00 was spent by the farmers on purchase of fertilizer in a farming season. Given mean farm size of 3.89 hectare under conservation, a ratio of N1,105.40 is spent on fertilizer per hectare of farmed land. Liming was another option the farmers adopted to conserve their soil.

Factors Affecting Adoption of Soil Fertility Management and Conservation Practice

Adoption of soil fertility management and conservation practice was captured as a ratio of the number of practices the farmer adopted and the number of practices listed. The result is presented in Table 3.

The coefficient of labour was positively signed and related to adoption of soil fertility and conservation management practices at 10% level, indicating that the more labourers available to a farmer, the higher likelihood event of adoption. Conservation cost includes all the money a farmer will have to spend on adopting soil fertility management and conservation practices. The negative coefficient which is significant at 5% implies that if this cost is high, farmers will not adopt these practices. Of course, additional costs arising from conservation practice will reduce farmers' revenue from farming. That is a discouragement to adopting soil conservation practice. Extension services provide the link between research and the farmers. New farming innovations, including soil fertility and conservation management practices usually reach the farming community through extension. The more access a farmer has to these extension services, the greater his disposition to adopt soil conservation practices.

Challenges against Soil Fertility Management and Conservation

The farmers' responses on these challenges are presented in Table 4. About 86% of the farmers indicated that they faced these two major problems of non-availability of markets to sell farm produce and labour constraints. If markets are not available to dispose off-farm output, a large proportion of the produce will be either consumed or lost in poor storage conditions. This loss will discourage farmers from observing any form of soil fertility management. On the other hand, since most of the labour was from household members, its absence will pose a substantial challenge. High cost of soil fertility management materials and lack of credit to boost capital received about 79% responses from the farmers. It may be noted that the top four constraints towards soil fertility management practice are income-related.

CONCLUSION AND POLICY RECOMMENDATIONS

Accelerated soil erosion and declining soil fertility are among major constraints to agricultural production. The study identified organic manure application, inorganic fertilizers and liming as the commonest practices adopted and further showed that labour, conservation cost and extension services were the key variable that affected adoption of these soil fertility and conservation management practices in the study area. Non-availability of markets to sell products, farm labour constraints, high cost of soil fertility management materials and lack of credit to boost capital were the most influential challenges affecting the full adoption of soil conservation practices. These findings of this study reinforce the fact that in order to achieve sustainable soil fertility and conservation management, institutional and economic factors should be given special attention. Since adoption of many recommended soil conservation measures is still minimal in many areas, paying attention to factors which determine adoption is a top priority. In line with this, the following policy recommendations are made. Firstly, considering the positive effects of a farm's size and the negative effects of conservation costs on adoption, encouraging peasant farmers to cooperate, consolidating farms, setting agricultural cooperatives and stock farming could be a proper way to apply conservation methods. In this case, government could make supportive policies to encourage farmers, like granting financial aids or supplying some of the essential inputs to the cooperatives. Farming systems and extension education courses with relevant content may increase awareness about the effects and consequences of sustainable soil conservation practices among farmers while providing them with required knowledge.

EFFECT OF ORGANIC AND INORGANIC FERTILIZERS ON SOIL NON-NUTRIENT FUNCTIONS AND YIELD OF MAIZE ON AN ULTISOL IN ABAKALIKI, SOUTH EASTERN NIGERIA

J.E.Orji[1] & F.C. Okenmuo[2]

[1]Department of Soil Science and Environmental Management, Ebonyi State University, Abakaliki
[2]Department of Soil Science, University of Nigeria, Nsukka

ABSTRACT
The agronomic potential of organic and inorganic fertilizers as soil amendments was evaluated. The objective was to determine their effect on soil physical properties and grain yield. Four different manures (Poultry Dropping), NPK 15:15:15, Unburnt Rice Husk and Burnt Rice Husk) as the soil amendment and control were selected and set up in the field using randomized complete Block Design (RCBD). Amendments were applied at the rate of 0.3 t ha^{-1}, 5 t ha^{-1}, 5 t ha^{-1} and 5 t ha^{-1} for NPK, BRH, UBRH and PD respectively. The soil samples were analyzed for particle size distribution, bulk density, total porosity, hydraulic conductivity, % water retention, % Aggregate stability and % Dispersion ratio. The soil was sandy clay loam with moderate silt and low organic matter content. The result of the study showed significant increase in all the parameters studied relative to the control. The lowest bulk density and highest porosity at 90 DAP of 25% and 58% respectively were observed in the plots amended with PD. Results also showed that the plot amended with PD had the highest grain yield, the yield increase in amended plots was in the order of PD>NPK>UBRH>BRH>C. Amending soil with organic manure has better potential for enhancing soil properties for better crop yields.
Keywords: organic, inorganic, soil nutrients, maize, yield

INTRODUCTION
Soil remains the fundamental resource for agricultural production and the most important possession and input for farmers who use the soil as a medium for plant growth. Tropical soils have a wide range of limiting factors for agricultural use: these include nutrient deficiencies, acidity, low water storage and poor physical attributes occasioned by losses of organic matter due rapid oxidation, high temperature and heavy precipitation (Nnoke 2001; Bell and eng, 2005). Due to the heavy rains, the soil undergoes serious structural deterioration. The impacts of the drops separate the fine soil particles and the organic matter from the sand, and the soil pores get clogged. This condition accentuated by long periods of cultivation without addition of amendments triggers leaching, runoff and erosion (Rouw, 2005).

Fertilization will be required to correct and maintain the nutrient balances, increase productivity of the soil so as to raise yields and obtain maximum results from the improved varieties and other practices. Agronomists have long recognized the benefit of maintaining and increasing soil organic matter which enhances soil fertility, water retention and crop production (Mbah and Mbagwu, 2003). A fertile soil is that capable of supplying nutrient to plant in adequate amount and in suitable proportion during growing season while a productive soil is one which is capable in its normal environment to produce a particular plant or sequence of plants under a specified management system (Dorah and Jones, 1996). Good soil management options can help in rehabitation of soils that are badly degraded (Igwe, 2005). Therefore, for a soil to remain fertile and productive especially in the tropics there is need for the application of organic and inorganic fertilizers which will help boost crop yields. Organic manures are derived from organic matter i.e. from plants and animals and their products e.g. Is farm yard manure while inorganic manures are manures that are man-made or manufactured artificially e.g. muriate of potash (Nnoke, 2005).

Although in Abakaliki, South East of Nigeria, some works have been documented on the use of organic and inorganic fertilizers for agricultural production, there is need for more works to inform the rural farmers on the best manure to adopt as well as the best way to use the various soil amendments in order to ameliorate the soil conditions. This study investigates the effect of organic and inorganic fertilizers on soil physical properties and yield of maize in Abakaliki, South East of Nigeria.

MATERIALS AND METHODS
Site description
The experiment was conducted at the teaching and research farm of the faculty of Agriculture and Natural Resources Management, Ebonyi State University, Abakaliki in Ebonyi State South Eastern Nigeria. The area is located within 06^{O} 4N and longitude 08^{O} 65^{O} E in the Derived Savannah Zone of Nigeria. The experimental site lies in the humid tropics with high rainfall and high temperature. The annual rainfall of the area is between 1800

– 2000mm. The annual temperature ranges between 21 – 29^{O}C and the relative humidity is between 60 – 80% during rainy season (Ofomata, 1975). The soil belongs to the order Ultisols and classified as Typic Haplusult (FDALR, 1985).

Materials

The soil amendments used include organic manure (poultry droppings) collected from Nkaliki poultry farm, Abakaliki, burnt and unburnt rice husks collected from the Abakaliki rice mill and NPK 15:15:15 purchased locally in Abakaliki. Maize variety (Oba Super II), used as a test crop was purchased at Ebonyi State Agricultural Development Programme (EBADEP).

Field Layout

The total land area of 588m^2 was demarcated into blocks (replicates) and plots. The experiment was laid out in a Randomized Complete Block Design (RCBD) with four replicates and five treatments. The rates of the application of the treatment are as follows; inorganic manure (NPK 15:15:15) at 0.3t ha^{-1} (0.6 kg/plot). Burnt Rice Husks (BRH) at 5t ha^{-1} (10 kg/plot), unburnt Rice Husks (UBRH) at 5t ha^{-1} (10 kg/plot), poultry Droppings (PD) at 5t ha^{-1} (10 kg/plot and the unamended/Control.

Soil Sample Collection

Soil samples were collected from the site before and after planting at the depth 0–20 cm with the aid of soil auger for laboratory analysis. four undisturbed core samples and foru auger samples were collected from the depth of 0 – 20cm in all the plots while the crops were still in the field. The auger samples were composited air dried at room temperature and sieved through a 2mm sieve for analysis.

Grain Yield

Harvesting of cobs was done at maturity, dried, threshed, weighed and the grain yield adjusted to 14% moisture content.

Laboratory Methods

Particle size analysis was carried out by pipette method (Gee and Or, 1994). Bulk density was analyzed by core method (Doran and Mieike, 1984) and total porosity was calculated from bulk density data as follows:

$TP = \left(1 - \frac{BD}{PD}\right) \times \frac{100}{1}$.

(Where TP = Total porosity, BD = bulk density and PD = particle density assumed to be 2.70gcm^{-3}) (Obi, 2000). Hydraulic conductivity was determined using constant head method (Stolt, 1997). Soil water rentention capacity was determined using gravimetric method (Obi 2000). Dispersion ratio was calculated from particle size analysis data using the formula; % DR= $\frac{water\ dispersion}{calgon\ dispersion} \times \frac{100}{1}$.

Aggregate stability was determined using the method described by Kemper and Rosonau (1998).

Data Analysis

Data collected were subjected to statistical analysis using Analysis of Vanarice (ANOVA) for Randomized Complete Block Design (RCBD). Significant means were separated using Fishers' Least Significant Difference (F-LSD$_{0.05}$) as recommended by steel and Torrie (1980).

RESULTS

The values of clay, silt and sand are 25%, 29%, and 46% respectively. The pH value of the soil was 5.3 in KCl and 6.4 in water (Table 1). Table 1 also showed that organic matter content including total nitrogen content of the soil was low. Table 2 showed that the bulk density at 90DAP was significantly affected by the treatment the lowest bulk density at 90DAP was found in the plots amended with PD which was 25% lower compared to the control. Generally, there was reduction in the bulk density of the other amended plots compared to the control. The results also showed that there was inverse relationship between soil bulk density and total porosity (Table 2). The table showed that at 90DAP the highest value of 46.9% for total porosity was obtained in plots amended with PD. The percentage increase in total porosity relative to control at 90DAP is in order of 34.2%, 38.7%, 39.1%, and 46.9% for BRH, UBRH, NPK and PD respectively. Table 2 also showed that the highest mean value for hydraulic conductivity of 1.09cm 1hr was obtained in the plots with PD followed by NPK. The value was 32.9% higher than the value obtained in the control plots. The table also showed the effect of the amendments on soil percentage water retention (%WR). The highest percentage of water retention of 49.40% was recorded by PD. Higher value relative to control were obtained in the soil amended with NPK, URBRH and BRH. The table showed that percentage aggregate stability increased significantly relative to control NPK, PD, UBRH and BRH showed significant increase relative to the control with mean percentage increments of 12.17%, 14.82%, 15.05% and 19.05% respectively. Table 2 also showed the effect of the amendments on percentage dispersion ratio. Although there was no significant increase, PD recorded the highest value and control had the lowest value for dispersion ratio.

Table 2 also showed that the application of several of amendments significantly (P = 0.05) increased the maize grain yield. PD with a cumulative yield of 2.1 t ha^{-1} had the highest grain yield while the lowest grain yield was recorded by the control.

DISCUSSION

The textural class of the soil was sandy clay loam, while the pH of the soil was slightly acidic and the result of the pre-planting analysis showed that the nutrient contents of the soil were low (Table 1). Generally there was a reduction in the bulk density values of all the amended plots when compared to the control at 90DAP. The lowest bulk density was found in plots amended with PD which may be because of the large quantity of organic matter in poultry dropping which helps in opening up the soil. This is in line with the observations of Abive *et al*., (2007). Bulk density of a soil is a measure of soil compaction and lower bulk density may result in easy penetration of roots, hence increase in the feeding area of the plant which will result in higher soil productivity Abu-Hamdeh *et al.,* (2006) and Anikwe and Nwobodo, (2002). All the plots amended with the various amendments recorded low bulk density when compared with the control (Table 2). The highest total porosity at 90DAP was obtained in plots amended with PD followed by NPK, UBRH and BRH. The order of increasing of hydraulic conductivity is PD>NPK>UBRH>BRH>C. The higher hydraulic conductivity in plots amended with PD, NPK, and UBRH could be attributed to the low bulk density and high total porosity that improve hydraulic conductivity. This corroborates the findings of Anikwe (2000) and Brady and Weil (1999) that higher hydraulic conductivity means better water transmission hence reduction in waterlogging. The highest value of 49.40% for percentage water retention was recorded by PD. Higher values relative to the control were obtained in the soil treated with UBRH and BRH. The higher soil percentage water retention obtained in the amended plots agrees with the initial of Obi and Ebo (1995) who stated that increased moisture content may be attributed to the colloidal content of the organic manure which increases soil water holding capacity. Higher values obtained in the percentage aggregate stability of NPK, PD, UBRH and BRH agrees with the earlier reports of Martens, (2000), Anikwe (2000) and Abiven *et al.*, (2007) that the addition of organic and inorganic fertilizer increases biological activities and the aggregate stability of the soil. The percentage soil dispersion ratio showed no significance difference among the treatments at P=0.05. The results showed that the highest value for grain yield was obtained from PD and the lowest was from the control. Other amendments such as BRH, UBRH, NPK treated soils increased grain yield by 87.5%, 100% 125% respectively relative to the control plots. This agrees with the earlier findings of Bierman, (2000) who stated that increase in the yield of maize has been obtained with the application of organic and inorganic fertilizers. The relative high yield obtained from the PD amended plots agree also with the findings of Maritus and Vleic (2001) who reported that the fertility of the soil provided by organic matter from manures had effects on flowering date, tasseling time, silking time hence the maturity and the crop yield.

CONCLUSION

Organic and inorganic fertilizers are useful soil amendments and improves the soil physical properties especially the organic manure like poultry droppings due to its high content of organic matter needed in the soil. The soil amendments NPK, UBRH, BRH also improved the physical properties of the soil and crop yield when applied appropriately but organic manure (PD) is the best option and is recommended.

ABSTRACT
This trial was conducted in the rainy seasons of 2006 and 2007 at the Research Farm of the Institute for Agricultural Research, Ahmadu Bello University, Zaria, to evaluate the influence of incorporated legumes and nitrogen application on total dry matter yield of two maize (Zea mays L.) varieties. The treatments consisted of two maize varieties (SAMMAZ 12 and SAMMAZ 27) and five nitrogen rates (0, 30, 60, 90 and 120kg N ha^{-1}) in the main plots while three green manure crops (Lablab (Lablab purpureus), Mucuna (Mucuna pruriens) and Soybean (Glycine max (L.)Merrill)) and a weedy fallow were accommodated in the sub-plots. The treatments were laid out in a split-plot design with three replicates. SAMMAZ 12 and SAMMAZ 27 were similar in dry matter accumulation. Plots that received nitrogen fertilization caused significant increases in maize dry matter yield compared with maize grown in plots without nitrogen treatment. Application of nitrogen at 60kg N ha^{-1} was found to be adequate for increased dry matter yield of maize. Incorporation of mucuna, lablab and soybean significantly incresed dry matter accumulation in maize plants compared with maize plants grown in plots with incorporated weedy fallow.

Keywords: dry matter, fertilization, legume, nitrogen

INTRODUCTION
Maize is one of the most widely grown crops in Nigeria especially in the Savanna zone of Nigeria, where it has been reported to account for over 70% of the maize production in the country (Uyovbisere *et al.*, 2001). The zone is known to be deficient in nitrogen (Singh, 1987) which is a very important plant nutrient and a major yield determining factor needed for increased maize production (Adediran and Banjoko, 1995; Shanti *et al*., 1997). This necessitates a regular addition of this nutrient to the soil either through inorganic or organic source. Economic challenges have made chemical fertilizers especially nitrogen, which are often used by farmers to correct depleting soil fertility, to be beyond the reach of the resource poor farmers who produce the bulk of food in Nigeria. The viable alternative is to opt for organic source to restore soil fertility. Legume incorporation as green manure has been a very promising cropping system approach in improving soil fertility through generation of organic matter which is a livewire for sustainable crop production. Soil organic matter is a vital regulator of various environmental constraints to productivity of crop (Woomer et al, 1994). Hence, soil residues are a generator of soil organic matter which maintains the physical and physic-chemical properties of soil, thus enhancing soil fertility such as soil exchange capacity and soil structure (Fenning, *et al*, 2009).
Crop growth and productivity depend on the degree of effectiveness of such a plant to absorb and mobilize the nutrients that are available in the soil for plant growth and dry matter accumulation (Adesoji, 2015a). Crop growth rate depends on the amount of radiation intercepted and its conversion into dry matter (Fageria, 2000). Total biomass production of a crop, without water limitations, is the product of solar radiation intercepted by the crop canopy over the duration of the cropping period and the efficiency at which the crop converts light energy into plant dry matter (Richards, 2000). Economic yield of any crop is dependent on the biomass performance of the crop which means the more the dry matter accumulation the more the economic yield of the crop. Thus, the higher dry matter per plant, the more assimilate it could translocate to fill the grains for consequent higher grain yield (Adesoji, *et al*, 2015b). Despite its importance, the information on the influence of incorporated legumes and nitrogen application on maize biomass is still scanty. Therefore, the objective of this study was to evaluate the effect of incorporated legumes and nitrogen on maize biomass performance.

MATERIALS AND METHODS
The study was carried out in the rainy seasons of 2006 and 2007 at the Research Farm of the Institute for Agricultural Research, Samaru (11^0 11^1 N, 07^0 38^1 E, 686 m above sea level) in the Northern Guinea Savanna ecological zone of Nigeria. The annual rainfall for the duration of the study in 2006 and 2007 was 1086.7 and 900.4mm, respectively. The soil of the experiment site was loam. The treatments consisted of two maize varieties

(SAMMAZ 12 and SAMMAZ 27), five levels of N (0, 30, 60, 90, and 120 kg N/ha), and three green manure crops (*Lablab purpureus, Mucuna pruriens and Glycine max* (L.) Merrill) and a weedy fallow. The experiment was laid out in a split-plot design with nitrogen and variety as main plot treatment and green manure as the sub plot treatment. The experiment was replicated three times.

Leguminous green manure crops were planted on the flat with narrower inter-row spacing of 37.5 cm. The lablab was sown at 2 stands per hole at 20cm within row and mucuna was sown at a stand per hole at 20cm within row. The soybean was planted drilled. The leguminous green crops were incorporated at 49 days (7weeks) after planting. After 3 days of incorporation, maize seeds were planted with two or three seeds per hole at a spacing of 25cm on the ridges of 75cm apart. The maize seedlings were thinned to one seedling per stand at two weeks after sowing. The experimental plot consisted of six ridges of 4.5m apart and 4m long (gross plot) and net plot was 3m x 3m (9m^2). The green manure crops were fertilized using 20kg P_2O_5 ha^{-1} and 10kg N ha^{-1} to boost their growth. Nitrogen fertilizer as urea (46%N) was applied to the maize at 2 and 6 weeks after sowing (WAS) according to treatment. Basal applications of 60kg P_2O_5 ha^{-1} and 60kg K_2O ha^{-1} were carried out at sowing. Weeds were controlled using Paraquat (Gramaxone) at 3 litres ha^{-1} to kill weeds that were not properly incorporated and hoe weeding was done at 6WAS.

Samplings on total dry matter were done at 6, 9 and 12 weeks after sowing (WAS) from three randomly selected plants from each plot (border rows). The samples were oven dried at a temperature of 70^{0}C to a constant weight and weighed using atop loading Metler P1210 weighing balance and the mean dry weight was recorded as a total dry weight(g) per plant. Total dry matter (kg ha^{-1}) was determined at harvest by cutting the entire plants in each net plot from ground level after they had been properly sun-dried and weighed using Salter scale model 250. The weight per plot was recorded. Stover yield was determined at harvest by weighing above ground dry weight of entire plants in each net plot after the cobs had been removed. The weighing was done using Salter scale model 250 and recorded. Data collected from the observations were subjected to statistical analysis of variance (ANOVA) as described by Gomez and Gomez (1984) using SAS package version 9.0 of statistical analysis (SAS institute, 2002). The differences among treatment means were separated using Duncan's Multiple Range Test (Duncan, 1955). Effects were considered statistically significant at 5% level of probability.

RESULTS

Variety effect was not significant on total dry matter per plant, total dry matter per hectare and stover yield (Table 1). Application of nitrogen beyond 30kg N ha^{-1} did not significantly increased total dry matter per plant in 20006 and 2007. However, addition of nitrogen caused the maize plants to accumulate more dry matter than maize plants in plots without nitrogen. Increasing N level up to 90 kg N ha^{-1} in 2006 and 30 kg N ha^{-1} kg N ha^{-1} in 2007 significantly increased total dry matter accumulation of maize plants at harvest. Application of nitrogen beyond 30 kg N ha^{-1} did not significantly increase stover yield both years under study (Table 1).

Incorporation of green manure crops performed significantly better on total dry matter plant, total dry matter per hectare and stover yield than the incorporation of weedy fallow in all the two years of study (Table 1). There was no significant difference among the leguminous crop incorporated on total dry matter plant in 2006 while incorporation of lablab produced significantly higher total dry matter per plant than incorporation of soybean in 2007. Incorporation of lablab performed significantly better on total dry matter per hectare than incorporation of mucuna and soybean in 2006 while incorporation of lablab produced significantly higher total dry matter hectare than incorporation of soybean in 2007. Incorporation of lablab produced significantly higher stover yield than incorporation of soybean in 2007.

DISCUSSION

Varietal effect between SAMMAZ 12 and SAMMAZ 27 on total dry matter per plant, total dry matter per hectare and stover yield was not significant which could be as a result of the inherent ability of earliness of both varieties. The similarity between both varieties could have been that they were genetically similar in the accumulation of dry matter. Significant increases obtained on total dry matter per plant, total dry matter per hectare and stover yield after application of nitrogen could be attributed to the significant increases observed on maize growth parameters such as number of leaves, plant height and leaf area index as earlier reported from another aspect of this study (Adesoji, *et al.*, 2013). The marked increases observed on these parameters could also be attributed to the important roles nitrogen plays in cell division, cell expansion and increase in size of all morphological parts (Idem, 1989), which could have enhanced chlorophyll production and photosynthetic ability of the maize plants for improved assimilate production in leaves for subsequent translocation and partitioning to various parts of the crops for increased biomass production. It has been reported in a path coefficient analysis in an earlier study that the most important contributors from growth parameters to maize grain yield were total dry matter per plant and crop growth rate (CGR) (Adesoji *et al*., 2015b).

The larger dry matter accumulation observed on maize plants that received incorporated legumes could be linked to the potency of green manure to increase soil nitrogen (Pushpavalli *et al*., 1994), release phosphorus (Singh *et al*., 1992; Palm *et al.*, 1999), maintain and renew the soil organic matter and improve the soil physical and chemical characteristics (Tiwari *et al*.,1980). The favourable maize dry matter accumulation in the legume green manure-treated plots in this study could be attributed to the increases in the amount of N fixed by legumes and quantity of N and P derived from the decomposition of the incorporated green manure crops.

CONCLUSION

Based on the results obtained from this study, it can be concluded that SAMMAZ 12 and SAMMAZ 27 exhibited similarity in dry matter accumulation. Nitrogen fertilization was observed to cause great improvement in dry matter yield of maize plants compared with plots without nitrogen which showed smaller dry matter accumulation. Application of nitrogen at 60 kg N ha^{-1} was found to be adequate to cause marked increases in dry matter accumulation in maize plants. Incorporation of mucuna, lablab and soybean enhanced great increases in dry matter accumulation in maize plants compared with incorporated weeded fallow which showed a lesser dry matter yield.

SOIL QUALITY ASSESTMENT OF AN EXISTING PLANTAIN (*MUSA SPP*) FIELD TREATED WITH POULTRY MANURE RATES IN EDO STATE NIGERIA

B. U. Agah & E. Idehen

National Agricultural Extension and Research Liaison Service, A.B.U, Zaria, Kaduna State, Nigeria
Corresponding author: bonyagah@gmail.com

ABSTRACT
Assessment of soil quality changes in an existing plantation could provide an indicator of the nutrient requirement of crops for sustain growth and yield. An experiment was conducted to evaluate soil quality assessment of an existing plantain (Musa Spp) field treated with poultry manure in the teaching and research farm of Ambrose Ali University, Ekpoma Edo state Nigeria in the 2015 cropping season. The treatment consists of five rates of poultry manure (0, 15, 25, 35 and 45 t/ha) arranged in a randomized complete block design (RCBD) and replicated three times. Selected soil physical and chemical quality indicators were asses on soil samples collected from two depth (0-15 and 15-30 cm) in the field. Results reveal that application of poultry manure does not significantly translate to an increase soil total N and pH. However, higher concentration of K and P were reported with the application of 35 tons/ha of poultry manure. Exchangeable Ca and Mg were significantly improve with the application of manure up to the highest rate of 45 tons/ha. Significantly higher percentage of organic matter was reported in all the plots which are intended to leave a residual effect. In all cases, higher plant nutrients were reported in the top soil than sub soil. The investigation however revealed that supplementary inorganic nitrogen is needed to balance the high K, Ca and Mg supply by 35 tons/ha of poultry manure for sustain growth of plantain under similar condition in Edo state.

Key words: Plantain, soil quality, soil depth, poultry manure

INTRODUCTION

Plantain (*Musa* spp) is one of the important staple foods in the tropical and sub-tropical regions of the world (Englberger *et al*., 2006). The fruit is an important source of carbohydrate, vitamins, proteins, potassium, iron, calcium, carotenes and ascorbic acid and also contains moderate amounts of thiamine, riboflavin, nicotinic and folic acid (Rasheed, 2003). Like most crops, Plantains require high amounts of nutrients for optimum growth and fruit production. Plantain cultivation has been reported to pose a significant declining effect on the soil nutrient reserve. For instance, the amounts of elements removed from the soil in the yield (Kg/Ha/Year) is K-1500; N-500; P-70; Ca-235; Mg-155; Mn-13; Fe-5.5; Zn-1.7; B-1.4; Cu-0.55 and their uptake of macronutrient is of the order; potassium (K) > nitrogen (N) > calcium (Ca) > magnesium (Mg) >phosphorus (P) and micronutrients in the order of manganese (Mn) > iron (Fe) > boron (B) > zinc (Zn) > copper (Cu) (Moreira and Fageria, 2009). In Edo State, farmers depend solely on the soil supply of most of the nutrients need of the crops thus making the yield of the crops to be sub optimal thereby compounding the current problem of food insecurity in the region. Research findings have shown some positive response of the crop to organic manure (poultry manure) as reflected in the size of bunches and fruits, total dry matter content and yield (Ndukwe *et al*, 2011). Similarly, even though most farmers seem to appreciate the positive role poultry manure could have on the crop yield, there is still a dearth of information on the frequency of application of organic materials base on soil test results to existing field. Hence, the objective of this study is to evaluate some selected physico-chemical soil quality indices of an existing plantain field treated with poultry manure rates in Edo state Nigeria.

MATERIALS AND METHODS

The experiment was sited at the teaching and research field of Ambrose Ali University, Ekpoma Edo State during the 2015 cropping season. The treatment consists of five rates of poultry manure (0, 15, 25, 35 and 45 t/ha) applied to a newly establish plantain farm arrange in randomize complete block design (RCBD) and replicated three times (3). Prior to field establishment and treatment administration, soil samples were collected from designated point across the field at a depth of 0 – 15 and 15 – 30 cm using an auger. The samples were bulk to form a composite sample upon which sub samples were taken out for physico-chemical analysis.

Similarly, at one year after field establishment, another group of soil samples were obtained from a depth of 0 – 15 cm and 15 – 30 cm base on individual plots to assess the nutrient status of the soil. All samples collected were air dried, sieved using 2 mm merge sieve and bagged in a well label polythene bags in readiness for laboratory analysis of the following physico-chemical properties; total nitrogen, exchangeable calcium, (Ca) magnesium (Mg) and potassium (K), available P, Soil pH, organic matter and soil texture. These soil properties were purposely selected based on their intensity of uptake as defined by Moreira and Fageria, (2009), and analyze using standard laboratory procedure as described by IITA (1991). Similarly the poultry manure use for this study was also analyzed using the same procedure and the results presented in figure 1 below.

Statistical analysis: The collected soil parameters were subjected to analysis of variance using GENSTAT Release 7.2DE, Discovery Edition 3 (GENSTAT, 2007) and the treatment means were separated using LSD at 5% and 1% level of probability.

RESULTS AND DISCUSSION

Results of the soil properties before planting of plantain are shown in Table 2. Results show that the pH of the soil was acidic at both the top (5.75) and sub (4.92) soil level. This pH value fall below the range of 5.0 to 6.8 reported for most agricultural soils in the tropics (Udo and Dambo, 1979); but represents the typical characteristics of ultisols of southern Nigeria. The pH value decreases with depth. Particle size distribution of the soil showed clearly that the soils are sandy loam and sandy - clay - loam at the 0-15 and 15-30 cm layer respectively with high proportion of sand and clay. Proportion of the main primary nutrients, N, P and K were all low except available P which was slightly higher in the 0-15 cm layer (68.99) than the sub soil (15- 30 cm) 60.03 mg/kg. N and K maintain the same trend at both depths. Irrespective of depth, base saturation were high in the soil with relatively higher values (99.80 %) reported in the top soil.

Soil properties at plantain fruiting

Result of the analysis of variance as shown in Table 2 indicates that pH of the experimental soil ranges from 5.04 to 5.962. The highest and lowest soil pH value was reported with the application of 15 and 45 tons/ha respectively of poultry manure. Application of poultry manure at higher rates tend to increase soil pH but not significant ($p<0.05$) to cause any serious changes on the soil pH status. This could be attributed to the lower pH value of the poultry manure incorporated. Soil pH on the other hand was significantly higher in the top soil (0-15 cm) than the sub soil (15-30 cm). Irrespective of soil depth, soil pH was strongly acidic thus depicting typical characteristics of ultisols of southern Nigeria. The concentration of nitrogen for instance fall within the range of 0.148 to 0.168 percent; which were consider low in all the treatment groups including the control. Significantly higher percent N was reported in the top soil than the sub soil. Increasing the rate of poultry manure does not translate to an increase soil N content. Similarly, the significant variation of N content with depth in all the treatments is a reflection of the high uptake/utilization of the available N in the top soil by the actively growing plant thereby creating no room for nutrient loss via leaching. Phosphorus content of soil was relatively higher in all the treatment including the control. The application of 35 tons/ha of poultry manure gave the highest (48 mg/kg) value of P. The higher value of P reported in the experiment could be related to the higher P content of the poultry manure (230 mg/kg) use in the trial in line with the work of Herencia *et al*. (2007) who reported that animal manure applied to soils have high soil P, K, Ca, Mg and NO_3 than soils to which inorganic fertilizers have been applied.

Potassium (K) content of the soil follow similar trend with other nutrients earlier discussed. K content of the soil fall within the range of 0.417 to 0.560 Cmol/kg. Increase application of manure does not significantly increase the K content of the soil. K was reportedly higher in the top soil than the sub soils. In practical terms, soil exchangeable K was within the standard range of 0.3 – 0.6 Cmol/kg and thus consider moderate. However, considering the fact that K is one of the limiting nutrient for plantain growth, relatively high (0.6 – 1.2) to very high (1.0 – 2 cmol/kg) K content is ideal to achieve significant yield of the crop. Research findings have shown that insufficient K supply reduces the total dry matter production and its distribution within the plant (Haifa, 2014). Calcium and magnesium content of the soil were moderate to high in all the treatment groups and posed no significant limitation to the continues existence of the plantation. As at the time of soil assayed, organic matter content of the soil were significantly higher in all the treatment with higher value reported in the 35 tons/ha rate of application. In general terms, the higher concentration of P, Ca, Mg, K and Mg observed in the top soil could be due to their limited mobility in the soil (Anderson *et al*., 2010).

CONCLUSION

Soil pH and texture were improved with increase application of poultry manure up to 45 tons/ha. All the nutrients were significantly higher in the top soil than the sub soil. The investigation however revealed that supplementary inorganic nitrogen is needed to balance the high P. K, Ca and Mg supply by the 35 tons/ha poultry manure for sustained growth of plantain under similar condition in Edo state.

USE OF MAIZE COB ACTIVATED CARBON TO REMOVE AMMONIA FROM AQUACULTURE WATER

A. Jauro & K. Ibisu

Department of Fisheries, Modibbo Adama University of Technology Yola P.M.B. 2076, Adamawa State, Nigeria
iliyasaj@yahoo.co.uk

ABSTRACT
This study using maize cob activated carbon to remove ammonia from aquaculture water was conducted at the laboratory of the Department of Fisheries, Modibbo Adama University of Technology Yola, Nigeria. The activated material was impregnated with 30% aqueous solution of potassium hydroxide (KOH) as activation agent. Ten juveniles of Clarias gariepinus of 7g average weight were randomly selected and stocked into four respective tanks and were administered diet of 30% CP (T1), 35% CP (T2), 40%CP (T3) and the fourth tank being the control was fed with 30% CP at 7% of body weight per day. Two hours after stocking, the water samples were collected from each tank and analyzed for ammonia. The results indicated positive presence of ammonia. 30g of the granular activated carbon was applied to each of the treatment tanks except the control tank. Then after three hours the water was collected and tested for ammonia concentration. The result indicates a reduction in the accumulation of ammonia but an increase of ammonia concentration in the control with the following correlation values between the treatment tanks and control: 0.08mg/l - 0.032, 0.22mg/l - 0.032mg/l, 0.32mg/l - 0.14mg/l and 0.08mg/l - 0.44mg/l and the correlation values are: -0.71984, -0.68166 and -0.32965. The data generated were analyzed statistically by using one way Analysis of Varriance (ANOVA). The mean and correlation were separated by Duncan Alpha range test.

INTRODUCTION

Ammonia is the major waste product in the elimination of excess amino acids from the breakdown of proteins in fish (Durborow et al., 1997). When fish is fed with high protein diet, they utilize the amino acids from protein digestion and excess amino acids are converted to ammonia which is excreted through the gills and in the faeces. In water, ammonia occurs in two forms represented as ammonium ions (NH4+) and unionized ammonia(NH_3). Between the two forms, the unionized form (NH3) is more poisonous to fish (Durborow et al., 1997). Ammonia is acutely toxic to fish and can cause loss of equilibrium; increased breathing, cardiac output, and oxygen uptake, and in extreme cases; convulsions, coma and death. Fish exposed to low levels of ammonia, overtime, are more susceptible to bacterial infections and will not tolerate routine handling (Svobodova et al., 1993). Several factors have been shown to modify acute ammonia toxicity in fresh water. Some factors alter the concentration of NH_3 in water by affecting the aqueous ammonia equilibrium,while other factors affect the toxicity of NH_3itself, either by ameliorating or exacerbating its effects (Kefi, 2008). Activated carbon is an environmentally friendly adsorbent which can be derived from many different local raw materials and can be produced in varying production processes. The raw materials used, activation process, and process parameters determine the physical properties and performance characteristics of the resulting carbon. Hence maize cob is readily available, commonly known and very cheap.

The performance of activated carbon is indicated by its adsorptive characteristics, which is derived from the specific surface area, pore size and pore volume, of the product (Lartey *et al*., 1999). The two basic methods of producing activated carbon from carbonaceous materials are thermal and chemical activation methods. Tsai *et al.*, (2001) reported successful production of activated carbon from corn cob with BET specific surface area exceeding 1600m2/g using a combination of the two methods. However, most products in the market are obtained from either thermal or chemical activation method. Some useful properties of activated carbon have been known since ancient times as stated by Bansal and Goyal (2005), Coulson and Richardson (2002), Beguin and Frackowiak (2010) and Jankowska *et al.* (1991)

The study was done to determine the use of maize cob activated carbon to remove ammonia from aquaculture water and determine the best level of application and its absorption time range.

MATERIALS AND METHODS

The method of Sichula *et al*.(2011) was adopted for this research. The Maize cob was obtained and thoroughly cleaned to remove unwanted particles. Then 100g of the material was weighed on a sensitive weighing balance and soaked in prepared 30% wt aqueous solution of potassium hydroxide in the ratio1: 6 and left overnight for twelve (12) hours.

Water was drained from the material and then oven dried for thirty minutes at a temperature of 100°C. Pyrolysis of the mixture was done using a Cestar 2123 model muffle furnace and charred for twenty (20) minutes at a temperature of 600^0C and cooled using a dessicator The sample was the washed with distilled water until the water pH was 6.5-7.0. This was done so that the materials being impregnated with the strong base doesn't increase the pH of the experimental tank water. After the washing, the material was again oven dried at a temperature 100^0C overnight and cooled. The activated carbon was then stored in an air tight bag.
Fourty juveniles of *Clarias gariepinus* were collected from Teaching and Research Fish Farm of the Department of Fisheries MAUTECH, Yola and acclimatized to the laboratory condition for one day. Thereafter they were transfered into the experimental tanks. Three experimental tank and one control tank were used. Ten juveniles of the *Clarias gariepinus* were randomly selected and stocked in each of the respective tanks. Tank 1 was administered diet containing 30% CP, tank 2 was administered diet containing 35% Cp and tank 3 was administered with 40% CP diet. The control tank was administered 30% CP diet. The fish were fed at 7% of the total body weight.
Thirty (30) grams of the granular activated carbon of mesh size 2-2.8mm were weighed and applied to the treatment tank 1, 2 and 3. In tank 1, the activated carbon was immersed to the bottom, in tank2, the activated carbon was suspended midway and in tank 3, the carbon were scattered on the surface of the water. While in the control tank no carbon was applied.
The water in each tank was tested for NH_3, pH and temperature before commencement of the experiment and thereafter at two hours interval until the adsorption limit of the activated carbon became constant.
The data collected were analyzed using one way Analysis Of Variance (AVOVA) and means were separated using Duncan Alpha range test. Correlation was used to compare the significant difference between the various treatment of means.

RESULTS AND DISCUSSION

Table 1 shows the *ammonia* concentration for a period of eight hours. At the initial time of zero hour, in the control, the highest value of *ammonia* is 0.44mg/l at the 8th hour while the lowest value of 0.05mg/l was recorded at the zero hour of the control. In treatment 1, at the initial time of zero hour, the *ammonia* was 0.05mg/l while the highest value of *ammonia* was 0.03mg/l at the 8th hour. In treatment 2, the lowest value recorded for ammonia was 0.05mg/l at the initial while the highest value was also 0.03mg/l at the 8th hour. And in treatment 3, the lowest value recorded for *ammonia* concentration was 0.05mg/l at zero hour and has the highest of value of 0.14mg/l being recorded at the end of the 8th hour with the respective values for Hydrogen potential (pH) and temperature during the experiment.

Figure 1 shows the *ammonia* concentration profile in the treatments and the control when *activated carbon* applied after 2 hours. In treatment 1, the level of *ammonia* reduced from 0.08mg/l to 0.03mg/l after the 8 hour. In treatment 2, the value of *ammonia* decreases from 0.22mg/l to 0.03mg/l after the 8 hour, while for treatment 3, the reduction was from 0.32mh/l to 0.14mg/l when the activated carbon was applied. In the control tank (without *activated carbon*) the *ammonia* concentration increased from 0.08mg/l to 0.44mg/l at the 8 hour.
In table 2, the mean *ammonia* concentration for the control tank did not show any significant difference throughout the 8 hours of the experiment. In treatment 1 (T1),the mean value obtained after 3 hours was significantly different from the mean values obtained after 4, 6 and 8 hours. In treatment 2 (T2), the mean value obtained after 2 hours was significantly different from the initial mean value and the value obtained after 4 hours. In treatment 3 (T3), the initial value was significantly different from all the other mean values obtained after 2 hours, 3 hours, 4 hours, 6 hours and 8 hours ($p<0.05$).
In Table 3, Treatment 1 is negatively correlated to the control (r=-0.71984), T2 is negatively correlated to control (-0.68166), and T3 is also negatively correlated to the control with a value of -0.32965 while T1, T2 and T3 are positively correlated. In Table 4, the quantity of *ammonia* increases from 0.08mg/l to 0.44mg/l at 8hours in the control tank (without activated carbon). In T1, the quantity reduces from 0.08mg/l to 0.03mg/l at 8hours. In T2 (with activated carbon) the quantity reduces from 0.22mg/l to 0.03 and in T3 (with *activated carbon*) the quantity reduces from 0.44 to 0.14mg/l at 8hours. The statistical analysis indicated significant negative correlation between the concentrations of *ammonia* and time (hours) in treatment 1 and control was found to be significant at r=-0.71984, 0.68166 in treatment 2 and for treatment 3 at r =- 0.32965.This agrees with the work of Sichula (2011) who fed the fish with 40% CP and after the application of the activated carbon, he noted the concentration decreases towards a constant value which indicates the adsorptive capacity of the *activated carbon* in the water. The result of the mean *ammonia* concentration in this experiment after the application of *activated carbon* shows that all the methods of application (bottom, midway and surface) of the activated carbon were effective however when the activated carbon was suspended midway of the tank (treatment 2) followed by when it was submerged

at the bottom of the tank (treatment 1). Sichula *et al*. (2011) carried out a related study and found the concentration of ammonia to decline when the *activated carbon* was produced using physical activation method and work done by Ajayi and Olawale (2009) proved that chemical activation method was more effective when a suitable precursor was selected. However, bottom application of activation carbon to aquaculture water may not be good for earthen ponds and concrete tanks with a lot of sediments at the bottom as this could block the micro pores of the activated carbon.

The result of this study differs from the result obtained by Sichula *et al.* (2011) due to the large quantity of the activated carbon applied which led to the short period of time before obtaining constant value of the ammonia being absorbed by the activated carbon.

CONCLUSION

In conclusion, the best method established from the experiment in the application of the activated charcoal was found to be more useful when the charcoal was suspended at the water column. And this could be attributed to the fact that the uneaten feed has the tendency of blocking the micro pores of the *activated carbon*. Therefore, by implication it means that it is not advisable to use the *activated carbon* in earthen ponds where there are a lot of soil sediments and other organic substances at the bottom. Likewise, scattering the *activated carbon* on the surface of the water is not very suitable as part of the *activated carbon* will be outside and this portion of the material may not be useful during the adsorption process.

The adsorption time range varied with the crude protein content of the feed administered which gave an indication that the more the accumulation of *ammonia* the more the quantity of the *activated carbon* that should be used.

ABSTRACT
Soil degradation has become the most important challenge to sustainable agriculture and food security. Soil degradation is a global problem caused by many factors including excessive tillage, inappropriate crop rotations, excessive grazing or crop residue removal, deforestation, mining, construction and urban sprawl. Consequently, per capita food production, income and savings have been falling. Nonetheless, despite the seriousness of soil degradation problems and its negative consequences on food security and income to individual households and the nation at large, the magnitude of the threat that soil degradation poses on current as well as future income and how best to address the problem is not well known. To meet the needs of an expanding global population, it is essential for humankind to recognize and understand that improving soil health by adopting sustainable agricultural and land management practices is the best solution for mitigating and reversing current soil degradation trends.
Keywords; Soil, degradation, deforestation, plant residues

INTRODUCTION
The term 'Soil degradation' refers to processes that causes a reduction in the capacity of the soil to produce goods and services for needs and benefit of current and future generations (Pittekow *et al*., 2014). Soil degradation is undesirable since it results in land becoming less useful and productive. The ability of soil to support plants and animals declines due to reduction in its capacity to retain and supply adequate moisture and nutrients required for optimal growth of crops (Sanchez and Swaminathan, 2005, Gracia-Franco *et al*., 2015). It is therefore, important that we understand what causes soil degradation and what is required to prevent soil degradation for sustained agricultural productivity and related services that the soil provides. Soil degradation is also the decline in soil quality caused by its improper use, usually for agricultural, pastural, industrial or urban purposes. Soil degradation is a serious global environmental problem and may be exacerbated by climate change (Graves *et al*., 2015). It encompasses physical, chemical and biological deterioration. Examples of soil degradation include: loss of organic matter, decline in soil fertility, decline in structural condition, erosion, adverse changes in salinity, acidity and alkalinity. Soils host the majority of the world's biodiversity and healthy soils are essential to securing food and fiber production and providing an adequate water supply over the long term. Ecosystem services provided by soils are integral to the carbon and water cycles and include cultural functions. There are strong links between climate change and soil condition. Increases in soil carbon can help to mitigate greenhouse gas emissions and enhance adaptation to climate change (Guo and Gifford, 2002; Johnson *et al*., 2009)

Soil Degradation
Soil degradation is the temporary or permanent lowering of the productive capacity of soil caused by overgrazing, deforestation, inappropriate agricultural practices, over exploitation of fuel wood leading to desertification and other man-induced activities (Wall and Six, 2015). Processes of soil degradation are grouped into six classes: (Van *et al*., 2013; Vepraskas *et al*., 1986; Willison *et al*., 1995). Water erosion, wind erosion, soil fertility decline, salinization, water logging and lowering of the water table. (i) Soil erosion by water includes inter-rill and rill erosion, gullying, and land sliding caused by clearing of vegetation and road construction. Soil erosion by wind produces sand dunes. (ii) Soil fertility decline refers to deterioration in soil physical, chemical and biological properties caused by (a) reduction in soil organic matter status, leading to decline in soil biological activity; (b) degradation in soil physical properties (structure, aeration, water holding capacity) caused by reduced organic matter(c) adverse changes in soil nutrient status, including reduction in availability of the major nutrients (N, P, K), initiation of micronutrient deficiencies and development of nutrient imbalances; and (iv) build up of toxicities (by heavy metals, xenobiotics, and acidification through incorrect use of fertilizers). (iii) Water logging is caused by over irrigation, and restricted infiltration of water into the soil. This lowers land productivity through rise in ground water close to the soil surface. (iv) Salinization refers to all types of land degradation brought about by increased concentration of salts in the soil. It occurs by planning mistakes and mismanagement of irrigation schemes (salinization in the strictest sense), and sodification (also called alkalinization), which refers to the dominance of the exchange complex by Na^+. (v) Lowering of the water table is brought about by pumping of ground water for irrigation which exceeds the natural recharge capacity. Pumping of water for urban and industrial

use also causes this form of land degradation. Other types of land degradation include (i) deforestation, (ii) forest degradation (reduction in biotic resources and lowering of the productive capacity of forests), (iii) range land degradation (lowering of the productive capacity of range lands), (iv) acid sulphate formation, (v) soil pollution, (vi) soil destruction through mining and quarrying activities, (vii) urban and industrial encroachment on to agricultural land, (viii) destruction of irrigation schemes, and (ix) potential effects of global climatic change (including global warming which may lead to modifications in the general atmospheric circulation, causing changes in rainfall pattern) (Amundson *et al*., 2015).

Causes of Soil Degradation

1. Physical factors, e.g. loss of fertile top soil due to water or wind erosion.
2. Chemical factors e.g. depletion of nutrients or the toxicity due to acidity or alkalinity (salinization) or water logging.

Physical Degradation

Physical degradation is caused when agricultural practices impact the physical property of soils in ways that result in adversely impacting critical soil functions (Lal, 2015). In intensively cultivated soils, repeated use of heavy farm machinery for tillage related activities often results in compaction and formation of hard pan at the plough depth. Compacted soil layers restrict root growth and penetration. Physical degradation is also caused by practices that expose the soil (cultivation) (Powlson *et al*., 2014) to direct impact of rain and wind causing soil erosion resulting in physical displacement of soil particles. High wind speeds particularly during summers, carry the smaller sized clay and silt particles that can remain suspended in the air for days (Lal, 2012). The heavier sand sized particles on the other hand move from one place to another to varying distances depending on wind velocity, soil condition, etc. Similarly, when high velocity raindrops strikes bares oil surface, the soil aggregates break down clogging the soil pores, causing much of rain water flow as runoff carrying the top organic matter rich soil with it.

Chemical Degradation

Chemical degradation refers to processes that cause changes in the chemical environment of soils adversely impacting their productive capacity. Amongst common farming practices, inappropriate use of chemical fertilizers and pesticides can contribute significantly to the degradation process (Sousana and Lemaire, 2014). Tate (2015) showed that prolonged use of heavy doses of fertilizers can result in soils becoming more acidic that has serious implications in terms of long term productivity of soils. Inappropriate, viz. imbalanced or excessive, use of fertilizers is a major cause of pollution of ground waters or surface water bodies resulting from inefficient use of applied nutrients. Distribution of wheat roots in sodic and normal soil, about 100 days from planting Results of most long term studies emphasize the need to use chemical fertilizers conjunctively with recycling of organic farm wastes for sustained productivity. Gaseous N2 losses from fertilizers constitute a significant part of GHG emissions from agriculture related activities contributing to global warming Turpault et al., 1996; Reay and Nedwell, 2004). Pest control chemicals utilised to eliminate unwanted pests (or weeds, insects etc) are also detrimental to living organisms in the soil, vital to soil health and productivity. Rational and wise use of chemicals is therefore important to minimise adverse impacts associated with their use. In a large fraction of irrigated agriculture, groundwater is the primary source of irrigation. Ground water invariably contains varying amounts of salts that tend to accumulate in the root zone over a period of time. Excessive salts in root zone are detrimental to plant growth and in extreme cases render the soil completely unproductive (Qadir *et al*., 2014)

Biological Degradation

Soils are a habitat to a large variety of flora and fauna that constitute a significant part of our biodiversity resource. Organic matter is the main food base of living organisms in the soil and soil organisms perform vital functions that contribute to sustained productivity of soils. Reduced recycling of organics through the soil is the primary factor leading to a decline in the extent and diversity of living organisms within it. Agricultural practices that donot emphasize integrated nutrient management involving the optimum use of on-farm residues together with such practices as tillage, burning of crop residues etc. cause depletion of organic matter and in turn result in loss of a soil's biological population. Other agricultural practices like mono-cropping where the same crop (eg cereals) are grown repeatedly year after year without adopting crop rotations also lead to decline in soil biodiversity. Punjab farmers burn crop residue to prepare land for next sowing.

CONCLUSION

Soil degradation is a complex issue. It is caused by the interaction of physical forces and human activities. Its impact is increasing and is having a negative effect on food production. Some areas are more badly affected than others but in a globalized world the impacts are felt worldwide. The method of dealing with soil degradation depends on the cause of the problem, but also the resources available to the host country. Degradation is likely to increase over the next decades as a result of: climate change; population growth; the use of increasingly marginal areas for living and food supply.

COSMOVISION IN SOIL RESOURCES MANAGEMENT

G. O. Chukwu & P.O. Osuji

Department of Soil science and Meteorology, Michael Okpara University of Agriculture, Umudike, Abia State
goddychukwu2003@yahoo.com

ABSTRACT
Cosmovision of soil resource management is an intellectual resources that can be lost due to globalization. Yet it sustained and still stains agriculture in traditional farming system. Some of the measures adopted includes presentation of sacred groove, agroforestry system, land rotations, inter-cropping system and organized manuring to prevent soil erosion and increase soil productivity. Having examined critically the importance of cosmovision, it is anticipated that familiarity with it and the culture of any area of interest in relation to natural resource management need to be studied to know where the people are and any interventions from outsiders to improve on the peoples knowledge.
Keywords: cosmovision, soil fertility, management, agroforestry

INTRODUCTION
Cosmovision refers to the way certain populations understand life, the world, and the cosmos. The relationships between the social world, the natural world, and the spiritual world are central to people's cosmovisions. Cosmovision explains the ways in which natural processes take place and the roles played by supernatural powers. Philosophical and scientific premises are made explicit (Haverkort and Hiemstra 1999).
Huizer (1999) describes it as a *"holistic awareness"*, an inner civilisation from which we can learn. For many rural, but also urban people throughout the world, their cosmovision still feeds many aspects of their life, including their spirituality, day-to-day actions, rituals, symbols and arts, food production, and relationships with nature and other community members. Cosmovision has a significant impact on the way people organize their lives. Traditional ecological knowledge has a historical continuity of resource use practice that is based on an integrated system of knowledge, practices, and beliefs including cosmology (Berkes*et al*., 2000). Therefore, knowledge about the cosmovision of a people is important for any outsider wanting to develop technologies together with them.
In 70 nations, over 370 million indigenous people have retained their cultural, social and economic characteristics that are distinct from those of the dominant societies in which they live (Schmidt and Peterson, 2009). This has far-reaching implications for field methods such as Participatory Technology Development. The case descriptions on PTD have generally been based on the assumption that farmers use a "western logic" in their experimentation. Anthropological research (e.g. Reader 1988) suggests that the cosmovision demands that more variables be taken into account than merely biophysical factors.
The cosmovision of soil resource management aim to improve situation in the soil and proper conservation and management of the soil, it is crucial to understand processes and relationships in the sociosphere. However, it is argued that a thorough understanding of cultural roots, beliefs tradition and power relations is essential for the conservation and sustainable management of resources at community level.

INDIGENOUS KNOWLEDGE
Indigenous knowledge (IK) is gaining increasing attention and its' importance in sustainable development is well-recognized (Warren and Rajasekaran 1993; Kolawole 2001; Samal *et al*, 2010). In various places in the world, scientists and indigenous people are collaborating to build bridges between modern science and indigenous knowledge, among others, to improve ecological management of a particular region (Reijntjes 2004, 41). Policy makers and agricultural development planners are beginning to recognize the need to understand indigenous knowledge systems and have shown renewed interest in this type of knowledge (Warren and Rajasekaran 1993).The importance of integrating indigenous knowledge into contemporary conservation and sustainable management of natural resources has also been well reviewed (Rist and Dahdouh-Guebas ;2006). Recognizing indigenous knowledge means acknowledges locally developed solutions, based on existing culture, values, and beliefs and practices which otherwise could be barrier in development efforts. Moreover, farmer's ideas which were in the past regarded as primitive or misguided are now being seen as appropriate and sophisticated (Chambers 1983). Farmers have quite a sophisticated knowledge of agriculture based on insights from several generation (Kolawole, 2011). Most of the cosmovision knowledge is taught to the young by elders orally. Much of that knowledge is preserved in the form of folk songs, proverbs, myths, and sages. Generally folk songs are mostly retained by village women, whereas the knowledge relating to the agricultural activities of men is often

preserved in the form of dance and instrumental music. Instruments, such as the sacred drum and horn are used at special occasions by elders (Linquist and Adolph 1996).

COSMOVISION IN SUSTAINABLE SOIL DEVELOPMENT

Historically, along with collection of forest resources the hunter gatherers or tribal societies have been practicing marginal agriculture. The agricultural practices of tribal communities follow some traditional norms including rituals, festivals and techniques. These practices are followed to increase the land fertility, soil conservation, moisture balance and pest control that subsequently have developed a wide range of site specific technologies (Haverkort, 1995; Cleveland, 1998). In India, the traditional agricultural practices may vary across the agro-climatic zones. The diversity in soil types and diverse geographical conditions lead to diverse agricultural systems. The important forms of agriculture in India are settled, shifting and agroforestry based agriculture systems (Ramakrishnan, 2002; Kala *et al*., 2008). All these forms of agriculture are under pressure with the changing land use practices, increasing human population, and overexploitation of land resources that have subsequently resulted in the land degradation, particularly declining soil fertility and escalating soil erosion. Land degradation has been a problem ever since humans settled the land and started domesticating plants and animals (Sanders, 2004), hence the farmers had devised some indigenous practices and systems of land use to maintain and restore the quality of their lands, which remained an indispensable tool for sustained crop production (Tekwa *et al.*, 2010). Unfortunately, these indigenous practices have seldom been recognized in the race for modernization and development; therefore, at present, most of such practices have reached to the verge of extinction.

However, the importance of traditional agricultural practices has been receiving attention for food security (Rajasekaran and Whiteford, 1992), quality control and for biodiversity conservation (Gadgil *et al*., 1993). Some agro-forestry based studies show that traditional agriculture enhances the soil quality and helps agriculture in a sustainable ways (Berkes, 1999; Ramakrishnan, 2002; Kala, 2012).

The cause-effect relationship between human activities, such as soil tillage and crop husbandry, and crop performance are accepted and understood. Agricultural production can be improved by improving husbandry practices. Yet, such husbandry practices are only part of reality. The other part includes the spiritual influence on rainfall, health, crop performance and yield. This is acknowledged and requires sacrifices, festivals and taboos for funerals, drumming and war crises during certain periods in the growing season.

SOIL AND WATER MANAGEMENT

Herweg (2002), described role of IK in soil management to overcome labor shortage and optimize farm operations. The practices described include working arrangements (sharecropping and animal fatting) and gradual terrace building for degraded farm plots. Use of manure, compost and crop residue, soil burning, temporary structure (trash line) and indigenous grass and vegetation strip. Review by Herweg shows the role of IK practices in improving physical soil properties, nutrient recycling and fertility improvement. Liniger *et al* (2011) reviewed best practices in sustainable land management in sub-Saharan Africa and described a case study on traditional water harvesting system focusing on runoff and floodwater farming in Ethiopia. There are also reviews on traditional conservation measures by Reij (1991), bench terracing for chat (*Catha edulis*), Nyssen, *et al.,* (2000) on traditional technique "daget" in Tigray and indigenous fallowing in Wolyita Zone (Amede, 2001).

Experiences on how traditional African soil and water conservation concepts can be matched with participatory approaches are accumulating. They are resulting in increased understanding of farmer livelihoods, and more and more programmes today put farmers in the centre of their activities. However, many of these programmes hardly address the African worldviews, beliefs systems and the traditional systems of land tenure on which these practices are based. In the development literature, a general lack of information about the spiritual dimension of soil and water has been observed. Traditional functionaries, such as the earth priests, the spirit media and rainmakers who are traditionally consulted for issues related to land and water management by rural people, are hardly involved in rural development projects. In practice, the divide between anthropologists and development workers with a technical focus is quite deep.

CROPS AND TREES

An overview of literature on traditional management of crops and trees reveals that the subjects most frequently dealt with are sacred groves, agro-forestry, plant breeding, and crop cultivation. Again, the literature gives more information about the bio-physical aspects of traditional use of trees and crops, than about the cultural and spiritual dimensions, with exception of the studies on sacred groves. Several studies stress the importance of sacred groves in relation to the efforts of the rural people to appease the spirits related to rainmaking, good crops or health. Traditional spiritual leaders play an important role in the management of these important patches of high biodiversity. Several authors also indicate that sacred groves can be an important starting point for development and rehabilitation of savannah areas, forests and wetlands.

Indigenous agro-forestry is widespread and several systems are described in literature. Farmers know the equalities of trees, what they can be used for, and the possibilities and limitations of combining trees with crops. Some tree species have a spiritual significance, which is reflected in taboos and rituals associated with them .Many studies on the traditional cultivation practices of crops, including traditional food crops and wild plants ,can be found.

LIVESTOCK KEEPING

Livestock systems in Africa are extremely complex. In a broad sense we can distinguish between two major livestock systems, which are the extremes of a continuum: livestock systems associated with settled farmers and pastoral husbandry systems. The role of animals in the spiritual life of African rural people is quite unique and has been the subject of several studies. Literature describes beliefs and practices related to livestock on aspects like feeding, breeding, animal health, small stock and wild animals.

Literature also shows the immense changes that African livestock productions systems are undergoing currently, especially the pastoral systems, due to modernization, population growth and government policies. It is necessary to look at indigenous knowledge related to livestock in the context of the culture of the people involved. In many ethno-veterinary and animal husbandry studies, this aspect has been overlooked, focusing mainly on the use of medicinal plants for curing diseases. There is much potential in activities that combine ethno-veterinary aspects with village based animal health care. There is a imbalance in the extent to which the different animal species are studied, and the use and importance of the species in rural peoples' lives. For example, most literature on fowl deals with chicken, though many families s use a combination of species including guinea fowls, ducks, turkeys and pigeons. There is potential for working with rural people, especially women, by focusing on these 'non-traditional' species.

The role of women related to livestock is subject to many changes. In some cases they become more involved in livestock, in others less; the effect on their social position and status also shows a wide variation. In the last decades there has been a decline in 'conventional' livestock projects, due to disappointing results, especially the range development projects, and the projects based on the import of exogenous breeds. Meanwhile, the number of 'innovative' projects, for example on ethno-veterinary medicine and village-based animal health care, has increased.

CONCLUSION AND RECOMMENDATIONS

Cosmovision is the secret behind sustainable land management in many rural communities in Nigeria and other parts of the tropical world. Familiarity with the cosmovision and the culture of any area of interest in relation to natural resource management, need to be studied to know where the people are and any interventions from outsiders to improve on the peoples knowledge. A non-bias, but critical relationship with the traditional and spiritual leaders, and with other members of the community is recommended.

ABSTRACT

Applying animal manure to the soil is one of the ways of improving the soil properties for crops production. An incubation study was carried out at the Department of Soil Science and Meteorology laboratory of Michael Okpara University of Agriculture, to investigate the effect of types of animal manure on some soil acidity indices. The treatments comprised of Poultry manure (PM), Pig waste (PW), Cow dung (CD), Goat manure (GM) and a Control (C which has no amendment). The application rates of the animal manure were 0t/ha, 1.5t/ha, 3.0t/ha, 4.5t/ha, 6.0t/ha, and 7.5t/ha. Their various grams equivalent were applied to 300 grams of soil used for the study. The applied treatments were replicated three times in a 4x6 factorial experiment in a Completely Randomized Design. The experiment lasted for sixty-three days and the leachates were analyzed at twenty-one days intervals. The pre-treatments soil analysis and the chemical composition of the treatments were determined. The following leachate analyses were determined: soil pH and exchangeable acidity using the standard laboratory procedures. The results obtained showed that at day one of the incubation, the leachates from containers that received PW significantly ($p \leq 0.05$) increased the pH to 7.1 when the treatments was applied at 7.5t/ha as against the control that gave 5.66. The value of pH 10 was recorded for the leachate of the PM amended soil at 7.5t/ha whereas the control gave 5.53 at the 42nd day of incubation. Treatments applied at 7.5t/ha irrespective of the animal manure type, gave the lowest significant ($p \leq 0.05$) mean values of 0.47, 0.15, 0.09 and 0.06comlkg^{-1} for exchangeable acidity at day 1, 21st, 42nd and 63rd day of incubation respectively. The results generated from the study gave an explicit indication that PM and PW have the abilities of increasing the pH and decreasing the exchangeable acidity of the soil leachate. Carrying out further research studies to authenticate the incubation result is recommended.

Keywords: Vertisols, animal manure, incubation, leachate.

INTRODUCTION

One of the natural functions of the soil is to support plant lives. This it does by providing the plants with the necessary nutrients for its growth and development. Unfortunately, these nutrients are always limited in the soil when the plants need them. The reasons for this may be because the nutrients are depleted by previous plant uptake, leaching or fixation. Fixing of nutrients usually take place in acidic condition. Soil gets acidifies when H^+ ions are released in the soil from processes which include transformation and cycling of C, N and S in managed ecosystems (Bolan, *et al.*, 2003). In acidic soils, there is decrease in pH, base saturation, and unbalanced availability of elements in the root environment as well as decrease of the acid neutralizing capacity (ANC) of the soil (Van Breemen, 1991).

Other situations found in acidic conditions are sorption of large concentration of H^+, which creates positive charges (Adriano, 2001) on the variable charge surface in soil. As soil acidic increases, there is a decrease in pH and this increases the concentration of Al, Fe and Mn in soil solution. When this happens, it leads to the adsorption or precipitation of phosphorus which will result in its unavailability for the crops and deficiency (Haynes, 1984). Many materials have been used to ameliorate the soil acidity, one of which is animal manure. Animal manure when added to acidic soil, increase the pH. This it does by forming phenolic humic –like materials which are organic anions and take up protons from the soil which raise the pH (Narambuye and Haynes, 2006; Haynes and Mokolobate, 2001). The incorporation of animal manure into the soil is a long term agricultural practice that had been used to improve the soil properties and fertility status of the soil. It is also an effective way of disposing the waste, which if left unattended to would cause environmental and health issues to the society (Sommer, *et al.*, 2013).

Various types of animal manure have different chemical compositions and as well as affect the soil properties different. It is important to determine the animal manure that would enhance the soil properties. It is therefore based on this fact that the objective of this work was established to investigate some chemical changes that occurs in the soil pH and exchangeable acidity of the soil leachate as types of animal manures were applied to the soil.

MATERIALS AND METHODS

The experiment was an incubation study carried out at the department of Soil Science and Meteorology laboratory at Michael Okpara University of Agriculture Umudike (05° 29` N, 07° 33` E and 122 m above sea level). The mean annual rainfall of Umudike is 2200 mm and this is distributed over a period of nine to ten months in bimodal rainfall pattern (NRCRI 2015). The soils used for the study were vertisols collected from the farms of some smallholder rural farmers located at Bende L.G.A (5° 74'N, 7° 52'E) of Abia State, Nigeria. Soil samples were collected randomly with a soil auger from the depth of 0- 15 cm. The samples were bulked, air-dried, ground, and pass through a 2.00mm sieve mesh. From the composite soil, 300g of the soil was taken for each treatment and weighed into 500mL plastic containers. Each of the containers was uniformly perforated at the base and a cheese cloth used to line the base of the beaker to prevent loss of soil. Another container of equal volume was fitted underneath it for the collection of the drained water. The containers with the soils were labelled appropriately and kept on the laboratory benches.

The treatments comprised of four types of animal manure namely: Poultry manure (PM), Pig waste (PW), Cow dung (CD), Goat manure (GM) and a Control (C which has no amendment). The animal manures were all collected from the livestock unit of Michael Okpara University of Agriculture, Umudike. They were cured for three weeks and were applied after being passed through a 2 mm sieve mesh. The application rates were in tons/hectare but their grams equivalents were applied because of the weight of the soil used. The rates were 0t/ha (control), 1.5t/ha (12.95g), 3.0t/ha (25.90g), 4.5t/ha (38.85g), 6.0t/ha (51.80g), and 7.5t/ha (64.75g). The chemical properties of the treatments are presented on Table 1.

Table 1: Chemical composition of the amendments used for the study

Properties	Cow dung	Goat manure	Poultry manure	Pig Waste
pH (H_2O)	5.86	5.78	6.98	6.62
% N	2.10	2.94	3.31	3.71
% P	0.86	0.82	1.66	0.94
% K	0.94	1.70	1.97	0.86
% Na	0.17	0.28	0.37	0.24
% Ca	2.51	2.52	4.92	3.12
% Mg	0.73	0.76	1.22	1.44

The treatments were added to the soils and both were mixed thoroughly. The experiment was a factorial experiment and the treatments laid out in completely randomized design (CRD). The treatments were replicated three times. The samples were incubated for sixty three days; the process started from Wednesday 8th July and ended on Wednesday 2nd August 2015. Thirty- three centiliter of deionized water was added to soil on 21st, 42nd and 63rd days of incubation and this stimulated the flow of the drainage water. The leachate samples from each of the containers were collected until the drainage water stopped over a period of 24 hours after which it was weighed. The following soil properties were determined; particle size analysis was done using Bouyoucos hydrometer method (Klute, 1965); soil pH was determined with the pH meter in water at a ratio of 1:2.5 soil to distilled water suspension (Thomas 1996); exchangeable acidity was determined by the method of Mclean (1982) as outlined by Udo *et al.*, (2009) using 1M KCI as the extracting solution and titrating with 0.01M NaOH, using phenolphthalein as the indicator. Others were organic carbon, which was determined by dichromate – oxidation method of Walkley and Black wet oxidation method as described by Nelson and Somner (1982); exchangeable calcium, magnesium, sodium and potassium were extracted with NH_4OAC. Calcium and magnesium were determined using Ethylene Diamine Tetra – Acetic (EDTA) titration method while potassium and sodium were determined by flame photometer (Rhoades, 1982). Effective cation exchange capacity (ECEC) was calculated as the sum of exchangeable basis (Ca, Mg, K & N) and exchangeable acidity expressed in cmol kg $^{-1}$. Available phosphorus was determined by Bray 2 method as described by Bray and Kurtz (1945) and total Nitrogen was determined by the micro Kjeldahl method (Bremmer and Mulvary 1965). The pH and exchangeable acidity of the leachates were determined using the methods of Udo *et al.*, (2009)**.**

The data generated were subjected to analysis of variance (ANOVA) for factorial experiment in Completely Randomized Design (CRD) using the GENSTAT package. The means were separated using the Fisher's Least Significant difference (LSD).

RESULTS AND DISCUSSION

The pre- treatment analysis of the soil is shown on Table 2. The result showed that the soil textual class was clay typical of vertisols. The soil values were 358gkg-^{1}, 314gkg-^{1} and 328gkg-^{1} for sand, silt and clay respectively. The pH of the soil was 5.5 and this value according to Chude *et al.*, (2004) is rated slightly acidic. The available

phosphorus was 19.10 $mgkg^{-1}$, the value was rated moderate according to Chude *et al.*, (2005) and it is above the critical level of 12 -15 $mgkg^{-1}$ given by Enwezor, *et al.*, (1989) for the soils of Southeastern Nigeria.
The result of the effect of animal manure types and rates on the pH of the leachate at day one of the incubation is shown on Fig 1. The result showed that there were no significant differences between the animal manure types and rates. The effect of the animal types and rates on pH of the leachate after 21 days of incubation show, that the applications of PM at all the rates gave higher pH leachate values than the rates of the other treatments. The highest significant ($p \leq 0.05$) leachate value was recorded at 7.5t/ha of PM. At the 42nd day of incubation (Fig 3), PM applied at 7.5 t/ha significantly ($p \leq 0.05$) increased the pH of the leachate. The values gotten for the applied poultry manure where statistically at par with the values obtained for leachates where PW were applied.
The applied PW significantly ($p \leq 0.05$) increased the pH of the leachate over the other treatments. Except for 0t/ha and 1.5t/ha, all the other rates of the PW had higher values over their counterparts rates. The highest significant ($p \leq 0.05$) value for the incubation at the 63rd day was obtained at the applied 7.5t/ha of PW. From the result of the mean effect of treatments on pH of leachate at days of incubation, PM gave the highest significant ($p \leq 0.05$) values of 6.67 and 6.87 respectively at the 21st and 42nd days of incubation. It was also observed that as the days of incubation progressed, the pH of leachate increased. Throughout the days of incubation, the treatments applied at 7.5t/ha irrespective of the treatment type, had significantly ($p \leq 0.05$) higher values over the other treatments rates. It was also observed that the pH of the leachates increased as the rates of application increased.
The result gotten on the effect of the animal manure types and rates on exchangeable acidity of the leachate at day 1 of incubation showed that there were no significant differences among the treatments and rates. At the 21st day of incubation, the rates of cow dung applied at 1.5, 3, 4.5 and 6t/ha had significantly ($p \leq 0.05$) lower exchangeable acidity values over the other treatments except at the 7.5t/ha where the poultry manure gave the lowest value of exchangeable acidity. At the 42nd day of incubation, all the rates of applied poultry manure significantly ($p \leq 0.05$) reduced the exchangeable acidity of the leachate over the other rates. The lowest reduction was recorded at the application of 7.5t/ha of the poultry manure. All the treatments and rates significantly ($p \leq 0.05$) reduced the leachate exchangeable acidity over the control at the 63rd day of incubation (Fig 10). From that same figure, the applied poultry manure at 7.5t/ha significantly ($p \leq 0.05$) reduced the exchangeable acidity of the leachate. The result has the mean effect of treatments on exchangeable acidity of the leachate at the days of the incubation. The result showed that there were no significant differences among the treatment means at the days of the incubation but the values of the exchangeable acidity decreased as the days progressed. The result obtained, which has the mean effect of rates on exchangeable acidity at days of incubation showed that at the days of the incubation, 7.5t/ha significantly ($p \leq 0.05$) reduced the leachate acidity.

DISCUSSION

The reason for the increase in the pH of the leachates of the soils that received poultry manure could be due to their humic fraction content. According to Noble *et al*., (1995), poultry manure contains humic fractions. These humic fractions are made up of mostly fulvic and humic acids and these occur as Ca-Fulvates and Ca-humates, which has the ability to increase the pH. This same reason was buttress by Wong *et al.*, (1998). They reported that the increase in the pH could be as a result of the functional group of the phenolic humic and fulvic materials from organic residue which are able to consume protons at their natural pH values, causing increased pH. Their capacity to consume protons is a major factor controlling their buffer characteristics and therefore their ability to neutralize soil acidity. The reason for the decrease in exchangeable acidity may be due to the fact that as the pH increases, the solubility of Al decreases and this makes Al to precipitate. Another reason for the decrease could be that the humus substances found in the manure may have form complex with Al and thereby detoxifying them. Organic acids from the poultry manure can form stable chelating complex with Al in solution (Stevenson and Vance 1989). The higher the rate of application of poultry manure, the more the pH increases and the lower the exchangeable acidity. Similar result of increasing application rates of chicken manure with progressive increase in pH of Ferralic Arenosol and Vertic Luvisol was observed by Dikinya and Mufwanzala (2010). It was also observed that the applied poultry manure and pig waste increased the pH as the day of incubation increased; this work is in agreement with the result reported by Rodella *et al.* (1995) who observed that there was an increase in soil pH from 4.90 to 7.50 in a 90 day incubation study when poultry manure was applied.

CONCLUSION

The study on the impact of types of animal manure on some soil acidity indices of the leachate of Vertisols in Bende L.G.A of Abia State Nigeria shows that animal manure: Poultry manure, Pig waste, Goat dung and Cow dung increased the soil pH leachate and reduced the exchangeable acidity all through the experimental period. Poultry manure and pig waste applied at 7.5t/ha gave outstanding results in improving the pH as well as reducing the exchangeable acidity. The study shows the potential of animal manure specially poultry and pig manure when applied to vertisols.

ABSTRACT
It is important to examine mechanisms of lead (Pb) sorption in soils to understand their bioavailability. The ability of the aggregates of two tropical soils to adsorb Pb was evaluated. Results obtained showed that equilibrium adsorption occurred faster on larger soil aggregate sizes. The adsorption of Pb on > 4, 2 - 1 and 0.5 - 0.25 mm soil aggregates of Amakama soils reached equilibrium in 180, 180 and 210 minutes, respectively. In Ajata-Ibeku soil, equilibrium was achieved in 120, 180 and 180 minutes, for > 4, 2 - 1 and 0.5 - 0.25 mm aggregates, respectively. Biphasic kinetics was observed, a rapid reaction rate followed by a slower reaction rate. Such biphasic kinetics suggested the presence of two types of sites - such as, external readily accessible sites and internal, difficult to access sites, with differing reactivities. Adsorptive efficiencies of the aggregates from the kinetics study varied in this order in both soils: 0.50 - 0.25 mm > 2 - 1 mm > > 4 mm. The quantity of Pb adsorbed by Ajata-Ibeku soils aggregates (3.39 mg/g) was higher than the quantity adsorbed by the Amakama soils aggregates (2.93 mg/g). The higher adsorption capacities obtained for Ajata-Ibeku soil relative to Amakama soil was attributed to the composition of the two soils. The distribution coefficients (K_d), were consistently higher in Ajata-Ibeku soils (213.7 l kg^{-1}) than in Amakama soils (33.2 l kg^{-1}), suggesting that Pb(II) was removed from solution by Ajata-Ibeku soils aggregates more than by Amakama soil aggregates. The distribution coefficients of Pb on the aggregates did not follow any particular trend in both soils, however, maximum partitioning of Pb to the solid phase of the soil aggregates was observed on 2 – 1 mm soil aggregates in both soils (692.05 and 12649.52 mg/kg in Amakama and Ajata-Ibeku soils, respectively).
Keywords: Tropical soils; Bio-availability; Sorptivity; Peds; Heavy metals; Contamination.

INTRODUCTION
Soil contamination by Pb is of great concern because of its toxicity to humans (Adriano, 2001). This element is used in many industrial, urban, and agricultural applications (Kabata-Pendias and Pendias, 1992; Adriano, 2001) and is often found at sites contaminated with heavy metals. Therefore, it is important for environmental scientists and engineers to understand its adsorption on soils aggregates, to be able to explain its bioavailability in the soil. The term 'sorption' has been used to describe the removal of metals in solution by the soil solid phase (Hooda and Alloway, 1998) including any retention mechanism that controls metals availability and mobility. When heavy metal ions are placed in aqueous soil system the ions tend to be distributed between the liquid and solid phases. Most of the metal ions become attached to the soil surface while some may penetrate the soil matrix. The metal ions attached to the soil surface is said to be adsorbed on the soil while the ones in the soil matrix is said to be absorbed by the soil. The two processes go together and are referred to as sorption. Since the amount of the metal ions absorbed by the soil is insignificant compared to the amount adsorbed on the soil, when a solution of metal ions is shaken with soil and the amount of metal ions left in the liquid phase is determined, the difference between the initial concentration of the metal ions in the liquid phase and the concentration after equilibration is often considered to be due to adsorption of the metal ions on the soil surface. The adsorption on soil particles would therefore be viewed as nature's process of removing the toxic metal from the environment and getting it sequestered. The consequences of heavy metal addition to a soil with high adsorption capacity will be lower than that with lower adsorption capacity. Understanding the sorption characteristics of Pb on soil aggregate sizes of two benchmark soils of southeastern Nigeria can improve management strategies aimed at reducing the bio-availability of this toxic metal in the study soils.

MATERIALS AND METHODS
Top soil (0 – 30 cm) of two tropical benchmark soils of southeastern Nigeria, represented by Amakama soil (Fine-loamy, mixed, semi-active, isohyperthermic Rhodic Kandiudult) and Ajata-Ibeku soil (Fine, mixed, semi-active, isohyperthermic Aquic Haplustalf) (Chikezie *et al*., 2010), were used in this study. Amakama is located on Lat: 5º 26′ 40″ N and Long: 7º 28′ 49″ E, while Ajata-Ibeku is located on Lat: 5º 32′ 51″ N and Long: 7º 33′ 34″ E. Amakama soil is formed on coastal plain sands, while Ajata-Ibeku soil is formed on Bende-Ameke (clay shales) formation. The two soils which will be referred to subsequently, as Amakama and Ajata-Ibeku soils, were chosen

for this study because they represent some important agricultural soils of southeastern Nigeria with contrasting parent materials and chemical properties. Field-moist soil samples were air-dried and sub-samples of the dry soil screened and fractionated into five different aggregate-size fractions. The remaining soil samples were ground and passed through a 2-mm sieve for background Pb determination.

Kinetics of Lead Sorption

In carrying out the kinetics study, three aggregate sizes (> 4 , 2 - 1 and 0.50 - 0.25 mm) were considered at ten contact times (30, 60, 90, 120, 150, 180, 210, 240, 270, and 300 mins). Batch experiments were performed by adding 40 ml of the metal solutions (100 mg/L Pb) to 2 g soil aggregate. The soil suspensions for each initial metal solution concentration were shaken on an end-over-end shaker (30 rpm) in a controlled room temperature (25^{o}C ±2) for 30, 60, 90, 120, 150, 180, 210, 240, 270, and 300 mins. The suspensions were filtered (Whatman No. 42) before the supernatants were analyzed for Pb using UNICAM 919 solar atomic absorption spectrophotometer (AAS). The adsorption amount was calculated as follows:

qe = (Ci – Ceq)V/m ……………………………………….(1)

Where qe the quantity of the adsorbate (metal) in milligram held by 1 g of the adsorbent (soil), Ci is the initial concentration (mg l^{-1}), Ceq is the equilibrium concentration (mg l^{-1}), V is the volume of solution (l), and m is the mass of adsorbent (g). Blank solutions were also prepared and analyzed.

In order to analyze the rate of adsorption and possible adsorption mechanism of lead onto soil aggregates, the pseudo-first-order and pseudo-second-order models were applied to the kinetics experiments data. The pseudo-first-order model is given as (Ho and Mckay, 1998):

In (qe – qt) = Inqe – K_1t ………………………………….. (2)

Where qt is the amount of lead ions adsorbed at time t (mg g^{-1}), qe is the amount of lead ions adsorbed at equilibrium (mg g^{-1}), and K_1 is the pseudo-first-order rate constant (min^{-1}) for the first-order adsorption. A plot of In (qe – qt) against t will give a straight line if the adsorption reaction obeys the pseudo-first-order reaction. The slope of the straight line is K_1, while the intercept is the natural logarithm of the metal ion adsorbed at equilibrium. The pseudo-second-order model was expressed as (Ho and Mckay, 2000):

t/qt = 1/K_2qe^2 + t/qe ……………………………………….. (3)

Where K_2 is the equilibrium rate constant of pseudo-second-order adsorption (g/ mg/min). Values of K_2 and qe were calculated from the slopes and intercepts of the linear plot of t/qt against t. The rate constants K_1, K_2, and qe and the correlation coefficient R^2 were calculated from the relevant plots. If the r^2 value is nearer to 1, it indicates that the respective equation better fits the experimental data, and the calculated q_e should also approximate the experimental q_e..

Sorption Isotherms as a Function of Initial Lead Concentration

Five soil aggregate-sizes were agitated in ten metal concentrations (50, 100, 150, 200, 250, 300, 350, 400, 450, 500 mg l^{-1} Pb - ranges which cut across concentrations regarded as 'normal' and toxic in real agricultural soils (Kabata-Pendias and Pendias, 1992)) of the metal, and 2 g soil aggregate was weighed into 100 ml soft bottle. Metal solution (40 ml) was added into 100 ml bottle containing soil sample and agitated on an end-over-end mechanical shaker for 210 mins, filtered through a Whatman No 42 paper, stored and analyzed on the AAS. The adsorption amount was calculated according to equation 3

RESULTS AND DISCUSSION

Characterization of adsorbents

Selected physico-chemical properties of the study soils are presented in Table 1. All the soils were moderately acidic in the surface horizons with differences between Amakama pH and Ajata-Ibeku pH being less than 0.5. In Amakama and Ajata-Ibeku soils, exchangeable acidity accounted for 86% and 72% of the ECEC, respectively, while Ca was the dominant cation in the two soils accounting for the 10 and 21% of the ECEC, respectively. Amakama soils had lower ECEC, pH, clay and organic matter contents than Ajata-Ibeku soils. The initial Pb in the two soils studied were 26.30 and 17.55 mg kg^{-1} in Amakama and Ajata-Ibeku soils, respectively. Available background Pb content of the Ultisol (Amakama soil) was greater than that of the Alfisol (Ajata-Ibeku soil). This was expected as the amounts of available Pb in the soils would be proportionally higher in soils with lower CEC value (Table 1), due to reduced adsorption of Pb. The fact that greater CEC in Ajata-Ibeku soil results in lesser background Pb suggests that exchangeable sites and not high affinity sites was responsible for metal levels in the soils. The mineralogy of clay particles (< 0.002 mm) as reported by Chikezie *et al.* (2010) showed that Amakama soil has mixed mineralogy dominated by kaolinite. Small quantities of goethite, gibbsite and haematite are also present. In the Ajata-Ibeku soil, the mineralogy is kaolinite in the upper 100 cm of the profile.

Sorption Kinetics

The effect of time on the amount of Pb adsorbed by select Amakama and Ajata-Ibeku soil aggregates (> 4, 2 - 1 and 0.5 - 0.25 mm aggregate-sizes) is shown that equilibrium adsorption occurred faster on larger soil aggregate sizes. The adsorption of Pb on > 4, 2 - 1 and 0.5 - 0.25 mm soil aggregates of Amakama soils reached equilibrium in 180, 180 and 210 minutes, respectively. In Ajata-Ibeku soil, equilibrium was achieved in 120, 180 and 180 minutes, for > 4, 2 - 1 and 0.5 - 0.25 mm aggregates, respectively. The plots revealed that the rate of percent Pb removal is higher at the beginning. This is probably due to presence of uncovered adsorption sites at the beginning of adsorption of Pb(II) ions. As surface adsorption sites become exhausted, the uptake rates are controlled by the rates at which the adsorbate is transferred from the exterior to the interior sites of the adsorbent aggregates. Extension of time beyond the equilibrium time obtained for each aggregate-size did not lead to more adsorption of Pb(II) ions. Thus, explaining the plateaus obtained in the curves. The number of available sites per unit mass of soil for adsorption increases with decrease in soil aggregate size. More sites for adsorption are therefore available on soils of 0.5 - 0.25 mm aggregate-size than on > 4 mm aggregates. This may also account for the longer time (210 min), 0.5 - 0.25 mm aggregates, with the largest surface area took to reach equilibrium in Amakama soil. It was therefore concluded that 210 minutes was sufficient for Pb adsorption to attain equilibrium in both soils. The quantity of Pb adsorbed by Ajata-Ibeku soils aggregates (3.39 mg/g) was higher than the quantity of Pb adsorbed by the Amakama soils aggregates (2.93 mg/g) (Table 2). The higher adsorption capacities obtained for Ajata-Ibeku soil relative to Amakama soil may be as a result of composition of the two soils. Chikezie *et al*. (2010) reported that the clay fraction of Ajata-Ibeku top and sub-soils were dominated by kaolinite and to a lesser extent by montmorilonite and very small goethite. They also reported that Amakama top and sub-soils contained clay mixture with less kaolinite and very small gibbsite, hematite and goethite. Sorption reactions are often more rapid on clay minerals such as kaolinite than on vermiculite and micaceous minerals. This is in large part due to the availability of sites for sorption. Kaolinite has readily available planar external sites and sorption on the planar sites is almost complete in minutes. The presence of montmorilonite, a 2:1 expanding clay mineral provides Ajata-Ibeku soil with greater cation exchange capacity than Amakama soil. Thus ensuring high metal sorption capacity as it provides the soil with multiple sites for retention of metals and high cation exchange capacity, an established factor regulating the sorption of heavy metals by soils (Kuo and Baker, 1980; Hooda and Alloway, 1998; Gomes *et al*., 2001). The initial faster rate of removal of Pb ion may be due to the availability of the uncovered surface area of the adsorbents, since adsorption kinetics depends on the surface area of the adsorbents (Veeresh *et al*., 2003). The variations in percentage removal of Pb by the three aggregate-sizes (> 4, 2 - 1 and 0.50 - 0.25 mm) of both soils show slight increase as the aggregate-sizes decrease. The sequence of increase in removal of the metal by the aggregates was: > 4 < 2 - 1 < 0.50 - 0.25 mm. The trend obtained is in the order of the surface area per unit mass of the soil which has direct relationship with the number of adsorption sites on the soils.

Sorption of Pb by Soil aggregates as a Function of Initial Metal Concentrations

The effect of soil aggregates on the removal of Pb(II) from soil solutions was studied with five aggregate sizes (> 4, 4 - 2, 2 - 1, 1 - 0.5 and 0.50 - 0.25 mm). The amount of metal adsorbed (mg kg^{-1}) when plotted against the equilibrium concentration (mg l^{-1}) produced a non-linear regression model that provides for drawing tangents at the points where adsorption started to drop, to locate the critical equilibrium concentrations of the metals in solution, at which, presence of metal in solution starts to reduce adsorption. The equilibrium concentration of Pb (x) (mg l^{-1}) at the maximum kinetics models described well the adsorption of Pb on both soils. Lead adsorption was obtained by equating the first derivative of Pb adsorbed (y) (mg kg^{-1}) with respect to equilibrium concentration (x) to zero, and the value of x substituted in the relevant equation. The data contained in these models were used to calculate a distribution coefficient or the partitioning between the solution phase and the solid phase, which is a ratio of solid phase concentration to solution phase concentration (Table 3). Examination of the data presented in Table 3 indicates that these coefficients were consistently higher in Ajata-Ibeku soils (213.7 l kg^{-1}) than in Amakama soils (33.2 l kg^{-1}), suggesting that Pb(II) was removed from solution by Ajata-Ibeku soils aggregates more than by Amakama soil aggregates. This could be attributed to the comparatively higher CEC, organic matter content, clay chemistry and moderate acidity of Ajata-Ibeku soil which promoted adsorption. Weber (1991) and Stevenson (1992) have reported that amount of clay and organic matter, pH, water content and some properties of the particular metal ion are some of the physicochemical properties that determine sorption properties of a soil. The distribution coefficients of the metals on the aggregates did not follow any particular trend in both soils, however, maximum partitioning of Pb to the solid phase of the soil aggregates was observed on 2 – 1 mm soil aggregates (692.05 and 12649.52 mg/kg in Amakama and Ajata-Ibeku soils, respectively). Average equilibrium concentrations of Pb were greater than 100 mg/l but less than 200 mg/l in Amakama aggregates, and greater than 50 mg/l and less than 100 mg/l in Ajata-Ibeku aggregates. Further enrichment of the soils with Pb beyond the reported upper limits did not result in any significant adsorption of the metal, but instead caused desorption of the heavy metal. This was so because at those solution concentrations almost all adsorption sites have been occupied by the metal concerned.

CONCLUSION

The study found out that the equilibrium time for Pb adsorption on soil aggregates was uniform after 210 mins across the two soils studied. However, a biphasic kinetics was observed, namely, a rapid reaction rate, followed by a much slower reaction time. The rapid reaction rate occurred at the external planar sites of the soil aggregates due to presence of uncovered adsorption sites at the beginning of the adsorption of Pb(II) ions. As surface adsorption sites became exhausted, the adsorption rates became slower and were controlled by the rate at which the adsorbate was transferred from the exterior to the interior sites of the adsorbent aggregates. Extension of time beyond 210 mins did not lead to more adsorption of Pb(II) ions by the aggregates. Adsorptive efficiencies of Pb from the kinetics study were more on soil aggregates with large surface area, compared with aggregates with smaller surface area, in both soils. Average maximum Pb uptake (3.84 and 3.43 mg g^{-1} for Ajata-Ibeku and Amakama soils, respectively) occurred on 0. 50 - 0.25 mm aggregates, while the least Pb uptake (2.74 and 2.44 mg g^{-1} for Ajata-Ibeku and Amakama soils, respectively) occurred on > 4 mm aggregates. Equilibrium adsorption capacities of Pb and their distribution coefficients (K_d) on Ajata-Ibeku soil aggregates were higher than those for Amakama soil aggregates. The kinetics data for the adsorption process of Pb fitted the pseudo-first-order kinetics model for Amakama aggregates, whereas the kinetics data obtained from Ajata-Ibeku aggregates fitted the pseudo-second-order kinetics model. This supports the assumption that the rate-limiting step of Pb adsorption onto soil aggregates varied with soil.

ABSTRACT
Phosphorus forms in textural size fraction of soils play important role in estimating P retention and release and thus its sustainable management. Phosphorus forms (total, organic, saloid, Al, Fe, Ca and residual) in textural size fractions of soils of three land units (upland, levee and backswamp) in Egbema were evaluated using sequential extraction procedures. Phosphorus forms in various size fractions differed distinctly (LSD 0.05) being a decreasing sequence for sand fraction of total P > organic P > occluded P > residual P > Fe-P > Al- P > Ca-P > saloid P > H_20 soluble P in the levee and backswamp and total P > organic P > residual P > Fe-P > Al- P > occluded P > Ca-P > saloid P = H_20 soluble P in upland units, total P > organic P > residual P > Fe-P > Al-P > occluded P > Ca-P = saloid P > water soluble P in the upland, total P > organic P > residual P > occluded P > Fe-P > Al-P = Ca-P > saloid P > water soluble P in the levee and total P > organic P > residual P > Fe-P > occluded P > Al-P > Ca-P > saloid P > water soluble P in the backswamp for silt fraction and total P > organic P > Fe-P > Al-P > residual P > occluded P > Ca-P > saloid P > water soluble P in upland, total P > organic P > occluded P > residual P > Fe-P > Al-P > saloid P > Ca-P > water soluble P in levee and total P > organic P > residual P > Fe-P > Al-P > occluded P > Ca-P > saloid P > water soluble P for clay fraction. Phosphorus forms were higher in clay than other textural fractions and in the subsoil than surface soil of most landunits. This suggests that clay soils will be most active in regulating P activities in the land units
Keywords: Phosphorus, Texture, lowland soils, landunits and southern Nigeria

INTRODUCTION

Phosphorus is a component of nucleic acids and nucleoside triphosphates, the basis of enzyme synthesis and energy transfer systems at the cellular level (Uzoho, 2010). It is associated with eutrophication of surface and ground water systems and thus important in the sustainability of environmental quality (Azadi and Baghernejad, 2016; Zhang and Li, 2016). Phosphorus involves in several complex soil reactions that affects its solubility and mobility. Its two forms are organic and inorganic, with the organic constituting 20-80% of total soil P and include inositol phosphate, nucleic acids, nucleotides, phospholipids and sugar phosphates (Mustapha et al., 2007; Uzoho, 2010). Inorganic phosphorus fractions include Fe-P, Al-P, Ca-P, Saloid bound P, Occluded and residual P and important in regulating soil P availability as well as losses through uptake, leaching and erosion (Azadi and Baghernejad 2016). Soloid bound P represent the easily soluble and loosely bound P fraction extractible with NH_4Cl, Al, Fe and Ca-P are fractions extractible with 0.5N NH_4F, 0.1N NaOH and 0.5N H_2S0_4 respectively
Distribution of soil phosphorus fractions varies and affected by land use types, landscape position, soil management, pH, redox potential and climatic condition (Solomon et al., 2002; Mustapha et al., 2007; Sheklabadi et al., 2014;Aminda Moreira de Carvalho et al., 2014; Ghulam, 2015) . Impact of land use, soil management and climate has been reported to include increased $NaHCO_3$ and NaOH inorganic P fractions at 5-10 cm soil depth under no-tillage in the rainy season and a high organic P concentration at 0-5 cm depth for no-tillage and 5-10 cm depth for conventional tillage systems in the dry season for Oxisols under Cajanus cajan land use type in Central Savanna region of Brazil (Arminda Moreira de Carvalho et al., 2014). Also, a decreased order of Total P > Fe-P > Al-P > Occlude Fe-Al-P > Reductant Soluble –P > Ca-P > Available P in surface and subsurface depths of various landscape positions have been reported for some Haplic Plinthaquults in Bauchi, Nigeria (Mustaphar et al., 2007). Others included high labile relative to occluded P in herbaceous perennial and reverse of occluded to labile fraction in annual agroecosystems (Crews and Brookes, 2014), available and Ca-P in plantation and Fe-P in arable in soils of three cropping systems in Lower Indo-Gangetic Alluvial plain, India (Ghulam, 2015) and high Ca-P in Andisols across Riparian buffer and adjacent cropped area in Dian Lake, China (Zhang and Li, 2016).
Concentration of soil P forms differs with textural class fractions. It has been reported that soil texture can modify P equilibrium and availability due to its influence on P sorption-desorption-diffusion processes and through soil organic matter mineralization (Suner and Galantini, 2015). Several workers have noted increased concentration

of P fractions in fine (clay and silt) than coarse soil fractions (Suner and Galatini, 2015; Zhang and Li, 2016). High concentration of P forms in the clay fraction has been ascribed to its being both a source for the labile and sinks for recalcitrant P fractions (Suner and Galatini, 2015) and enrichment of organic P in the fine fraction (Zhang and Li, 2016). Others noted that low inorganic P concentration in coarse particle size fractions could be as a result of assimilation by vegetation, transformation of inorganic P, leaching and erosion (Roberts et al., 2012).
Egbema lies in the low area of southeastern Nigeria with most it usually flooded during the raining. This causes the submergence of most of the soils and the alteration of the chemistry of some nutrients especially P. It has been indicated that P in submerged soils is dominated by Fe-P and Al-P fractions (Gbulam, 2015) since its concentration is in governed by drainage (Nartey et al., 1997). Phosphorus forms exist in soil textural fractions and this influences the soil P availability, retention and activities. Despite the relevance of soil texture in regulating the distribution of P forms, there appears a dearth of information in P status of soils of this area. The main objective of the present study was to determine the P forms in textural size fractions of low land soils of Egbema, southeastern, Nigeria.

MATERIALS AND METHODS

Study Location and Soil Sampling

The study location, soil sample collection and preparation have been described in another study (Uzoho *et al.*, 2016). Fractionation of particle size fraction was conducted using the method described by Sequaris and Lewandowiski (2003). Particle size distribution (Gee and Or, 2002), pH in 1:2.5 soil/water ratio (Thomas, 1996), Available P (Olsen, 1982), Exchangeable cations (Thomas, 1996), OM (Nelson, 1996) and bulk density (Blake and Hartage, 1986). Phosphorus fractionation was conducted on the first (surface) and second (subsoil) depths of each land unit using sequential extraction technique as outlined by Hedley *et al*., 1982).

Statistical Analysis

Data generated on phosphorus forms was subjected to Analysis of variance (ANOVA) and means separated using LSD at 5% probability levels.

RESULTS AND DISCUSSION

Phosphorus Fractions

Concentration of P forms in sand, silt and clay size fractions of soils of the various land units are presented in Tables 3, 4 and 5 respectively. Phosphorus forms in the sand size fractions of the various land units differed significantly LSD (0.05) being a decreasing order of total P > organic P > occluded P > residual P > Fe-P > Al- P > Ca-P > saloid P > H_20 soluble P in the levee and backswamp and total P > organic P > residual P > Fe-P > Al-P > occluded P > Ca-P > saloid P = H_20 soluble P in upland (Table 3). Concentrations of the different forms were higher in the sub than surface soil of most land units. Averaged over horizons, upland land unit had the least concentration of the P forms while the difference between levee and backswamp varied depending on forms.

Differences in P forms of the silt size fractions differed distinctly (LSD 0.05) and decreased in the order total P > organic P > residual P > Fe-P > Al-P > occluded P > Ca-P = saloid P > water soluble P in the upland, total P > organic P > residual P > occluded P > Fe-P > Al-P = Ca-P > saloid P > water soluble P in the levee and total P > organic P > residual P > Fe-P > occluded P > Al-P > Ca-P > saloid P > water soluble P in the backswamp (Table 4). Concentrations of most forms were lower in surface than subsoil of some land units. Averaged over surface and subsoil horizons, mean concentrations of most P forms followed a decreasing sequence of levee > upland > backswamp.
Phosphorus forms in clay fraction of the soils differed seriously with soil horizons and landunits (Table 5). Averaged over soil horizons, concentrations decreased in the order total P > organic P > Fe-P > Al-P > residual P > occluded P > Ca-P > saloid P > water soluble P in upland, total P > organic P > occluded P > residual P > Fe-P > Al-P > saloid P > Ca-P > water soluble P in levee and total P > organic P > residual P > Fe-P > Al-P > occluded P > Ca-P > saloid P > water soluble P. Concentration of most P forms were better in the subsoil than surface soils and with mean value in the levee significantly (LSD 0.05) higher than the other land units. In general, P forms of the soils varied between land units, horizon depth and textural size fractions. Variation in P forms due to landscape position, soil depth, land use, management practice, soil and textural fractions have been reported (Mustapha et al., 2007; Malik and Khan, 2012; Sheklabadi et al., 2014;Aminda Moreira de Carvalho et al., 2014; Ghulam, 2015; Suner and Galatini, 2015; Zhang and Li, 2016). Concentrations in textural size fractions were higher in the levee than backswamp and upland land units probably due to depressed P sorption in the levee as a result of poor drainage (Ghulam, 2015). Concentration of large number of the P forms were higher in the subsoil than surface horizons of most land units due probably to burial of sediments at lower depths with alluvial deposition and from leaching or erosion by runoff (Zhang and Li, 2016). Nartey et al.(1997) noted increased distribution with depth of two landscapes with those of well drained soils due to profile maturity and those of low

lying soils due to drainage. Variation in most P forms in textural size fractions included high concentrations in clay and silt than sand fractions for most land units. Similar observations have been reported for clays and fine size fractions and ascribed to existence of surfaces for P retention (Suner and Galantini 2015; Zhang and Li, 2016) and accumulation of sesquioxides (Nartey et al., 1997). It could also be attributed to the enrichment of organic P in the finer particle size fractions (Christensen, 2001).

CONCLUSION

Phosphorus forms in textural size fractions differed significantly with landunits and soil horizons with mean distribution being a decreasing order of total P > organic P > occluded P > residual P > Fe-P > Al- P > Ca-P > saloid P > H_20 soluble P in the levee and backswamp and total P > organic P > residual P > Fe-P > Al- P > occluded P > Ca-P > saloid P = H_20 soluble P in upland units for sand fraction, total P > organic P > residual P > Fe-P > Al-P > occluded P > Ca-P = saloid P > water soluble P in the upland, total P > organic P > residual P > occluded P > Fe-P > Al-P = Ca-P > saloid P > water soluble P in the levee and total P > organic P > residual P > Fe-P > occluded P > Al-P > Ca-P > saloid P > water soluble P in the backswamp for silt fraction and total P > organic P > Fe-P > Al-P > residual P > occluded P > Ca-P > saloid P > water soluble P in upland, total P > organic P > occluded P > residual P > Fe-P > Al-P > saloid P > Ca-P > water soluble P in levee and total P > organic P > residual P > Fe-P > Al-P > occluded P > Ca-P > saloid P > water soluble P for clay fraction. Concentration of most P forms were higher in the clay than other textural fractions and in the subsoil than surface soil of most landunits

IMPACT OF AGRICULTURAL ACTIVITIES ON WATER QUALITIES OF OHAIYIMIRI RIVER UMUDIKE, SOUTHEASTERN NIGERIA

P.O. Nwosu, C. O. Ochuba, V. Okeke, O.S. Chukwuemeka & M.N. Enyinna

Soil Science Laboratory, National Root Crops Research Institute Umudike, Abia State Nigeria
paulonwosu@yahoo.com

ABSTRACT
The impact of agricultural activities on the qualities of the waters from Ohaiyimiri Umudike rivers which flows across the Western farms of the National Root Crops Research Institute Umudike was investigated. Results indicated that some of the physical parameters studied varied from one sampling point to another. The water PH, temperature, Electrical conductivity and total dissolved solids variations also causes changes in some aspects of the water chemistry. The oxidation reduction potential, the salinity and electrical conductivity reflected I the values obtained in total dissolved solids (124.80 to 1638.0mgl^{-1}). Chloride, Phosphate, Calcium, Potassium and the mineral nitrogen in all the sampling points, fell within the range recommended by the World Health Organization and Nigerian Industrial standards for portable water. The NH_4^-N (2.80-140mgl^{-1}), the Ca (40.10-168.3mgl^{-1}) K (0.86-4.10mgl^{-1}) and P (0.485-0.80mgl^{-1}). I provide adequate mineral for aquatic life and irrigation advantage. The heavy metals in the soil were also low but high at the entering point of the river to the study area because of the human influence and traffic flow at the point. However, inspite of the use of modern agricultural inputs across the study sites, the water quantities remained recommended for aquaculture and irrigation.
Keywords: Agriculture activities, water quantities Ohaiyimiri river.

INTRODUCTION
Water is unarguable the most essential and precious of all natural resources, it is a universal solvent that provide the ionic balances and nutrients needed to support all forms of life (Okorie and Nwosu, 2014). The amount of water on the planet earth is estimated at 1388 billion cubic meters, out of which only 37.5 billion cubic meters are fresh water, 1348 billion cubic meters are salt waters in the oceans 8450 million cubic meters as ground waters and 127 billion cubic meters as lakes and rivers (Chorus *et al;* 1998). Water quality relates to physical, biochemical and biological characteristics of such water bodies as lakes, rivers and oceans used for drinking and other uses (Lamikanra, 1999; FAO, 1997). Recently water quality monitoring has become a matter of concern because of the careless disposal of effluents, runoff from agricultural field, atmospheric deposition, domestic and industrial discharges to aquatic dispositions.
An agricultural activity which is our major target in this study and other land uses within the water sheds has great impact on the water quality of rivers. The qualities may degrade due to changes in the land cover patterns and management practices as human activities increases. Some of the identified effect of agricultural activities on river bodies includes nutrient dynamics, water quality deterioration and destruction of spawning ground for aquatic life's (Nwadiora and Orji 1985). Recent agricultural transformation has encouraged use of chemical substances such as inorganic fertilizers, pesticides, herbicides and hormones in food production. Reckless use of these chemical substances creates nutrient imbalance, soil acidification and contaminations of surface and underground water systems. (Zublena *et al;* 1999; Nwosu *et al;* 2014). The objectives of the present study is to evaluate the impact of agricultural activities on water qualities of Ohaiyimiri River which transverses the Research farms of National Root Crops Research Institute, Umudike through Michael Okpara University of Agriculture Umudike and beyond.

MATERIALS AND METHODS
Water samples were collected along the Ohaiyimiri River which ran across the Research farms in the Western and of the National Root Crops Research Institute Umudike, Abia State, and Southeastern Nigeria. Umudike lies between latitudes 5^0 29" N and longitudes 7^0 32" E at altitudes of 122m above sea level. The climate is essentially humid tropical characterized by wet and dry seasons, with an average annual precipitation of 2164mm. The vegetation is secondary forest tending towards derived Savannah (Nwosu *et al*; 2013).

Sample Collection
The sampling was carried out in April 2016. A clean sample bottle was initially rinsed with water from each sampling points and place inversely to the water flow until the container is filled avoiding any air space in the sample bottle. Sampling was collected from the end of the river across the bridge along Umuahia- Ikot - Ekpene Road (OBR1) and subsequently at a distance of 200m apart through the residential quarters (NRQ2), the staff

school (NSS3), through the farms (NRF4), (NRF5) (NRF6) (NRF7) (NRF8) the dam (NDM9) and the boundary to MOUAU (NBM 10).

Laboratory Analysis

The samples were taken to soil science laboratory of the National Root Crops Research Institute, Umudike for physical, Biochemical and chemical analysis according to the methods of Udo *et al;* (2009).The water pH was measured using glass electrode pH meter while the electrical conductivity with conductivity meter. Total dissolved solids (TDS) were measured with a multimeter for water analysis. The dissolved oxygen (DO), salinity, Oxidation Reduction Potential (ORD) was also determined by the use of $H_1$9828 Hannah multimeter (Nwosu *et al;* 2015). Total Nitrogen, Ammonium-Nitrogen and Nitrate Nitrogen were determined by the semi-micro Kjedahl method Chloride was determined by the silver Nitrate titration method using potassium chromate as indicator (Ajayi *et al;* 2008), Total Hardness, Calcium and Magnesium were determined by EDTA versanate complexometric titration method, Phosphorus was by spectrophotometric method, potassium and sodium by the flame photometric method. The micronutrients were determined by the Atomic absorption spectrophotometer (AAS) method. The results were subjected to statistical analysis using the means.± standard deviation of triplicate analysis.

RESULTS AND DISCUSSION

The impact of some land use and farming activities of the research farms of the National Root Crops Research Institute on some physical quantities of the waters of Ohaiyimiri Umudike flowing across the Western end of the institute is shown in Table 1. Water temperature measured at the point of sampling ranged from 27.60±0.96 to 30.80±0.79^{0}C, the temperatures were high at the point of much activities; OBR1, NRF5 and NDM9. The pH an important limiting chemical factors for aquatic life is disturbed in the acidic weakly acidic and basic levels having a wide range of PH 4.90±0.06 to 9.60±0.14. It is obvious that with the range of this pH values some biochemical reactions of aquatic organisms will be disrupted in the extreme acidic and alkaline pH. The electrical conductivity measures the flow of electrical current in water which is an indirect measure of some inorganic dissolved solids in the water body (Sridhar, 1999). The electrical conductivity ranged between 1.96us to5.28us, this is an indication of presence of inorganic substances in the water body. Total dissolved solids had values that are in agreement with values obtained in the electrical conductivity and the oxidation-reduction potential; between 124.80 to 1638mgl^{-1} total dissolved solids are highest in the residential area of the institute and are above the WHO 1984 and 1995 standard for portable water.

Table 2 is showing some chemical characteristic of the river as influenced by agricultural activities oxidation reduction potential is in the range of 26.50 to 125.50mv, the water across the residential area had the highest values 125.50 and 60.30mv, the salinity is low while the inorganic nitrogen form are widely spread without any definite pattern NH_4^-N and $N0_3^-$N are in the range of 2.80-28.40mgl^{-1} and 1.40-9.80mgl^{-1} respectively. Nitrogen is important to all forms of life it is the byproduct of living organisms which includes such natural materials as proteins and peptides, nucleic acids, urea and numerous synthetic organic materials.(streamkeeper's field guide, 1991). The values obtain for chloride 35.45 to 88.60mgl^{-1}, Calcium 40.10 to 168.30mgl^{-1} potassium 0.86 to 4.10mgl^{-1} and phosphorus 0.48 to 0.825mgl^{-1} respectively were also with the desirable and permissible levels in drinking and irrigation water. (WHO, 2007; NIS, 2007). Chloride is an essential anion for osmotic and water current balance, it is of no known health implication but buffers the water body (Amajor *et al;* 2012). Phosphorus and calcium are also important mineral elements in aquaculture, they enriches the water body and improve plant growth and other microorganism leading to eutrophication and increase in biochemical oxygen demand.

Table 3 is shoeing the heavy metal concentration in the water body as influenced by the activities across the NRCRI Umudike on the Ohaiyimiri River. The effects of these metals in water ranged from being beneficial through troublesome to dangerously toxic. Some metals are essential; others adversely affect aquaculture depending on their concentration (Obodo, 2001). The following heavy metals were investigated in the water; Zinc, Iron, Copper, Lead and chromium. The values obtained were 1.24 to 16.20mgl^{-1}, 4.28 to 182.20mgl^{-1}, 0.18 to 2.92mgl^{-1} 0.034 to 0.94mgl^{-1} and 0.036 to 0.096mgl^{-1}, of Zn, Fe, Cu, Pb and Cr respectively. The highest level of the metals is seen in OBR1 sampling point. The high heavy metal concentration at the OBR1 sampling point could be because of the activity that goes on at the point which included car washing, heavy traffic that moves across the Umuahia Ikot-Ekpene road and the seemingly stagnant nature of the water.

CONCLUSION

The results obtained from this study showed that generally most of the mineral elements in the water samples occur in trace and moderate quantities. They are essential nutrients for many photosynthetic autotrophs and have been identified as growth factors. The concentrations are less serious environmental problem. There are many factors that has influenced the impact of farming operations on the quality of the river, which may include the water current, the temperature and pH, fluctuation, the presence of aquatic plants in the water have been beneficial to the healthy nature of the water bodies. The river had been identified as a good for aquaculture and irrigation practices.

COMPARATIVE ASSESSMENT OF NUTRIENT STATUS OF SOIL UNDER *HEVEA* (NATURAL RUBBER*)* BUDWOOD GARDEN OF DIFFERENT AGES AND THEIR UPTAKE

*** E.G.O. Ogidi, I.K. Okore & J.C. Dike**

Rubber Research Institute of Nigeria, Sub-station Akwete, P.M.B 02 Akwete, Abia State, Nigeria
ogidyke@yahoo.com

ABSTRACT
The soil chemical properties and leaf nutrient contents of Hevea budwood garden of different ages (2, 5, 10, 15, 20 years) were assessed at Rubber Research Institute of Nigeria, Substation Akwete, Abia State, Nigeria for proper fertility management scheme. Soil samples were collected at the depth of 0 - 15 cm across the various budwood garden ages and corresponding leaf samples obtained from budstick for nutrient content determination before the annual cut back or harvest. Samples were analyzed using standard procedures. Samples were analyzed using standard procedures. Generally, soil pH was higher in the older gardens with the values ranging from 5.2 – 5.8 between 10 and 20 years old garden. The concentration of organic carbon, total nitrogen, available phosphorus and exchangeable bases followed the same trend as the pH and their values differed significantly (P < 0.05). The age of the budwood gardens significantly (P < 0.05) affected leaf nitrogen, phosphorus, potassium and calcium contents except magnesium, with the values obtained from older budwood gardens being relatively higher. The results show inadequate soil nutrient concentration for the production of vigorous budwood materials. Hence, consistent routine soil nutrient assessment is required for adequate nutrient supply and production of healthy and viable Hevea planting materials.
Key words: Budwood, soil nutrient, foliar nutrient, nutrient, *Hevea* planting material.

INTRODUCTION

Rubber (*Hevea brasiliensis*) is predominantly grown in southern Nigeria where the soils are characterized by low fertility and productivity due to high rainfall regime and intensity and associated leaching of nutrients and weathering (Igwe *et al*., 1995; Awodun *et al*., 2007). Therefore the need for sustainable soil nutrient management programme and this requires knowledge of the soil's nutrient status and or its physico-chemical properties (Nwosu *et al*., 2015; Ehigiator *et al*., 2015). Rubber being propagated mainly through vegetative methods, exhibits tree to tree intra-clonal variation in growth and yield which reduces the realization of maximum returns of rubber yield (Seneviratna, 2000; Senevirathna *et al*., 2007).

Budwood gardens are generally established for the multiplication of desired clones for production of quality rubber planting materials. According to Mercykutty (2014), the quality of budwood plants from which buds are harvested for budding, contribute to the quality and growth of plants and optimum yield will not be attained even with favourable environment if the scion used is not a high yielding one. Budwood garden being a regular bearer that puts forth budstick materials for budding during season flush needs sufficient and continuous supply of nutrients for regeneration. Absence or scarcity of essential elements in the soil cause nutrient deficiencies in the plant and so affect vital processes. Soil and plant analysis have been used extensively as a diagnostic tool for assessment of the nutritional status of crop (Rupa *et al*., 2014) and is based on the relationship between the concentration of nutrient elements in specific leaves at certain stages of plant development and the growth performance of plants (Monastraf, 1975; Rupa *et al*., 2014).

In rubber, no previous investigation on the effect of budwood garden age on soil properties and nutrient content of leaf has been carried out. Most established budwood gardens in Nigeria are more than 15 years old with the assumption that it would not deteriorate the quality of budwood / budstick or buds as juvenility is maintained through cutting back the budwood plants every year. Thus, challenges in maintaining budwood nurseries are transferred to plantation. The nutrient content of budwood leaves vary depending on the genotype and soil. The present investigation was undertaken to assess the soil chemical properties and nutrient uptake that may occur over time in the budwood garden of different ages.

MATERIALS AND METHODS

The research was carried in 2013/2014 *Hevea* planting material production season at the Rubber Research Institute of Nigeria (RRIN), Substation Akwete, Abia State (longitude 7^0 00′ and 7 ^{0} 19′ E and latitude 4 ^{0} 50′ and 4^0 65′). The soil is a typical tropudult with rainfall distributed over nine to ten months in a bimodal rainfall pattern. These are early rain (April - July) and late rain (August - October) with five months of dry season and a short dry spell in August. The monthly maximum air temperature ranged from 28 to 35 ºC (NRCRI , 2008 ; Kamalu *et al*.,2014).

The soil (0- 15cm depth) and plant samples were taken from budwood gardens of 2, 5, 10, 15 and 20 years old. Both (plant and soil) samples were collected in replicates of three before the annual cut back. The soil samples were air dried, sieved with 2mm sieve and analyzed for potential of hydrogen (pH), Organic carbon (O C),total nitrogen (N), available phosphorus (P- Bray- 1), exchangeable Potassium (K^+), Magnesium (Mg^{2+}) and Calcium (Ca^{2+}).The plant samples were processed by washing and oven drying for 48hrs, at the temperature of 70 ^{0}C. The samples were analyzed for N content, using micro- kjeldahl method and the P, Ca, Mg and K contents determined using wet oxidation method, all as described by IITA (1979). Data collected were subjected to analysis of variance using Genset, 2008 and significant means separated with Least Significant Difference (LSD).

RESULTS

Soil properties chemical

The chemical properties of the soil indicated low fertility status and significantly differed ($P < 0.05$) except pH (Table 1). The soil pH recorded ranged from 4.5 to 5.8 showing very strongly to strongly acidic soil conditions. These values generally increased as the budwood garden age increases. The increased acidity was however highest in 5- year old budwood garden and lowest in 20 – year old budwood. Organic carbon followed similar trend as the pH with a mean of 1.43 %. 20 – year old budwood garden recorded the highest organic -carbon value of 1.82 %, while 5 – year old budwood garden had the lowest value of 0.92 %. Total nitrogen (N) % was significantly lower in younger budwood garden ($P > 0.05$) and the % concentration increased with the increasing age of the budwood garden (Table 1). It ranged from 0.01 to 0.15 % with a mean of 0.08 %. 20 – year old budwood garden had the highest mean total nitrogen value of 0.15 %, which could be as a result of its deep root to absorb decomposed materials. However, 2 and 5 – year budwood garden had the lowest mean value of 0.01 %. The available phosphorus (P) varied significantly and ranged from 2.53 to 10.11 Mg/kg indicating relative availability in the soil. 20- year old budwood had the highest P concentration 10.11 Mg/kg with 5 – year budwood recording the lowest value of 2.53 Mg/kg. The Calcium values ranged from 0.98 to 3.10 Cmol/kg with a mean of 2.07 Cmol/kg indicating that the soil is moderate in calcium. Calcium is needed in small quantities for tree plants. The highest mean calcium value of 3.01 Cmol/kg was obtained by 20 - year budwood garden, while the lowest value was obtained in 5 – year old budwood garden. Potassium levels in the soils varied significantly ($P < 0.05$) and ranged from 0.44 Cmol/kg (5 – year budwood) to 0.91 Cmol/kg (20 – year budwood) with a mean of 0.65 Cmol/kg. Similarly, Magnesium levels in the soil ranged from 0.28 Cmol/kg to 0.90 Cmol/kg with a mean of 0.58 Cmol/kg; increasing with increase in budwood age except in 5 – year budwood garden (Table1).

Leaf nutrients

Leaf N, P, K, Ca, Mg contents from budwood garden of different age as analyzed are presented in Table 2. The concentration of nutrients in the leaf varied among the budwood ages. The N content of the leaves differed significantly among the budwood ages. 20 – year budwood garden recorded the highest N (4.82 %) and 5 – year budwood garden the lowest N (2.11 %). The budwood ages significantly differed with respect to P and K concentrations. Concentration increases as budwood ages increases and ranged from 0.12 %, 0.99 to 0.72 %, 1.11 % with mean value of 0.44 %, 0.98 % for P and K respectively for 2 – year budwood garden and 20 – year budwood garden. The concentration of Mg and Ca in budwood leaves widely varied. The values of Ca were generally higher compared with Mg. Highest % Ca was observed in 20 – year budwood garden (1.44 %) and the lowest % Ca in 2 – year budwood garden (0.44 %). The % Ca concentration in 20 - year budwood was at par with 15 – year budwood garden. The concentration of Mg in the leaf ranged from 0.12 % (5- year budwood garden) to 0.15 % (20-year budwood garden) with a mean value of 0.16 %.

DISCUSSION

Plants and soils in the tropical rainforest are in equilibrium involving an almost closed cycling of nutrients achieved by a very high rate of litter production, rapid mineralization and a rapid attainment of equilibrium with respect to organic matter relationships (Bernherd-Raversat, 1987; Vitousek and Sanford, 1986; Terborgh, 1992). However, whenever the vegetation is cleared for cultivation, the plant – soil relationship is disrupted irrespective of whether field or tree crops are planted (Adejuwon and Ekanade, 1988). The differences observed in the soil and leaf nutrient properties in the budwood garden confirmed these assertions. The studied soils are acidic and are within the pH range obtained by Attoe and Amalu, 2005; Pusharajah, (2005); Kamalu *et al.*, (2014) for *Hevea* cultivation. The variations in acidity gradient across the buwood ages could be attributed to influence of leaching on younger budwood garden beyond plant root reach. This is in agreement with findings of Foth (2006). Though, the Organic carbon was higher in older budwood garden, the values obtained were less than the critical value and is considered low (Chude *et al*.; (2011; Malami *et al*., 2011). The low organic carbon content in the younger budwood garden may be attributed to the low organic input relative to older gardens where annual pruning (cut back) takes place with the foliage being left in situ, thus contributing to the soil organic matter. The younger budwood gardens therefore need soil amendments to increase the soil pH value by application of liming materials (Onwuka *et al*., 2009; Whalen *et al*., 2000; Nikoli and Matsi 2011). Nitrogen in the soil followed a similar trend as organic carbon. Though, the total nitrogen (TN) increases with respect to the age of the budwood garden, the TN values were lower than the range obtained by Kamalu *et al*., (2014) at 0 – 18 cm soil depth. This is similar to the finding of Oku *et al*., (2012) that there is huge nutrient accumulation in older rubber plantations preventing direct rainfall impact and nutrient leaching. Furthermore, it is deduced that the low level of nitrogen in younger budwood garden could be due to low levels of phosphorus as fixation of nitrogen is influenced by phosphorus availability in the soils (Malami *et al*., 2011). Relatively lower P range obtained was lower than the P values obtained by Lekwa and Whiteside (1986) and Kamalu *et al*; (2014). The exchangeable bases (Ca, K amd Mg) were higher in older budwood garden. According to London (1991), tropical soils with Ca levels as low as 0.2 Cmol / kg are good for agricultural crops and forest tree for growth as it is needed in small quantity. Similarly, London (1991) reported that Mg levels of 0.5 Cmol / kg in the soil are considered deficient in the tropical environment. Thus, Mg levels obtained in the 2 – 5 years budwood garden are inadequate, hence requires soil amendments for better budwood growth. Potassium levels showed a direct relationship with the trend of soil Mg. General higher values of Ca, K and Mg in older budwood garden could be due to higher pH that favoured the decomposition of accumulated litter fall (Malami *et al*., 2011; Ipinmoroti and Ogeh, 2014).. Similarly, the foliar nutrient contents followed the same trend with soil nutrient status of the budwood garden across various ages. Phosphorus, magnesium and calcium concentrations increase as the budwood ages increases. The significantly higher foliar nutrient concentration from the older budwood garden relative to the younger ones could be partly attributed to their well developed root system that have been found to enhance nutrient uptake and conservation among tree crop management systems.

CONCLUSION

The soils studied were low in pH. The concentrations of organic carbon, total nitrogen, available P, potassium were inadequate, while calcium and magnesium were moderate. Though the elements were generally higher in older budwood garden, constant monitoring of soil and leaf nutrient status in budwood garden is necessary for proper soil amendment or improvement for efficient budwood garden growth and development, consequently the production of viable planting materials.

ABSTRACT
Experiments were carried out at the student experimental station, Kabba college of Agriculture Kabba, Kogi State in 2014 and 2015, to investigate the effects of different rates of cow-dung manure on the soil properties, growth and yield of Bambara groundnut. Seed were obtained from International Institute Tropical Agriculture, Ibadan. There were five treatments which were as follows: 0t/ha, 2t/ha, 3t/ha, 4t/ha and 5t/ha. The treatment were arranged in a Randomised Complete Block Design and replicated three (3) times. Data was taken on soil physical and chemical properties, agronomic traits such as plant height, leaf area, stem girth and number of leaves. Yield parameters taken were grain weight per plot and yield (t/ha). The data were statistically analyzed using GENSTAT. The analysis of variance (ANOVA) was performed to find out the significance of variation among the treatments while the significant difference between mean treatments were separated using least significance Difference at 5% level of probability. The study indicated that plots treated with 5t/ha cow dung produced the highest pod yield per plot (4.64kg) and seed dry weight (3.80t/ha) and improved better the soil physical properties. It is therefore concluded that plant should be treated with 5t/ha to get good yield of Bambara nut in the study area.
Keywords: Cow dung, Manure, Legume species, Different rate, Subterranean, Bambara groundnut,

INTRODUCTION

Bambara groundnut (*Vigna subterranea (L) Verdc*) is a pulse with subterranean fruit-set and is cultivated by small holders over much of semi-arid Africa (Linnemann and Azam-Ali, 1993). The crop is a legume species of Africa origin (Borget, 1992). Food legumes have a major role to play in the fight against malnutrition. The protein of bambara groundnut is of good quality and has surplus lysine with complement cereals in the diet Ocran et al., (1998). The composition of the seed from the point of view for human nutrition is very well balanced, as they contain 20% soluble carbohydrate and 8% fats (Messiaen, 1992). It is high in protein unlike ordinary groundnut contains very little oil (Tweneboah, 2000). The high carbohydrate (65%) and relatively high protein 18% content of bambara groundnut make it a complete food (Doku, 1995).

In Nigeria, bambara groundnut (*Vigna subterranea (L) Verdc*) was for a long time at par with cowpea (*Vigna uniguiculata*) in terms of production and utilization. The status of the nut however, started to decline from 1970's with introduction of high yielding varieties of groundnut (*Arachis hypogaea*) and pest control methods of cowpea (Doku,1995). The majority of ultisols located in the southern guinea savanna zone of Nigeria are strongly weathered and inherently low in nutrients and organic matter. Crop yields on these soils are low (Ogundare, 2012). Even though farmers are advised to use inorganic fertilizer, this input is scarce and beyond their reach. Also the use of inorganic fertilizers alone to sustain high crop yield has not been quite successful due to enhancement of soil acidity, nutrient leaching and degredation of soil physical and organic matter status.

Bambara groundnut was ranked the third most important legume after groundnut and cowpea in semi-arid Africa (Linnemann and Azam-Ali, 1993), but has not been accorded due attention in research. Little research has been done to date to improve bambara groundnut. The work done on the crop has been limited to mass selection of a few local varieties, followed by purification phase for the main agronomic characteristics. International Institute of Tropical Agriculture (IITA) has recently evaluated a large collection of bambara groundnut comprising more than 1000 introduction collections from all over Africa (Baudoin and Mergeai, 2001). The researcher tends to find out how the use of cow dung manure will improve soil properties, growth and yield of bambara groundnut in the study area.

MATERIALS AND METHODS

Experimental site

The experiment was carried out for two consecutive growing seasons (2014 and 2015) at the research site of Horticultural Section, College of Agriculture, Kabba. The site is located at latitude of 07° 35' N and longitude of 06° 08' E and is 423 m above sea level, in Southern Guinea Savanna Agro Ecological Zone of Nigeria, where the dry seasons are dry and hot while, wet seasons are cool. The rainfall spans between April to November with peak in June. The dry season extends from December to March. The mean annual rainfall is 1570mm per annum with an annual temperature range of 18°C - 32°C. The mean relative humidity (RH) is 60% (Meterological data, 2011). The major soil order within the experimental site is Gleysol (Higgins, 1957; Babalola, 2010).

Determination of soil physical properties

Soil Physical properties were taken at 30 and 60 days after planting. Five undisturbed samples were collected at 0-15cm depth from each plot using core samplers and were used for the determination of bulk density, total porosity and gravitational moisture contents after oven dried at 100^0C for 24 hours. Total porosity was calculated from the value of bulk density and particle density. Soil temperature was determined at 15.00 hr (3pm) with a soil thermometer inserted to 5cm depth. Five readings were made per plot at each weekly determination.

Experimental Design

The experiment was laid out in a randomized complete block design (RCBD) with three replications to investigate the effect of different rates of cow-dung manure on the soil properties, growth and yield of bambara groundnut (*vigna subterranea)*. The experiments were arranged in a randomized complete block design (RCBD) and replicated three times. The treatments consisted of the followings: T1= 0t/ha of cow dung, T2 = 2t/ha of cow dung, T3= 3t/ha of cow dung, T4= 4t/ha of cow dung and T5= 5t/ha of cow dung. The seeds for the experiment were collected from International Institute Tropical Agriculture, Ibadan. Sites were cleared manually using cutlass and later ridged with hoes and in the field, Seeds of Bambara nut were sown on a flat bed. Organic manure were uniformly spread on the flat beds and incorporated with hoes two weeks before planting. The seeds were planted at the rate of two - plant-per-hole at a spacing of 50cm by 30cm which make up forty- nine stands per plot. Plots were weeded manually at three weeks intervals. Data collected were statistically analyzed using GENSTAT. The analysis of variance (ANOVA) was performed to find out the significance of variation among the treatments while the significant difference between mean treatments were separated using least significance difference at 5% level of probability.

RESULTS AND DISCUSSION

Properties of the Experimental Site and Chemical Properties of Cow Dung Used

The properties of the soil at the site of the experiment are presented in Table 1. The soils are predominantly sandy, slightly acidic with relatively high bulk density. The organic matter, total N, available P, exchangeable K and Ca were low. The chemical composition of cow dung used is show in Table 2. The chemical characteristics of cow dung shows relatively high in essential nutrients required for the growth and development of crop. However, C/N was also high (15.9). The properties of the soil at the site of the experiment are presented in Table 1. The soils are predominantly sandy, slightly acidic with relatively high bulk density. The organic matter, total N, available P, exchangeable K and Ca were low.

Physical Properties of the soil as affected by application of different rate of cow dung

The physical properties of the soil as affected by application of different rate of cow dung are presented in Table 3. Significant difference was observed in soil porosity and soil moisture content, while, both bulk density and soil temperature were not affected significantly. Highest bulk density and least values of both porosity and soil moisture content were observed in plots without cow dung amendment. Plots treated with cow dung were significantly better irrespective of the rate of it application than plots without cow dung application. However, no significant difference in the soil porosity and soil moisture content of the amended plots irrespective of the rate of application. The result agreed with the findings of (Agbede 2007) and Ewulo et al. (2008). They found that soil bulk density reduced and moisture content increased in the plots where poultry manure was applied. This was attributed to the enhancement of soil organic matter by organic residues applied. No significant response was observed in soil temperature as a result of treatment imposed irrespective of it rate of application.

Growth Characteristics of Bambara nut as affected by application of different rate of cow dung

Effect of different rate of cow dung on growth characters of Bambara nut are presented in Table 4. Plant height, number of leaves, stem girth and leaf area were significantly affected by the application of different rate of cow dung. It was also observed that all the growth characters increased with increase rate of cow dung. Plots treated with 5t/ha producing highest plant height, number of leaves, stem girth and leaves area while, the least values of all these were observed in the control plots. Cow dung improves the growth characters of Bambara nut which agreed with findings of Suge *et al*. (2011). They attributed the better performance of crop in term of growth characters to gradual release of nutrient by the organic manure applied.

Yield Characteristics of Bambara nut as affected by application of different rate of cow dung

Table 5 presented the effect of application of different rate of cow dung on yield characters of bambara nut. Pod yield per plots and seed dry weight were significantly affected. Both pod yield per plots and seed dry weight in tons per hectare increased with increase rate of application of cow dung. Pod yield per plots and seed dry weight per hectare were highest in plot treated with 5t/ha cow dung while, the least values of pod yield per plot and seed dry weight in tons per hectare were lowest in unamend plots. All the plots with the application of cow dung increased yield better than plots without cow dung. The findings corroborated the work of several workers that organic residues increase growth and yield of crops Ogundare et al. (2014) on okra; Akpeokhai et al. (2014) ; Bello et al. (2013) on maize and Agbede (2007) on sorghum.

CONCLUSION

The study indicated that plots treated with 5t/ha cow dung produced the highest pod yield per plot (4.64kg) and seed dry weight (3.80t/ha) and improved soil physical properties. It is therefore concluded that plant should be treated with 5t/ha to get good yield of Bambara nut in the study area.

ABSTRACT

Urban cultivation is characterized by intensive vegetable-crop production all year round to meet the demand of burgeoning urban populace and offers ecosystem services of sustainable recycling of municipal waste in food production. In this study, long term effect of three different fertilizer management (treatments) were selected as practiced in the Kubanni area of Zaria, northern guinea savanna of Nigeria, and they include (i) municipal waste (MW) application (ii) mineral fertilization (MF) and (iii) No fertilization (control; NF), to monitor soil quality. Three undisturbed soil cores and three disturbed soil samples were collected from two soil depths (0-15 and 15-30 cm) taken diagonally across the farmland of each fertilizer management. Physical and chemical soil properties were determined by routine analytical procedures. Municipal waste treated soils have the lowest bulk density values compared to the other two treatments with values of 1.34 g cm^{-3} in 0-15 cm and 1.39 g cm^{-3} in 15-30 cm. Total porosity was 47% and 48% in the upper and lower soil layers, respectively, and statistically differ ($p<0.01$) from the other two treatments. Similar trend was observed for water retention, hydraulic conductivity and aggregate stability in both wet and dry sieving methods. Soil pH in $CaCl_2$ and H_2O were close to neutral in MW treated soils, with organic carbon contents of 1.92% in the upper soil depth although, it was not statistically different ($p>0.05$) from MF treated soils with values of 1.74%, and higher exchangeable bases (Na^+, K^+, Ca^{2+}, Mg^{2+}) were obtained in MF soils. These findings have important implications to places where water is a limiting resource, or in the face of climate-related uncertainties not only for urban cultivation but for rain-fed crop production due to enhanced water retention and improved soil structural conditions with the applications of municipal waste.

Keywords: soil quality, nutrient management, urban cultivation, municipal waste, water retention.

INTRODUCTION

The current trend of urbanization in the world and West Africa in particular, necessitates increase in food production to meet the teaming urban population. Urban cultivation entails crop production in open spaces within cities and is often characterized by intensification under continuous year round cultivation (Abdulkadir et al., 2013). Although urban cultivation is an avenue that ensures a steady supply of vegetables and crops to urban markets, intensification of production leads to nutrient depletion characteristic of most African farming systems (Stoorvogel and Smaling, 1990). Integrated nutrient management (INM) which involves complementary use of organic and inorganic fertilizers has been suggested to improve productivity of most depleted soils (De Jager, 2007), which became widespread in the 1990's and 2000's. Integrated nutrient management practices have been shown to have significant influences on physical and chemical status of many agricultural soils. Nigerian savanna Alfisols are characterized with poor structural stability and liable to compact (Ogunwole et al., 2001). However, these properties were shown to improve or change with management practices such as tillage and fertilizer application strategies.

The Kubani area in Zaria, Northern Guinea Savannah of Nigeria is an intensively cultivated fadama-like land located in the urban province. Farmers adopt different fertilizer management practices to sustain productivity among which is the application of organic amendments from municipal waste sources. Emphasis is placed on nutrient supply of this practice with little attention to the role it plays on soil physical status.

The objectives of this work are to access and compare the physical and chemical properties of soils subjected to different fertilizer management under urban cultivation practices in Zaria, northern guinea savanna of Nigeria.

MATERIALS AND METHOD

Site description and management

The study was situated at the Kubani Fadama-like site of Zaria LGA at the Kaduna state, Nigeria, longitude 07^0 41'E and latitude 11^0 10' N with an annual mean rainfall of 1060mm (Oluwasemire and Alabi, 2004). Alfisols are the major soil order in the northern guinea savannah of Nigeria (Jones and Wild, 1975). The Kubanni farmers engage in year-round continuous cultivation with irrigated crop and vegetable production during dry periods.

Three farms were chosen for the study to represent three fertilizer managements i.e. plots or farmlands fertilized mainly with municipal waste (MW), mineral fertilizer (MF) and a control site with no fertilization (NF).

Soil sampling and analysis

Three undisturbed soil cores were taken from each sampling depth (0-15 and 15-30 cm) from three random spots per farm plot (treatment), making a total of 54 (i.e. 3 samples x 3 random points x 2 soil depths x 3 farm plot) soil cores. Disturbed samples were taken from the same spots as the soil cores but were bulked per sample depth i.e. 3 samples per depth per farmland (3 samples x 2 soil depths x 3 farms/plots). Disturbed soil sample taken were analyzed for physical and chemical properties while soil cores were used for determining bulk density by method of Blake and Hartge (1986). Chemical properties determined include soil pH in water and $CaCl_2$with 1:1 soil to solution ratio, organic matter and exchangeable bases. Particle size distribution, total porosity (F), saturated hydraulic conductivity and aggregate stability (wet and dry sieving method) were all determined using standard laboratory procedure.

Data Analysis

Data were subjected to analysis of variance (ANOVA) to assess the effect of the different fertilization on soil properties. Treatment means were separated using the least significant difference (LSD) and Spearman's correlation was also conducted on the data to measure the association of soil organic matter and some selected physical properties. All data was analyzed with SAS Statistical package (SAS Institute, 2001).

RESULTS AND DISCUSSION

Chemical properties

Soil reaction shows the three soils having pH ranges of 5.9 to 7.3 (slightly acidic to neutral) with no significant difference ($p>0.05$) with treatment and soil depth (Table 1). The soils treated with municipal waste had a near neutral pH when compared to the other treatments. This could be attributed to the buffering capacity of organic matter on soil reaction. The MF treatment exhibited a slightly near acidic reaction. Municipal waste applied to the soils was found to have high organic contents of up to 38% (data not shown). This is characteristic of most wastes because it contains high amounts of organic material that is compostable. Soil organic carbon (SOC) in the municipal waste (MW) and mineral fertilization (MF) treatments were not statistically different ($p>0.05$), but both treatment had significantly higher ($p<0.05$) SOC contents than the control (NF) at both soil depth (Table 1). Soil organic matter was higher in MW soils due to addition of municipal waste while as for the MF treatment, it may be due to the wastewater used to irrigate the farms during the dry season as the MF field is located close to the wastewater source. This may be the reason why the some of the farmers do not have to add further organic amendments as their plant nutrient needs are met by the nutrient-rich wastewaters (Abdulkadir et al., 2013). The low soil organic matter in the NF treated soil could simply be attributed to non-incorporation of organic materials to the soil. Across all the treatments, exchangeable bases are moderate in values and optimum for crop production. There was no statistical difference in exchangeable sodium in all the treatments although higher values were obtained in MF treatment. This may be unconnected with slight additions of these bases in mineral fertilizers which contributed to higher values of Ca^{2+} and Mg^{2+} of soils in MF than the other treatments.

Physical properties

Soils were sandy loam in texture and did not differ in the percent clay, sand and silt across all the treatments (data not shown). There was an increase in clay content with depth which as often, is attributed to clay eluviation from the surface as a result of continuous cultivation and tillage (Shirani et al., 2000). Bulk densities of all the treatments ranged from 1.34 – 1.57 Mg m^{-3} (Table 2). Although these values are within the limit of good root penetration, there was a significant difference ($p<0.01$) among the bulk densities of the three farmlands. The MW treatment had low bulk density compared to MF and NF treatment and differ statistically from the two treatments. However, the latter two were statistically at par ($p>0.05$) at both soil depths. Low bulk densities for MW treatments could be as a result of addition of organic amendment which had an influence on the soil structure (Sommerfeldt and Chang, 1987; Arriaga and Lowery, 2003) when compared with MF and NF farmlands. Total porosity (F) of MW varied with that of the other treatments. Soil with municipal waste applied to them had significantly higher ($p<0.05$) porosities than the other two treatments, which were statistically at par (Table 2). This implies that there will be adequate drainage and moisture retention in MW fields as compared to the other fields. Studies have shown an increase in total porosities of soils with organic amendments (Zhang et al., 2006) which is usually has more volume and less weight thus increase the number of and water held in soil pores. The lower porosity of the MF field could be due to non-contribution of organic material towards improving soil porosity which was found to reduce soil porosity of sandy loam soils in the North-eastern part of Nigeria.

High porosity of MW could be attributed to low bulk density and improved soil structure following increased addition of organic materials. Measured saturated hydraulic conductivity (Ks) values across the different treatments are presented on Table 2.

There was a significant difference between the three fields for all soil depths but there is no significant difference within a treatment with depth. There was a slight decrease in Ks with depth for all three fields. Municipal waste treatment had a significantly higher ($p<0.05$) Ks than MF and NF soils. High total porosities of MW from organic amendments would have influenced the transmission properties of the soil vis a vis saturated hydraulic conductivity. Studies have shown a significant increase in Ks and water flow with organic matter additions (Arriaga and Lowery, 2003; Schjonning et al., 2002). Similar trend was observed for dry and water stable aggregates for both soil depths. Similar observation was made by Obi et al. (1995) for soils in southern Nigeria on the influence of organic and inorganic amendments of soil properties.

Relationship between some of the soil properties

Soil properties correlated with organic carbon content (SOM) to explain certain processes taking place in the soil. Saturated hydraulic conductivity had a significant positive correlation ($p=0.001$) signifying that organic matter content has an influence in water movement in the soil (Table 3). The higher the organic matter content, the more rapid the movement of water between the soil pores. The correlation of bulk density showed a negative correlation which was significant ($p=0.001$) signifying that lower bulk density is associated with an increase in organic matter content and vice versa. These results are consistent with findings that indicate the positive impacts of organic additions on soil retention properties that affect soil processes.

CONCLUSION

The Kubanni farms of Zaria practice urban agriculture and are known for intensive crop production with little or land to fallow in order to meet the increasing demand of growing populace. This study showed that municipal waste additions to soils in Kubanni farms increased soil organic matter content at the two soil depths (0-15 and 15-30cm). The soils under municipal waste (MW) application had a lower bulk density, higher total porosity, saturated hydraulic conductivity, water retention and aggregate stability than soils fertilized with mineral fertilizer (MF) or no fertilization at all (NF). Although some of the differences with MF were not statistically significant, values of the soil properties were slightly higher in MW than MF. This was further indicated by the strong correlation between organic carbon and above mentioned soil properties. These findings have important implications for continuous cultivation in dry-land farming, and where water is a limiting factor for crop production. Thus, suggesting that application of organic waste could reduce the amount of water used per irrigation cycle at the same time improve the water retention and transmission properties of the soil.

Table 1: Chemical properties of the study plots under different fertilizer management

Soil Depth (cm)	Plot/ treatment	Organic carbon (%)	Soil pH		Exchangeable bases ($cmol^+kg^{-1}$)			
			H_2O	$CaCl_2$	Na^+	K^+	Ca^{2+}	Mg^{2+}
0-15	MF	1.74^a	5.9	5.3	0.81	0.46	13.51	1.79
	MW	1.92^a	7.3	7.0	0.32	10.5	1.51	1.81
	NF	0.57^b	6.4	6.3	0.23	0.09	12.01	2.50

ABSTRACT
The eco-toxicological effect of lead pollution is established and enormous. Although there is a lot of awareness on this, mining communities like Ihieututu remain at risk. In Ishiagu and hence Ihietutu, this risk is further heightened by the fact that there is also inadequate water supply. As a result of this, the people of Ihieututu like other communities in Ishiagu depend on surface water to meet their potable water need. Therefore continuous monitoring of lead levels in this critical resource that the people so direly need, to ensure its safety, is imperative. In the light of the above, lead concentration was assayed in three (3) wells and five (5) streams in Ihietutu that serve as sources of potable water using Atomic Absorption Spectrophotometer (AAS). These stream include; Ihukoyi, Okuiyi, Isiovia, Iyiokpu and Akpuadu. Lead concentrations in these streams were found to be 28.528 ± 0.998 mg/l, 0.000 ± 0.000 mg/l, 34.171 ± 2.993 mg/l, 34.244 ± 2.890 mg/l and 34.171 ± 0.998 mg/l for Ihukoyi, Okuiyi, Isiovia, Iyiokpu and Akpuadu respectively. From the result obtained, four (4) of the five (5) streams were found to be contaminated with lead. However, lead was not detected in all well water samples analyzed. This could be attributed to the tendency of lead to adsorb tightly to soil particles.
Keywords: lead, potable water, Ishiagu

INTRODUCTION
The demand for industrial raw materials and the need to earn foreign direct investment (FDI) led to the growth and development of the mining sector. One of the important metals mined is lead. It is the commonest heavy metal, making up 13 mg/kg of the earth's crust (WHO,2011). Archeological research indicates that lead has been used by humans for numerous purposes for more than 5000 years (Hill, 1999). Today lead is still an important metal not only to industrialized nations but also to developing nations who increasingly seek ways of earning more revenue.

However, lead has been found to be highly toxic. This is because lead is an element with no known physiological benefit to living things. Nevertheless, it displaces other elements with very important roles in metabolic processes of living organisms. The harm lead cause to living things is aggravated by the fact that when it gets into the environment, it persists. Its persistent nature is because it is an element. Thus, it cannot be broken down or destroyed. According to (WHO 2010a), when lead finds its way into the system of animals like humans, it is distributed to the brain, liver, kidney and bones and can be stored in the blood, teeth or bones. This is to say that, when lead finds its way into the system of animals including man, it accumulates in these vital organs until certain threshold concentrations are exceeded. At this point, the toxicological effect of lead exposure begins to manifest. Lead accumulation may then result in cardiovascular problem; during pregnancy, lead exposure may cause miscarriage, still birth, low birth weights, premature births and birth defects (Blacksmith Institute, 2007). Lead has also been identified as a possible human carcinogen by the International Agency for Research in Cancer IARC, (2006). Children are even much more vulnerable to lead toxicity. This is because their body can absorb about 4 – 5 times more lead than the adult body; hence even at the lowest level, lead is toxic to children (WHO, 2010b). Put differently, adults absorb only about 5-15% of all the lead they ingest, and generally retain less than 5% of what is absorbed Juberg *et al*., (1997). However, absorption of inhaled lead is much higher, about 50%. On the other hand, children absorb much more of what they ingest. They are able to absorb approximately 30-40% of all ingested lead. The efficiency with which lead is absorbed in children may even get to 50% of all ingested lead. This difference in efficiency of lead absorption has been attributed to physiological and metabolic differences Juberg *et al*., (1997). Furthermore, the brain damage that result from lead exposure in children is irreversible and includes mental retardation, decreased Intelligence Quotient (IQ), shortened attention span, loss of executive function, increased risk of dyslexia and diminished productivity (Blacksmith Institute, 2007). The negative effect of lead exposure on humans may be better revealed by the fact that mild mental retardation and cardiovascular problem alone, caused by lead exposure have been estimated to amount to almost 1% of total global disease burden, with developing countries bearing significant portion of this burden Fewtrell *et al*., (2004). Lead exposure may ultimately culminate to death as observed in the case of lead toxicity in Zamfara State in Northern Nigeria where over one hundred and sixty three (163) people died between March and June 2010. The above causality figures include one hundred and eleven (111) children (BBC News, 4 June 2010).

The detrimental effect of elevated level of lead in the environment is not limited to animals. Plants are also affected negatively. Precisely, lead contamination has been found to cause poor growth, low yield, hinder seed germination, root elongation and seed development in plants Pourrut *et al*., (2011).

Due to the myriad of negative health and environmental effects of exposure to lead and other heavy metals, they should be and are being strictly monitored. However, unlike developing nations, developed nation have become efficient in this regard; thus, they initiated, promoted and implemented the prohibition of the use of lead in house hold utilities and as an additive in gasoline. Precisely legislative measures were gradually introduced to reduce lead exposure by removing lead from paint, food cans, water pipes and gasoline in Europe since 1970s. Leaded petrol was banned from 2000 with exception possible until 2005 (European Food safety Authority, 2012). Although the use of lead as an addictive in gasoline and other household utilities was forbidden by 2005 in most countries, demand for lead have not declined. In 2010, world mine production was estimated to be 4.1 million metric tons while world consumption of refined lead stood at 9.35 million metric tons (Murtala, 2011). Demand for lead worldwide is expected to grow. This is mainly because of increased consumption in China which is being driven by growth in the automobile market (Esteves, 2008).

In Nigeria, the realization of the economic potentials of the solid mineral sector and the decline of crude oil prices, which is the main revenue earner of the country, have made the need to diversity the nations' economy urgent. As a result of this, the Federal Government has undertaken a number of reforms within the sector in order to not only expand the nations non – oil foreign revenue, but to also attract FDI. Because of these reforms, there is significant increase in investments in the sector from not only Government Based Agencies but also from foreign and national private sector organizations. However, it is in the small scale mining category that interests and activities have grown most significantly (Lawal, 2002; Murtala, 2011). This category of Miners have been found to lack necessary capacity to initiate Environmental Protection Measures. Thus, the environmental burden of their mining activities is on the host communities rather than these Small Scale Miners (Lawal, 2002; Okeke, 2008; Murtala, 2011).

Water bodies and soil are often at risk of contamination, due to the nature of lead mining,. When this happens, local populations are invariably affected. Although, whichever the route of exposure, once lead leaks into the environment, the burden of its detrimental effect falls on living organisms, pollution of water bodies have far reaching consequences. This is because both plants and animals depend on water as a critical resource for their survival. Furthermore, lead is much more mobile in water than in soil and as result can reach sites far removed from the site of contamination when suspended in water.

Hence, there is a need for continuous monitoring and assessment to ensure not only the safety of local populations and the agricultural produce from such communities but also environmental sustainability in all mining locations in the country. This is more so as preventive measures have always been found to be better than curative measures. In fact, according to (Gould 2009), the cost-benefit ratio of implementing preventive measures against contamination and associated toxicity is better than for vaccines, which have long been described as the single most efficient global health intervention. Therefore, the aim of this study is to ascertain the presence or otherwise of lead in potable water sources in Ihieututu Community in Ishiagu, Ivo Local Government Area of Ebonyi State, Nigeria; and to determine the concentration of lead where present.

MATERIALS AND METHOD

Study Area

Ihietutu is one of the villages in Ishiagu, Ivo Local Government Area of Ebonyi in South Eastern Nigeria. It is the only community in Ishiagu where lead has being mined and is still being mined. Ishiagu is located approximately in latitude 5^o60^oN and longitude 5^o60^oN and experiences wet and dry season climate. The rainy season usually stretches from April till October while the dry season usually lasts from November to March. Maximum temperature in Ishiagu is about 32^o C while minimum temperature is about 24^o C in July.

According to 2006 National Population Census, the population of Ishiagu was 17,250 people (NPC, 2011); and the people of Ishiagu are mainly farmers. There is inadequate water supply in Ishiagu, hence Ihietutu. Therefore, the people of Ihietutu like other communities in Ishiagu depends on surface water. These stream include; Ihukoyi, Okuiyi, Isiovia, Akpuadu and Iyiokpu. There has been not less than 10 years of mining activities in the Study Area.

Sample Collection

Water samples were collected, in August 2015, from three (3) wells and five (5) rivers located in Ihietutu. The samples were collected using 500ml plastic containers. These plastic container and all glass wares used were washed with detergent solution followed by 20% nitric acid and then rinsed with tap water and distilled water. To collect the sample, the plastic containers were submerged in the river at a depth of about 5cm. One (1) sample was collected from each well, while two (2) samples were collected from each stream. One sample was collected upstream while the second sample was collected downstream for each of the streams sampled.

Sample Preservation and Equipment Used

To preserve the sample, 1ml of concentrated nitric acid was added to each 500ml of sample water collected. This was done at the earliest possible time after sample collection. Atomic Absorption Spectrophotometer was used in the assay for lead in the sample waters.

Sample Digestion Procedures

To ensure the removal of organic impurities from the samples and thus prevent interference in analysis, the samples were digested with concentrated Nitric acid. 5 mL of conc. HNO_3 was added to 100 mL of sampling water into the 250 mL conical flask then heated on a hot plate and evaporated till 20 mL was left. After cooling the flask again 5 mL of conc. HNO_3 was added and the flask heated on the hot plate. The digestion was continued till 10 mL was left and finally filtered and diluted with distilled water into 100 mL of volumetric flask and stored in the refrigerator.

Standard Preparation

The stock solution of Lead was prepared by dissolving in a liter volumetric flask 24.62g of Lead nitrate with 68% of nitric acid. The mixture was shaken and the flask made up to the 1 L mark with the nitric acid. Calibration solution of lead ion was prepared from the standard stock by serial dilution.

Sample Analysis

Analytical grade reagents and distilled water were used throughout this study. Chemicals used were obtained from RIEDEL-DE HAEN, Germany. Lead Nitrate was used for preparation of lead standard while nitric acid was used for sample digestion. The digested water samples were analyzed for the presence of lead using Atomic Absorption Spectrophotometer. The calibration plot method was used for analysis. The wave length for the determination of lead was 283.31nm. The digested samples were analyzed in triplicates with the average concentration of the metal displayed in mg/l by the instruments after extrapolation from the standard curve.

RESULTS AND DISCUSSION

Average lead concentrations in the rivers were determined as shown in table 1 above. From the result obtained, all the rivers were found to contain lead except Okuiyi whose lead concentration is below detectable limits. Average lead concentration in the contaminated rivers were 28.528 mg/l, 34.171 mg/l, 34.244mg/l and 34. 171 mg/l for Ihukoyi, Isiovia, Iyiokpu and Akpuadu respectively. From the result for the assay of lead in wells located in Ihietutu as contained in Table 2 above, all the wells tested were found to either contain no lead or lead concentrations below detectable lead range. Therefore, lead was not detected in all the samples collected from the selected wells.

Recent research has shown that some of the negative health effects of lead exposure to living organisms occur at levels of exposure that were previously considered safe (Bolger *et al*., 2000). This discovery brings to question previously accepted safe limits for lead exposure. Nevertheless, one thing is incontrovertible. Lead is harmful and once concentration of lead in the environment exceeds certain threshold, its toxic effect begins to manifest. All life forms, namely, plants, animals and microorganisms in the soil, as well as aquatic organisms, are affected negatively. In this study, lead was assayed in five (5) rivers in Ihieututu as listed in Table 1. These rivers include, Ihikoyi, Okuiyi, Isiovia, Iyiokpu and Akpuadu. Lead was also assayed in three (3) wells located in Ihieututu.

Four of these five rivers, namely; Ihikoyi, Isiovia Iyiokpu and Akpuadu were found to be heavily contaminated with lead. Average lead concentration in these rivers ranged from 28.528, 34.171, 34.244 and 34.171 mg / l for Ihikoyi, Isiovia Iyiokpu and Akpuadu respectively. Lead concentration in these rivers exceeded the minimum acceptable lead concentration in portable water [1]. However, lead was not found in the water sample collected from wells sank in this community. The implication of this is that lead contamination is still limited to the surface waters only. Hence, underground water in the locality is still safe as a source of potable water. Contamination of these rivers are likely a product of mining. This is more so as the community is a rural community with no major highway and low vehicular traffic. There is also no presence of industries except for the mining industry.

Since the people of the community depend on these rivers for agricultural purposes, including fishing; and as sources of potable water, this will have far-reaching impact on the wellbeing of the people and the environment. Precisely, on the micro-environment, it will lead to poor plant yield and decreased animal productivity. Considering the high volume of annual rainfall and the nature of soils in South Eastern Nigeria which is prone to erosion, the poor plant yield and hence poor plant cover that result from lead leakage into the environment will

also lead to increased erosion in the area. This will invariably lead to increased mobility of the contaminant. Lead concentrations were found to exceed minimum acceptable limits. As a result of this, humans within the locality, especially those who depend on these rivers as their means of potable water, may also be exposed to the chronic hazards of lead ingestion.
On the macro-scale, decreased plant yield which may be observed in the micro-environment as a result of lead toxicity may aggravate global warming. This is because; there will be increased escape of greenhouse gases like carbon dioxide into the atmosphere. These gases would have been hitherto trapped by these plants and converted to useful biomass.

CONCLUSION AND RECOMMENDATION

From the result obtained 80% of the surface waters source in Ihietutu was found to be contaminated with lead. However, lead was found not to have percolated to underground waters in the area. This could be attributed to the tendency of lead to adsorb tightly to soil particles. The above view is supported by the assertion of UNEP (2011) that as a result of this tight adsorption of lead to soil, groundwater is not at high risk from lead infiltration through topsoil although heavily contaminated sites may pollute localized groundwater especially in acidified conditions. It is necessary to put measure in place to prevent further contamination while the people should be enlightened on the dangers of continued use of the contaminated rivers as potable water sources. As an alternative, more boreholes and wells should be sank in the community. Again, it is essential that local populations, especially young children, living in the community undergo medical assessment to determine the amount of lead in their blood. This will enable the commencement of treatment and remediation regimes where necessary.

Table 1: Average concentration of lead in samples collected from the five (5) streams located in Ihieututu

	Sample	Lead Concentration (mg / l)		
		Upstream	Downstream	Average ± SEM
1.	Ihikoyi	27.822	29.233	28.528 ± 0.998
2.	Okuiyi	0.000 (ND)	0.000 (ND)	0.000 ± 0.000
3.	Isiovia	32.054	36.287	34.171 ± 2.993
4.	Iyiokpu	32.054	36.287	34.171 ± 2.993
5.	Akpuadu	34.876	33.465	34.171 ± 0.998

ND: Not Detected

Table 2: Result obtained from the assay for lead in water samples collected from three (3) different wells located in Ihietutu

	Sample	Absorbance	SD	RSD	Concentration (mg / l)
1.	Well 1	- 0.156	0.0015	- 0.9349	0.000 (ND)
2.	Well 2	- 0.155	0.0038	- 2.4225	0.000 (ND)
3.	Well 3	- 0.156	0.0024	- 1.5128	0.000 (ND)

ABSTRACT

Changes in agricultural land use patterns influence how much and at what rate carbon is sequestrated in or released from soil. Carbon sequestration was investigated in three soil vegetation ages (7 years vegetation age, 14 years vegetation and 21 years vegetation age. From the results, sand contents ranged from 835.2 – 889.2g/kg, clay content ranged from 92.6 – 122.6g/kg. Organic carbon content was generally low ranging from 3.99 – 5.67g/kg. Carbon sequestration ranged from 1295 – 1611gcm^{-2}. Carbon sequestration result therefore showed that 14 years vegetation sequestered the highest amount of carbon with value of (1611gcm^{-2}) while the least was obtained 7 years vegetation age. It was observed that vegetation age do not have any bad effect on the carbon sequestration. Therefore, I recommend that attention should be given to soils of South Eastern Nigeria on rates at which carbon is sequestered in them for optimum carbon accumulation to be ascertained in Agricultural activities and production.

Keywords: carbon sequestration, soils, vegetation age, effect

INTRODUCTION

Carbon in agricultural soil contributes positively to soil fertility, crop production and overall soil sustainability (Lal, 1999). Carbon is one of the non-mineral elements or nutrient element needed by plants for the completion of their life cycle (Hodges 2002). Carbon is gotten from air by plants during the process of photosynthesis and it is found in all living organisms and also the major building block for life on earth and as well found in vegetation as plants biomass and in soil as soil organic matters (Ecological Society of America 2006). Soils are important reservoirs of active organic components such as carbon and it plays a great role in the global cycle of the element and such, soil can be either as source or sink for atmospheric CO_2 depending on land use and management of soil and vegetation (Lal, 2005). Over 60% of the world's carbon is held in both soils and more than 40% and the atmosphere as carbon dioxide; 20% (Stevenson, 1994).

Carbon sequestration is the active removal of carbon from the atmosphere and depositing it in a reservoir. Carbon sequestration is the long term capture that occurs in biomass, soil, oceans, and underground sinks such as aquifers, saline deposits, and gas reserves (Lal 2004). Carbon can be stored in the soil as soil organic matter and soil organic matter is a complex mixture of carbon compounds consisting of decomposing plants and animal tissue, microbes, protozoa, nematodes, fungi, bacteria, (Ecological Society of America, 2006). Since soils differ in their responses to different land use practices and management system, it is important to investigate more closely the influence of agricultural land use practices on carbon sequestration. Therefore, a good knowledge of carbon sequestration and storage in soils is important for development in soil and reducing its adverse effects. More so, this study tends to determine the effects of vegetation age on carbon sequestration in soil of South Eastern Nigeria. The objective is to determine the effect of vegetation age on carbon sequestration and to determine the physio-chemical properties of the soil of the study area.

MATERIAL AND METHODS

Study Area

The study was carried out at Eziudo in Ezinihitte Mbaise Local Government Area of Imo State, South-Eastern Nigeria. The area lies between latitude $5^0$28' and $5^0$41'N and longitude $7^0$20' and $7^0$48'E with an altitude of 143m. The mean annual temperature range of the study area is 27^0c – 30^0c with the hottest period been between February and April (Ofomata, 1975). The parent material is coastal plain sands (Ofomata, 1975). Farming is the major socio-economic activity of the area.

Pre-field study

Reconnaissance visit was conducted on the study sites and information was gathered from the farmers and land owners through oral interview to find out the number of years the land has remained under its current land use.

Soil sampling and laboratory analysis

A profile pit was dug in each of the three different vegetation ages (7 years, 14 years, 21 years) respectively. Soil samples were collected from the profile pits in each of the three different vegetation age ranging from 0 – 20, 20 – 40, 40 – 60, 60 – 80 and 80 – 100cm. The samples were bulked, taken to the laboratory, air dried sieved using 2mm sieve and used for determination of some physical and chemical properties following procedures outlined by FAO (2002). Carbon sequestration (gCm^{-2}) was calculated using $OCgkg^{-1}$ x $BDgcm^{-3}$ x Horizon thick (Batjes 1996).

Experimental design

The experiment was a factional experiment arrange in randomized complete block. Design (RCBD) with two (2) treatment land use and age.

Data Analysis – Data obtained where subjected to ANOVA. Significant means were separated using LSD at 5% (0.05) probability. Level.

RESULTS AND DISCUSSION

Soil physical properties

The sand content of the varying vegetation ages ranged from 835.2 – 889.2gkg^{-1}. Silt and clay content ranged from 18.2 – 57.2gkg^{-1} and 92.6 – 122.6 gkg^{-1} respectively. However, sand contents of the three vegetation ages differed significantly ($P \leq 0.05$) while no significant differences. were observed in the silt and clay fractions of the three vegetation ages (Table 1). From the results, it was observed that vegetation age had little or no influence on the particle size or fraction of the soil. This observation agrees with the findings of Ahukaemere *et al* (2015).
The Bulk density values ranged from 1.44gcm^{-3} in 7 year old vegetation to 1.64gcm^{-3} in 21 year old vegetation. Significant different or variable was recorded or obtained in the Bulk density values of the soils investigated or studied. In view of this, age of vegetation has significant effect on soil compaction. Generally, the Bulk density values obtained from this study were low compared to the critical limit of 1.75 – 1.80gcm^{-3} of soil survey Staff (2003) where root restriction can occur.

Chemical Properties of the Studied Area

pH and TN

Result of the chemical properties of the studied soil are shown in Table 2, result shows that the P^H ranges from 5.11 – 5.70 respectively. It was observed that the highest value was obtained in 14 years vegetation age and the lowest in 7 years vegetation age and this low value obtained in 7 years vegetation may be as a result of the acidic condition of the soil Silver *et al*, (1994).
Total nitrogen of the soil ranged from 0.356 – 0.494g/km^2 in vegetation ages, significantly ($P < 0.05$) higher value (0.494g/cm^2) was recorded for total nitrogen in 14 years vegetation and 7 years vegetation ages respectively. According to (Landon 1991), these values were rated low (< 0.1%) to medium (0.2 – 0.5%) irrespective of the vegetation ages. Management practices that maintain or slightly increase soil nitrogen such as grazing (Burke *et al*, 1999, Verchot *et al*, 2002), will likely result in limited carbon sequestration, management practice that reduces soil nitrogen will result in net carbon losses from the system as a result of proliferation of microbial population under such condition.

Organic Carbon and Carbon Sequestration

The result of organic carbon and carbon sequestration content of the soils is shown on table 3. From the result, OC ranged between 3.99 and 5.67g/kg^{-1}. From the result, it was observed that the organic carbon content of the studied vegetation ages did not differ significantly and it can be as a result of the mitigating the effects of anthropogenic carbon emissions (Lal, 2004). However, carbon sequestration range from 1295gcm^2 – 1611gcm^2 in 7 years, 14 years, and 21 years vegetation ages respectively. These values of carbon sequestration are not contrary to the findings of Clark *et al*; (2004) who reported that older forest sequester less carbon than younger ones. This trend in reduction in carbon sequestration of the soil profile is consistent with the understanding that the ecosystem will reach a steady state, and a change in management and in inputs would be required to sequester additional carbon (Conant *et al*; 2001, Swift; 2001).

Effect of Vegetation age on Carbon Sequestration

Carbon stored in forest ecosystem depends fundamentally on forest age and management practices (Post and Kwon, 2000; Paul *et al*, 1997; Pregitzer and Euskirchen, 2004). As shown in Table 4 .The highest (5.67gkg^{-1}) organic carbon content was recorded in 14 years vegetation age followed by 7 years (4.19gkg^{-1}) and 21 years. Vegetation (3.99gkg^{-1}) vegetation ages respectively. As expected carbon sequestration followed similar trends with organic carbon. The highest (1611.40gcm^2) was recorded in 14 years vegetation age followed by 21 years (1302gcm^2) and 7 years (1295gcm^2). The findings of this study was in disagreement with the works of Clark *et al* (2003) who recorded higher carbon sequestration in young stands compared to the order stands.

CONCLUSION

This study was done to determine the effects of vegetation age on carbon sequestration in the soils of South Easter, Nigeria. This was done because soil organic carbon plays important roles in soils as good knowledge of carbon sequestration in soils is important for the management and reducing the adverse effects of carbon in the atmosphere.

Table 1: Physical Properties of the Studied Soils

Veg. Age	Sand (g/kg)	Silt (g/kg)	Clay (g/kg)	MC %	BD (g/kg)	TP %	SCR

FERTILITY EVALUATION OF SOILS OF RUBBER PLANTATIONS IN THE COASTAL PLAINS SAND, IMO STATE

E.P Ukaegbu

Dept. Of Agricultural Science, Alvan Ikoku Federal College of Education Owerri
E-mail: emekaprosper2@yahoo.com

ABSTRACT
Study evaluated soils of Rubber plantations in the coastal plains sand, Imo State, based on fertility. Plantations were found on Alluvium, Delta and Coastal plains sand. Using physico-chemical properties, the soils generally rated between 39.4% (S_3) and 52.3% (S_2), with most being moderately suitable. The main limiting factors were texture (clay content), OM, ECEC, TN, K. Site on Delta, which soil was classified as Oxyaquic Paleudult or Haplic Ferralsols rated best.
Keywords: fertility, soils, coastal plains sands, rubber

INTRODUCTION
Rubber (*Hevea brasiliensis*) is a tropical crop with high industrial value. Komolafe et al (1979) record that products such as tyres, foam cashions, raincoasts etc are made from it. With the downturn in Nigeria's economy resulting from low prices and production of crude oil, Rubber is one of the cash crops to invest in so as to diversify the economy.
Asawalam and Ugwa (1993) as well as Ugwa et al (2006) evaluated the lands of rubber-growing belt of Nigeria and found low fertility of the soils as the main limitations to the cultivation of rubber plant. These studies were generalized and did not cover local variations of soils.
Rubber plantations are supported by different soils in the coastal plains sand of Imo State. With input requirement being a consideration in land evaluation (FAO, 1976), it is yet to be seen how varying fertility potentials of soils of location of study could influence their suitability ratings for rubber cultivation. The study thus evaluated soils of rubber plantations in the coastal plains sand of Imo State.

MATERIALS AND METHODS
The coastal plains sand of Imo State is within Lat. $5^0 15^| N$ and $5^0 45^| N$, and Long $7^0 30^| E$ and $6^0 45^| E$. It has mean annual temperature of 27^0-28^0C (80^0-82^0F) (Monanu, 1975a); total annual rainfall of 2250-250mm, with three dry months (Monanu, 1975b). The vegetation is rainforest which is dominated by oilpalms (*Elaeis guineensis*) and dominant geology/parent material is coastal plains sand, as shown by table 1.
Sites of rubber plantations in the location of study were identified and located by free survey technique. Soil samples were taken from a quarter of an hectare within each of the six sites as indicated in table 1. Five samples, spread the entire area sampled, were taken from each of 0-20cm and 20-40cm depths and bulked, such that each site had a bulked sample for each depth. A total of twelve (12) bulked samples were thus taken for laboratory analyses.
Samples were air-dried and sieved with a sieve of 2mm mesh size. Using standard routine analyses procedures as documented by Udo et al (2009) the following parameters were determined – particle sizes, pH, Organic Carbon/Organic matter, total nitrogen, Available phosphorus, Exchangeable bases, Exch. Acidity, Effective cation Exchange Capacity (ECEC), Base saturation (BS). The micronutrients (Fe, Cu, Zn, Pb, Mn) were determined using Atomic Absorption Spectrometry.
Soil parameters were rated based on critical values recorded in literature. Productivity/suitability rating indices of parameters and soils were expressed as percentage of their optimal rates using an adaptation of the scheme by Jasbir et al. (1988) given as:

$$\frac{\text{Actual rating}}{\text{Optimal rating}} \text{x} \, 100$$

Suitability rating index values were referred to the rating scale of Dent and Young (1981) to determine the suitability class of parameters and soils.

RESULTS AND DISCUSSION
Rubber plantations were found on different soils (table 1) in the location, namely – Alluvium, Subrecent Alluvium, Colluvium, Coastal plains sand. The classes of soils are as shown on table 1. Physico-chemical properties of the soils are given in tables 2 & 3, while their productivity rating are given in table 4.

Textural classes of soils at topsoil are sand, loamy sand, sandy loam and sandy clay loam; while at the subsoil they are loamy sand, sandy loam, and sandy clay loam. Soils textures are optimal at sites 4, 5 and 6 where they have rated S_1 (highly suitable) and S_2 (moderately suitable) on the basis of clay content taking 35% as optimal (Sys, 1975). The rest of the sites have rated either marginally suitable or not suitable. With drought resistance being low for rubber (Young, 1976), higher clay content for the generally sandy soils will obviously improve moisture content as well as fertility. With OM contents ranging between 0.79-4.88g/kg it is low and generally rates not suitable (N). This is attributed to high rate of decomposition. With soils' pH ranging between 4.2 and 5.7, the soils are generally strongly acidic. Using an optimal pH of 5.3 (Young, 1976), the soils' pH values have rated S_1 (highly suitable) in all cases. This agrees with Watson (1989) who notes Hevea to grow well on acid soils. With ECEC values ranging between 4.6cmol/kg and 9.7cmol/kg, which values are low, they reflect dominance of 1:1 type of clay and low ability to retain nutrients. Both exch. Ca & Mg are generally not deficient in the soils. Of all the bases, only K is limiting as it has rated mainly between S_2 & S_3 using 0.25me/100g as optimal value. With values ranging between 25% and 80%, most of the soils have rated moderately suitable (S_2) in terms of Base saturation (BS). Using the value of 0.15% as optimal, total nitrogen contents of the soils have rated not suitable (N) in all sites. Using 25mg/kg as optimal, av.P has rated moderately suitable in most cases.

The main issues with the micro-nutrient elements are the possibilities of Fe toxicities in sites 1,2,5,6, and those of Mn in sites 3&4.

From table 4, the main factors limiting fertility potentials of the soils and ofcourse their stabilities for rubber cultivation are clay content (texture), OM, ECEC, TN, K. The soils' productivity ratings ranged between 39.4% (S_3) and 52.3% (S_2).

Average ratings of the soils are in the order, site 5>4>1>2=6>3, with most rating moderately suitable (S_2). The higher the rating the less the amount of inputs required.

CONCLUSION

Rubber plantations were found on different soil units of the coastal plains of Imo State namely, Alluvium in the river valleys, colluvium on slopes, subrecent alluvium in the Delta, and the well drained flat coastal plains sand. Most of the soils have rated moderately suitable (S_2) in terms of fertility with the main limitations being texture, OM, ECEC, TN, K. The range of suitability ratings of the soils is narrow.

ABSTRACT
Tiga Dam was built in an attempt to improve food security through irrigation project. The study therefore investigated the socio-economic impacts of the Dam as perceived by farmers in Kura Local Government area of Kano State. A random sample of One Hundred and Ten (110) irrigation farmers in Kura Local Government Area was used for the study. Findings from the study shows that majority of the farmers are males; 87.3% who are subsistence farmer. More than half of the farmers; 59.1% recorded an improvement in farm yield. Few of the farmers (34.5%) reported reduction in water flow to the tribute while 61.8% claimed it has provided them with social amenities. Involvement of farmers in livestock farming and fish production is rather low among the farmers which might be a contributory factor to the claim of job opportunities by the Dam. The study revealed that construction of Dams has brought displacement of some farmers (70.9%) most of whom were not adequately compensated (68.2%). It is therefore recommended that farmers should be enlightened more on the need to imbibe integrating crop farming with other agricultural enterprises, provided with sufficient farming lands and ensure adequate flow of water in the irrigation channels. Readdressing compensation of the displaced farmers will ensure prosperity and development of the area.
Key words: Irrigation farming, socio-economic Impact, Improved livelihood

INTRODUCTION

The importance of water resources in the socio-economic development of any nation cannot be over emphasized. Water is essential for economic growth, human health and environment with agriculture being the major user in most countries. Increasing need of water upon agricultural development may be met by intensive and extensive use of available water resources. An assumed and regulated supply of agricultural water for ground and surface resource is the basic and essential aspect upon which any future planning of irrigation depends. According to Basak (2009), the main purpose of water resource management includes industrial water supply, irrigation, and flood control among others.

Irrigation has been defined as the application of water to the soil for the purpose of supplying moisture essential for plant growth. It is also undertaken to provide an insurance against droughts, for cooling the soil and atmosphere. It equally provides a more favourable environment for plant growth (Mohammed, 2002). Irrigated agriculture has expanded enormously over the past five decades resulting from a revolution in irrigation development. One of the goals of irrigation farming is the provision of right amount of water at the right time for plant growth and development. Consequently, it ensures sustainable agriculture with its economic benefits. Globally, massive investments have been made in the development of irrigation scheme. In Nigeria, according to NINCID (2009), recent survey suggest that 39% of the land mass is potentially suitable for agriculture and out of this between 4.0 and 4.5 million ha (approximately 4.5 to 5.0%of the land) are judged suitable for irrigated agriculture but only 1.1 million ha can be supported fully by the water available, the remaining 3.4 million ha being Fadama. The benefit of irrigation (which is the artificial supply of water for agricultural crop growth) in Nigeria is not limited to food supply alone but it also serves as a source of income and employment during the slack period of rain-fed agriculture.

Tiga Dam was constructed in an attempt to improve food security through irrigation project schemes. It covers an area of 178 square kilometers with about 2000 cubic meters. Water from the Dam supplies the Kano river irrigation project as well as Kano city (African Research Review, 2008). Despite the significant contribution of irrigated agriculture to increasing food production and to overall socio-economic development, irrigation has come under increasing criticism over the past decade for concerns such as socio-economic inequity, social disruptions and environmental changes that are attributed to irrigation development and reservoir construction. The paper aims at finding out the socio- economic impact of Tiga Dam on the irrigation farmers in Kura Local Government Area of Kano State. Specifically the study aimed to: (i) identify the socio- demographic characteristics of irrigation farmers in the study area; (ii) examine the socio-economic impact of Tiga Dam on the irrigation farmers.

MATERIAL AND METHODS

The study was conducted in Kura Local Government area of Kano state of Nigeria. Kura is bordered by Madobi L.G.A on the west, Garun Malam in the west, Dawakin Kudu in the North and Bunkure in the south. Questionnaire was used in collecting data from three wards in the study area (Karfi, Imawa, Bauren Tanko). A total sample of 110 farmers ware randomly selected. Descriptive statistics (frequency count and percentage count) was used for the analysis.

RESULTS AND DISCUSSION

Table I above shows that majority of the respondent are married (81.8%) and 87.3% are males while few 12.7% of the respondent belong to the female gender. This is consistent with Salisu (2001) and Adeoti (2006) who reported that more men were found in farming than women and that irrigation is majorly a male affair in Northern Nigeria. Most of the farmers; 45.5% are found within the age group of 41 and 50years of age. Farmers in their reproductive age cover 30% (31-40years) of the respondents. About 35% of the respondents have passed through secondary education which is closely followed by 29.1% who claimed quranic education as their maximum exposure of education. The farmers in the study area can be refer to as small scale farmers as more than half of the respondents;54.6% have a farm size of 1-2acres of land while 50.9% claimed to have access to their farmland through inheritance.

Table II shows the impact of the Dam as perceived by the respondents. More than half of the respondents rated their farm yield using the irrigation as having experience an increment as 59.1% of them claimed an improvement in crop yield. Agrarian revolution in Nigeria is incomplete without due recognition of the socio-economic implication of irrigation. It is therefore obvious that socio – economic benefit are important features of Irrigation projects which promotes maximum yield per hectare. A few percentages of the respondents are practicing fish farming (21.8%) while a huge percent; 78.2% are not fish farmers. The same trend was recorded in livestock farming, where farmers who are not involve in livestock farming (70.9%) are too huge compared to those who raise livestock as a result of the presence of the Dam (29.1%).According to the respondents, the Dam has done well in the area of provision of social amenities as claimed by 61.8 percent of the farmers while 38.2 percent said it has made provision for employment in the area. Some of the respondents; 34.5% complained of reduction of water flow to the irrigation channels which resulted in reduction of their farming activities. Majority of the farmers; 70.9% passed through resettlement due to the construction of the Dam, out of which only 31.8% are adequately compensated.

CONCLUSION AND RECOMMENDATIONS

This study revealed that majority of the respondents in the study area is youths whose views and assessment of the irrigation scheme brought about by the existence of Tiga Dam should be reliable. The characteristic gender composition of the respondents describes a typical rural community in northern Nigeria where men are the ones majorly engaged in farming while women are expected to remain at home for the domestic activities.

The revelation made by most of the respondents on their recorded improved yield as result of the irrigation facilities is an indicator of positive impact of the Tiga Dam on their economic and as well as social developments. Another aspect of perceived improvement is the involvement of some farmers in fish farming and livestock husbandry. These enterprises are expected to create diversification of business and thereby making farmers actively engaged in productive activities throughout the year. The few proportion of respondents involved in these mixed farming systems may be linked with inadequate awareness or possibly small size holdings of farm lands in vogue among farmers of the area.

The existence of the Dam is noted to bring about development of social amenities and job creations even though most of the respondents are not satisfied for not been compensated after been displaced from their homes and farm lands to give way for the irrigation scheme.

On the basis of the findings of the findings, the study suggests fostering good relationship between government and the farming communities and make way for real agricultural development in the area .

ABSTRACT
The need for mechanization of Agriculture in Nigeria and West Africa has become more acute in recent years due to the urgent need to accelerate food and fiber production for the teeming urban and rural population. This study explored empirically the role of Agricultural mechanization in the development of Nigerian economic and industrial development. The problems of Agricultural mechanization were identified and probable solution was discussed. The benefits of agricultural mechanization were highlighted. The level of mechanization in Nigeria was also discussed and its impact analyzed.
Keywords: Mechanization, economic development, Nigeria

INTRODUCTION
Food security is a major concern in many parts of the world including West Africa, and Nigeria in particular. Of the 98.3million hectares of Nigeria's arable land-mass,72% of this has cultivation potential but only 35% of the arable land is under actual cultivation. Despite the high proportion of cultivated landmass relative to the total available space, food production to feed the teeming populace has remained a mirage with the advent of commercial oil exploration in the early 1970s (Adamade and Jackson 2014). Agriculture has the potential to stimulate economic growth through provision of raw materials, food, jobs and increase financial stability. In Nigeria, agriculture remains the most basic part of the economy, since it is the largest sector in terms of share in employment.

Agriculture is an important occupation in Nigeria with over 70% of her population depending on it directly or indirectly for livelihood. It provides the bulk of employment, income and food for the rapidly growing population as well as supplying raw materials for agro-based industries. World current agricultural production has an average growth rate of 1.8% as compared to the 3% in the 1960s and therefore at a lesser pace than the demographic growth (Asoegwu and Asoegwu, 2007). However, agricultural holdings are generally small and scattered; farming is often of the subsistence variety, characterized by simple tools and shifting cultivation Large-scale agriculture, however, is not common. "The man with the hoe" still remains an apt description of the Nigerian farmer today. The Nigerian agricultural industry, populated as it is by aged and ageing peasants, has progressively developed into a world of drudgery for losers, shunned and despised by Nigerian youths. In spite of decades of immense expenditures and investments into agriculture, in terms of money, men and materials, by national and international governments and agencies, the average Nigerian farmer remains an indigent serf, regarded by today's youths as a dreadful anachronism (Odigboh, 2000).

The need for mechanization of Agriculture in Nigeria and West Africa has become more acute in recent years due to the urgent need to accelerate food and fibre production for the teeming urban and rural population. Pellizzi (1992) summarized the primary objective of agricultural mechanization as: to minimize production cost, optimize protect quality, product the environment and minimize farm production flexibility. In simple terms agricultural mechanization is the process whereby equipment, machineries and implements are utilized to boost agricultural and food production.

Agricultural mechanization is an enterprise that creates wealth and youth empowerment in which one litre of palm oil or groundnut oil is more expensive than one litre of petrol or diesel in Nigeria. It has the potential to stimulate economic growth through provision of raw materials, food, jobs and increase financial stability. Mechanization of agriculture helped transform American agriculture from the situation where one farmer fed 5 people in 1880 to that where one farmer could feed 80 people in 1982 (Ani and Onwualu, 2002). With 90% of Nigeria's agricultural work done with hand tools, 7% with animal-drawn tools and only 3% with engine powered technology, it is understandable that with the over 70% of the population engaged in agriculture, self-sufficiency in food still a mirage (Onwualu and Pawa, 2004). In future, Nigeria would become the third most populous country in the world, and through better understanding of agricultural mechanization, will be able to be self-sufficient in food production, rather than a country, pre-dominantly agricultural, but not able to produce adequate food for its populace (Abimbola,1984). Hence Agricultural mechanization is a panacea for Economical and industrial development.

According to Anyanwu *et al*. (1997), the role of agriculture in transforming both the social and economic framework of an economy cannot be over-emphasized. It is a source of food and raw materials for the industrial sector, it is also essential for expansion of employment opportunity, for reduction of poverty and improvement of income distribution, also for speeding up industrialization and easing the pressure on balance of payment. In effect, it has been the source of gainful employment from which the nation can feed its teeming population, providing the nation's industries with local raw materials and as a reliable source of government revenue. Agricultural development is considered to hold the key to economic development for most Sub-Saharan countries including Nigeria. (Olukunle, 2012)

Agricultural Mechanization will boost productivity and help to maintain low food prices. Mechanization, encompassing the entire scope and usage of animal or motor power, can significantly increase the productivity of human labour and improve the quality of life for large scale, small scale and cooperative holdings. It involves the use of tools, implements and machinery to improve the efficiency of human effort and labour. The most appropriate machinery and power source for any operation depends on the work to be done and the relative desirability, affordability, availability and technical efficiency of the options. Reynolds (1993) revealed that agricultural mechanization can promote the economic development by increasing the supply of food available for domestic consumption and releasing the labour needed for industrial employment. According to him, agricultural mechanization can promote economic development of underdeveloped countries in four distinct ways:

a) By increasing the supply of food available for domestic consumption and releasing labourneeded for industrial employment.
b) By enlarging the size of the domestic market for the manufacturing sector.
c) By increasing the supply of domestic savings and
d) By providing foreign exchange earned by the agricultural exports.

Current mechanized agriculture includes the use of tractors, trucks, combine harvesters, airplanes (crop dusters), helicopters, and other vehicles. Modern farms even sometimes use computers in conjunction with satellite imagery and GPS guidance to increase yields.

Mechanization was one of the large factors responsible for urbanization and industrial economies. Besides improving production efficiency, mechanization encourages large scale production and improves the quality of farm produce. On the other hand, it displaced unskilled farm labor, causes environmental pollution, deforestation and erosion.

Two broad stages of farm mechanization process have been identified viz: Mechanization of power intensive operations e.g. land preparation, threshing etc. which generally precedes the Mechanization of control-intensive operations e.g. weeding, harvesting etc. (Ani and Onwualu, 2002).

Problems of Agricultural Mechanization in Nigeria

The agricultural sector despite many decade of neglect remains the highest employer of labour in Nigeria. The sector employs about 70 percent of the labour force in the country.

Despite this huge number of persons engaged in agriculture, the sector has been unable to meet the food demands of Nigeria. This has led to massive importation of food in to the country. There are many constraints to successful farm mechanization in Nigeria and they include fragmentation of farmlands or small landholdings due to problems of land tenure system, poor capital base (IFPRI, 2010), scarcity of farm machinery and equipment, insufficient farm inputs, poor infrastructural facilities, land degradation, poor social and economic structures. The constraints to mechanization as they apply to large scale farms in Nigeria as a whole are (1) access to credit, (2) non-setting up of manufacturing and repair services by entrepreneurs, (3) no improved infrastructure, (4) non-affordable and secure access to complementary inputs (fuel, electricity, and larger consolidated plots of land), (5) worst legal and regulatory capacity to protect the rights of owners of machinery, and (6) lower efficiency and capacity of public sector for implementing policy. Resolving these constraints should be the policy objectives of the government (IFPRI, 2010).

Benefits of Agricultural Mechanization

The benefits of Agricultural mechanization cannot be over emphasized especially with the drive to achieve food sufficiency. These are as follows:

- Mechanization will boost the food production which will lead to exportation of the excess in the production so as to generate income for the country through foreign exchange earnings.
- Agricultural mechanization had made the level of information dissemination to increase.
- Farmers are aided in improving marketing processes such as packaging, grading and standardizing commodities and reducing losses in the marketing channels, ware housing and storage.
- Farm mechanization encourages multiple cropping which was not possible under traditional farming.

Level of Agricultural Mechanization in Nigeria

The level of mechanization in Nigeria relates to the evolutionary processes that have been influenced by certain socio-economic and natural barriers. By way of classification, the following are the different classes of mechanized farming equipment's and tools in Nigeria: Hand Tools Technology (HTT), Draught Animal Technology (DAT) and Engine Powered Technology (EPT) (Adamade and Jackson, 2014).

Solutions to Problems of Mechanization in Nigeria

According to Anazodo (1975), there are certain pre-requisites for an effective farm power and machinery in traditional farm systems. Some of these factors that aid agricultural mechanization may include:

(a) A growing desire by farmers for better machinery and tools

(b) A government sympathetic to mechanization developments.

(c) Education, Research, and extension programs.

(d) Establishment of agricultural mechanization

There is need for the agricultural engineers to key into the new paradigm shift of value-chain approach where they identify specific points of interventions that are problem solving. Specialization and deeper efforts are indeed expected from the agricultural engineers who are to naturally lead in the mechanization of the Nigerians agriculture.

Farmers should be encouraged to come together and form farming-disposed cooperatives so as to attract incentives for farming and to be able to provide needed financial aids and farm inputs when and where necessary. Such registered cooperative bodies will enjoy government's protection in their businesses. The cooperatives will be able to acquire farm equipment for mechanized farm, which an individual would not be able to achieve. Farm tractors and the accessories should be readily available for farmers to hire at subsidized rates and road constructions by governments are necessary. There should also be awareness campaign for farmers to imbibe the spirit of using findings from research institutes buy innovations in farm mechanization for their farms.

CONCLUSION AND RECOMMENDATIONS

Agriculture holds the key to the future of Nigeria, key to industrialization, key to sustainable fiscal and economic diversification and self-sustainability with the help of mechanization. Since the world is shifting emphasis from the traditional nut and bolt technology in agriculture to a wider spectrum through information technology, Nigerian agricultural engineers and environmentalists should brace up and get involved in the new technologies for the best interest of the farmer and his environment. The low rate of adoption and utilization of appropriate mechanization technologies among others has remained one of the major factors militating against agricultural production in Nigeria.

Based on the foregoing, the paper suggests that proper education and training of the manpower in mechanization technologies should be encouraged and also government should enact decrees and policies that encourage mechanization.

ABSTRACT
Maize is an important food crop in the Savanna zones of Nigeria where its productivity is highly influenced by drought and fertility problem especially low nitrogen. Drought mainly occur both at the beginning and during the growing season, which significantly reduces maize productivity. Therefore early-maturing varieties that are tolerant to drought or extra-early maturing varieties that escape drought were desirable in these agro-ecological zones. Several efforts are being made at IITA to develop or identify drought-tolerant maize varieties that are adapted to the Savannas of West Africa. This study evaluated three sets of maize varieties that have been identified either to tolerate or escape drought. The drought-tolerant maize varieties were evaluated on farmers' fields in two LGA of Kano states of Sudan northern Nigeria. Generally, the on-farm yields of the maize varieties evaluated were higher than the average grain yield reported for the local variety in both locations. Among the varieties evaluated, the result shows that 2011 TZE-W DT STR Syn maize variety was significantly higher by 27.66 % and 166.36 % than that of 2013 DTE STR-W SYN and local maize varieties respectively. Since most of these varieties attain their physiological maturity in late September when rainfall intensity is drastically reduce, it therefore, recommended that DTMA seeds should made available for farmers in this zone for agricultural sustainability.
Keywords: Participatory, on-farm evaluation, drought tolerant maize, Sudan Savanna

INTRODUCTION

Maize (*Zea mays* L.), is an important staple crop especially in the savannah ecology of Nigeria. More than 50 % of the maize produced in the country is from the savannas where the best yields are recorded. Despite the immense potential of maize production and productivity in the savannas, its production is greatly constrained by recurrent drought due to climate variability and changes (Bency, 2000). Rainfalls are erratic and native soil nitrogen is low owing to very low organic carbon production and continuous cropping practices prevalent among farmers in the savannah. Maize farmers in the zone reported losses of 90 percent due to drought, 60 % due to striga and about 85 % due to low soil N (Byrne *et al*., 1995). Improving yield levels in the zone require development and adoption of robust maize varieties (OPVs) and hybrids that are tolerant to these stresses especially drought. In order to ensure rapid adoption of such varieties by maize farmers, their participation in the development process is of great value in line with the latest paradigm shift in which technology development is increasingly demand driven.

Recently, maize breeders at IITA developed several early, extra-early, intermediate and late maturing white and yellow-endosperm source populations, OPVs, and hybrids; several of which combine tolerance to drought, low soil nitrogen with resistance to *S. hermonthica* and MSV. Most of these products originate from the DTMA project are yet to be released in partners countries while several other new varieties and hybrids have been developed which need to be tested in on-farm enable their release and promotion. In many instances, several of these varieties produce yields that are higher than the old varieties farmers are using. In addition to the superior grain yields, the new varieties have end-users preferred traits in addition to tolerance to drought. In order to mitigate the incidence of yield reduction caused by stress such as drought that could also lead to food insecurity, poverty and malnutrition as well as poor performance of poor resource small holder farmers. In this project, a participatory on-farm evaluation of drought tolerant varieties of maize is proposed in which farmers should play active role in cultivation.

MATERIALS AND METHODS

Study location

On-farm study was conducted at two locations in Kano state namely: Kura and Rano LGAs in the Sudan Savanna zone of Nigeria. Kano State is located at latitude 11°30^{1}N and longitude 8°30^{1}E with land area of 20,760 km^2. Its vegetation falls mostly within the Sudan Savanna Zone (Kura and Rano LGAs inclusive). The climate of Kano State is the tropical wet and dry type. Annual average rainfall in the area range from 884-1200 mm (from north to south of the state) which is characterized by one peak period (mono-modal), usually attained in August with average temperature of warm to hot throughout the year at about 25±7°C. FAO/UNESCO genetic classification,

classified the soil as leached tropical ferruginous soil developed on deeply weathered pre-Cambrian Basement Complex rock overlain by Aeolian drift of varying thickness (Malgwi *et al.*, 2000).
Selected farmer fields were demarcated into three plots measuring 10 m x 10 m (100 m^2) per plot. The plots were allocated by A, B and C; plots A and C were planted with different improve variety while plot B was as check, planted with farmer variety (local variety). The trials were randomized among the farmers within the selected communities in each location. Each set was replicated three times in each location where a farmer represents a replicate (Table 1).
The fields were sprayed with glyphosate (4 l/ha) at two weeks before land preparation for weeds control. The land was ridged at 0.75 m apart using manual hand plough power as a source of tillage in all the locations and earthed up at 8 weeks after sowing. Maize seeds were planted on 22ndJuly to 8th August, 2015 in all the farmer fields in both locations. The maize seeds were sown manually, two seeds per hole at intra-row spacing of 25 cm and later thinned to one plant per stand at 2 weeks after planting (WAP) to give approximately plant population of 53,333 plants ha^{-1}.

Table 1. List of varieties/hybrids and number of farmers participated in on-farm trials

Set	Hybrid/OPV maize varieties	Number of farmers	Maturity period
1	TZEE-W STR 104 BC2	6	Extra early
1	2013 TZEE-W Pop DT STR	6	Extra early
1	Local variety	6	Late
2	2013 DTE STR-W SYN	6	Early
2	2011 TZE-W DT STR Syn	6	Early
2	Local variety	6	Late
3	(TZEQ1 4 x TZEQ1 33) x (TZEQ1 24 x TZEQ1 25)	6	Intermediate
3	(TZE1 63 x TZE1 108) x TZE1 59 x (TZE1 87)	6	Intermediate
3	Local variety	6	Late

Fertilizer application and weeding

Fertilizer application was at the rates of 120 kg N/ha, 60 kg P_2O_5 ha^{-1} and 60 kg K_2O ha^{-1}were the source was urea for N, single supper phosphate (SSP) for P and muriate of potash for K and maintained in all the farmer fields in both locations. Urea (N) fertilizer application was applied in 2 doses; first application was done 10 days after sowing while the remaining part was applied as second dose at 6 week after sowing by opening a hole of 3-4 cm depth at the base of the maize stand and covered with soil (band application). Weed was control by applying pre-emergence herbicide (4 l/ha) at planting and manual weeding using hole was subsequently employed at 4 WAS and also earthing up at 8 WAS before harvesting.

Sampling and processing

Plant sampling was conducted by cutting the maize at ground level, stacked in sheaves, air-dried and manually threshed in accordance with treatments (variety). The following measurements were obtained: Ear and plant heights, cob weight and grain yield for net plot of 7.5 m^2.

Plate 1: Showing harvested varieties of DTMA varieties at right and left hands while local variety at the center *Maize plant height measurement*

Maize plant height and ear height were measured at harvest. This were done from the base of the plant (soil surface) to the apex of the flag leaf with the aid of a 2 m long calibrated wooden pole (plant height). The ear height was obtained by measuring the plant height from the base of the plant to the point of the ear elongation from the stem. Data obtained were recorded in cm.

Data analysis
Data obtained were subjected to analysis of variance (ANOVA) using the mixed linear model of SAS (SAS Institute, 2009).

RESULTS AND DISCUSSION
SET 1: Yield and yield components of maize variety
The results of the yield and yield components of maize variety in set 1 obtained from both study areas are presented in Table 2. The highest grain yield was observed in variety TZEE-W STR 104 BC2, followed by 2013 TZEE-W Pop DT STR variety and least in local variety. The percent differences between the improve varieties and local variety were 70.51 % and 35.74 % respectively. Whereas TZEE-W STR 104 BC2 variety had significantly higher grain yield than 2013 TZEE-W Pop DT STR variety by 25.68 %. Similar observations were obtained in yield components (ear weight and cobs number) while reverse was in the case of growth parameters which were consistently higher in local variety.
The grain yield obtained in accordance with study location is presented in Table 3. Based on location, Kura had a higher grain yield per hectare than Rano, however in all the improve varieties evaluated and as well as local variety. Percentage differences were 40.96 % for TZEE-W STR 104 BC2 maize variety, 16.31 % for 2013 TZEE-W Pop DT STR maize variety and 13.26 % for local variety. The variation in grain yield across the locations may reflect wide variation in the native soil fertility and genotypes differences of these varieties.

SET 2: Yield and yield components of maize variety
The yield and growth components of two maize varieties in set 2 evaluated in the two locations are recorded in Table 4. The result shows that 2011 TZE-W DT STR Syn maize variety was significantly higher by 27.66 % and 166.36 % than that of 2013 DTE STR-W SYN and local maize varieties respectively. However, yield obtained from 2013 DTE STR-W SYN maize variety was significantly higher than the local variety with percent difference of 108.65 %. The same trend of grain yield distribution observed among the varieties evaluated was found in yield components except in growth parameters which were consistently higher in local maize variety than improve varieties. Differences observed between the DTMA varieties and local variety could be attributed to late planting which affected the performance of local variety due to low rain at reproductive stage. This finding is in conformity with that of Amaza *et al*., (2008).
The result of grain yield obtained in accordance with study location is presented in Table 5. Based on location, the grain yield recorded in all the varieties evaluated in set 2 was consistently higher in Kura than ranowith

difference of 1.49 % for 2013 DTE STR-W SYNmaize variety, 1.30 % for 2011 TZE-W DT STR Synmaize variety and 9.21 % for local maize variety. Grain yield differences observed among the DTMA varieties including the local variety might be as a result of earlier planting of varieties at Kura location than Rano farmer fields. This suggest that planting DTMA between second weeks to last day of July would give better grain yield than planting early August irrespective of locations.

SET 3: Yield and yield components of maize variety

The results of the grain yield, yield and growth components of maize variety obtained from both study areas are presented in Table 8. The highest grain yield was observed in (TZE1 63 x TZE1 108) x TZE1 59 x (TZE1 87) maize variety followed by (TZEQ1 4 x TZEQ1 33) x (TZEQ1 24 x TZEQ1 25) maize variety and least in local variety. The percent differences between local maize variety and improve two maize varieties were 68.98 % and 61.52 % respectively. Whereas (TZE1 63 x TZE1 108) x TZE1 59 x (TZE1 87) maize variety was significantly at par (TZEQ1 4 x TZEQ1 33) x (TZEQ1 24 x TZEQ1 25) maize variety in terms of grain yield but with 4.62 % difference. Similar observations were obtained in yield components (ear weight and cobs number) while reverse was in the case of growth parameters which were consistently higher in local maize variety. This could be due to delay in planting these varieties especially local varieties which required good rainfall distribution for optimum production. A study conducted in Northern Savanna by Yusuf et al., (2009) reported that high grain and yield components of maize could be as a result of favourable soil moisture and good distribution of rainfall until harvest. The grain yield obtained from maize varieties evaluated in set 4 is presented in Table 9. Based on location, Kura had a lower grain than Rano in all the maize varieties evaluated except local maize variety which was higher in Kura study location. Percentage difference was 15.87 % for (TZEQ1 4 x TZEQ1 33) x (TZEQ1 24 x TZEQ1 25)maize variety, 26.36 % for (TZE1 63 x TZE1 108) x TZE1 59 x TZE1 87) maize variety and 27.31 % for local variety. Generally, variation in grain yield among the maize varieties across both locations may be as result of difference in soil fertility (soil N), genotypic make up and partly planting date. Maize grain yield obtained in Savanna zones of Nigeria; mainly due to late planting, uneven distribution of rainfall during reproductive stage and short duration of rainfall (Omeke, 2016)

CONCLUSION

The study revealed that DTMA varieties were outstanding in performance with above 10 % higher than local varieties in both locations which is mainly influence by drought and low fertility problem. Therefore, we encourage farmers to cultivate DTMA varieties in these areas prone to late on-set of rainfall and short distribution for food security and improvement of poor resource farmers.

RECOMMENDATION

Based on the findings of the study, it is recommended that; Farmers acknowledge the outstanding performance of most DTMA varieties over the local variety. Training should be conducted on capacity building to enhance farmers' adoption rates and sustainability of production. The project should make the DTMA seeds readily available to the farmers since they are preferred than their local variety.

ABSTRACT
The study was carried out to analyze the fruit and vegetable market chain in Shomolu Local Government Area of Lagos state. A survey of fifty marketers randomly selected in Bariga and Bajulaye markets in the area formed the sample used. A descriptive research design was used in the study and data were collected using oral interviews and a well-structured questionnaire. Data were analyzed using frequency counts, percentage, market margins, marketing channel analysis and linear regression model to identify existing marketing channels used by vegetable marketers, determine the profitability of fruit and vegetable and isolate factors that affect quantity supplied of fruit and vegetable along the market chain. The study revealed that majority (74%) of the marketers are females. The average age of the fruit and vegetable respondent was (35.5). Local government harassments, lack of support from government, poor market stall, high cost of transportation and inadequate finance were the most perceived problems of marketing by the fruit and vegetable respondents. Channels that included local markets had high total gross margins. The regression analysis showed that quantity of fruit and vegetable supplied, price of fruit and vegetable, access to market information, access to internet service and distance from the market are factors that influenced supply of fruit and vegetable in the markets. Among other things, measures that easy access to credit, reduce multiple taxes and permit on sellers are recommended.
Key Words: Marketing channels, Fruit and vegetable, Shomolu Local Government, Regression analysis

INTRODUCTION
Vegetable constitute the most important and inexpensive component of a balanced diet, which people now realize due to their high nutritive values indispensable for the body. Originally, vegetables were collected from the wild by hunter-gatherers and entered cultivation in several parts of the world, probably during the period 1,000BC to 7,000BC, when new agricultural way of life developed and fruits and vegetables are produced seasonally, but the market requires products throughout the year. As technology improved and consumer incomes increased, it became possible to provide fresh produce year-round. Fresh tropical fruits are on winning ground in world markets as to recent statistical figures (Babatola, 2004.). Its production has risen by 7% annually since 1997 and the bulk of these fruits (98%) are grown in developing countries. The main reason for increase in demand of tropical fruits is the growing familiarity of consumers with tropical fruits; their taste, nutritional value and cooking qualities.
The knowledge of domestic consumers of the benefits of fruits and vegetables is confined to very few varieties of fruits and vegetables. Hence, domestic demand with the exception of few widely known tropical fruits is generally small and various studies show that people generally consume fruits and vegetables on a daily basis without considering them as basic. Abay (2007) stated that the production of fruits and vegetable is seasonal and price is inversely related to supply. During the peak supply period, the prices decline. The situation is worsened by the perishability of the products and poor storage facilities. Along the market channel, 25% of the product is spoiled. According to UNESCO (2005), lack of concerted public support, scanty information, poor understanding of how the market chain works and lack of systematic documented knowledge are main threats that hampered the benefit of the sector. Thus, comprehensive data collection along the chain is a must to envisage the direction of input-output flows. If these jeopardy are not well addressed right onwards, it is obvious the country's competitiveness would trail far behind the existing stage. Even though fruit and vegetable are economically and socially important, fruits and vegetable marketing channel and their characteristics have not yet been studied and analyzed for local markets in Lagos state. Hence, the focus of the study to investigate fruits and vegetable market chains and factors affecting fruit and vegetable supply in Shomolu Local Government Area (SLGA). The outcomes here, hopefully will narrow the information gap on the subject and will contribute to better understanding on improved strategies for reorienting marketing system for the benefit of small farmers and traders. Therefore, the objectives of the study are to: identify the major fruits and vegetable marketing channels; estimate the marketing margins within the fruits and vegetable market chain; determine the factors affecting the quantity of fruits and vegetable supplied to the market.

METHODOLOGY
Shomolu is a Local Government Area in the Ikeja division of Lagos State. It is one of the sixteen LGAs of metropolitan Lagos. It is located in the northern part of Lagos city. According to 2006 population census, it has 402,673 inhabitants. Most of its inhabitants are Yorubas. It is a major nerve center for commercial printing activities in Lagos. Also because of its enormous population, it has attracted huge commercial and industrial

activities. Shomolu local government area harbours several industrial and commercial enterprises. The town is plagued by problems of overcrowding, poor housing and inadequate sanitation. Other articles of trade here is the marketing of agricultural produce such as rice, fruits, beans, garri, meat, vegetables, fish etc.

Survey research design was used. All the fruit and vegetable marketers in the two main markets within the local government area namely, *Bajulaye* and *Bariga* formed the population for the study. The sample for the study comprised 50 fruit and vegetable sellers from the two markets randomly selected using the Simple random sampling. A well-structured questionnaire as well as oral interview was used to collect data. The questionnaire was divided into two sections, Section A was designed to gather information on personal data of respondents, while Section B was designed to gather information on the perceived problems, channels of marketing, favourability of sources of supply, distance from farm of supply, how they get latest information about prices etc., used in analyzing the fruit and vegetable market chain. Where necessary, the questionnaire was read to the respondents in vernacular and responses documented accordingly.

The data collected were summarized using frequency counts and percentages, while the marketing margin analysis was used to determine the profitability of fruit and vegetable along the market chain. A simple linear regression analysis was used to estimate the factors that affect the supply of fruit and vegetable.

Gross Market Margin Analysis:

$$\text{TGMM}= \frac{Cprice - Pdprice}{Cprice} X100$$

$$\text{GMMp} = \frac{Cprice - MGM}{Cprice}$$

$$\text{Pdshare} = \frac{Pdprice}{Rtlprice}$$

Where:
TGMM = Total gross marketing margin
GMMp = Producer's gross marketing margin
MGM = Marketing gross margin
Csprice = Consumer's price
Pdprice = Producer's price
Rtlprice = Retail price
Pdshare = Producer's share

The regression model was specified as follows:

$$Y_i = \alpha_i + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \ldots\ldots + \beta_i X_i + \upsilon_i \text{ ------------------------ (1)}$$

Where: Yi = quantity of fruit and vegetable supplied to market
α_i = Intercept
$ß_i$=Coefficient of the ith explanatory/independent variable
X_i = Vector of explanatory variables
U_i = disturbance term

Hence, the equation for the quantity of fruits and vegetables supplied is: Quantity of fruits and vegetables Supplied = α_i+ $ß_1$Gender + $ß_2$Age+ $ß_3$Household size + $ß_4$Edu + $ß_5$Distance + $ß_6$ Experience + $ß_7$Quantity Supplied + $ß_8$Price + $ß_9$Internet + $ß_{10}$Market Information + $ß_{11}$ credit + Ui

RESULTS AND DISCUSSION

Figure 1 presents channels through which fruit and vegetable move from the production site until they reach the final buyer. According to Teka (2009), a marketing channel involves a series of intermediaries through which fruit and vegetable pass from producers to consumers. As Figure 1 shows, the 2nd channel- Producer-local market-consumer has the highest rank. It also means that the local market will have the largest share from the sales because the goods will be sold at a price that will bring about high income. Four marketing channels were identified for fruit and vegetable in the study area as indicated in Table 3 and figure 1. The results revealed that most of the fruit and vegetable goes through channel-2, followed by channel-3 and channel-4. Channel-1 accounted for the least of the fruit and vegetable in the market. The possibility here is that the producer does not make enough profit from channel-1.

In this section the factors that influence the supply of fruits and vegetable are presented and discussed. A simple linear regression models were employed to analyze the factors that affect the supply of fruit and vegetable.

Table 4 presents the determinants of the supply of fruit and vegetable. The result shows that among the eleven hypothesized determinants of market supply of fruit and vegetable, five variables were found significant. These are quantity of fruit and vegetable produced, price of fruit and vegetable, access to market information, access to internet service and distance from the market. The coefficient of multiple determinations (R^2) was estimated (0.876) and adjusted R^2 value was 0.846. This means that 87.6% of the variation in the dependent variable is explained by the explanatory variables included in the model. Furthermore, the adjusted R^2 of 84.6% which is significant further consolidated the goodness of the model. The result in table 4 shows that the quantity produced is significantly and positively related to marketed supply of fruit and vegetable at 1% significance level. The value of the coefficient for production of fruit and vegetable implies that an increase in production of fruit and vegetable by one unit per hectare resulted in an increase in farm level marketable supply of fruit and vegetable. Similarly, the result shows that the price of fruit and vegetable is significantly and positively related to marketed supply of fruit and vegetable at 10% significance level. This complied with the law of supply that price and quantity supplied are directly related. Thus as the price fruit and vegetable increase in the market, farmers will supply more quantity of fruit and vegetable to the market to get better returns for the products. A priori, access to market information is positively related to market supply of fruit and vegetable at 10% significance level. As hypothesised access to internet service affected the marketed supply of fruit and vegetable positively and significantly at 5% significance level. This might be because internet service enables the traders to have better knowledge about how to get better production and productivity, and creates awareness about new technologies. Distance from the market is significantly and negatively related with the marketed supply of fruit and vegetable at 1% significance level. As the distance from the production area to market place become farther and farther, the producers supply lesser quantity of fruit and vegetable to the market. This is might not be unconnected with the nature of the product (i.e. perishability) and the costs which are related with transportation and handling.

RECOMMENDATION AND CONCLUSION

This study investigated the fruit and vegetable marketing chains in Shomolu Local Government area of Lagos with the aim of unravelling the routes through which fruit and vegetable reached consumers in this area. Based on this study, it is recommended as follows: One, as revealed by this study, marketing channel affects profit margin thus, Fruit and Vegetable marketers should be assisted in identifying the best channel. Two, marketers should form cooperatives in order to arrest price volatility within the fruit and vegetable supply chain. Three, since rents and permits are charged on each sellers, Government should provide adequate market stall for the marketers to store and display their goods. Excess taxes are spread on price thus escalating prices and reducing demand/ sales, government should help streamline multiple permits and taxes imposed on fruit and vegetable sellers. Finally, Policies that ease access to loan and financial support to agribusiness should be promoted.

ABSTRACT
Fresh aerial yam was processed into high quality aerial yam flour (HQAYF), whole-meal high quality aerial yam flour (WHQAYF), aerial yam fufu flour (AYFF) and whole-meal aerial yam fufu flour (WAYFF). The flours and the raw aerial yam were subjected to chemical analyses to determine their proximate, total carotenoid, minerals and phytochemical compositions. This was to evaluate the effect of processing on the food quality of aerial yam. The result of the proximate compositions indicated that there were losses in moisture and starch contents while dry matter, crude protein, crude fibre, fats, ash and carbohydrates appreciated with processing. The result in total carotenoid composition showed that there were 27.5% to 40.3% losses in WHQAYF and HQAYF respectively while the losses recorded for AYFF and WAYFF were 89.3% and 92.9% respectively. The only mineral that that indicated losses was potassium (K), calcium (Ca), sodium (Na), phosphorus (P) and magnesium (Mg) increased with processing. The result in phytochemicals showed that there losses of all the phytochemicals with processing, thereby bringing them down to the level where they are harmless for both human and animals.
Keywords: Aerial yam, processing, proximate, carotenoid, minerals, phytochemicals, chemical analyses.

INTRODUCTION
Yam is one of the oldest food crops of tropical origin which belongs to the family of Dioscoreaceae and one of the oldest groups among the angiosperm (Onwueme, 1978). The report of IITA, (1992) stated that there were about six (6) economically important species of yam grown as staple food in Africa. They were; *D. rotundata* (white yam), *D. cayenensis* (Yellow yam), *D. alata* (water yam), *D. esculentum* (Chinese yam), *D. dumentorum* (bitter yam) and *D. bulbifera (*aerial yam). Orkwor, (1992) contended that the preferred yam cultivar in eastern banks of River Niger was *D. rotundata.* Observation has shown that there is a growing demand of *D.alata* in Cross River state, Akwa Ibom state and environs. Also, the work of Aniedu & Oti, (2011) showed a number of recipes and delicacies which can be made from *D.alata.* However, evidence has shown that some of these 6 yam species are becoming extinct as they are rarely seen in the market and hence feature rarely in daily meals of people in Nigeria. One particular yam specie of interest, is the aerial yam (*D.bulbifera* – aerial yam*)*. The observance of this fact, led Nwosu, (2014) to state that *D.bulbifera* was traditionally eaten when boiled, fried, roasted or cooked with vegetables in time past and because *D. bulbifera* tend to darken during cooking made consumers regard it as being inferior to other types of yam and this has led to the crop going extinct. Hence, Aniedu, *at al*, (2016) investigated into the food quality of this crop and reported that the aerial yam was rich in food nutrients and had high naturally occurring carotenoid composition which needed to be exploited for improved rural nutrition and food sufficiency in Nigeria. Consequently, this study aims at evaluating the effects of some processing methods on the food quality of this crop in order to explore other uses to which the crop can be put so as to ensure that the crop does not go into extinction but rather there will be need to increase its cultivation for its increased contribution towards improved nutrition and food sufficiency in Nigeria. The main aim of the study was to evaluate the effects of processing aerial yam into unfermented and fermented flours on its food quality. The specific objectives were to evaluate: i. the effects of processing aerial yam into unfermented flours (high quality aerial yam flours) on its proximate, total carotenoid, minerals and phytochemical compositions; ii. the effects of processing aerial yam into fermented flours (aerial yam *fufu* flours) on its proximate, total carotenoid, mineral and phytochemical compositions.

MATERIALS AND METHODS
The aerial yam landrace was procured from yam farmers in Bende area, Abia state, Nigeria. The aerial was processed as follows:

Chemical Analysis
The four (4) processed aerial yam flour samples of high quality aerial yam flour (HQAYF), whole-meal high quality aerial yam flour (WHQAYF), aerial yam *fufu* flour (AYFF) and whole-meal aerial yam *fufu* flour (WAYFF) and raw aerial yam were analyzed for the following; proximate compositions, minerals (calcium, sodium, phosphorus, potassium and magnesium) and phytochemical compositions, using the methods described by AOAC (1995).

Carotenoid analysis
The total carotenoid composition of the flour samples and the raw aerial yam were analyzed, using the method of Harvest-plus protocol (2004) as follows; 5g of each of the samples was grinded with the aid of hyflosupercel in 50ml of cold acetone and filtered with suction through a Buchner funnel with filter paper. The filtrate was extracted with 40ml of petroleum ether (P.E.) using separating funnel while saturated sodium chloride was used to prevent emulsion formation. The lower phase being water was discarded while the upper phase was collected into a 50ml volumetric flask, making the solution pass through a small funnel containing anhydrous sodium sulfate to remove residual water. Then, the separating funnel was washed with P.E. and the standard flask made up to 50ml mark. The absorbance at 45ml of the solution was taken using specifophometer and the total carotenoid contents were calculated thus;

$$\text{Total carotenoid } (\mu/g) = \frac{A \times \text{volume} \times 10}{A1\%_{1cm} \times \text{sample weight (g)}}$$

Where A = Absorbance, Volume = total volume of extract (50ml), A1%1cm = absorption coefficient of carotenoid in P.E. (2592)

Statistical analysis
The ANOVA and mean separation by Least Significant Difference (LSD) at 5% probability levels of proximate, total carotenoid, vitamins, minerals and phytochemical composition scores were carried out using SAS version 8, 2000.

RESULTS AND DISCUSSION
The results of the proximate compositions of the samples in Table 1 showed that the moisture and starch contents were highest (71% and 28.6% respectively) in the raw aerial yam sample while about 90% moisture loss was observed in the processed samples (which ranged from 7.2% - 7.7% in WHQAYF and AYFF respectively), the starch loss in processed aerial yam ranged from 8.4% to about 30% in WHQAYF and WAYFF respectively. The result in Table 1 also showed a significant increase in dry matter, crude protein, fats, ash and carbohydrates contents in the processed samples. The unfermented samples of WHQAYF and HQAYF were significantly (P=0.05) higher in crude protein than the fermented samples of AYFF and WAYFF while carbohydrates and starch were significantly (P=0.05) higher in AYFF and WAYFF than in WHQAYF and HQAYF. The result did not show obvious significant (P=0.05) differences among processed samples in crude fibre and fats.

The result in Table 2 indicated that there were great depletions of carotenoid with fermentation which were 89.3% and 92.9% in AYFF and WAYFF respectively while the rate of carotenoid losses was 27.5% and 40.3% in HQAYF and WHQAYF respectively (unfermented flours).

The picture is clearer in Fig.5 which showed that total carotenoid of raw aerial yam reduced from 8.44μg/g to 5.041μg/g and 6.12μg/g in WAYF and HQAYF respectively. It was observed that fermentation further depleted total carotenoid contents from 8.44μg/g in raw aerial yam to 0.90μg/g and 0.60μg/g AYFF and WAYFF respectively. This confirmed the report of Aniedu and Omodamiro (2012) which observed that there were high losses of carotenoid when pro-vitamin A cassava was processed into flour. The work further stated that when fermentation and drying process were involved in processing pro-vitamin A cassava into flours, there was almost a complete loss of carotenoids.

The result in Table 3 revealed that calcium, sodium, phosphorus and magnesium contents of aerial yam increased with the processing of the raw bulbs into flours. These minerals were significantly (P=0.05) higher in unfermented flours (WHQAYF and HQAYF) than in the fermented flours (AYFF and WAYFF). The potassium was the only mineral that showed some losses with processing with the losses in fermented flours being significantly (P=0.05) higher than the unfermented flours.

The phytochemicals as are regarded as anti-nutrients but latest findings by Liu (2004), Higdon (2007) and Rao, *et al* (2010) have shown that phytochemicals are useful in numerous ways particularly when they are found at low levels in foods e.g.

- 1. Saponin – checks replication of cells in the body.
- 2. Tanin – acts as pesticides and helps in poultry production at 0.15 -0.2% levels inclusion in feeds.
- Phenol – precursor of aspirin, used as analgesic and antiseptic. Its lethal to human at 300 -500μg/kg food.
- Alkaloids – antimalarial, anti-asthma, anti-cancer, etc.
- Flavonoids – anti-viral, anti-cancer, anti-inflammation, anti- allergy.

In Table 4, the results revealed that there were sizable losses of all the phytochemicals with processing of aerial yam into the various flours. However, the levels at which the phytochemical occurred in raw aerial yam were seen to be beneficial both for human consumption and for compounding feeds for animals. Hence, whether aerial yam is used raw or processed, the level of its phytochemical composition would not constitute any danger to health.

CONCLUSION

The aerial yam is a crop to be examined critically for its use as health food for humans, in compounding animal feeds and for pharmaceutical purposes due to its high carotenoid contents and phytochemical compositions. As processing into unfermented flour retained high level of carotenoid, there is need to explore the possibility of producing new food forms of the crop from the unfermented flours and the raw crop.

ABSTRACT
Financing value addition via processing of root and tuber crops into other foods and industrial products have several social and economic implications on rural economic development. This study focused on the empirical investigation of financing value addition of root and tuber crops among producing households in Abia state, Nigeria. The specific objectives were to ascertain the various sources of finance available for value addition and determine the respondents' reasons for value addition. Multistage sampling technique was employed in the selection of 250 respondents across 5 Local Government Areas of Abia state. Structured questionnaire was used to obtain data from the respondents and the data collected were analyzed using descriptive statistics. The results of the descriptive statistics showed that most of the respondents were: between 40 – 59 years, married, with household size of 6 - 10 persons, and farm size of 1 - 3 hectares. Most respondents' major source of financing value addition was personal savings and their major reasons for financing value addition were to increase farm income; satisfy consumers and prevent spoilage. The study thus recommends that farmers should join cooperatives to have easy access to finance and other agricultural incentives from government while government on its part should address through policies bureaucratic bottlenecks involved in accessing agricultural loans.
Key words: financing, value addition, root and tuber crops

INTRODUCTION
Root and tuber crops have been the major sources of carbohydrate and other food nutrients to a vast majority of people living in sub-Saharan Africa. Root and Tuber crops are frequently grouped together because they are bulky, perishable and vegetatively propagated. Root crops are the edible energy-rich underground plant structures developed from modified roots, for example, cassava and sweet potato; while tuber crops are those crops in which the edible energy-rich storage organs develop wholly or partly from underground stems such as yam, cocoyam and ginger (Eke-Okoro *et al.*, 2014). A study by Gregory, Mark and Claudia (2000) on "Root and Tubers for the 21st Century; Trends, Projection and Policy Options" has shown that root and tuber will continue to play a significant role in developing-country food systems because they contribute to the energy and nutrition requirements of over 2 billion people and will continue to do so over the next two decades.
In Nigeria, root and tuber crops such as cassava, sweet potato, yam, cocoyam, and ginger play vital roles in the food security of Nigerians (Eke-Okoro *et al*., 2014). However, root and tuber crops just like other agricultural produce are perishable in nature, thus most rural farmers do not get the desired reward for their effort as most of their products perish few days after harvest hence, the need for value addition. Value addition which involves the the process of transforming these roots and tuber crops into other food, feed and industrial products will help to increase demand, ensure attractive prices and lead to sustainable agriculture, poverty alleviation and rural economic development. However, engaging in meaningful value addition requires financial capital which may be beyond the purview of rural households. Inadequate finance has been identified by researchers as one of the major challenges facing the adoption of value added processing technologies (Aniedu *et al*., 2012; Onubuogu and Onyeneke, 2012; Omoare *et al.*, 2014). Given the expanding market potentials of value added root and tuber products, coupled with the fact that successive governments over the years have allotted funds for agricultural purposes through different agencies and financial intermediaries, there is a compelling need to empirically investigate how root and tuber crops producing households in Abia state finance the production of value added root and tuber products. This study is gerared towards facilitating the realization of sustainable agriculture and rural economic development in Nigeria.

METHODOLOGY
The study was carried out in Abia State, Nigeria. It is one of the 36 states in the country created in 1991 from part of Imo State. It is located in the South-East geopolitical zone of the country. The State lies between longitudes 04^0 45' and 06^0 07' North and Latitude 07^0 00' and 08^0 10' East. It is bounded by Imo State to the West, Ebonyi and Enugu States to the North, Cross Rivers and Akwa Ibom States to the East and Rivers State to the South. The State covers an area of about 5,243.7 square kilometers which is approximately 5.8 percent of the total land area of Nigeria (Independent National Electoral Commission, 2008). It has a population density of 580 persons per square kilometer and a projected population of 3,395,414 persons growing at an annual rate of 2.83 percent (National Bureau of Statistics, 2014). Administratively, it has 17 Local Government Areas (LGAs), three

Senatorial districts and 3 Agricultural Zones with Umuahia as the State capital. The climate of the State is tropical with two seasons namely, rainy season which starts from March to October; and dry season which commences from November and ends in February of each year. The inhabitants are predominantly Igbos, and practice Christianity and African Traditional Religions. Agriculture is the major occupation of the people and subsistent agriculture is prevalent (Agwu *et al.*, 2014). They produce crops like cassava, yam, cocoyam, sweet potato, ginger, rice, maize, oil palm, rubber, cocoa, banana, and various types of fruits. For the purposes of this study, five root and tuber crops namely, cassava, sweet potato, yam, cocoyam and ginger were selected for empirical investigation, as they constituted the main root and tuber crops produced by rural households in the State.

The study employed multistage sampling technique in the selection of respondents. First, 5 LGAs namely: Ikwuano, Isiala Ngwa North, Isiala Ngwa South, Bende and Ohafia were purposively selected out of the 17 LGAs in the State based on the reponderance of root and tuber crops producing households in the areas. Secondly, 1 autonomous community was randomly selected from each of the LGA making a total of 5 autonomous communities. Thirdly, 2 villages were randomly selected from each of the autonomous community making a total of 10 villages. Finally, 250 respondents comprising 50 households engaged in the production of each of the root and tuber crop studied namely: cassava, sweet potato, yam, cocoyam and ginger were purposively selected across the 10 villages in the study area.

Data were sourced using questionnaire and oral interview to elicit information from the respondents. Data collected were analyzed using descriptive statistics such as frequency distribution tables, percentages, and likert scale. In order to address the objective on reasons for financing value addition, 5 point likert scale rating technique was employed. The rating was in this order: Strongly Agree (SA) = 5, Agree (A) = 4, Undecided (U) = 3, Disagree (D) = 2, and Strongly Disagree (SD) = 1. The mean score was calculated thus: $5 + 4 + 3 + 2 + 1 = 15/5 = 3$. Using the interval of 0.05, the upper limit cut-off point was $3.00 + 0.05 = 3.05$, while the lower limit was $3.00 - 0.05 = 2.95$. **Decision Rule:** Mean scores less than 2.95 (i.e. MS < 2.95) were regarded as not important; those between 2.95 and 3.05 (i.e. 2.95 < MS < 3.05) were regarded as important; while those greater than 3.05 (i.e. MS > 3.05) were regarded as very important.

RESULTS AND DISCUSSION

Sources of financing value addition of root and tuber crops employed by the respondents

The result of the sources of financing value addition among root and tuber crops producing households as depicted in Table 1 indicated that majority of the respondents financed value addition with equity finance from their personal savings. Cocoyam producing households recorded the highest percentage whereby, all the respondents financed their value adding activities from personal savings. This was followed by ginger producing households where majority (96%) of the respondents financed their value addition activities with personal savings and the remaining 4% obtained finance by borrowing from family and friends. Then yam producing households, where majority (90%) of the respondents financed value addition with personal savings, while about 10 percent utilized funds from friends and Cooperative Societies. Thereafter, sweet potato producing households which had majority (86%) of the respondents financing value addition with personal savings while about 14 percent obtained finance from family and friends. Lastly, cassava producing households where most (58%) of the respondents financed value addition with personal savings while about 40 percent obtained finance from informal financial sources and the remaining 2 percent utilized finance from Microfinance Banks. The probable reason for this result is that most of the respondents were small-scale farmers, cultivating between 1 to 3 hectares of land with low investment. This result is in line with the findings of Okereke, (2013) and Ikwuakam, (2013) who found that most farmers finance their productive activities with their personal savings and funds borrowed from informal credit sources. The informal credit sources have some attractive features such as: collateral free lending, proximity, timely delivery and flexibility in loan transaction. According to Asogwa *et al.*, (2014), low patronage of banks may be due to the concentration of banks in the urban areas and inability of small scale farmers to present the needed collateral for bank loans, as well as the bureaucratic bottlenecks associated with sourcing loans from banks.

Reasons for value addition among the respondents

The major reasons for value addition among root and tuber crops producing households in descending order of importance as shown in Table 2 were to: increase farm income satisfy consumers, prevent spoilage, enhance the nutritional content, reduce bulkiness and increase the shelf life. These findings on reasons for value addition among the respondents concurs with Ememwa *et al.,* (2008) who observed that processing perishable farm produce reduces bulkiness, diversifies consumption, enhances acceptability and marketability, increases shelf life and contributes significantly to household food security and income generation since wastage is minimized.

CONCLUSION

This study had shown that root and tuber crops producing households in the study area mainly employed eqiuty finance in the form of personal savings in carrying out their activities.This hinders them from engaging in meaningful value addition and adversely affect their monthly farm income. Also, most of them are non members of agricultural cooperatives. Thus, root and tuber producing households are advised to join cooperative societies in order to have easy access to cooperative finance and other agricultural incentives from government.

EVALUATION OF PRE- EMERGENCE HERBICIDE FORMULATION FOR THE MANAGEMENT OF WEEDS IN POTATO

T.Y. Dalyop[1], C. O. Amadi[2] & Christy Pwol Gyang[1]
[1]Potato Research Program, National Root Crops Research Institute, Kuru- Jos, Plateau State
[2]National Root Crops Research Institute Umudike, Abia State
E-mail: *dalyopty@yahoo.com*

ABSTRACT
An experiment was carried out to evaluate a newly introduced pre-emergence herbicide in the management of weeds in potato production during 2011 cropping season. The herbicide was Pendilin with Pendimethalin 500gm/l. EC as active ingredient a pre - emergent herbicide formulated for the control of broad leaved weeds and grasses with a recommended application rates of 2.5-4.0 L./ha. The experiment was carried out at Potato Research Programme experimental field Kuru (09^0 44^{1}N 08^{0}44E and altitude 1351m) during 2011 cropping season. Experimental design was Randomized Complete Block Design replicated three times. Potato variety used as test crop was Nicola a popular variety with the farmers. Result of the effect of the pre emergence herbicides on plant vigour, weed density, weed biomass and yield of potato was significant ($p<0.05$). Pendalin at the rate of 4 liter/ha and atrazine at the rate of 4 liters/ha gave weed densities of 2.11 and 2.67/0.25m^2 compared to the control with a density of 7.00/0.25m^2. Both fresh and dry weed biomass was significantly higher in the control (2.33 and 0.271kg/plot respectively). For the rates, result showed that application of the herbicides at high concentration significantly ($p<0.05$) suppressed the weeds than lower rates and the control irrespective of the herbicides. It is recommended that in addition to pre emergence herbicides, post emergence herbicides be use followed by at least one manual weeding for effective weed management in potato as from the 4-6 weeks after planting. Pendilin is therefore strongly recommended as a pre-emergent herbicide to be use in potato production.
Keywords: Herbicide formulation, management, weeds, potato

INTRODUCTION

It has been established severally that weeds are a major problem in crop production generally. Weeds compete with the crops for space, light, moisture and soil nutrients. Weeds can also serve as alternative host for pests and diseases (Agpad, 1987). Weeds are also known to lower human efficiency and cause drudgery (Melifonwu, 1999). Akobundu, (1987) reported that weeds are the most underestimated pests in tropical agriculture that are often been associated with the drudgery that characterized peasant agriculture. Akobundu (1987) stated that weed results in 65% reduction in the yield of root and tuber crops and takes 25% of the total labour use in the production. Nwokocha (1987) had shown that yield reduction of about 50% is possible in potato production as a result of weeds infestation. All these calls for concerted effort at weed control in crop production.

Weeds can be managed either culturally, mechanically, biologically, chemically and through an integrated approach. There are two major ways is which weeds are controlled in Nigeria today, these are manual and chemical. The use of cover crops to suppress weed had also been shown to be effective (Chikoye *et al*., 2001) Manual weeding is capital intensive, time consuming and full of drudgery which had made it unattractive.

New improved agricultural inputs are getting into the market on a daily basis. Herbicides are essential in the management of weeds in potato production. Several herbicides and their rates had been screened and found effective in the control of weeds in potato and other crops production.

There are approximately 140 herbicides active ingredients (Vencill, 2002; Mallory-Smith and Retzinger, 2003). Most of these basic forms of herbicides are further refined and formulated, creating several hundred commercial products. It is natural to evaluate them viz a viz the existing ones in the management of weeds in potato production. The objectives of the study were; to evaluate the new herbicide formulation in the management of weeds in potato and to compare its efficacy viz a viz the existing ones being used in the management of weeds in potato. Lastly to determined the best rate for optimum weed control.

MATERIALS AND METHODS

An experiment was carried out to evaluate a newly introduced pre-emergence herbicide by an agrochemical company (African Agro) based in Kano state in the management of weeds in potato production. The herbicide brought was Pendilin with Pendimethalin 500gm/l. EC as active ingredient a pre - emergent herbicide formulated for the control of broad leaved weeds and grasses with a recommended application rates of 2.5-4.0 L./ha. The experiment was carried out at Potato Research Programme experimental field Kuru (09^0 44^{1}N 08^{0}44E and altitude 1351m) during 2011 cropping season. Experimental design was Randomized Complete Block Design replicated three times. Potato variety used as test crop was Nicola a popular variety with the farmers. Potato was planted at a spacing of 30cm inter and 100cm intra row given a gross plot size of 24m^2. Fertilizer NPK was applied at planting at the rate of 100kg/ha each of N, P_2O_5 and 40kg/ha K_2O as band application. Atrazine (ai =Atrazine

500SC) a pre-emergent herbicide with a recommended application rates of 2.5 – 4L. /ha was used as a check herbicide. The herbicides were applied after planting (0WAP) using a CP3 knapsack sprayer at the following rates; Pendilin applied at 4, 3.25 and 2.5 liter/ha, Atrazine applied at 4, 3.2 and 2.4 liters/ha and absolute control (No herbicide application). Weed biomass was taken using a quadrat of 0.5x0.5m (0.25m^2) at 6 weeks after planting (WAP). Thereafter the potatoes were weeded manually. Harvesting was done at 12WAP. Data collected were; plant establishment at four weeks after planting (4WAP), a score of weed density and plant vigour, fresh and dry weed biomass at 6WAP, final stand count and tuber yield at 12WAP. Data collected were subjected to analysis of variance and means separated by LSD at 5% level of probability,

RESULTS AND DISCUSSION

Results of the effect of the pre emergence herbicides on establishment count, weed density, plant vigour, weed biomass and yield of potato are presented in Table 1. The result revealed a significant ($p<0.05$) effect in all the parameters measured with exception to plant establishment. Higher rates of the herbicides led to vigorous growing plants as the result shows. Pendilin applied at the rate of 4 liters/ ha and atrazine (check) at 4 liters/ha gave the most vigorous growing plants compared to the absolute control. The effect of herbicides on weed density and biomass shows that they suppressed the weeds. Higher rates irrespective of the herbicides gave significantly low weed densities than the control. Pendalin at the rate of 4 liter/ha and atrazine at the rate of 4 liters/ha gave weed densities of 2.11 and 2.67/0.25m^2 compared to the control with a density of 7.00/0.25m$^{2.}$ Both fresh and dry weed biomass was significantly higher in the control (2.33 and 0.271kg/plot respectively)

Effect of pre – emergence herbicides and rates on fresh and dry biomass of weeds (kg) /0.25m^2 are presented in table 2. Result shows significant ($p<0.05$) effect in the herbicides and rates on fresh and dry weed biomass. Interaction between herbicides and rates was not significant ($p<0.05$). There was no significant difference in the fresh and dry weed biomass between the new herbicide pendalin (1.71kg and 0,155kg/0.25m^2) and the check herbicide atrazine (1.81 and 0.113/0.25m^2) in terms of weeds management though pendalin was numerically better. For the rates, result showed that application of the herbicides at high concentration significantly ($p<0.05$) suppressed the weeds than lower rates and the control irrespective of the herbicides

Herbicides had been known to control weeds if applied effectively without phytotoxic effect on the crops. The low weed densities and biomass mass can be attributed to the herbicides applied as the result shows. As the rate increases, the densities and biomass reduces. This has further been ascertained with higher weed density and biomass recorded in the control. Balthazar and Barium (1986) and Olofintoye (1997) reported that pendimethalin (pendilin) a pre emergent herbicide as for grass – weed control. Yield and yield attribute of the potatoes were also significantly affected. Result shows that there is a positive relationship between herbicides application and yield performance as seen on final stand count, tuber number and weight. Weeds have been known to interfere with normal crop growth and yield leading to low yield. This fact is corroborated by the findings of Akobundu, (1987) who stated that weeds are the most underestimated pests in tropical agriculture and can results in 65% reduction in the yield of root and tuber crops. Nwokocha (1987) had shown that yield reduction of about 50% is possible in potato production as a result of weeds infestation. This shows that weed management translate to high yield.

CONCLUSION

It has being established that weeds adversely affect potato production resulting in low yields. Result of the study revealed that the herbicide Pendilin applied at 4 liters/ha did suppressed weeds infestation in the first six weeks of potato production though not significantly different from the check herbicide (atrazine) applied at 4liters/ha. It is therefore deduced from the finding of this work that pendilin is a credible alternative to atrazine or any other pre emergence herbicide in potato production. For the desire result recommended rates of the herbicide be use for effective management of weeds in potato. It was observed that the potency of the herbicides is shot lived for the period of crop growth.

It is recommended that in addition to pre emergence herbicides, post emergence herbicides be use followed by at least one manual weeding for effective weed management in potato as from the 4-6 weeks after planting. Pendilin is therefore strongly recommended as a pre emergent herbicide to be use in potato production.

ABSTRACT
A gross margin analysis of cocoyam production at National Root Crops Research Institute Umudike done in 2015 planting season was carried. The experimental study showed that the enterprise is profitable. Labour constituted about 42.90% of total variable cost of production, which is the most important resource in cocoyam enterprise. One-hectare cost of cocoyam production was N573,480 while total revenue was N936,400 and gross margin was N362,920. The study showed that the result of profitability analysis of cocoyam production is profitable by returning N1.63 to every N1.00 spent. There is need therefore to encourage farmers to go into rapid production of cocoyam to enhance their revenue, food security and livelihoods.

INTRODUCTION
Cocoyam (Colocasia esculenta and Xanthosoma mafia) is an important carbohydrate staple food particularly in the southern and middle belt areas of the Nigeria (Asumugha and Mbanaso, 2002). Cocoyam is a stem tuber that is widely cultivated in the tropical regions of the world and is a well – known food plant which has a long history of cultivation with Nigeria being the largest producer of cocoyam (3.45mt) in the world (9.97mt) and accounting for about 34.57% of the total output (FAOSTAT, 2013). In the last decade, attention has been focused on means of eliminating food insecurity and hunger worldwide. The targets of the first Millennium Development Goal (MDG) between 1990 and 2015 are to halve, the proportion of people who suffer from extreme hunger and people, whose income is less than $1 a day (FAO, 2005).
Expansion in cocoyam production has therefore the potential of bridging the wide demand and supply gap, and enhancing the income (thereby reducing poverty) of the rural farmers, particularly the vulnerable group. Opata and Nwaeze (2009) reported that many rural people, particularly women have gained interest in the production, processing and marketing of cocoyam, essentially because of the rapid increase in its share of the urban market in Nigeria.
Resource allocation to cocoyam is significantly low when compared to crops such as yam and cassava (Okorji and Obiechina,1995; Okoye,2006). Production has not been given priority attention probably because of cocoyam's inability to earn foreign exchange and its unacceptability to the high income groups for both consumption and other purposes (Nweke, 1987; Onyenweaku and Eze,1987). The need for increased food production to meet the demand of ever-increasing population in Africa, where population growth rate is higher than the rate of increase in agriculture production had been long emphasized (World Bank, 1992).
The production is labor intensive with most operations carried out manually at the traditional level (Okoye, 2006). Zuhair and Hunter, (2000) reported that the cultivation of cocoyam is declining. To meet the demand for cocoyam, there is need to increase its production (Eze and Okorji, 2003).The study will therefore serve as a basis for information to the farmers on cocoyam profitability which is expected to drive increased cultivation of the crop.

MATERIALS AND METHODS
Six cocoyam cultivars NCe 001, NCe 002, NCe 003, NCe 004, NCe 011, NCe 012 of the *Colocasia* spp were used for the study which was carried out at NRCRI, Umudike in 2015 planting season. Data, such as resource allocation which includes; labour in mandays, inputs, cost items as well as output (yield) and value of produce were taken. Data was analyzed using the Cost and Returns analysis procedure on per hectare basis.

RESULTS AND DISCUSSION
Table 1 show that output per hectare was 4,682kg. The total value of production was N936, 400 at the cost of N200/kg for cormels and corms respectively. Total variable cost of production was N573,480. Labour constituted about 42.90% of total variable cost of production. This implies that production is labour intensive because most operations were carried out manually. This followed the findings of Okoye, (2006) and Okoye *et al*., (2004). The results show a gross margin of N362,920, indicating that cocoyam is profitable by returning N1.63 for every N1.00 spent. This excludes the fixed costs which most times are minimal and not significant due to depreciation.

CONCLUSION
The study estimated the gross margin for cocoyam production per ha in NRCRI Umudike. The results of the gross margin analysis showed that cocoyam production is profitable by returning N1.63 to every N1.00 spent. Farmers should be encouraged to go into cocoyam production since it is a highly profitable venture. Given that cocoyam

is an important staple food in Nigeria, any attempt to increase its productivity would be a right step towards the resolution of the food crisis especially in Nigeria. Farmers are therefore encouraged to go into rapid production of cocoyam since it is highly profitable. This will enhance their revenue, improve food security and livelihoods among cocoyam farmers.

ABSTRACT
This study was conducted during the 2014 cropping season to investigate the effects of plant spacing and phosphorus fertilizer application on the performance of cowpea. The treatments consisted of factorial combinations of three row spacing including 75 cm x15cm, 75cm x25cm and 75cm x35 cm as well as four levels of phosphorus fertilizer of 0, 25, 50 and 75 kg/ha. The treatments were laid in a Randomized Complete Block Design (RCBD) replicated three times. The result of the study showed that wider spacing significantly (P<0.05) increased number of leaves, number of branches and pod length whereas narrow spacing significantly improved most of the yield parameters measured. However, plant height was not significantly influenced by plant spacing. Result also showed significant response to applied phosphorus fertilizer on pods per plant, number of seeds, 100-seed weight, pod dry weight and grain yield. Phosphorus fertilizer significantly ($P \leq 0.05$) enhanced growth characteristics of cowpea: plant height, number of leaves, number of branches and pod length in all the weeks of measurement. From the results, it was observed that interaction between spacing and phosphorus fertilizer application was significant with the best result for 100-seed weight obtained at 35cm x 75 cm alongside application of 50 – 75kg/ha P whereas pod dry weight, and grain yield were higher at spacing of 15cm x 75 cm at the rate of 75 kg/ha of phosphorus fertilizer application.
Keywords: Effects, phosphorus fertilization, performance, cowpea

INTRODUCTION:

Cowpea (*Vigna unguiculata* (L) Walp) is an important grain legume and the most diverse of the cultivated species. In most traditional African Societies, farmers sow cowpea in a wide space which eventually affects the total production of cowpea. Decrease in plant spacing means increasing the plant population in a given area of land, and this leads to an increased competition among plants for soil moisture, nutrients, light and space. Hamad (2002) and Asiwe and Kutu (2009) all reported that cowpea plants produced at the lowest densities, set good number of pods than those at the higher densities. Webber *et al.* (1966) found that soybean plants produced at highest densities were taller and more sparsely branched. Abdelrhim (2010) observed that optimum spacing not only utilize soil moisture and nutrients move effectively but also avoid excessive competition among the plants. Ndor *et al.* (2012), it reported that spacing had significant response on almost the entire growth and yield parameters assessed. Malami and Samai'la (2012) reported that intra-row spacing affected stand establishment count, plant height, leaf width, number of leaves and leaf canopy while both inter and intra-row spacing of 100 and 25 cm respectively recorded the highest yield.

Tropical soils are inherently low in nutrients particularly nitrogen and phosphorus (Haruna *et al*., 2011). The deficiency of phosphorus in some of these soils is so acute in some cases that the symptom manifest in the plant. Application of phosphorus fertilizer therefore has great impact on crop yield (Alaam *et al.,* 2003). This is more so on highly weathered and leached soils in tropical and temperate regions of the world where soil acidity causes infertility and is a general limitation to crop production (Von Uexkull and Mutert, 1995). Despite its importance in plants growth and metabolism, phosphorus is the least accessible macro-nutrient and hence most frequently deficient nutrient in most agricultural soils because of its low availability and its poor recovery from the applied fertilizers (Balemi and Negisho, 2012). The low availability and poor recovery of phosphorus is due to the fact that it readily forms insoluble complexes with cation such as aluminum and iron under acidic soil condition Phosphorus is critical to cowpea yield because it stimulates growth, initiates nodule formation as well as influence the efficiency of the rhizobium legume symbiosis (Haruna and Aliyu, 2011). Accordingly phosphorus is required in young cells such as shoot and root tips where metabolism is high and cell division is rapid. Ndakemi and Dakora (2007) reported that phosphorus aids in flower initiation, seed and fruit development. El-Habbasha *et al.,* (2005) reported that increasing phosphorus levels increased number of leaves, stem weight, number of pods, weight of pods and seeds per plant, 100-seed weight and seed yield of groundnut. Abdel-ati (2000); Haruna and Usman (2013) showed that number of pods per plant, pod yield per plant, seed yield per plant, number of seeds per pod, 100 seed weight and seed yield per hectare were significantly increased by the application of 30 kg P ha^{-1}. FAO (2005) recommended about 30kg of phosphorus per hectares in the form of single super phosphate. Singh et al, (2011) reported highest yield of 60kg/ha of P and suggested that, that may be the optimum as further application may or may not increase yield. Yakubu *et al.* (2010) and Uzoma *et al.* (2006) reported that phosphorus application at 20 and 40 kg/ha P improved the performances of cowpea significantly but the best performance was obtained with 40 kg Pha^{-1}

MATERIALS AND METHOD

The study was conducted at the Teaching and Research Farm, University of Calabar, during the 2015 late cropping season. Calabar is in the humid forest zone of Nigeria and lies within latitude 05^0 29'N and Longitude 08^0 44'E. Annual rainfall of Calabar ranges from 1200mm to 2500mm and are bimodal in distribution with peaks in July and September.

Random soil samples were taken from 0-15cm depth of the study site at the beginning of the experiment and composited. This was then taken to the laboratory for physico-chemical analysis using suitable laboratory procedures as described by IITA (1979). The experiment was a 3 x 4 factorial experiment laid out in a randomized complete block design with three replications. Treatments included three row spacing (75cm x 15cm, 75 cm x 25cm, 75 cm x35cm) and four rates of phosphorus fertilizer (0, 25, 50, 75kg/ha). There were a total of 12 treatment combinations each of which was replicated thrice. The total field size 13m x 40.8m (530.4m^2) while each experimental plot measured 3m x 2.5m (7.5m^2). Two seeds of Cowpea variety- Sampea 7 (obtained from the Institute of Agricultural Research, Samaru, Zaria) were planted per hole at a planting depth of 2.5cm and later thinned to one plant per hole two weeks after planting. Single superphosphate fertilizer was incorporated into the soil one week before sowing, manual weeding was done 2 and 5 week after planting (WAP). Data were collected on plant height, number of leaves and number of branches, each taken from 10 plants randomly sampled from the two inner rows of each plot at 3, 5 and 7 weeks after planting (WAP). Other data collected included; pod length (cm), number of pods per plant, number of seeds per pod, 100-seed weight (g), dry pod yield (tonnes/ha) and grain yield (tonnes/ha. Data collected were subjected to statistical analysis using analysis of variance (ANOVA) according to Gomez and Gomez (1984) and significant means compared using the Fishers' least significance difference (FLSD) at the 5% level of probability.

RESULTS AND DISCUSSION

The soil texture at the experimental site was classified as loamy sand (10.7, 9.0 and 80.3% clay, silt and sand respectively). The pH (4.9) was very low and exchangeable acidity (3.2cmol/kg) was high. The Nitrogen (0.10%), potassium (0.09cmol/kg), calcium (1.4cmol/kg) and magnesium (0.07cmol/kg)) contents as well as base saturation (44.44%) and organic carbon (1.20%) were low whereas, phosphorus content (39.89mg/kg) was high. The effects of plant spacing and phosphorus fertilizer application on vegetative growth of cowpea at different growth stages are presented in Table 1. Plant spacing did not significantly ($P \geq 0.05$) influence the height of cowpea at 3, 5 and 7 WAP. However, planting cowpea at a spacing of 25 x 75cm had the tallest plants in all the sampling periods. The number of leaves were significantly ($P \leq 0.05$) influenced by spacing at 3, 5 and 7 weeks after planting. Cowpea planted at 15 cm x 75 cm produced significantly ($P \leq 0.05$) more leaves compared to those planted at 25 cm x 75 cm which in turn produced significantly ($P \leq 0.05$) more leaves than those planted at 35 cm x 75 cm. On the other hand, cowpea planted at 35cm x 75 cm had significantly the highest mean of number of branches per plant compared to other plant spacing. Application of phosphorus fertilizer had significant ($P \leq 0.05$) effect on plant height and number of leaves at 3, 5 and 7 WAP. At 3, 5 and 7 WAP respectively, application of 50 kg P_2O_5/ha produced significantly ($P \leq 0.05$) taller plants when compared to those that received 75kg/ha P_2O_5 and 25kg/ha P_2O_5 respectively. Conversely, 75kg/ha P_2O_5 produced significantly ($P \leq 0.05$) more leaves compared to application of 50 kg/ha P_2O_5 which in turn produced significantly ($P \leq 0.05$) more leaves than the 25kg/ha P_2O_5 application at 3 and 7 WAP but At 5 WAP, application of 50kg/ha P_2O_5 produced the highest number of leaves but this was not significantly ($P>0.05$) different from the number of leaves produced at 75kg/ha P_2O_5. At 3 WAP, there was no significant difference between the number of branches produced when P was applied at the rate of 50 and 75 kg/ha respectively but at 5 and 7 WAP, application of 50kg/ha P_2O_5 produced significantly higher number of branches per plants when compared to application of 75kg/ha P_2O_5. Plants in the control plot were significantly the least in terms of growth.

Both spacing and P application significantly ($P \leq 0.05$) influenced yield components of cowpea (Table 2). Cowpea planted at widest plant spacing (35cm cm x75 cm) produced significantly more pods and longer pods compared to those planted at 25cm x 75 cm and 15 cm x 75 cm respectively. However, cowpea planted at a spacing 25cm x75 cm produced significantly more seeds per pod compared to those planted at 35cm x 75 cm which in turn had significantly more number of seeds per pod than those planted at 15 cm x 75 cm whereas, cowpea planted at 35cm cm x75 cm had significantly higher 100-seed weight compared to those planted at 25cm x 75 cm and 15 cm x 75 cm respectively. Pod dry weights at spacing of 15 x 75 cm and 25 x 75 cm were not significantly ($P \geq 0.05$) different although they were significantly when compared to those planted at 35 cm x 75 cm but cowpea planted at 15cm x 75cm had significantly higher grain yield compared those planted at 25cm x 75cm and 35 cm x 75 cm which had significantly the least grain yield. P fertilizer significantly ($P \leq 0.05$) influenced the pod length, number of pods per cowpea plant as well as number of seeds per pod. Application of 50 kg/ha P_2O_5 produced significantly the longest and highest number pods per plant/ number of seeds per pod when compared to 75kg/ha P_2O_5 and 25kg/ha P_2O_5 respectively. However, both 50 and 75kg/ha P_2O_5 had statistically similar 100-seed weight and pod dry weights which were higher than those at 25kg/ha P_2O_5 whereas, 75kg/ha P_2O_5 produced significantly higher grain yield of cowpea when compared to that at 50 and 25kg/ha P_2O_5 respectively.

Spacing and phosphorus fertilizer had significant ($P \leq 0.05$) interaction effects on the height of cowpea at 5 WAP, number of leaves produced by cowpea at 3, 5 and 7 WAP and number of branches at 5 and 7 WAP. Cowpea planted at 25 cm x 75 cm and application of 50kg/ha P_2O_5 produced taller cowpea plants with more number of branches though at 5 WAP, planting cowpea at 25cm x 75 cm and 50 kg/ha P_2O_5 had the highest number of branches per plant but this was not significantly different from the number of branches produced when cowpea was planted at a spacing of 35cm x75 cm with 25kg/ha P_2O_5 application, 35cm x 75 cm with 50kg/ha P_2O_5 and 35cm x75 cm with 75kg/ha P_2O_5 application respectively. Also, planting cowpea at 15cm x 75 cm with 50kg/ha P_2O_5 produced the highest number of leaves but this was not significantly ($P \leq 0.05$) different from those produced when cowpea was planted at a spacing of 15cm x 75 cm but 75kg/ha P_2O_5 was applied. Also, cowpea at a spacing of 25cm x 75 cm which received 50kg/ha P_2O_5 produced significantly longer pods, more pods seeds per pods when compared to those produced in other treatment combinations. Pod dry weights obtained at 25 cm x 75 cm alongside the application of 50 kg/ha P_2O_5, 35 cm x 75 cm with 75 kg/ha P_2O_5 as well as 15 cm x 75 cm with 75 kg/ha P_2O_5 did not differ significantly from each other. There were no interaction effects of spacing and phosphorus fertilizer application on grain yield. The very low soil pH coupled with low nitrogen, potassium, calcium, magnesium, organic carbon contents and base saturation but with high phosphorus content was observed from the soil analysis. These properties are typical of highly leached ultisols as observed by Agbede (2009).

The study revealed that wider plant spacing enhanced growth as observed in number of leaves as well as number of branches. This may be due to less competition among plants for space, soil moisture, nutrients, light and carbon dioxide. The results also revealed that narrow spacing tends to favor most yield attributes such as number of pods per plant, pod dry weight and grain yield. This agrees with the results earlier obtained by Haruna et al. (2011), Haruna and Usman (2013), Asiwe and Kutu (2009) and Hamad (2004) who indicated that cowpea plants produced at the lower plant densities set good number of pods than those at the higher densities.

Growth attributes such as plant height, number of branches and numbers of leaves were significantly increased by the application of phosphorus fertilizer. Thus, an indication that the cowpea variety utilized the phosphorus fertilizer applied judiciously in growth and development processes. These could be attributed to the fact that phosphorus is required in large quantities in shoot and root tips where metabolism is high and cell division is rapid (Ndakidemi and Dakora, 2007). It also stimulates root and stem growth, initiate nodule formation by enhancing the general efficiency of the rhizobium – legume symbiosis leading to enhanced nitrogen fixation as observed by Haruna and Aliyu, 2011). However, Singh *et al*., (2011) had suggested that application beyond 60kg/ha P may or may not influence the growth of cowpea. It was observed that application of P generally improved the yield of cowpea. The significant yield response of cowpea to phosphorus application could be attributed to the role of phosphorus in seed formation and grain filling (Haruna and Aliyu, 2011), in flower initiation, seed and fruit development (Ndakidemi and Dakora, 2007), improvement in the pod length, number of pods per plant, pod yield per plant, seed yield per plant, number of seeds per pod, 100 seed weight and seed yield per hectare (Abdel-ati, (2000) Krasilnikoff *et al*., (2003), El-Habbasha *et al*., (2005), Nyoki *et al*., (2013) and Haruna and Usman (2013). Additionally, P has been reported to stimulate growth, initiate nodule formation as well as influence the efficiency of the rhizobium legume symbiosis (Haruna and Aliyu, 2011). The result also showed that the highest number of pods per plant, highest pod yield as well as grain yield were recorded at 50 or 75kg/ha P_2O_5. This agrees with the observation of Singh *et al*., (2011) who obtained the highest cowpea yield when 60kgha-1 of P was applied and suggested that that may be the optimum as further application of phosphorus may or may not increase yield of cowpea.

CONCLUSION

Narrower plant spacing out yielded wider spacing but the latter performed better in terms of vegetative character. Also, increasing levels of P improved both growth and yield characteristics however 50kg/ha P_2O_5 is as good as 75kg/ha P_2O_5

Table 1: Effects of spacing and phosphorus fertilizer on the vegetative growth of cowpea

ABSTRACT
The impact of Neem (Azadiradita indica) seed extract (NSE) on the growth performance, haematology and serum cholesterol of broiler chicks was evaluated in a study that lasted 35 days. 225, 7 day old broiler chicks were randomly assigned to five treatment which contained 0, 15, 30, 45 and 60ml NSE per litre of water representing $T_{1,}$ T_2, T_3, T_4, and T_5 respectively in a completely Randomized Design. Each treatment was replicated three times with 15 birds in each replicate. Feed and water were given ad libitum. There was no significant (P>0.05) differences in weight gain, feed and water intakes, feed conversion and protein efficiency ratios of the birds among the treatments. NSE had significant influence (P< 0.05) on the packed cell volume, red blood and white blood cells. There was no significant (P>0.05) difference in the haemoglobin, serum protein, albumin, globulin, triglyceride and cholesterol level of the birds. There were marked (P>0.05) variations in the glucose, HDL and LDL of the blood. In conclusion, results of this study indicate that NSE could therefore be used in broiler production without any deleterious effect on the growth, haematology and serum biochemical parameters of broiler chicks.
***Keywords*: Azadiradita indica, broilers, growth, haematology, serum cholesterol**

INTRODUCTION
In Nigeria, many herbal products have been used as growth promoters and preventive remedies for several infections in poultry birds because of their availability, suitability, lower cost of production, reduced risks of toxicity and minimum health hazards. Researchers have identified several beneficial chemical compounds in medicinal plants, which play an important role in improving production and immune system of birds against different diseases and have strong medicinal value and could be effectively utilized as natural growth promoters to replace antibiotics and other synthetic feed additives (Durrani et al., 2007). Neem tree as one of the most researched tree in the world has attracted world-wide prominence due to its vast range of medicinal properties like antibacterial, antiviral, antifungal, antiprotozoal, hepatoprotective and various other properties without showing any adverse effects (Kale et al., 2003). Although the beneficial effects of incorporating neem leaf and seed meal into poultry feeds on the performance have been reported, data on the effects of neem seed extract on the health status and growth performance of birds are still scanty. The study therefore is to determine the effect of neem seed extract on the performance, haematology and serum biochemistry broiler chicks.

MATERIALS AND METHODS
The experimental protocol was approved by the Animal Care Committee of the Ebonyi State University, Abakaliki, Ebonyi State, Nigeria. 225, 7 day old broiler chicks were randomly assigned to five treatment which contained 0, 15, 30, 45 and 60ml NSE per litre of water representing $T_{1,}$ T_2, T_3, T_4, and T_5 respectively in a completely Randomized Design. Each treatment was replicated three times with 15 birds in each replicate. Feed and water were given *ad libitum*. Data on weight gain, feed intake and feed conversion ratio
At the end of the feeding trial, 2mls of blood sample were collected from 4 birds that were randomly selected from each replicate and put into sample bottles containing ethylene diamine-tetra acetic acid (EDTA) which served as anticoagulant for haematological analysis (Jain, 1986). Another 2mls of blood sample were collected for serum biochemical indices such as triglyceride, total cholesterol, total glucose, high density lipid, low density lipid, total protein, albumin and globulin were evaluated.
Data were analyzed according to the ANOVA model, using the GLM procedure of the Statistical Package for the Social Sciences (SPSS, 1999). When significant treatment effects were observed, differences between treatment means were tested by Duncan's multiple range test (SPSS, 1999).

RESULTS AND DISCUSSION

The result on the effect of *A. indica* seed extract on the growth performance of starter broilers are presented in the Table 1. There was no significant (P>0.05) difference in weight gain, feed and water intakes, feed conversion and protein efficiency ratios of the birds among the treatments.

Table 1: Effect of *A. indica* seed extract on the growth performance of starter broilers

Parameters	T_1	T_2	T_3	T_4	T_5	SEM
Initial body weight (g)	125.75	124.82	125.74	126.14	125.91	83.68
Final body weight (g)	1303.88	1249.44	1145.90	1202.91	1291.79	55.25
Bodyweight gain (g)	1178.13	1121.62	1020.16	1076.77	1165.88	55.68
Daily weight gain (g)	42.07	40.06	36.46	38.45	41.62	1.97
Total feed intake (g)	2338.16	2328.79	2221.13	2370.30	2363.72	134.51
Daily feed intake (g)	83.50	83.17	79.32	84.64	84.41	4.80
Total water intake (ml)	4785.89	4953.75	4517.93	4724.59	4858.40	292.60
Daily water intake (ml)	170.92	176.91	167.27	175.87	173.50	11.31
Feed water ratio	1:2.03	1:2.12	1:2.10	1:2.08	1:207	0.09
Feed conversion ratio	1.97	2.07	2.17	2.20	2.03	0.09
Daily protein intake	17.53	17.46	16.65	17.77	17.72	1.00
Protein efficiency ratio	2.40	2.29	2.18	2.17	2.19	0.28

The comparable weight gain of the birds fed neem seed extract and the control is an indication that quantity of toxicants (terpenes and limonoids) (Ogbuewu et al., 2001; Kabeh and Jalingo, 2007) was negligible to have depressed the growth of the birds served the treated water. The lack of variation in feed and water consumption of the birds is an indication that the concentration of active principles salanolide meliacin (Garg, 1989) and tignic acid (Lale, 2002) were within the tolerable limits of the birds fed neem seed extract. Significant (P>0.05) differences did not exist in feed conversion and protein efficiency ratios among the treatment groups This is an indication that the Neem leaf extract did not impair nutrient availability, digestion, absorption and utilization. This is evident in the comparable weight gain of the birds (Onu and Aniebo, 2011).

The effects of neem seed extract on the haematology indices of broiler starter as presented in Table 2. There were significant (P< 0.05) differences in the PCV, RBC, WBC and MCH of the birds among the treatment. NSE significantly decreased the PCV and WBC of the birds as the level increases (Gowda et al., 1998; Biu et al., 2009). There was no significant difference in the HB, MCV and MCHC of the birds among the treatment. The haematological values were still within the moral range for healthy broiler chicken reported Anon (1980).

Table 2: Haemogical parameters of starters broilers served *A. indica* seed Extract supplement

Parameters	T_1	T_2	T_3	T_4	T_5	SEM
Packed cell volume (%)	27.67^a	27.00^b	26.67^c	26.33^d	24.26^e	0.3
Haemoglobin (g/dl)	9.20	9.00	8.81	8.33	8.23	0.33
Red blood cell (x10^6/L)	2.02^b	2.30^b	2.18^b	2.82^b	2.36^b	0.09
White blood cell (x10^6/L)	23.06^a	21.86^b	20.86^c	20.50^d	19.33^e	0.79
Mean cell volume (FL)	120.43	125 07	119.33	118.33	112.43	16.29
Mean.corpusular Haemoglobin (pg)	45.43^a	39.27^a	40.73^a	29.53^a	35.10^a	1.84
Mean corpuscular Haemoglobin Conc.(g/dl)	33.23	33.33	33.23	31.73	33.40	0.70
Triglycerde (mg/dl)	127.33^b	146.27^b	137.00^b	152.13^b	130.23^a	3.48
Total cholesterol (mg/dl)	96.67	90.20	113.77	114.70	103.77	16.02
Total glucose	57.43	59.87	63.27	64.23	74.47	3.48
High density lipid (mg/dl)	33.43^{ab}	36.70^b	38.37^b	40.07^b	43.33^a	0.74
Low density lipid(mg/dl)	56.23^a	49.33^b	49.50^b	43.20^{bc}	36.40^c	1.68
Total protein (g/dl)	7.83	7.87	7.13	7.93	7.53	0.15
Albumin (g/dl)	4.67	4.63	4.50	4.67	4.33	0.17

a, b, c.d means with different superscript differ significantly.

The treatment did not significantly (P>0.05) influence the protein, albumin, globulin, triglyceride and cholesterol level of the blood. There were marked (P>0.05) variations in the glucose, HDL and LDL of the blood. The non-significant (p>0.05) effect of NSE on total protein, cholesterol, glucose and albumin obtained suggests nutritional adequacy of the NSE for starter broilers. In conclusion, results of this study indicate that NSE could therefore be used in broiler production without any deleterious effect on the growth, haematology and serum biochemical parameters of broiler chicks.
