Constraints to Value Addition in Cassava Processing in Emohua Local Government Area, Rivers State, Nigeria

G. I. Wilcox and C. M. Tasie
Department of Agricultural Science, Ignatius Ajuru University of Education, Rumuolumeni, Rivers State, Nigeria
Correspondence E-mail: willygcox68@gmail.com

Abstract
This study was carried out to examine the constraints to value addition in Emohua Local Government Area, Rivers State, Nigeria. The specific objectives are to identify the socio-economic characteristics of cassava farmers in the area, estimate costs and returns to cassava processing; and identify constraints to cassava processing and marketing. A three-stage random sampling technique was used to obtain primary data from72 respondents used for the study. Descriptive statistics was used to analyze the data used for the study. Analysis of the costs and returns revealed that processing cassava to fufu gave the highest Net Returns even though processing cassava to all the three products was profitable. Furthermore, the constraints experienced by processors in carrying out their activities and marketing their various products include bad roads leading to high transportation cost and high cost of fire wood. The study therefore recommends the need for processors to have access to infrastructural facilities and improved processing technology to enable them take advantage of the emerging market-oriented cassava products so as to improve their means of livelihood.
Keywords: Value Addition, Constraints, Fufu, Tapioca, and Rate of Returns

Introduction
In other to increase the shelf life of agricultural products and also add value to them, it has become necessary to study the various products coming out from cassava, a major staple grown, eaten and traded in different forms in Emohua Local Government Area(LGA) by smallholder farmers to increase their income. Cassava (*Manihotesculenta*), which has its origin from Latin America (Agwu, Anyanwu and Kalu, 2015) has gained global attention as an important root crop in Africa with Nigeria producing the highest quantity (54 million metric tonnes annually) globally (FAO, 2013). This crop, as has been captured by several literatures is a crop that is flexible, withstands drought and diseases and has the ability to thrive on low quality soils (Meridian Institute, 2014).Its roots are good sources of ethanol (Ani, Agbugba, & Baiyegunhi, 2013; Agwu *et al.,* 2015) and are rich in minerals, vitamins, starch and protein (Akpan, Okon, Jeiyol, Nkeme, & John, 2013)
Cassava root is processed into granulated substances called *garri* that is consumed by almost every Nigerian (Akpan *et al.,* 2015). According to Ani (2010) the consumption per capita is very high and it provides about 80 % of the total energy intake of many Nigerians. It can also be processed to get other by-products such as: flour, chips, *Fufu, Tapioca, starch etc* .By processing into other products, there is value addition(which in effect increases the farmer's income) and increase of the shelf life of the crop. However, there are challenges: it is generally observed that there is low level of investment in small scale cassava processing to value added products. This is evident in the predominance of women most of whom are resource poor in cassava processing enterprises; income derived from other products of cassava is small compared to garri and the challenges involved in the process.For these reasons, the study considers the following objectives: identify the socio-economic characteristics of cassava dealers; identify the various products from cassava; determine the costs and returns to cassava value addition and identify the constraints to cassava value addition.

Materials and Methods

The study was carried out in Emohua L.G.A. of Rivers State, Nigeria. It is one of the twenty three (23) Local Government Areas in the State and is divided into two geographical regions: Emohua Central and Emohua North respectively. The study population comprised of male and female cassava producers and processors/marketers operating in the L.G.A. A three-stage random sampling technique was used to select respondents for the study. At stage one three communities each were purposively selected from the two geographical locations (Emohua Central and Emohua North) based on the volume of cassava processing activities. At the second stage, two villages were selected randomly from each of the three communities selected from the two geographical locations to arrive at the twelve villages. At the third stage, six respondents (which include 2-producers, 2-processors and 2-marketers) were identified and randomly selected from each of the 12 villages to arrive at seventy two respondents. A structured questionnaire was used to collect primary data on the quantity of cassava that was used for each product, cost of processing the cassava into the various products like gari, *fufu* and *tapioca* and the cost of cassava that was used. Descriptive statistics such as frequencies and percentages were used to analyze the processing methods of selected cassava products (gari, *fufu* and *tapioca*) in the study area, the constraints associated with their processing and marketing. Rate of returns per naira on investment was used to analyze the returns on investment of marketing of the selected cassava products. Data were analyzed using cost and return analysis, R/C ratio and value addition analysis.

Analytical Method

Data was analyzed using descriptive statistics (means and percentages).The Rate of Return on Investment (RRI) shall be specified as:

$$RRI = \frac{\text{Net Income (NI)}}{\text{Total Cost (TC)}}$$

Where:

N I = TR-TC

TR = Total revenue from the cassava products

TC = TFC + TVC = Total cost of cassava products

TFC = Total fixed cost such as cost of frying pan, sieve, bags, frying spoon, tripod stands, knives, etc.

TVC = Total variable cost such as cost of fresh tuber, cost of transportation, cost of firewood, labour cost, cost of oil, etc.

TC = Total Variable Cost (TVC) + Depreciation

$$\text{Depreciation} = \frac{\text{Total Cost of assets - Salvage value}}{\text{Useful life}}$$

Results and Discussion

Estimated Cost and Returns to Cassava Processing into Garri, *Tapioca* and *Fufu*

The costs and returns to cassava processing into garri, tapioca and *Fufu* are as presented in Table 1. The result from the survey showed that an average of 100Kg of Cassava was processed into *garri* within a production cycle that took an average of five (5) days. The labour costs incurred included cost of peeling, milling, sieving, washing and frying. Milling was mainly done by men. The amount spent on labour on cassava to be processed into garri accounted for 18.18% of the total cost. 13.64% of the total cost was spent on the purchase of fire wood, kerosene and frying pot. The remaining 68.18% of the total cost were accounted for by other inputs. Also, some of the processors add palm oil to their garri in order to differentiate their product as well as enhance acceptability and preference. The average price of garri was ₦ 3,200.00/basin. The Net Returns was estimated at ₦ 1,600.00/100kg of cassava. The implication is that processing cassava to garri is profitable. An average of 100kg of cassava was processed to tapioca over a production cycle of 2-3 days after soaking. While 69.77% of the total costs of processing *tapioca* were incurred on cassava tuber, 14.42% was spent on labour with the remaining 15.81% spent on other inputs. With an estimated price of *tapioca* at ₦3,500.00/basin, the total value was ₦14,000. The Net Returns for processing tapioca was therefore ₦3,250.00/100kg of cassava. This implies that processing cassava to tapioca is a profitable enterprise in the study area. An average of 100kg of cassava was processed to *fufu* over a production cycle of 7 days. While 73.53% of the total costs of processing *fufu* were incurred on cassava tuber, 9.8% was spent on labour with the remaining 16.67% spent on other inputs. With an estimated price of *fufu* at ₦4,000.00/bag the total value was ₦16,000. The Net Returns for processing tapioca was therefore ₦5,800.00/100kg of cassava. This implies that processing cassava to *fufu* was a profitable enterprise in the study area as it brought more earnings than garri and *tapioca*. This is in agreement with findings from Muhammad-Lawal, Omotesho, and Oyedemi (2013) which shows net returns of garri ₦4,343.86; *fufu*₦5,931.28 and *lafun* ₦5,038.84 respectively.

Constraints to Cassava Value Addition

The results of the findings in relation to the constraints faced by the processors during the process of value addition to cassava for the production and marketing of garri, tapioca and *Fufu* are as presented in Table 2. It showed that bad road leading to high transportation cost and high costs of fire wood are serious problems encountered by the processors. This affected the cost of value addition in the area and is in line with the findings of Muhammad-Lawal *et al*. (2013) and Umeh (2013). High cost of kerosene and palm oil are not serious problems encountered by the processors for production of garri, tapioca and *Fufu*. However, the higher returns recorded for tapioca and *Fufu* are as a result of the reduction in labour costs as opposed to the processing of garri.

Conclusion and Recommendations

The analysis of value addition in cassava processing in Emohua LGA showed that in cassava processing there were variations in the Net Returns to the various products of cassava processed. However, *fufu* had the highest returns, this is in spite of the fact that all the products of cassava processing in the area namely garri*, tapioca* and *fufu* are profitable. To be able to derive the highest financial benefits to cassava processing, it is recommended that good roads be constructed in order to reduce the cost of transportation of cassava and its products, Processors are encouraged to go into cooperatives in order to harness their resources and provide themselves with technology that can improve value addition to cassava and that Garri and *fufu* which are the major income earners serve as a comparative advantage over other items from cassava as this would help the women to improve on their income and socioeconomic status.

Abstract
The study was conducted in 2017 to assess the effect of rural–urban migration in Igabi local government of Kaduna State, Nigeria. Data were collected using structured interview from 81 randomly selected farmers and were analysed using descriptive statistics. Results showed that 49.9% are within the age class of 42-60 years. Eighty five percent (85%) of the respondents are male and 87.6% were married. Majority (60.5%) of the respondents went through formal education. More than half (63%) are farmers, of which 42% cultivate between 0.5-3ha of land. Most prominent causes of rural-urban migration are lack of social amenities (77.8%), unemployment (72.8%) and poverty (66.7%).Seventy-two percent (72%) of the respondents indicated that migration resulted in low agricultural productivity, 61.7% decrease in farmers income, 53.1% reduced communal participation among others. It is therefore recommended that social amenities should be provided by all tiers of government to discourage rural-urban migration.
Keywords: Rural-urban migration, social amenities, agricultural production

Introduction
Nigeria was previously an agriculture economy and the agricultural sector was contributing about 80% of the total Nigeria export. Then, about 75% of Nigeria total population live in the rural area and obtain their means of livelihood from agriculture. But ironically, this sector has been doing badly in the past few years for example, in 1965 agricultural export accounted for as much as 76% of the Nigeria foreign exchange, 43% in 1970 while the contribution falls to about 6% in 1976, 3.9% in 1989 and 1.4% in 1992. (African development bank, 2012).
Many factors have contributed to the poor performance of agricultural sector but one of the major factor is rural-urban migration (especially by youth) which involves the shifting of labour force from rural areas to urban centers in search of employment, better living standard, freedom of religion and others too numerous to mention, one of the factor affecting rural-urban pattern of migration is the storage of agricultural labour supply needed for agricultural production (Frimino,2006),Chinsinga, (2015) pointed out that the rural-urban pattern of migration takes more young men than women out of the rural area, resulting in many women becoming the heads of household and been responsible for agricultural production. Frimino, (2006) pointed out that the youth perform the most tedious jobs in the farm. It is also documented that, in most cases, the works of rural youth include, clearing of farm, road, clearing of village street crops and animal processing, livestock raising, artisan production etc. With more youth migration into urban areas to earn a living, more aged people are now left to accomplish the task associated with farming, especially the task which are reserved for the youth. Therefore, there is no doubt the added responsibilities will reduce agricultural production, (Nwosu, 2009). Several factors are responsible for rural urban migration, viz; the rural push factors and the urban pull factors. The rural push factors are family pressure, unemployment, inadequate infrastructure like electricity, good and portable water, good roads, hospitals and persistence of poverty. While the urban pull factors include employment opportunities, presences of infrastructural facilities like good roads, hospitals, good drinking water. This results in the gradual movement of young productive able-bodies, educated and skilled individuals away from the rural areas living behind children, old and unskilled persons thereby resulting in low socio-economic life standard among rural dwellers,

(Adepoju 2006). Rural-urban migration is also associated with a decrease in farmers income, stagnation, rural development, and shortage of labour during cropping season with resultant effect on agricultural production and supply at large. To investigate this problem, the study attempted to describe; the socio-economic characterises of rural farmers, the causes and effects of rural-urban migration in the study area

Methodology

Igabi local government area is in the guinea savannah region of Nigeria on the latitude 10^0 47' 0" North, 7^0 46' 0" East (Maplandia 2012). Its inhabitants are mostly farmers and cattle rearers. Primary data were used in this study. The primary data were obtained from farmers (household heads) through structured questionnaires that were administered along with personal interview. Data were collected in 2017 from 81 Sorghum farmers in Igabi local government using the random sampling technique. Descriptive statistics was used to analyse and summarize the source data through the use of measures of central tendency such as frequency distribution, mean, percentages and ranking procedures.

Results and Discussion

Table 1 presents the socio-economic characteristics of the farmers in the study area. Result revealed that the modal age group of the respondents was 42-61. The minimum age of about 21 years may be an indicator of less participation of youth in farming activities as mostly are engaged in educational activities whilst a reasonable number are engaged in rural-urban migration. This can be evident by the fact that a great proportion (32%) of the respondents had either secondary or tertiary education. The farmers were predominantly male (85.19%). Majority of the respondents were married. More than half (74.9%) of the respondents are literate with most of them possessing minimum of primary school education, while 39.51% had no formal education and 20.99% had tertiary education. This implies that farmers in the study sites can follow simple written instructions and other extension publications for better understanding of the recommendations of agricultural production. About 42% of the respondents had 0.5-3.0ha of farm land, while only 7.41% had 5.5-8.0ha of farm land, signifying that most of the farmers are small scale farmers. Household size of about 10 is the modal class with up to 33.3%, while the minimum is between 11-21 persons consisting of 31% of the population of the respondents. Majority (86.4%) of the farmers had farming as their primary occupation, while about 26% are artisans with small proportion of the respondents in the civil service (9.88%). The result from Table 1 also revealed that 40.7% of the respondents had enjoyed farm credit i.e. they have access to credit.

Table 1: Respondent socioeconomic and institutional factors

Socioeconomic Variables	Options	Frequency	Percent
Age	< 21	1	1.23
	22-41	13	16.05
	42-61	40	49.38
	> 61	27	33.33
Gender	Male	69	85.19
	Female	12	14.82
Marital Status	Divorce	6	7.41
	Married	71	87.65
	Single	4	4.94
	Widow	6	7.41
Educational	Non Formal	32	39.51
	Primary	23	28.39
	Secondary	9	11.11
	Tertiary	17	20.99
Farm size	0.5-3.0	34	41.98
	3.0-5.5	24	29.63
	5.5-8.0	6	7.41
	>8.0	16	19.75
Household size	1 – 10	27	33.33
	11 – 21	25	30.86
	> 21	29	35.8
Primary occupation	Farmer	51	62.97
	Civil servant	8	9.88

Causes of Rural-urban Migration

Several factors have been identified by literatures as the cause of rural-urban migration. In Igabi local government area of Kaduna State the following factors (Table 2) have been identified by the respondents. The leading cause of migration to urban centres is lack of social amenities in the various rural settlements, this accounted for 77.8% and ranked 1st among other causes. Unemployment accounted for 72.8% cause of rural urban migration and ranked 2nd. Other causes of rural urban migration includes poverty (66.7%), poor education (53.1%) and poor standard of living (48.1%). The results agrees to the findings of Ango *et al* (2014), Uddin (2013) and Aworemi *et al* (2011) that lack of social amenities, unemployment and poor education standard are among the factors that highly determine rate at which rural-urban migration takes place. This implies that, the youths engaged in migration to urban settlements do so as a result of constraints due to poor state or lack of social amenities, unemployment and poor education. Possible Government and intervention by all related stakeholders in providing the basic needs of the rural settlers will result to a decrease in the rate of migration to urban centres, which has a direct effect on agricultural productivity the settlements.

Table 2 Causes of Rural-Urban Migration in Igabi LGA

Cause	Percent	Ranking
Lack of social amenities	77.8	1st
Unemployment	72.8	2nd
Poverty	66.7	3rd
Poor education	53.1	4th
Poor standard of living	48.1	5th

Effects of Rural-urban Migration on Rural Community

Like most themes in social change and development, the problem of rural urban migration and its impact is a complex subject. One thing however is clear; the phenomenon of rural-urban migration is grounded in the persistent inequality in the allocation of social and economic infrastructure such as pipe borne water, good roads, electricity, health facilities, and industries, among others in rural and urban communities. However other effects (Table 3) have been recognized by farmers in the study area. Low agricultural productivity accounts for over 72.8% of the effects of rural urban migration, followed by reduction in farmer's income (61.7%), reduction in communal participation with 53.1%. This implies that, the rate at which youth migrate to urban centers has led to decreased agricultural productivity, which in turn led to a decrease in farmer's income. This is so true because the most energetic of the community had left for a better life in urban centers leaving behind the older ones whom are aged and cannot produce a reasonable quantity of food and even if one has the capital to use hired labour, he still won't get it and the little ones been present will be left with too much to be done. Consequently, since the demand for labour increases, therefore the amount also appreciates.

Table 3 Effects of Rural-Urban Migration in Igabi LGA

Outcomes	Percent	Rank
Low agricultural productivity	72.8	1st
Reduced farmer income	61.7	2nd
Reduced communal participation	53.1	3rd
Older ones are left behind	46.9	4th
Under-development	44.4	5th
Increased cost of agricultural labour	33.3	6th
Loss of traditional activities	18.6	7th

Source: field survey 2016.*Multiple Responses recorded

Conclusion/Recommendations

The study indicated that rural-urban migration has caused a decline in agricultural production in the study area. This is majorly caused by lack of social amenities, unemployment and poverty in the study area. The recommendations that could possible redress the problem of rural-urban migration includes;

i. Provision of social amenities in rural communities by the government
ii. Orientation of the youths on the available opportunities they could invest in their communities.
iii. Building of youth's and the aged persons capacity in activities they can engage in to further increase their revenue and chances of shunning migration to urban centres.

Determinants of Investment Behaviour among Orange-Fleshed Sweetpotato Root Entrepreneurs in North Central Nigeria

J.T. Nyor* and J.A. Mbanasor
Department of Agribusiness and Management, Michael Okpara University of Agriculture, Umudike – Nigeria. **Email of the corresponding author:* nyorjude@gmail.com

Abstract
This study examined determinants of investment behaviour in OFSP root production in North Central Nigeria. Multistage sampling was used to select 174 root entrepreneurs in Benue, Nasarawa and Kwara States. Structured questionnaire designed for a single visit was used in data collection. Descriptive statistics was used to achieve objective one and multiple regression analysis was used to realise objective two. The result shows that volume of savings, root output, owned land and root price have positive coefficients and have significant influence on investment behaviour among orange-fleshed sweet potato root entrepreneurs in the study area. Policies to enhance savings; and give access to input and output markets were recommended to improve investment behaviour in OFSP root production in the study area.

Keywords: Investment, Behaviour , Orange Fleshed, Sweetpotato root

Introduction
The importance of orange-fleshed sweet potato (OFSP) in the socio-economic lives of people in Sub-Saharan Africa (SSA) and Nigeria in particular cannot be overemphasized. Orange-fleshed sweetpotato is both an economic and nutritional crop. All parts of the sweetpotato crop can be processed into diverse products of economic or food value (Afuape, 2014). Sweetpotato roots are mostly used for human consumption, animal feed, production of fermentation products (such as wine, liquor) and for sugar production (Eklund *et al*., 2013; Tewe, Ojeniyi, and Abu, 2003). Sweetpotato roots are cooked together with cowpea, lima beans, sesame, millet and or other root crops to make a traditional porridge. Afuape (2014) opined that packaged sweetpotato fries and crisps have emerged as micro- to small-scale business, contributing to employment generation at rural, semi-urban and urban areas. In spite of the enormous benefits of OFSP, it has been observed that there is low level of investment in OFSP production in Nigeria. Fawole (2007) stressed that the main constraint to sweetpotato production sustainability is lack of investment to ensure the availability of quality sweetpotato roots and roots throughout the dry season since they serve as planting materials in the next crop cycle. Sahan and Mikhail (2012) stated that investment in agriculture that focuses on the production of food staples often provides the best opportunities for reducing poverty and improving food security in less developed regions, particularly in Africa. Osundare (2013) noted that very low domestic savings is a major constraint to investment in Africa, including Nigeria. Since investment is always characterized by risk and uncertainty (Amu, Offei-Ansah, Gavor, 2012), especially in agriculture, where poverty is more pronounced among small-scale farmers. This underscores the importance of understanding the investment behaviour among OFSP entrepreneurs. Understanding the determinants of investment behaviour of OFSP entrepreneurs will provides an important insight into the process of capital accumulation that when properly managed lead to economic growth and development. Arising from the forgoing and considering the importance of the OFSP root production in economic growth, sustainable strategies for food security and livelihoods in Nigeria, it is imperative and urgent to investigate the determinants of investment behaviour of OFSP root entrepreneurs in North Central Nigeria. There seem to be a dearth of information on what are the drivers of investment behaviour among OFSP root entrepreneurs in Nigeria. This paper attempted to fill the knowledge gap. The objectives of this study were to: (i) examine OFSP root production systems, and (ii) analyse the determinants of

investment behaviour among orange-fleshed sweetpotato root entrepreneurs in North Central, Nigeria.

Methodology

The study was conducted in the North Central geo-political zone of Nigeria. This geo-political zone was chosen based on the intensity of orange-fleshed sweetpotato root production. Multistage sampling procedure was employed to select the respondents in this study. In first stage, three selected states were Benue, Nasarawa and Kwara were purposively selected based on their distinct OFSP production (National Root Crops Research Institute, NRCRI, 2012).In second stage, Gboko, Konshisha, Vandeikya, and Makurdi were selected from Benue state while Karu, Lafia, Nasarawa Egon, and Jenkwe Development Area were selected from Nasarawa state while Ilorin East, Ifelodun, and Patigi, were selected from Kwara state. In the third stage,174 farm households were randomly selected local government areas based on sampling frame from the respective ADPs for the analysis of determinants of investment behaviour among OFSP root entrepreneurs. Data were collected with aid of structured questionnaire. Descriptive statistics and multiple regression model were used in analysing the data

Results and Discussion

The result of OFSP root production systems is presented in Table 1. The result reveals that the dominant cropping system practiced in OFSP root production is mixed cropping system. About 84.5 percent of the OFSP root households practiced mixed cropping system. This result is in consonance with the findings of Adebisi *et al.*,(2015) which they reported that sweetpotato is intercropped with some major crops such as yam, cassava, maize, soybean in Nigeria. Majority of the sample households (47.7%) practiced cut grass and burn technique of land preparation. The practice of bush burning has serious implication on soil fertility.

Table 1: Distribution of Orange-Fleshed Sweetpotato Root Households by Production System (n=174)

Item	Category	Frequency	Percentage (%)
Cropping System:	Sole cropping	27	15.5
	Mixed Cropping	147	84.5
Land Preparation:	Cut grass and burn	83	47.7
	Use Chemical	34	19.5
	Weed clearing	57	32.8
Land cultivation:	Flat soil	6	3.4
	Ridges	82	47.1
	Mounds	86	49.4
Number of production cycle/year:	Once	64	36.8
	Twice	110	63.2
Weed Control Method:	Manual Weeding	127	73.0
	Chemical	47	27.0
Number of weeding/production cycle:	Once	147	84.5
	More than once	27	15.5
	No	120	69.0
Use of Fertilizer:	Yes	54	31.0
	No	120	69.0
Type of Fertilizer used:	Organic/Animal Waste	119	68.4
	Inorganic	55	31.6
Use of irrigation system:	Yes	38	21.8
	No	136	78.2

Source: Field survey data (2016)

The result reveals that about 49.4 percent used mounds as seed bed for OFSP production. Majority (63 %) of sample OFSP root households cultivate OFSP twice a year. Majority (73 %) of the sample households practiced manual weeding as a method of weed control. This suggests that OFSP root households employed a lot of labour in weed control. The result in Table1 also shows that 84.5

percent Households weed their farm only once per OFSP root production cycle. About 69 percent do not use fertilizer on their OFSP root farms. The result also shows that about 78.2 percent of sample households do not have access to irrigation. The implication is that majority of the OFSP root households depend on rain fed farming, thus surrounding their investment with risk of inadequate rainfall. The result of analysis of determinants of investment behaviour among OFSP root entrepreneurs is presented in Table 2. The double log functional form of multiple regression models was accepted as lead equation based on its high of $R^2$and minimum standard error. The shows that majority of the explanatory variables have positive coefficients. The positive sign implies that these variables have positive influence on investment behaviour among OFSP sweetpotato root entrepreneurs in the study area.

Source: Computed from field survey data (2016)
***Sig. At P≤0.01; **Sig. at P≤0.05; *Sig. at P≤0.10. Figures in parentheses are t-test statistics. Accepted Model is double log regression.

The coefficients of volume of savings, root output, owned land and root price are positive and are statistically significant at 1% level of probability indicating that 1% increase in volume of savings, root output, owned land and root price will increase OFSP root farm investment by 0.092%, 0.844%, 0.185% and 0.076% respectively. Variables with negative coefficients indicate negative influence on investment behaviour in OFSP root production. The coefficient for specialisation was negatively assigned. This suggests that an OFSP root entrepreneur tends to invest more in diversified farm business to avoid total failure. This behaviour is understandable in view of the uncertainty surrounding agriculture in Nigeria. This result is consistent with Minot *et al*., (2006) and Ibrahim *et al*., (2009) who separately asserted that as farmers switch from subsistence food production to commercial agriculture, crop diversification will typically increase. The accepted double log multiple regression model is well behaved. The R^2 coefficient is 0.622 and the R square adjusted is 0.583. This implies that 58% variation in OFSP root investment behaviour is explained by the independent variables included in the regression model. The F-statistics is 3.978 and statistically significant at 1% probability level indicating the overall significance of the accepted regression model.

Conclusion

This study examined the determinants of investment behaviour among orange-fleshed sweetpotato root entrepreneurs in North Central, Nigeria. It is concluded that volume of savings; OFSP root output, owned land, and root price are major determinants of OFSP root production in the study area. The policy implication is that effort aimed at increasing the savings of the entrepreneurs, increase in OFSP root output, access to land and increase in output price could increase investment in OFSP root production in the study area.

Abstract
The performance and cost- benefit of raising broiler chickens using Hyphaene thebaica seed meal (HTSM) diets was experimented; the process lasted for 56 days. Five experimental diets were formulated to meet nutrient requirement standards of broilers (NRC, 1994). Diet 1(0 % HTSM) served as the control while diets 2,3,4 and 5 contained 5, 10, 15 and 20% HTSM respectively replacing maize in the diets of birds. A total of two hundred and twenty five (225) day-old broiler chicks were randomly allotted into five treatment groups with three replicates of fifteen birds each. Each group was assigned to the five experimental diets in completely randomized design (CRD). Throughout the experimental period, feed and water were provided ad libitum for all treatment groups. There were significant differences (P<0.05) in all the parameters measured except total feed intake (P>0.05). The final live weight and total body weight gain of birds fed 0, 5 and 10 % HTSM diets (1995.68-2100.02 g and 1895.63-1999.97 g) were significantly better (P<0.05) compared to those fed 15 and 20 % HTSM diets (1217.58-1500.03 g and 1117.55- 1399.98 g). Birds fed 5 %HTSM diet gave the highest revenue (₦ 1990.14) while the least revenue (₦ 1365.81) was obtained among birds fed 20 %HTSM diet. The best profit (benefit) was obtained from birds fed 10 %HTSM diet. The cost - benefit ratio was the highest (1.84) among birds fed 20 %HTSM diet and least (0.81) among birds fed 10 %HTSM diet. It was concluded that 10 %HTSM diet was better since the lower the cost - benefit ratio, the more economically effective the diet.

Key word: broiler, performance, Cost- Benefit, Hyphaene thebaica seed meal

Introduction
The ever-increasing cost of livestock feeds with the attendant increase in the cost of animal products such as meat, eggs and milk has necessitated that there is the need to explore the use of non-conventional feed ingredients in the feeding of domestic animal (1,2,3). Doum palm (*Hyphaene thebaica*) is an African palm tree, common in Upper Egypt, originally native to the Nile valley, bearing an edible fruit which is glubosequandrangular, about 6 x 5 cm with a shinny orange-brown to deep chestnutskin (epicarp). It belongs to the family *Arecaceae* commonly known as doum palm, Dum Nut or ginger bread tree. Research on the fruit pulp has shown that it contains nutritional trace minerals, proteins and fatty acids, particular the nutritionally essential linoleic acid (4). (5) reported that the mesocarp of Doum palm fruits contains 8.10 % ash, 0.95 %ether extract, 0.01 %protein, 89.25 %carbohydrate, 3655.9 Kcal/kg Metabolizable energy while (6)showed that the fruit pulp contains 4.91% proteins, 5.26% fat, 4.5% ash and 85.33%total carbohydrate. This study therefore aimed at evaluating the performance and cost benefits of broiler chickens fed*Hyphaene thebaica* seed meal based diet.

Materials and Methods
The research was carried out at the Poultry unit of the Teaching and Research Farm of the Department of Animal Science, Federal University, Gashua, Yobe State, Nigeria. It has an area of 772km^2 and Coordinates: 12°52′5″N 11°2′47″E. The hottest months are March and April with

temperature ranges of 38-43°C. In the rainy season, June-September, temperatures fall to 23-28°C, with rainfall of 500 to 1000mm (7).

Preparation of *Hyphaene thebaica*seed meal (HTSM)

The dried *Hythebaica* fruits were purchased from Gashua market, Yobe state, in the North Eastern part of Nigeria. The fruits were crushed with machine and the kernels were discarded. The mesocarps were then milled to particle sizes to pass through a 3mm sieve, using a hammer mill. Other feed ingredients such as maize, soyabean, wheat offal, maize bran etc were purchased from Gashua market.

Experimental Diets

The experiment was in two phases (starter and finisher), five diets were formulated to meet nutrient requirement standards of broilers (8). Diet 1(0 % HTSM) served as the control while diets 2,3,4 and 5 contained 5, 10, 15 and 20%HTSM respectively replacing maize in the diets of birds. The gross composition of the experimental diets and their analysed nutrient contents are presented in Table 1.

Experimental Birds and Design

A total of two hundred and twenty five (225) day-old broiler chicks were purchased from a reputable distributor. They were raised on commercial broiler starter diet for one week, after which they were randomly allotted into five treatment groups with three replicates of fifteen birds each. Each group was assigned to the five experimental diets in completely randomized design (CRD). Throughout the experimental period, feed and water were provided *ad libitum* for all treatment groups. This was accompanied by necessary prophylactic medication and vaccination. The experiment lasted for a total of 56 days.

*HTSM=Hyphaene thebiaca seed meal **To provide the following per kilogram of feed: Vit. A, 10,000 iu, Vit. D3,2000 iu, Vit. E, 5iu; Vit.K, 2mg; Riboflavin, 4.20mg; Vit. B12, 0.01mg; Panthotenic acid, 5mg; Nicotnic acid, 20mg; Folic acid, 0.5mg; choline, 3mg; Mg, 56mg; Fe, 20mg; Cu, 10mg; Zn, 50mg; Co.125mg.NFE: Nitrogen Free Extract =100-(%CP+%CF+%EE+%Ash).

Data Collection

The cost/kg feed was obtained by adding the cost of procuring the various feed ingredients in a particular treatment and dividing with the total feed consumed. Cost of total feed consumed was calculated by multiplying total feed consumed in each treatment with the cost/kg feed. The cost/kg weight gain was obtained by multiplying the cost/kg feed with feed conversion ratio (feed : gain). The benefit or profit index was obtained as:

R - PC

Where:

R = Revenue

PC = Production cost.

The cost benefit ratio was obtained by dividing the cost of production by the benefit (profit).

Statistical Analysis

Data generated from the study were subjected to one-way analysis of variance (ANOVA) using SAS Software (9). Means were separated with Duncan multiple range test at 5% level of significance.

Results and Discussion

The results of the performance and economic analysis of broiler chickens fed HTSM diet is shown in Table 2. There were significant differences ($P<0.05$) in all the parameters measured except total feed intake ($P>0.05$). The final live weight and total body weight gain of birds fed 0, 5 and 10 % HTSM diets were significantly better ($P<0.05$) compared to those fed 15 and 20 % HTSM diets. The total cost per kg feed decreased with increasing levels of HTSM in the diets due to the cheaper cost of *Hyphaene thebaica* seed (₦ 55.81/kg) compared to maize (₦120.00/kg) which is the dietary component replaced by HTSM in the diets. The cost of feed/kg weight gain was least for birds fed 15 %HTSM diet (₦381.79) while those on control had the highest cost (a difference of up to ₦45.69).Birds fed 5 %HTSM diet gave the highest revenue (₦1990.14) while the least revenue (₦1365.81) was obtained among birds fed 20 %HTSM diet. The best profit (benefit) was obtained from birds fed 10 %HTSM diet. The cost benefit ratio which is the ratio of the cost of the production expressed in monetary term relative to its benefits also expressed in monetary term was highest (1.84) among birds fed 20 %HTSM diet and least (0.81) among birds fed 10 %HTSM diet. This indicates that 10 %HTSM diet was better for the study since the lower the cost benefit ratio, the more economically effective the diet.

Table 2: Effects of Different Dietary Levels of HTSM on Performance andEconomic benefit of Broiler chickens (0-8weeks)

	Dietary levels of *Hyphaene thebaica* seed meal (%)					
Parameters	**0%**	**5%**	**10%**	**15%**	**20%**	**SEM**

Benefit (Profit) (₦)	1058.50^{a}	1077.84^{a}	1097.05^{a}	785.94^{b}	480.30^{c}	62.09
Cost benefit ratio	0.87^{a}	0.85^{a}	0.81^{a}	1.14^{b}	1.84^{c}	0.21

abc= mean with different superscripts on the same row are significantly different ($P<0.05$), SEM= Standard error of mean, P = Probability value. Cost of production = Cost of feed + Cost of medication + Cost of day old chicks. Revenue based on ₦950 /kg live weight. USD1=₦360

Conclusion

It was concluded that up to 10 % raw HTSM diet was economical and can be included in broiler diet as replacement for maize.

Abstract
The study was conducted to examine the socio-economic characteristics of farmers involved in the melon cakes processing and marketing, compare difference between their incomes before and after embarking on the melon cakes processing venture The analytical technique adopted in achieving the objective of the study was the descriptive statistics (percentages, mean and frequency) and Paired Samples Test. The result showed that 43.3% were within the age range of 31 - 40 years. The study revealed that the mean income of the respondents after the processing of melon cakes business was ₦63,602.31, while their income before they started the traditional melon cakes value addition business was ₦21,200.00, with a difference of ₦42,402.31. This implies that the incomes of the women melon cakes producers were higher than their incomes before they embarked on the business. Therefore, it is recommended that melon farmers should be encouraged to form cooperative societies in order to facilitate easy access to agricultural information and benefit from agricultural programmes of the government

Keywords impact, Melon cake, Livelihood and farmers.

Introduction
The Traditional Egusi cake popularly known as "AhuIsu" in Ahaba-Imenyi, Isuikwuato Local Government Area of Abia State, is taken as alternative for meat. It is revenue yielding and enhances foreign exchange earnings in Nigeria. Melon (Egusi) is widely produced in West Africa with Nigeria accounting for about 65% of total production. The areas of high melon seed production in Nigeria include, Enugu, Abia, Benue, Nasarawa, Taraba, Kogi State. Melon seed (Colocynths citrulluslanatus) is rich in vitamins: fat, protein, vitamin B6 etc.The soft light yellow husks can be eaten together with the seeds, especially when mixed with African oil bean (Ugbaa). Melon is used as cover crop in farming; hence it reduces labour cost for weeding (Udealor, 2010). The melon seed can be manually or mechanically peeled or removed (Oti, 2012). The melon seed is ground as a flour and used in making soup "Egusi soup". It can also be processes into Traditional melon cake (Ojieh,2007). Also, the molded small melon cakes (akpuruakpu egusi) used in making soup can be eaten in place of meat. Melon contains protein 23.4% comparable to other plant proteins such as soya bean, cowpea and pumpkin etc (Amos, 2009). Melon seed can be processed to extract the oil content in it. The oil can be used as a vegetable oil. The fat content is 45.7% comparable to pumpkin seed oil. It contains 62.8% fatty acid which human body needs for healthy functioning, and which cannot be obtained from other food crops, except through food supplements. Human body needs this kind of fat (FAO. 2012). Melon fibre from both husk and seed stood at 12% which is high compared to other legumes. It contains up to 10.6% carbohydrate compared to other legumes. Also, it is rich in amino acid which human body needs for healthy living. Egusi is the richest in the mineral phosphorous potassium, magnesium, calcium and sodium (Aniedu, 2004). Women farmers in Ahaba Imenyi are majorly engaged in processing into melon seeds cakes. Only 20 (16.66%) are civil servants, the rest are either full-time farmers or combined farming with petty trading. Since the women farmers in the area depend largely on traditional agriculture for subsistence, any meaningful effort for their effective participation and improved living standards must be directed toward improving their production, processing and storage technology.

Processing melon seeds into cakes for sale is high income yielding and foreign exchange earnings. Therefore, there is urgent need to encourage women farmers and to bring them' to the limelight of sustainable agricultural development worthy of the new millennium. This research study therefore takes a critical on the extent of women participation in production, processing and sales of melon cakes for improved conditions/standards of living and poverty reduction in the study area.

Methodology

The study was conducted in Ahaba-Imenyi, Isuikwuato Local Government Area of Abia State.Isuikwuato is presently made up of three administrative units (Imenyi, Oguduassa and Isuamawo),.There are five major melon cakes processing communities among the five villages in Ahaba-Imenyi, Isuikwuato Local Government Area of Abia State namely: Amaogudu, Amaiyi, Ahaba-Ehuma, Ihe-Okwo and Ihenzu Villages. All the five communities were purposively selected; and data were collected by means of structured questionnaire. A total of 120 respondents were sampled. The list of melon cakes processing traders was obtained from the Agricultural Development Extension agent in the LGA. The analytical technique adopted in achieving the objective of the study was the descriptive statistics (percentages, mean and frequency) and Paired Sample Test.

Results and Discussion

Socio-Economic Status and General Living Standard (GlS) Of the Respondents before and after Processing and Sales Of Melon Cakes in The Study Area

The Socio-economic status and general living standard of the respondents were assessed under the following; age, education, occupation, family size, income, experience, marital status, membership of cooperative societies, type of housing, toilet facilities, source of drinking water and source of lighting. The results of the analysis for the socio-economic profile and Paired samples test incomes of the respondents (Before) and their incomes (After) sales of the melon cakes are presented in the Tables 1 and 2 respectively.

Age of respondents

The dominant age range was 46-55 years, which accounted for 33% and 36% before and after the sales respectively. The implication is that majority of the respondents belong to the middle-aged group that are known for their physical ability, productiveness, mental alertness and effectiveness more than older farmers (Amos,, 2009).

Table 1. Socio-economic Characteristics of the Respondents

Source: Field Survey, 2018

Occupation
On occupation, about 53% and 58% of the trainees before and after the melon cakes processing business respectively.58% were full-time farmers while their counterparts part-time farmers represented 42% (before the business) and 47% (after the business) of the sampled respondents. This explains why the full-time farmers tend to be less amenable to income diversification than their part-time counterparts.

Marital status
88% of the respondents are married. This implied that majority of the married women dominated this group. This is in line with the proposition that women play vital role in food production, processing and marketing n Nigeria (Asumugha, 2012).

Education
Also, the result showed that 33% and 36% of the respondents had secondary education, while 15% and 23% had tertiary education, before and after the sales respectively. The number of respondents who had primary education increased from 17% to 21%. According to Okoye *et al* (2008), educated farmers are more receptive to changes while farmers with little or no education are conservative to accept changes and innovations. The percentage of respondents with non-formal education (35% and 20%) confirms their perception.

Income
Table 1 showed that about 33% and 27% of the respondents between the family size of 1 – 4 persons fell within the income range of ₦10,000 - ₦29,999 per trading period before and after the melon cakes processing venture respectively. The respondents between the family size of 5 – 8 persons recorded 25% (before) and 30% (after), fell within the incomes range of N30,000 –

N49,999. The incomes of the pre-dominant family size of 9 – 12 persons ranged between N50,000 – N69,999 which recorded 42% and 43% respectively

Household size

Household Size of the respondents before and after the melon cakes processing venture were 8% and 13% respectively for persons between the age range of 1 – 4 years; 38% (after), and 27% (before) for 5 – 8 years respondents; and 60% (after), and 54% (before) for the respondents aged 9 – 12 years per family. The dominant class was 9 - 12 persons per family of the respondents. Although a priori expectation is in favour of increased profitability of larger families in the adoption of innovation, the cost of adoption is another issue to be considered. This is in line with the perception of Sabo (2006) who posited that large family size necessitated respondents to diversify their businesses for increased returns, to sustain their families.

Membership of cooperatives

From Table 1 about 42% of the respondents belonged to Cooperative Groups, before the melon cakes business, whereas the percentage increased to 58% after the trading period. This indicates that out of 58% women melon cakes-cooperators, only 32% of them belonged to none. The difference in the two classes of respondents implies that membership of cooperatives enhanced participation in the processing of into melon cakes. This is in support of Aniedu (2004) who opined that cooperative membership enhances participation and access to information on government agricultural programmes.

Table 2 showed that the mean income of the respondents after the processing of melon cakes business was ₦63,602.31, while their income before they started the traditional melon cakes value addition business was ₦21,200.00, with a difference of ₦42,402.31. This shows that the incomes of the respondents after the sales (trading period) are higher than their incomes before they started the processing of melon cakes business. It could be inferred that the sale of melon cakes business impacted positively on the incomes of the respondents.

Table 2: Paired samples test incomes of respondents (Before) and incomes of the respondents (After). (n = 120)

Variables	Mean	Paired Mean	95% Confidence Interval of the Difference	
			Lower	Upper
Respondents' Income After their Trading period	63,602.31*	42,402.31*	9,771.02	15,941.64
Income Before their Trading period	21,200.00*			

*P ≤ 0.05 Source: Computed from field survey (2018)

Conclusion

The study revealed that the mean income of the respondents after the processing of melon cakes business was ₦63,602.31, while their income before they started the traditional melon cakes value addition business was ₦21,200.00, with a difference of ₦42,402.31. This implies that the incomes of the women melon cakes producers were higher than their incomes before they embarked on the business. Therefore, it is recommended that melon farmers should be encouraged to form cooperative societies in order to facilitate easy access to agricultural information and benefit from agricultural programmes of the government.

Socio-Economic Determinants of FADAMA III Rice Production Programme among Small Holder Farmers in Edo North Agricultural Zone, Edo State, Nigeria.

G.F. Okwuokenye
Department of Agricultural Economics and Extension, Faculty of Agricultural Sciences, National Open University Of Nigeria, Km 4, Kaduna Zaria Express Way, Kaduna, Kaduna State.
Email:***okwuokenyegoddy@gmail.com***

Abstract
The study examined socio-economic determinants of fadama III rice production programme among small household farmers in Edo North agricultural zone of Edo State, Nigeria. It determined the effect of participating in the programme and examined the socio-economic determinants of respondents. TwoLGAswere randomly selected for the study. Ninety-three participants and non-participants farmers were randomly selected and used for the study. Data were analyzed using descriptive and inferential statistics. Results of T – test analysis showed that the average income of farmers participants and non-farmers participants in fadama III programme was ₦305,913.87 and ₦219,892.47 respectively. The study therefore recommended that government should ensure equitable and timely distribution of farm inputs among the farmers and more rice farmers should be brought into the scheme so that more persons standard of living can be improved.
Keywords: rice, production, participation, production, farmers, projects, determinants

Introduction
Rice (Oryza sativa) is one of the world's most important cereals, serving as a staple food for the population of most countries, including Nigeria (Okwuokenye and Onemolease, 2010). In an attempt to revamp the declining trend of rice production the then President Obasanjo's administration thought otherwise by encouraging local production through federal government policies like supply of improved inputs and subsidy on basic farm inputs, special rice programme, the Presidential initiatives on rice, cassava, livestock, etc. and most recently, the Fadama III programme that supports rice production. Report of Fadama III Rural Agricultural Projects (2010) defined fadama as flood plains and low land areas underlined by shallow aquifers and found along Nigeria's rivers. The report also stated that the scheme operates through small scale community owned infrastructure. This suggests the fact that smallholder farmers are the main or foremost thrust of fadama III programme. No work seemed to have been carried out in particular in the study area, hence this study is important and timely. In achieving this goal, the study examined the socio-economic characteristics of the fadama III small household farmers engaged in rice production in study area, identified the inputs provided to the farmers by the programme and examined the effects of respondents participation in the programme on farm income level.
The hypotheses were stated in their null forms. They are;
H_{o1}: There is no significant difference in farm income of small household rice farmers' participants and non-participants of fadama III programme

Materials and Methods
The study was carried out in Edo State, it has 18 LGAs with the capital seat at Benin City. The state is characterized by rainy and dry seasons with an annual rainfall of 2,500 mm and 1,500 mm in the Coastal areas and extreme North respectively (NAEC, 2008). The study was carried out in Edo North senatorial zone of Edo State. Two (Etsako East and Etsako West) out of five (5) LGAs where fadama is practiced were randomly selected for the study. From the LGAs Agenebode and Agbede were respectively selected for the study. Fifty (50) small household rice farmers were then

randomly selected from the fadama communities. This brought the total number of respondents administered with the research instruments to one hundred (100). Ninety-three (93) of the retrieved instruments suitable for analysis were then used for the study. An equivalent number of non-participants of the programme were also randomly sampled per community for comparative purpose.Data were sourced directly from the respondents by means of validated questionnaire instruments Data were analyzed using descriptive(frequency table, percentage and mean) and inferential statistics (t – test).

T – test was used to analyze hypothesis two. The formula for t- test is as shown below:

$$T = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{(s_1^2/n_1 + s_2^2/n_2)}} \qquad df = n_1 + n_2 - 2 \text{ ; (Madukwe, 2004)}$$

Where:

$\bar{x}_1$ = the mean of group 1;

$\bar{x}_2$ = the mean of group 2

S_1 = standard deviation for group 1; S_2 = standard deviation for group 2

S_1^2 = variance of the first group; S_2^2 = variance of the second group

n_1 = size of the first group; n_2 = size of the second group; √ = square root

Decision rule for t – statistics: if $t_{cal} > t_{tab}$ = reject null and accept alternative hypothesis; vice versa

Results and Discussion

The socio-economic characteristics of the respondents are shown in Table 1.It revealed that majority (72%) of the farmers were males while few (28%) were females. Findings of Aghanenu and Onemolease (2012) support this result. The average age of the respondents was 43.4 years and majority (39.78%) fell into the age bracket (40 – 49 years). The result indicates that the respondents were young and active. The result is in consonance with that of Fakoya and Daramola (2008).In educational level, most of the respondents (77.42%) had formal education and so could be described as literates with majority (40.86%) having a minimum level of primary school education. Similar result regarding low educational level was reported by Obasi (2005). Most (68.82%) of the respondents were married implying they were responsible. Aghanenu and Onemolease (2012) supported the dominance of married farmers in fadama programme. The average household size of the respondents was 9 persons and majority (35.48%) of them belonged to this group (7 – 9 persons). Most of the farmers (50.54%) have farm size of 2.1 – 4.0 ha. The mean was 3.10 ha. The result indicated that the respondents are small household farmers and it is in line with the result of Mgbada (2006).Farm experience of the respondents revealed that majority (46.24%) had 10 – 14 years rice farming experience. The average farm experience was 12.42 years. The result indicated that the farmers are well experienced in rice farming. The result of Aghanenu and Onemolease (2012) was in consonance with this finding.

Inputs Provided by Fadama III Programme in Rice Production

The inputs provided to the farmers under the scheme in rice production are showed in Table 2. They were provided in different quantities to different farmers. The most supplied input according to most (88.17%) of the respondents was fertilizer, followed by improved varieties of seeds (73.12%). Additionally, 65.59% and 60.22% of the respondents respectively indicated that herbicides and insecticides were provided. Other inputs though poorly provided include tube wells/boreholes, motorized pumps and construction of irrigation channels which 41.94%, 36.56% and 11.83% of them respectively indicated were provided by the scheme. The result showed that the fadama III programme provided many different inputs sufficient,but not well spread to make remarkable success to all the farmers in rice production.

Table 2: Inputs provided by Fadama III Programme

Inputs provided	Frequency	percentage
Construction of irrigation channels	11	11.83
Motorized pumps	39	41.94
Tube wells / boreholes	34	36.56
Improved varieties of seeds	68	73.12
Fertilizer	82	88.17
Herbicides	61	65.59
Insecticides	56	60.22

*Source: Field survey, 2017.*multiple Responses Recorded*

Income Range (₦,000) of Respondents

The annual rice farm income of the respondents revealed that most (33.33%) of the fadama III programme participants earned an income of between ₦200,000 – ₦299,000, while most

(35.48%)of the non-participants of the programme earned between ₦100,000 – ₦199,000(See Table 3). The average farm earnings of programme and non-programme participants were ₦305,913.78 and ₦219,982.47 respectively. The difference in their average farm income was ₦86,021.31 and this was in favour of the programme participants. The result suggests that farmers' participation in fadama III programme had indeed enhanced farmers' income. Taiye *et al*., (2006) agreed with this finding as they noted that participating in farmers' programme helps to enhance farmers' productivity and consequently their income.

Table 3: Comparative Analysis of Rice Income between Participants and Non-Participants of Fadama III Programme

Income-range	Fadama participants (n = 93)			Fadama non-participants (n = 93)		
(₦'000)	Freq.	Percentage	Mean	Freq.	Percentage	Mean
< 100	4	4.30	₦305,913.78	14	15.05	₦219.892.47
100 – 199	14	17.20		33	35.48	
200 – 299	29	33.33		21	22.58	
300 – 399	25	24.73		19	20.43

500 & above	7	7.53		2	2.15	

Source: Field Survey, 2017; Difference in income between the groups = ₦86.021.31

Test of Difference in Income of Farmers and Non-Farmers of Fadama III Rice Programme

The results in Table 5 showed that the average income of farmers participants in fadama III programme was higher (₦305,913.87) than that of non-farmers participants (₦219,892.47). The difference between the two categories of farmers was ₦86,021.31 and this was significant at the 5% level. Based on the result, the alternative hypothesis was accepted. The result thus confirms the positive impact of fadamaIII programme. Findings of Taiye *et al.,* (2006) agreed with this finding. They acknowledged that participating in agricultural programmes helps to enhance farmers' productivity and income.

Table 4: Effect of Farmers' Participation in FADAMA III Rice Production on Income Level of Respondents (t - test)

FADAMA III Membership Status	N	Mean Income ₦	Difference (₦)	t - value
Farmers FADAMA III members	93	305,913.87	86,021.31	29.312*
Non-farmers FADAMA III members	93	219,892.47		

**Significant at the 5% level (Critical t – value = 1.289)*

Conclusion

Findings o the study concludes that participating in fadama III programme in rice production has positively influenced the farmers' income. The average farm income of programme participants was ₦305,913.87, while that of the non-participants was ₦219,892.47. The difference of ₦86,021.31 was in favour of the former, thus confirms its positive impact. From the findings of the study the following were recommended;The farmers noted that the inputs provided by the programme were not uniformly distributed. On this note, government should try to ensure an equitable distribution of farm inputs. This will help to increase farmers' productivity, and since there was a huge difference between participants and non-participants of the fadama III, it is therefore recommended that more rice farmers should be brought or allowed into the scheme so that more persons standard of living can be improved.

Analyzing Levels of Market Orientation among Cassava, Yam and Cocoyam producers in Abia State, Nigeria

Ukeje B.A, Onyemauwa, N.C., Ekah O.E., Ogbonna N.K., Uchechukwu U.N. and Chimaroke, O.
National Root Crops Research Institute, P M B 7006, Umudike, Abia State, Nigeria
Email: loveadanma@yahoo.com

Abstract
Rural farming households in Nigeria have a long tradition of producing primarily for home consumption and they only rely on the markets for the foods they cannot produce on their farms. However, due to changing economic trends, particularly in the face of rising poverty among rural households, the pattern of household production was such that most of the rural household productions are sold to the market for income in order to meet the financial obligations of the households. This paper examines the level of household reliance on some market purchased root and tuber crops to sustain the farm family food needs in Nigeria. Primary data collected from 96 households randomly selected from 4 villages were analysed using a simple descriptive statistics. The study revealed that, the mean quantity sold for cassava (≈744kg) was the highest followed by the quantity consumed (≈286kg). However, Cassava and yam (76%) ranked highest in the percentage distribution of farmers, based on the type of root and tuber crop produced in Abia State. Therefore, the study concludes that there is a high level of market orientation of cassava and yam only by the rural households and it varies significantly across poverty levels in the study area.
Keywords: Levels, Market orientation, Producers, Nigeria

Introduction
Understanding the changes in the share of food consumed by the rural farming households that is from the market in the face of changing socio-economic environment in which they operate is very important for several reasons (Onubuogu and Onyeneke, 2012) . It, for instance enables us to see how the rural farming households, who have hitherto in the previous year's been able to meet substantial parts of their home consumptions of food from own production and how much of own food produced offered to the market have been affected by the changing social, economic and political environments in the country (Hernandex *et al*., 2007). Looking across poverty levels is also desirable so as to see the effect of household poverty on the degree of market orientation of both the poor and non-poor households (Weatherspoon and Reardon, 2003).This paper is another effort in food demand studies with a view to understanding the level of market orientation of rural households and also to determine the appropriate points of policy intervention in food supply programmes. Furthermore, the role of markets in poverty and food intervention programmes needs to be better understood in the country in the face of changing socio-economic factors such as population, personal income levels, rapid rate of urbanization and tastes. Therefore, there is need for an assessment of the household food demand in the context of the role of the rural markets with a view to providing the empirical evidence required to understand the issues involved in designing an appropriate mix of policies for national and regional food and market planning (McCullough *et. al*., 2008). There are comparatively few published articles that have addressed the level of market orientation of cassava, yam and cocoyam producers in Nigeria. The study attempted to analyze the level of market orientation of some selected food crops.

Methodology
A purposive sampling technique was used in selecting a state and respondents. Abia state was chosen based on Cassava, Yam and Cocoyam production. Two local government areas was selected,

four communities, four villages was also selected, finally, twelve cassava, yam and cocoyam farmers were selected based on the number of registered farmers in that area, making it a total of 96 farmers. However, these respondents comprised of producers, processors and marketers. Information were elicited from the respondents by means of focused group discussion, interview schedule and structured questionnaires. Data were analyzed using descriptive statistics, means and percentages.

Results and Discussion

Socioeconomic Characteristics of the Respondents

The result in table 1 pointed out that 85% of the respondents were within the age range of 35-44 years with a mean age of 40 years. This implies that majority of the respondents were young and are ready to accept innovations, this in line with Poison and Spencer (1991). Dominance of female (54%) as against 45% male, suggests that root and tuber crop production is gender sensitive and requires more women than men, this is in agreement with Anyiro *et al* (2013). Also majority (90.6%) of the respondents were married also acquired basic education. This result is in line with the findings of Onubuogu and Onyeneke, (2012) who posited that education and training enhances farmers' productivity and market oriented production objective .Household size between 5-10 persons had 84.3% with the mean household size of 6 persons. The large household size is attributed to the need for cheap and dependable labour derivable for on-farm and off-farm activities. This finding is in agreement with the findings of Onubuogu *et al*, (2014) reported the most farm families have large household size between 5 to 10 persons with mean of 6 persons. Furthermore, 60.3% of the respondents fell within the monthly income level of ₦41,000 - ₦60,000, with mean income of ₦45,620. This shows that market orientation of cassava, yam and cocoyam can be found to be very lucrative as the income of the farmers are higher than normal.

Levels of Market Orientation
Sampled respondents mentioned quantity of root and tuber crops sold in kg in the available markets. These were summarized and presented in Table 2.

Table 2: Mean Value of the Allocation of Household Root and tuber Crop Productions (n=96)

Type of Root and Tuber Crop	Quantity Sold (Kg)	Quantity Consumed (Kg)	Quantity given as gift (Kg)
Cassava	743.5417	285.5208	70.41667
Yam	142.5521	88.33333	30.72917
Cocoyam	19.07292	6.020833	2.927083

Source: Field Survey, 2016

The pattern of household production was such that most of the rural household productions are sold to the market for income in order to meet the financial obligations of the households. Thus in agreement with Ololade and Olagunju (2013) report which earlier posited that income enhances productivity and promotes standard of living by breaking vicious cycle of poverty of small scale farmers. Some of the root and tuber crop produced goes into home consumption while some households give their farm produce as gifts to friends and relatives. This is firmly rooted in the tradition of Africans that you have to be your brothers' keeper. Apart from gifts some other uses also occur in that category. According to Eke-Okoro (2011), root and tuber crops play significant roles in the food economy of Nigerians. The root and tuber crops sector provides job opportunities and generate income for Nigeria.

Output Size of Cassava, Yam and Cocoyam Production
Figure 1 shows the percentage distribution of farmers based on the type of root and tuber crop produced. From the result; planting cassava and cocoyam ranked lowest (4%), followed by Cassava only (20%) and the highest of them all is Cassava and yam (76%). Eke-Okoro (2011) also posited that the importance of cassava in the lives of many Nigerians cannot be over-emphasized.

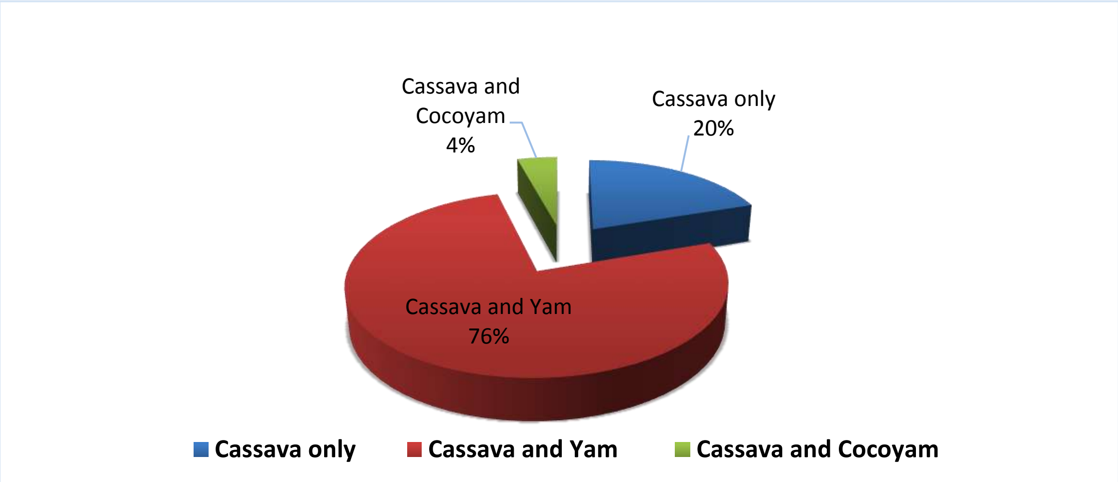

Figure 1: Percentage Distribution of farmers based on the type of root and tuber crop produced
Source: Survey Report, 2016

As food, it comes first among the root and tuber crops despite the respect yam commands as a ceremonial crop. He also mentioned that the advantages of cassava as a candidate crop for hunger alleviation, poverty eradication and food security include tolerance to drought, low demands on soil nutrients, and capacity for providing good root. While yam (*Dioscorea spp)* are major carbohydrate staple and provides food for over 60 million people in West Africa. The importance of yam in Nigeria and indeed throughout the West African yam belt is not only for its role as a major food staple but also its socio-cultural significance in the life of the people. Cocoyam (*Xanthosoma sp: Colocasia sp*) are also important staple in Nigeria ranking third among the root and tuber crops after cassava and yam. Nigeria is the world's largest producer of cocoyam and has an increased production output for more than 12 million tonnes. (NRCRI, 2000).

Conclusion

The study concludes that there is a high level of market orientation of cassava and yam only by the rural households and it varies significantly across poverty levels in the study area. Policies that would enhance the income generating activities of the rural households in the study area is desirable so as to enhance their food purchasing power, reduce food insecurity and reduce poverty relative to food. Furthermore, there should be an appropriate policy that would take care of the anticipated changes in the structure of food demand as poor households tends to become non-poor, when their income increase.

Cassava Production in Kogi State, North Central Nigeria: A Review

Godwin Adu Alhassan
Department of Crop and Soil Sciences, Faculty of Agricultural Sciences, National Open University of Nigeria, Kaduna Campus.+2348036792970; adugodwin@yahoo.com

Abstract
Cassava production in Kogi State North Central Nigeria was purely subsistence about two decades ago but now it has assumed the status of a cash crop, providing food and incomes in a sustainable manner to millions of people in the State. Kogi State is one of the major producers of cassava in Nigeria with over 4.16million metric tonnes annually. Favourable climate, good soils, cassava-based farming system, available large-scale processors, donor supported projects and over dependence of the population on the crop as a major source of carbohydrate and enterprising farmers contributed in making Kogi State the highest producer of cassava in Nigeria. The cassava value chain in the State has been able to meet the challenges of the nation through job creation, wealth generation and industrialization. A two-year cycle of cassava fresh root glut has been a major problem facing producers which could be reduced through increased diversification of processing options, expanded markets and informed end users. For the State to remain relevant in the cassava industry there is the need to increase area cropped and yield per hectare, more emphasis on production for industrial use and be less dependence on cassava for food.
Keywords: Cassava, Production and Kogi State

Introduction
Cassava (M*anihotesculenta, C*rantz) is a versatile crop that is critical for food security in Africa, Asia and Latin America. Millions of smallholder producers rely on cassava for their subsistence especially during lean season. Globally, the largest producer of cassava in the world is Nigeria followed by Brazil, Thailand, Zaire and Indonesia (FMARD, 1999). In Nigeria, cassava is one of the most important crops. It is the most widely cultivated crop in the central and southern parts of the country in terms of area devoted to it and number of farmers growing it. Cassava has also increased in importance in the Middle Belt in recent years. It is fast replacing yam and other traditional staples within the production belts. The major food products from cassava in Nigeria are gari (creamy-white, partially gelatinized, roasted, free flowing granular flour with a slightly fermented flavour and sour taste), fermented flour, unfermented flour (sundried cassava chips milled in the form of flour) and akpu (fermented wet paste) (PIND,2011). The high industrial and market potentials of cassava have attracted private sector interests. For instance, in Cote d'Ivoire and Nigeria, Nestle is now using cassava starch rather than maize starch in its manufactured culinary broths. This multinational company is supporting producers, providing them with improved cassava varieties and buying their roots. Brewers are also focussing on brewing cheaper beers using locally grown crops as substitute for imported barley. Those in the biofuel technology are not left out in the use of cassava for the production of cheap biofuel. In the ceramics industry, it is used as a binder.

Strength of Kogi State in cassava production
The strength of Kogi State in cassava production and utilization lies with its natural endowment with a people that depends on cassava for their survival and sustenance. Kogi State was created out of former Benue and Kwara states along with eight others on 27th August, 1991. The State is located within the equator and thus spans the tropical rain forest on the southern fringes and the woody derived savannah and Guinea savannah in the northern extreme. There are approximately 228,964 farm families in Kogi State (Kogi ADP,1997).Rainfall pattern in Kogi State is generally adequate with enough sunshine which are ideal for most agricultural crop production.Generally,

the soils of Kogi State consist of ferruginous tropical soils, forest soils, which are rich in humus and moderately acidic with low organic matter content. Alluvial soils abound along the Niger and Benue valley and their flood plains.The cultivation of food crops such as rice, yam, cassava, sorghum, maize, millet, cowpea and groundnut prevail the agricultural practice, while mixed cropping is the common farming system.. Cassava based mixtures are most common in the farming system. Average farm size is between 2-3ha per farm family with average family size of 6-7 persons. Cassava is widely grown in all the LGAs of the state. Indeed, it is grown by almost every household (RTEP 1997)

Opportunities for cassava production in Kogi State
Kogi State is one of the major producers of cassava in Nigeria. It produces over 4.16million metric tonnes of fresh cassava roots annually from over 269,270 hectares of cassava farms (Kogi ADP 2014).The major production outputs are from Ankpa, Dekina, Kabba-Bunu, Ijumu LGAs. Before the cassava production revolution of the early part of this millennium, cassava was utilized mainly as food in the State leaving little for industrial uses most of which were rudimentary and rural based. The little starch produced was for local laundry services. There were 134,635 cassava farms in Kogi State on an area of 269,270 hectares (Table 1). Average yield per hectare was 12 tonnes which was the national average.

Status of cassava production in Kogi State
Kogi State is the largest producer of fresh cassava roots in Nigeria (NFRA, 2008). It produced over 4.16million metric tonnes annually (Table 2). Starting from1994, when the first Crop Area Yield Survey (CAYS) was conducted, cassava production in the State was 1.227mmt from an area of 121,260 hectares with a yield of 10.12t/ha. Production of cassava continued to increase in Kogi State to 2.794mmt in 1999 from an area of 182,790ha and a per hectare yield of 15.28tonnes. This improved performance was due mainly to the funding intervention of the Cassava Multiplication Project (CMP) which was inherited from Benue State after the States creation exercise of 1991. The CMP came to a technical close in 1998.Expectedly, cassava production declined in year 2000 (2.506mmt) and yield per hectare also reduced (13.47t/ha) (Table 2). From 2003 to 2011, production of cassava in Kogi State again improved with an all high figure of 5.032mmt and a yield per hectare of 19.32 (Kogi ADP, 2017). This feat could be attributed to the funding intervention by the Root and Tuber Expansion Programme (RTEP) of the Federal Government of Nigeria (FGN) supported by the International Fund for Agricultural Development (IFAD).
Following this improved production, the problem of glut emerged in the cassava supply chain. The challenge was how to encourage producers to continue production at a profit. Cassava producers were seriously experiencing glut which was cyclic in nature; a two year cycle of cassava fresh root glut followed by two year scarcity. The main task of the ADP was to ensure the availability of planting materials every year in order to sustain production and reduce the cassava glut.

Table 2: Cassava production in Kogi State (1994 - 2017)

Year	Production ('000)	Area cultivated ('000)	Yield/ha
1994	1227.90	121.26	10.12
1995	1635.16	128.19	12.75
1996	1858.28	145.64	12.75
1997	2319.21	178.69	12.97
1998	2771.38	183.17	15.13
1999	2794.32	182.79	15.28
2000	2506.00	186.00	13.47
2001	2704.00	177.90	15.19
2002	2785.12	177.90	15.65
2003	2854.85	173.20	16.48
2004	2969.63	175.24	16.94
2005	2666.41	180.75	14.75
2006	3394.71	214.18	15.84
2007	3631.94	243.96	14.88
2008	3741.90	252.84	14.79
2009	4011.26	269.27	14.89
2010	4396.34	289.96	15.16

Source: APS, Kogi ADP (1994-2017),*Production figures from 2014 – 2017 were yet to be certified

Stimulation of processing to reduce cassava glut

The next hurdle was to reduce or eradicate the problem of glut experienced by producers every two years. The component of RTEP called Diversification of Processing Options and Products had to be implemented in detail in Kogi State. Recipes of cassava and end users were identified, staff of the Kogi ADP were trained and product demonstrations were conducted in all the zones and major locations in the State. Master bakers were trained to the use ten percent High Quality Cassava Flour (HQCF) as substitute for wheat. Model Cassava Processing Centreswere established across the RTEP participating Local Government Areas of Ankpa, Dekina, Igalamela/Odolu, Okehi, Yagba-West in addition to similar ones atIjumu and Lokoja. The establishment of these model processing centres was a major milestone in the quest to modernize cassava processing. This major intervention brought about improved processing capacity amongst processing groups arising from the use of modern processing equipment, enhanced product quality through training and better packaging. Production of cassava roots increased steadily due to availability of improved planting materials which were distributed to producers to support the supply of fresh roots to the existing processing centres. Local fabricators were trained and empowered to provide maintenance services to producers and processors.

Job creation in the cassava industry

The cassava value chain has great opportunities for job creation, wealth generation and industrialization. There are a number of enterprises within the cassava value chain that could boost the actualization of these three noble potentials. From field survey conducted among producers and processors, it was revealed that a hectare of cassava could gainfully employ a person for a year, while a 1.50 ton per day capacity gari factory could engage 75 people (Table 3). From the table below, gari processing factory was the highest employer of labour while cassava production employed the least number of persons.

Table 3: Employment generation by cassava-based enterprises in Kogi State

Type of enterprise	Capacity	No employable/yr (person)
Cassava production	1ha	1
Processing into gari	1.50 ton/day	75
Processing into cassava chips	1.50 ton/day	30
Processing into HQCF	1.50 ton/day	35
Processing into HQCF	5.00 ton/day	70

Source: Field observation

Apart from these core enterprises in the cassava value chain, there are a number of other ancillary service providers and chain actors that employed persons. These included transporters, tractor operators, spare parts dealers, agro-dealers, spray gang operators, food vendors etc.

Challenges of cassava production and utilization in Kogi State

The main challenges to production and utilization include the followings

- Poor rural infrastructure (bad rural roads and near absence of water in most rural areas)
- Drudgery in production and processing
- Limited land for mechanization
- Limited tractors and implements
- Adulterated agro-chemicals
- Weak and poorly manufactured sprayers
- Unstable market prices for fresh cassava roots
- High cost of cassava cuttings
- High transport cost

Envisaged level for cassava production and processing in Kogi State

For Kogi State to remain as a leader in cassava production, the State and other stakeholders in the industry should rededicate their efforts in achieving the underlisted targets.

- Increasing yield/ha to at least 35tons
- Increase State production to 40.00million metric tons
- Area cropped to cassava to increase to about 350,000ha
- Emphasis on production for industrial use (starch and feed)
- Less dependent as food

Recommendations to achieving the goals for cassava production in Kogi State

- There should be more land cleared for cassava production. This is a major constraint to production. In other to attract youths to join the revolution, the State should provide cleared and tractorable land.
- Sustained full mechanization of the entire production and processing value chains. Simple labour saving devices in both production and processing would greatly revolutionalize the cassava industry. This include tractors, planters, sprayers, peelers, packers/trucks, harvesters etc
- While small and medium scale producers and processors are encouraged to thrive, the State should provide enabling environment for private sector participation which is key for cassava revolution.
- Governments (State and Local Government Areas) should as a matter of necessity provide a favourable environment to doing business in the State. These include among others adequate security and rural infrastructures (rural roads, potable water supply and electricity).

Conclusion

Cassava production has come to stay in Kogi State as the crop is the main staple of most of the farm families of the State. To drastically reduce poverty and unemployment, government should intensify efforts to promote rural economy and enabling environment for entrepreneurial development through the provision of rural infrastructures especially roads and potable water. Private sector participation is key to the vision of the State.

Influence of Socioeconomic Factors on Yam Production Output in Umuahia Agricultural Zone of Abia State, Nigeria

I.N. Nwokocha, C. S. Onwusuribe and H.N. Anyaegbunam
Extension Services Programme. National Root Crops Research Institute, Umudike. P.O. Box 7006 Umuahia Abia State. E-mail:*ivyamaka.nn@gmail.com*

Abstract
The study was carried out to assess influence of socioeconomic factors on yam production output in Umuahia Agricultural Zone of Abia State. Structured questionnaires were used to elicit information from the farmers. Multi-stage sampling method was used in data collection the study. One block from the zone was purposively chosen, because of her engagement in production of yam in the zone. Four circles were randomly selected and 30 farmers from each of the four circles were randomly selected for the study. In all 120 respondents were used as the sample size. List of farmers collected from the community head served as the sample frame. Data were analyzed using descriptive and inferential statistics. Result showed that majority of the respondents (55.8 %) were males,46.7% of the farmers who responded were between 41-50 years, greater percentage of the respondent (69.2%) were married andabout 48.3 % of the respondents had between 5 and 9 household members. The result of the regression analysis revealed that yam production output was influenced by some socio-economic factors such age, education, farm size and labour since these factors were significant at 10% and 1% levels. The study concluded that socioeconomic factors had much influence on yam production output in Umuahia Agricultural Zone and therefore, it is recommended that male farmers in the area should be encouraged to participate actively in yam production so as to increase the output of yam production since sex was significant but negatively related to yam production output in the study area.
Key words: Factors, Yam, Production and Output.

Introduction
Yam is one of the tuber crops produced in Nigeria and it has as many out of which six are economically important staple species. They are *Dioscorea rotundata* (white guinea yam), *Dioscorea alata* (yellow yam*), Dioscorea bulbifera* (aerial yam), *Dioscorea esculenta* (Chinese yam) and *Dioscorea dumetorum* (trifoliate yam). Out of these, *Dioscorea rotundata* (white yam) and *Dioscorea alata* (water yam) are the most common species found in Nigeria (Anozie *et al.,* 2014). Yams are grown in the coastal region in rain forest, woody savanna and southern savanna agro ecology.In many yam-producing area in Nigeria, it is said that "yam is food and food is yam" (Bolarinwa and Oladeji, 2009).Yam production in Nigeria has more than tripled over the past 45 years from 8.7 million tons in 1961 to 31.3 million tons in 2006. This increase in output is attributed more to the large area planted to yam than to increased productivity (Izekor and Olumese, 2010).Though the area cultivated to yam production is still being increased, production growth rate declined tremendously from average of 27.5% between 1986 and 1990 to 3.5% in the period between 1991 and 1999 (FAO, 2002). Yam crop forms a staple food for most people of the tropics. Yam tubers are eaten in different forms include eating it boiled, fried, pounded or made into yam powder for fufu. As food crop, the place of yam in the diet of Nigerians cannot be overemphasized. It contribute more than 200 dietary calories daily, for more than 150 million people in West Africa as well as serving as an important source of income (Babaleye, 2003).Yam also plays vital roles in traditional culture, rituals and religion as well as local commerce of African people (Izekor and Olumese, 2010). Due to the importance attached to yam, many communities in Nigeria celebrate the new yam festival annually (Ibitoye and Onimisi, 2013). Yam production has been on decrease in Umuahia agricultural zone of Abia state despite its numerous importance.

Hence, the study to determine the influence of socio-economic factors on yam production output in the study area. The objectives of the study are to describe the socio-economic factors influencing yam production

Methodology

The study was carried out in Umuahia Agricultural Zone of Abia State. Structured questionnaires were used to elicit information from the farmers. Multi- stage sampling technique was used in data collection. One block from the zone was purposively chosen, Ikwuano LGA, because of her level of engagement in yam production in the zone. Four circles were randomly selected and 30 farmers from each of the four circles were randomly selected for the study. In all 120 respondents were used as the sample size. Data were analyzed using descriptive statistics and inferential statistics such as frequency, percentages and multiple regression model. The model is implicitly stated as;

$Y= (X_1, X_2,\ldots\ldots X_6,X_7+u)$

Where

Y = Output (kg)

X_1 = Age (years)

X_2 = Sex (male or female)

X_3 = Education (number of years spent in school)

X_4 = Farming experience (years)

X_5 = labour (man-days)

X_6 =Farm size (hectare)

X_7 = Membership of association (member or non-member)

u = Error term

Results and Discussion

Results in Table 1 shows that majority of the farmers (46.7 %) fall between 41-50 years. This implies that yam production and its increase output requires able bodied men. This finding is in agreement with Waziri *et al.* (2014) who opined that majority of farmers within the age range of 41 to 50 years are still in their active age, more receptive to innovation, more technically efficient, effective and could withstand the stress and strain involved in yam production.

Table 1: Distribution of Respondents Socio- Economic Characteristics in the Study Area n = 120

Variables	Frequency	Percentage
Age		
20-30	2	1.7
31-40	33	27.5
41-50	56	46.6
51-60	15	12.5
61 and above	14	11.6
Sex		
Male	67	55.8
Female	53	44.2
Educational attainment		
Non-formal	4	3.3
Primary school	20	16.7
Secondary school	56	46.7
Tertiary education	40	33.3
Marital status		
Single	37	30.8
Married	83	69.2
House hold size		
1-4	17	14.2
5-9	58	48.3
10-14	32	26.7
15-19	13	10.8
Farming experience		
1-5	11	9.2
6-10	27	22.5
11-15	45	37.5
16-20	28	23.3
21 and above	9	7.5
Labour source		
Own labour	12	10.0
Family	35	29.2
Hired	25	20.8
Family and hired	48	40.0

Source: Field survey, 2016.

The result also shows that majority of the farmers constituting 96.7% possess formal education. Most of the farmers (55.8 %) were male while about (44.2 %) were female. Traditionally, it is believed that women in Igbo land are not meant to cultivate yam and it requires a lot of energy for its production. According to Ironkwe and Ewuziem (2010), traditionally yam is regarded as ‘‘Man's crop’’. Greater percentage of the respondents 69.2 % was married. Farming is a necessary condition for families to lift their households out of poverty and ensure hunger free situation in homes. This agrees with the findings of Augustine *et al.,* (2008) who found that over 70% of the married couples were involved in yam production in South Eastern Nigeria. Majority of the respondents (48.3%) have between 5 and 9 household members. Traditionally, yam production is a labour intensive enterprise, family size is a necessity for the size of the farm and increase in production of yam in the area (Nahanga and Vera, 2014). Table 1 also shows that 37.5% of the farmers had farming experience between 11-15 years while about 23.3% of the farmers had farming experience of between 16-20 years. Farming experience enable farmers to set realistic targets. This finding corroborates the finding of Ironkwe, *et al.,* (2007), that experience improves farmers' production skills such as good planting methods and the use of improved seeds.

Table 2. Multiple Regression Analysis of Socio-economic Factors Influencing Yam Production Output in Umuahia Agricultural Zone

F-statistics	3.078***	1.707*	3.169***	4.316***

Source: Field Survey, 2016. Key: *** = significant at1% level, * = significant at 10% level. + Experiential

Result of Table 2 reveals the result of multiple regression of socio-economic factors influencing yam production output Among the four functional forms, the exponential form was selected as the lead equation because of a high R^2 (0.511) value, number of significant variables and appropriate a priori expectation. The R^2 indicated that 51%variability in yam production output was explained by the independent variables. F ratio was also highly significant at 1%, indicating goodness of fit. The results in table 2 depict that sex is significant at 10% but negatively related to yam production output in the study area. The result shows that female farmers were more in yam production in the study area and this will affect the output of yam since yam is labour intensive, more demanding in term of agricultural practices and regarded as man's crop. Educational attainment was found significant and positively related to yam production output at 10% level. The result implies that the more educated a farmer had, the more the farmer puts in necessary practices and techniques that can improve yam production output. Ume, *et al.* (2013), state that education helped to facilitate adoption as it makes one to be more objective in evaluating innovation, which will influence his or her production. The result also shows that labour source was significant but negatively related to yam production output. It means that the more labour requirement in the farm, the lesser production output. This could be as a result of misallocation or over utilization of labour (Anyaegbunam *et al*, 2016). Farm size was significant and positively related to yam production output at 1% level. This means that the larger the farm size, the more yam production output in the study area.

Conclusion

The study concluded that socio-economic factors such sex, age, education, farm size and labour influenced yam production output in Umuahia Agricultural Zone since these factors were significant. Therefore, it is recommended that male farmers in the study area should be engaged in yam production so as to increase the output of yam production, since sex was significant but negatively related to yam production output in the study area.

Analysis of Cooperative Societies Credit Delivery in Umuahia North Local Government Area of Abia State, Nigeria.

S.E. Ogbe [1]. and K.U. Asanya [1].
[1]Department of Entrepreneurial Studies, Michael Okpara University of Agriculture Umudike.
Email: talk2samogbe@yahoo.com

Abstract
The study examined cooperative society's credit delivery in Umuahia North Local Government Area of Abia State, Nigeria. The specific objectives include determining the criteria for selection of members and the status/trend of loan application and approval. A purposive sampling technique was used in selecting the sample used for the study. Data was collected with the aid of well-structured questionnaire and secondary data. Data were analyzed using descriptive statistical tools such as frequency distribution, means, percentages and Paired T-test. Eight cooperatives societies were purposively selected for study. The study showed that majority of the respondents in the zone agreed that cooperatives must adhere to the necessary criteria for selecting members; non-adherence to the stipulated conditions could lead to derailment of the cooperative aims and objectives. More so, the result showed that there was access to cooperative credit in Umuahia North, since the Average Approval Rate was 60.85%. An indication that farmers had good access to cooperative loan. The study therefore recommends that the funding of business enterprises among the cooperatives should be based on their mandates; this measure will ensure the sustainability of cooperative activities and quick realization of goals and objectives. Cooperatives should ensure speedy treatment of loan request, this will help reduce the idle time and facilitate greater outreach to clients.
Key words: Cooperative Societies, Credit, Delivery, Agriculture

Introduction
In most third world countries (Nigeria inclusive), agriculture dominates the nation's economy. It has been established that about 70 percent of Nigeria's population is engaged in agriculture (Obasi and Agu, 2000) while 90 percent of Nigeria's total food production comes from these small farms and 60 percent of the country's population earn their living from these small farms (Oluwatayo, Sekunmade and Adesoji 2008; Izekor and Alufohai, 2010 and Awotide, Aihonsu &Adekoya. 2011).). It is the cooperative that embraces all type of farmers and a well-organized and supportive cooperative is a pillar of strength for agriculture in Nigeria (Ijere, 1981;Izekor and Alufohai, 2010). Credit is considered as a catalyst that activates other factors of production and makes under-used capacities function for increased production (Ijere, 1998).Credit is defined as financial resources obtained at certain period of time with an obligation to repay at a subsequent period in accordance with the terms and condition of the credit obtained (Ijaiya and Abdulraheem, 2000; Awotide *et al*., 2011The informal source of credit is more popular among small scale farmers which may be due to the relative ease in obtaining credit devoid of administrative delay, non-existence of security or collateral, flexibility built into repayment which is against what is obtained in the formal sources, (Afolabi and Fagbero,1998 ;Izekor and Alufohai, 2010). Aryeetey (1997) noted that the informal rural financial sources in Africa perform better than the formal system because the institutional lending system has failed to meet the objective for which they were set up. Ojo(2005), observed that the institutional lending system has failed to meet the objective for which they were set up The cooperative societies have been identified to be a better channel of credit delivery to farmer in term of its ability to sustain the loan delivery function (Alufohai, 2006).It is against this backdrop that this study aimed to determine cooperative societies' effectiveness in credit delivery to agricultural and non-agricultural enterprises in Umuahia North Local Government Area of Abia State, Nigeria. The objectives of the study include to; determine the socio-economic characteristics

of cooperative societies in the study area, the type of agro-based enterprises funded and criteria for selecting members among the cooperative societies, the status/trend of loan application and approval, determine the effectiveness of credit delivery to agricultural and non-agricultural enterprises and determine the effect of cooperative society's credit on beneficiaries of agro-based enterprise growth. It is hypothesized that there is no significant difference among the growth parameters of selected agro-based enterprises production before and after cooperative credit in Umuahia North.

Methodology

North was purposively selected for the study due to high level of cooperative societies activities interaction of cooperative societies and the agricultural projects/ programmes (i.e FADAMA III and Abia State Agricultural Development Programme (ADP)) which the researcher believed was an avenue to reach out to the cooperatives. The population for the study consists of 64 cooperatives registered in Umuahia North Local Government. A purposive sampling technique was adopted in the study. The list of all registered cooperative societies were obtained from the Cooperative Office at Umuahia North Local Government Area Headquarters. The total of 8 cooperative societies were selected due to the level of interaction of cooperative societies and the agricultural projects/ programmes (i.e FADAMA III and Abia State Agricultural Development Programme (ADP). Primary and secondary data were used in this study. Data for the study was collected using a well-structured questionnaire administered to respondents who were cooperative officials and were involved in cooperatives activities. The secondary data were collected from the publication of the selected cooperatives and from the State Ministry of Cooperatives, Rural Development and Poverty Reduction. Data collected were analyzed using descriptive statistics such as means, frequency distribution, and percentages.

Results and Discussion

Criteria for selecting members among the cooperative societies

The criteria for selecting members among the cooperative societies is presented in Table 4.3

Table 1: Criteria for selecting members among the cooperative societies

S/N	Variables	Frequency	percent
1.	Members must reside within the area of the operation of the cooperative	8	100
2.	Location of the members business must be within the area of operation of the cooperative	8	100
3.	Willingness to purchase at least the mandatory share capital	8	100
4.	Willingness to attend meetings	8	100
5.	Willingness to be financially committed	8	100
6.	Willingness to be a member	8	100

Source: Field survey, 2017

Table 1: shows that the respondents in Umuahia North all (100%) agreed that members must reside within their area of the operation of the cooperative, Location of the members business must be within the area of operation of the cooperative, Willingness to purchase at least the mandatory share capital, Willingness to attend meetings, Willingness to be financially committed and Willingness to be a member. The lack of adherence to the stipulated conditions could lead to derailment of the cooperatives aim and objectives.

Status/trend of loan application and approval

The status/trend of loan application and approval is presented in Table 4.4.

Table 2 Average numbers of loan application and approval across the cooperatives in Umuahia North.

	Loan Request						Loan Approval						
Name of cooperative	1st Q	2nd Q	3rd Q	4th Q	Total	$\bar{X}$	1st Q	2nd Q	3rd Q	4th Q	Total	$\bar{X}$	App Rate(%)
Ndiagbor	57	60	48	56	221	55.3	32	38	37	44	151	37.8	68.33
Chiluru Farmers	5	-	10	-	15	3.8	3	-	2	-	5	1.3	33.33
Green Revolution	15	5	5	-	25	6.3	9	2	4	-	15	3.8	60
Otu-Obi	11	-	4	4	19	4.8	7	-	2	3	12	3	63.2
Ubibia Cocoa	-	18	-	-	18	4.5	-	15	-	-	15	3.8	83.33
Yes-We-Can	5	30	15	-	50	12.5	5	10	3	-	18	4.5	36
Umunne-ato	11	4	5	-	20	5	4	1	3	-	8	2	40
Ikemba	7	-	3	-	10	2.5	3	-	3	-	6	1.5	60
Total	**111**	**117**	**90**	**60**	**378**	**94.5**	**63**	**66**	**54**	**47**	**230**	**57.5**	
Average	**13.9**	**14.6**	**11.3**	**7.5**	**47.3**	**11.8**	**7.9**	**8.3**	**6.8**	**5.9**	**28.8**	**7.2**	**55.52**

Source: Field survey, 2017

Table 3: shows the difference in loan applied for and approved across the cooperatives societies in Umuahia North. Ubibia Cocoa farmers had the highest approval rate of 88.33%, while Chiluru Farmers had the least value of 33.33%. The table further revealed that Ndiagbor had 221 loan request and 151 loan approval for the year 2016 with their mean as 55.3 and 37.8 respectively as the highest mean across the cooperatives, while Ikemba had the least mean of 2.5 and 1.5 for loan applied for and applied for the first, second, third and fourth quarters of 2016.

Analyses of loan application and loan approval

Analyses of loan application and loan approval is presented in Table 4.5,

Table 3 Analyses of loan application and loan approval

Quarterly	Average number of application	Average number of approval	Approval rate
Quarter 1	111	63	56.76%
Quarter 2	117	66	56.41%
Quarter 3	90	54	60%
Quarter 4	60	47	78.33%
Total	378	230	60.85%

Source: Field survey, 2017

Table 3: shows that an average of 111 loan applications was received in the first quarter for the year 2016 and 63 loan applications were approved giving an approval rate of 56.76%. 117, 90 and 60 loan applications were received, while 66,54 and 47 were approved for the second, third and fourth quarter of the year 2016 respectively, giving an approval rate of 56.41%, 60% and 78.33% respectively. In all, cooperatives societies in Umuahia North received a total of 378 loan applications and approved 230 within the first, second, third and fourth quarter of the year 2016 giving an overall approval rate of 60.85%. An indication that farmers had good access to cooperative loan. This result is in line with the study of Ajah *et al* (2013). The result of Ajah *et al* (2013) showed that in all, the cooperatives societies received a total of 1999 loan applications and approved 1891 within the period of eight years giving an overall approval rate of 94.5%, an indication that farmers had good access to cooperative loans.

Test of Hypothesis

Hypothesis 1-HO_1: There is no significant difference in the production of the selected cooperative societies agro-based enterprises activities before and after cooperative credit.

In order to ascertain whether there is any significant difference in the production before and after cooperative societies credit, the paired t-test was used and the result is presented in Table 4.

Table 4: Significant difference in the production of the selected cooperative societies agro-based enterprise activities before and after cooperative credit.

Growth Parameter	Individual mean	Std Deviation	Std Error Mean	Pooled Mean	Df	T-cal	T-tab
Production before	131066.67	159451.99256	29111.8118	130600.00	29	4.486	1.699
Production after	261666.67						

Source: Field survey, 2017

Decision rule: if T calculated is >T tabulated, reject Null hypothesis and accept alternative otherwise accept the null hypothesis and reject the alternative hypothesis.

Table 4. shows that T calculated for production before and production after was 4.486, while T tabulated was 1.699 with the mean percentage of 99.6%. This means that T calculated is greater than T tabulated, so therefore the alternate hypothesis is accepted meaning that there is a significant difference in the production of the selected cooperative societies agro-based enterprises in Umuahia North. The significant difference in the production could be due to the collaboration of cooperatives with extension workers from relevant government agencies in the state.

Conclusion and Recommendations

It was concluded that there was a positive and significant difference in the production before and production after of the selected cooperative societies, indicating that there is a cooperative society's credit has effect on their agricultural activities. Base on the findings, the following recommendations were made; Cooperatives could avoid loan repayment problems if the cooperatives adhere to the conditions for selecting loan beneficiary, Cooperatives should focus on funding one type of enterprise so as to be effective and efficient in their credit delivery function, Government through relevant agencies should ensure that adequate funds are made available to cooperatives. In addition, policies geared towards improving the capital base of the cooperative societies and managerial abilities that will aid loan repayment capabilities of the co-operators will go a long way to increase the approval rate and reduce the idle time to zero.

Effects of Macroeconomic Variables on Agribusiness Performance in Nigeria

A.E. Osuala and C.C. Opara
Department of Banking & Finance, Michael Okpara University of Agriculture, Umudike, Nigeria.
Corresponding Author's *E-mail: osuala.alex@mouau.edu.ng*

Abstract
The response of agribusiness to changes in macroeconomic environment is an important factor in the success of any reform programme in agricultural sector of Nigeria. This study examined the effects of macroeconomic variables on agribusiness performance (AGB) in Nigeria using time series data from 1970 to 2016 collected from the Central Bank of Nigeria (CBN) statistical bulletin. Using the General-To-Specific Auto-Regressive Distributed Lag (ARDL) estimation technique, the results show that only real exchange rate (RER) was very significant in positively influencing agribusiness performance in Nigeria both in the short and long run. The study recommends that the government should intensify price policy measures and other measures that will enhance agribusiness performance in Nigeria.
Keywords: Macroeconomic, Agribusiness and Performance

Introduction
United Nations Industrial Development Organization (UNIDO, 2011) described Agribusiness as an aggregate of sub sectors of agriculture and the proximate agro-allied industries. *Yumkella*, Kormawa, Roepstorff and Hawkins (2011)*elaborated* on this definition to include a wide range of intermediate activities that generate economic values, comprising of not only commercial farming but also broadly include input supplies, agro-processors, traders, exporters and retailers which could be segmented into component groups of: Agricultural input industry; Agro-industries products (food, beverages, leather, textile, etc.); Equipment for processing; and Financing, marketing and other related services. According to Desmond and John (2009), agribusiness emphasizes the interdependence of the various subsectors within the production chain with the aim of adding value to both producer and the consumer. This suggests that for agribusiness to perform successfully in an economy, the interlink between the subsectors or component units must be properly activated and coordinated in order to create a continuous flow of activities, goods and services and information sharing for the purposes of adding value to both the producer and the consumer. The performance of agribusiness in Nigeria is very critical, and apparently seen as a most reliable vehicle of economic growth of the country given the abundant human and material resources, friendly ecological conditions and a wide range of market potentials. If properly harnessed, it can stabilize economic growth, create employment opportunities, and enhance the livelihood of the people living in poverty, in addition to becoming a socially inclusive strategy (Alemayehu, 2014). Indeed, a performing agribusiness is capable of forming the bedrock of the most desired diversification of the Nigerian economy.

Notwithstanding its potentials and past contributions to the economic performance of the nation, there are indications of either stagnated or declining performance at all levels of the production chain. Nigeria, a once major exporter of groundnut, cocoa, palm produce, biggest poultry producer in Africa and other food crops is now a major importer of food items. Nigeria's food import bills stood at ₦33.02 billion in 2010; in 2011, the bill rose to ₦44.3 billion. Available statistical information showed that food demand in Nigeria was increasing at the rate of 3.5% as against the output of 2.5% with a population growth rate of 3.18% (Nto and Mbanasor, 2011).

In an effort to enhance the efficient performance of the agribusiness subsector, various Nigerian governments had formulated and implemented various policies to redirect economic trend to the path of performance. These include Austerity measure, Structural Adjustment Program, Deregulation, Guided deregulation, etc. Many Institutions and schemes were also created such as the River Basin Development Authorities, National Accelerated food Production (NAFP), Operation Feed the Nation (OFN), Directorate of Food and Rural Infrastructure, etc. In spite of these laudable efforts made by various Nigerian governments in committing resources and implementing programs and policies to boost agribusiness, not much seemed to have been achieved. A good macroeconomic policy target and a robust knowledge of behavior of specific macro-economic variables on agribusiness are necessary for redirecting agribusiness to the path of performance in Nigeria. Prominent among these macro-economic variables are: exchange rate, rate of inflation, interest rate, money supply growth, change in real gross domestic product, unemployment rate, government expenditure and net export (Aroriode and Ogunbadejo, 2014; Kadir and Tunggal, 2015).Several studies have been carried out to determine the effects of macroeconomic variables on the performance of production agriculture, agro-allied manufacturing, agro-processing, etc., but not so much information or a holistic study of the agribusiness subsector'sresponse to macro-economic variables changes in Nigeria is known, at least, to the best of the knowledge of the authors.

In the light of the foregoing, the present study analyzed the effects of selected macroeconomic variables, on agribusiness performance in Nigeria from 1970 to 2016. The scope was selected to cover the periods of oil boom and glut in Nigeria.

Methodology

Research Design

The design of the study is ex-post facto. This is because it relied on secondary data collected to investigate the effects of macro-economic variables on agribusiness performance in Nigeria which was set as the primary objective of the study.

Sources and Method of Data Collection

The annual time series data used in the study were collected from the Central Bank of Nigeria Statistical Bulletin, and World Development Indicators Data Base 2017. The data set was collected on each of the selected macro-economic variable specified in the model, and on the proxy for agribusiness performance from 1970 to 2016. Agribusiness performance was proxied by the aggregate growth of the contribution of agriculture real GDP, agro-manufacturing/processing contribution to real GDP, hotel and restaurants services addition to real GDP. The indicator for Non-Oil Export was the ratio of Non-Oil Export to Total Merchandise Exports; real GDP-which is GDP deflated for inflation; crude oil revenue was used as proxy for crude oil export.

Model Specification

The model adopted for this study was influenced by the work of Kadir and Tunggal (2015) who investigated the impact of macroeconomic variables toward agricultural productivity in Malaysia. They stated their model as:

$$LnAGDt = \beta 0 + \beta 1LnEXCt + \beta 2LnEXPt + \beta 3LnGEXPt + \beta 4LnINFt + \beta 5LnMSt + \beta 6INTt + \mathrm{ut}1.$$

Where $LnAGDt$ is the log of agricultural productivity, $LnEXCt$ is the log of the exchange rate, $LnEXPt$ is the log of net exports, $LnGEXPt$ is the log of government expenditure, $LnINFt$ is the log of the inflation rate, $LnMSt$ is the log of money supply, $INTt$ is the interest rate and Ut is the stochastic error term.

Equation (1) was however modified to reflect the focus of the study which is the performance of Agribusiness in Nigeria. Hence the model for the present study is given as:

$$ln\,AGB_t = \beta_0 + \beta_1\, ln\,GDP_t + \beta_2\, ln\,FIM_t + \beta_3\, ln\,NOE_t + \beta_4\, ln\,FPI_t + \beta_5 \ln INF_t + \beta_6 \ln RER_t + u_t \quad (2)$$

where AGB is Agribusiness performance growth; GDP = change in Gross Domestic Product, FIM = Food import growth rate; NOE = Non-oil export growth; FPI = Foreign private investment; INF = Inflation rate; RER = Real exchange rate;*ln* = natural logarithm of the variable, and is t = time period.

Equation (2) predicted that agribusiness performance was positively affected by all the independent variables. The model was linearized so as to standardize the variables.

Data Analytical Technique
The estimation of data was carried out using the General-to-Specific Autoregressive Distributed Lag (ARDL)/Bounds testing technique for testing the long-run co-integrating relationship among the time series variables. According to Pesaran & Shin (2001), the Bounds testing approach has some advantages over conventional co-integration testing approaches because it can be used with a mixture of I(0) and I(1) data, and again, it involves just a single-equation set-up, making it simple to implement and interpret.
As a preliminary step in ARDL/Bound testing, we employed the Augumented Dickey Fully Unit root test to confirm the order of integration of the time series variables. This is necessary because the presence of an order of integration higher than I(1) such as I(2) will invalidate the use of Pesaran and Shin computed F-statistics which is based on the assumption that the underlying variables must be either I(0) or I(1) or mutually integrated. The bounds testing approach was used to confirm the presence of co-integration, i.e. long-run relationship between the variables.

Results and Discussion
The result of the unit root test is presented in table 1

Table 1: Results of Unit Root Tests

Variable	ADF		Order of integration	Philip Perron		Order of integration
	Levels	First difference		Levels	First difference	
NOE	-2.2937	-5.9662	I(1)	-2.2532	-7.2025	I(1)
RER	-0.5074	-4.5956	I(1)	-2.5382	-4.6918	I(1)
FPI	-3.6778	-	I(0)	-3.6778	-	I(0)
INF	-3.0657	-5.7704	I(1)	-3.1644	-14.0650	I(1)
GDP	-4.4860	-	I(0)	-4.5339	-	I(0)
FIM	-3.7582	-	I(0)	-3.7398	-	I(0)
AGB	-4.3365	-	I(0)	-5.3311	-	I(0)

***Source**: Authors' compilation from Eviews printout.*

The result of the unit root test presented in Table 1clearly confirms the existence of a mixed order of integration. Therefore, any attempt to specify the dynamic function of the variables in the level of the series will be inappropriate and may lead to spurious regression. Based on the foregoing, it became necessary to use the ARDL/bound testing approach to test for co-integration.

Table 2: **Result of the General-to-Specific ARDL Bounds Test**
The General-to-Specific ARDL Bounds approach systematically eliminates all the non-significant variables in the model, leaving only the statistically significant variable(s). In this regard, only RER was adjudged significant.
Null hypothesis: No long-run relationship existed

Test statistics	Value	K
f-statistics	14.31575	1

Critical Value Bounds

Significance	10 Bounds	11 Bounds
10%	4.04	4.78
5%	4.94	5.73
2.5%	5.77	6.68
1%	6.84	7.84

K = number of regressors
Source: *Researcher Computation Using E-view 9*

As shown in Table 2, the joint null hypothesis of no long-run relationship was rejected at both 5% and 1% levels of significance. This was based on the fact that the calculated F-statistic value of 14.31575, exceededthe upper and lower bounds critical values of Pesaran and Shin computed F-statisticsat 5% level meaning thatthere is a long-run co-integrating relationship between agribusiness performance and the selected macroeconomic variable, RER.

Table 3: Result of the ARDL Co- integration and Long Run Form

Dependent Variable: LOG(AGB)
Selected Model: ARDL(2, 0)
Date: 07/26/18 Time: 06:18
Sample: 1970 2016
Included observations: 45

Cointegrating Form				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
DLOG(AGB(-1))	-0.26146	0.11987	-2.18118	0.035
DLOG(RER)	0.016469	0.004837	3.404584	0.0015
CointEq(-1)	-0.36756	0.074327	-4.94516	0

Cointeq = LOG(AGB) - (0.0448*LOG(RER) + 3.1152)
Long Run Coefficients

Variable	Coefficient	Std. Error	t-Statistic	Prob.
LOG(RER)	0.044806	0.013994	3.201878	0.0026
C	3.115165	0.048733	63.92269	0

The short-run estimates from the model were reported in Table 3. The coefficient of $ECM_{t-1}$was found to be moderate in magnitude, negatively signed as expected and statistically significant at 5% level. It demonstrates that there is a long run relationship between the variables. The coefficient of ECM term is (-0.36756), which suggests a moderate adjustment process. The result suggests that nearly 37 per cent of the disequilibria of the previous year's shock adjust back to the long run equilibrium in the current year. The coefficient of real exchange rate (RER) was statistically significant both on the short- and long-runs. However, contrary to some earlier studies, RER made a significant positive impact on agribusiness performance in Nigeria within the reference period. This result is however in tandem with the findings of Obayelu and Salau (2010) who reported that agricultural output responds positively to increases in exchange rate both in the short and long run. Serial correlation test clearly suggests the absence of autocorrelation as can be seen from Table 4. The final model from the General-to-specific ARDL approach was found to be stable judging from the stability test, F-statistic and R^2. A possible explanation is that increases in the exchange rate lead to increases in aggregate agricultural output probably due to more foreign exchange earnings by farmers through exportation of their products.

Table 4: Breusch-Godfrey Serial Correlation LM Test:

F-statistic	1.745559	Prob. F(2,39)	0.1879
Obs*R-squared	3.697251	Prob. Chi-Square(2)	0.1575

Conclusion and Recommendations

The study investigated the effects of macroeconomic variables on agribusiness performance in Nigeria using time series data from 1970 to 2016. Using the General-To-Specific Auto-Regressive Distributed Lag (ARDL) estimation technique, the results showed that only real exchange rate (RER) was very significant in positively influencing agribusiness performance in Nigeria both in the short and long run. It observed that a possible explanation for the development could be that increases in the exchange rate lead to increases in aggregate agricultural output probably due to more foreign exchange earnings by farmers through exportation of their products. The study therefore recommended that the government should intensify price policy measures and other measures that will enhance agribusiness performance in Nigeria.

Determinants of Household Beef Consumption in Obio Akpor Local Government Area, Rivers State, Nigeria

A. Henri-Ukoha[1], P.A. Ekunwe[1], V.C. Ugwuja[1], and B. Dumka[2]
[1]Department of Agricultural Economic and Extension, University of Port Harcourt, Choba, Rivers State
[2]Department of Agricultural Education, Federal College of Education (Technical), Omoku, Rivers State
Email of corresponding author: *adanna.henri-ukoha@uniport.edu.ng*

Abstract
The study was undertaken to analyze the determinants of household beef consumption in Obio Akpor Local Government Area of Rivers State. Specifically it, determined the quantity of beef demanded on monthly basis by the household consumers and determined the factors influencing the demand for beef in the study area. The primary data used in analysis were collected from sixty randomly selected households in the study area through the use of interview schedule and a well-structured questionnaire. Statistical tools such as frequency counts, mean, percentage and Ordinary Least Square regression were used for data analysis. The results showed that Income spent on beef was 5.24 and that high-income earners spent 2.33% of their income on beef consumption, while low income earners spent 5%. The Cobb-Douglas functional form gave the best line of fit with R^2 value of 0.67. Household size, income level and education level of the respondents were the most significant variables that influenced the household demand for beef in the study area. The major constraint was poor hygiene of abattoir. Abattoirs should be educated on food sanitation process so as to minimize the poor hygienic condition of the abattoirs, Its efforts should be made by the government and other relevant stakeholders to reduce the price of beef by providing the beef producers and marketers with the necessary infrastructures, land and modern technologies so that it can be made affordable to all categories of consumers.

Key Words: Beef, household, consumption, demand

Introduction
Food is a necessity for human growth and meat plays a key role to provide the body with the basic nutrients needed for growth (Aborisade and Carpio, 2017). Nigeria is the largest meat producers in Africa and also the highest meat consumers (Osho and Asgher, 2005). Beef is among the most widely consumed meat in the world, accounting for about 25% of the world meat production after pork and poultry at 38% and 30% respectively (Food and Agriculture Organization, 2002). Meat is a source of protein, vitamins, minerals, micronutrients and fats. Its consumption in adequate quantities facilitates proper functioning of the immune system, mucous membrane and metabolic processes (Biesalski, 2005). The meat from cattle, goat, sheep, pig and poultry including offals are the main sources of protein (Britton, 2003). Animal protein however, is said to possess superiority over other sources of protein. Animal proteins are generally referred to as complete protein because of the presence of different amino-acids in them (Oloyede, 2005). Meats such as beef, being important source of protein, have played important roles in the pattern of food consumption in Nigeria. Beef products are known worldwide as a very important diet because of its high nutritive quality and significance in improving human health (Amao, Oluwatayo and Osuntope, 2006). In addition, consumption of meat reduces the risk of cancer, aeoteriosclerosis and adiposity, while prolonging the onset of diabetes (Ezedinma, Kormawa and Chiamu, 2006). It has been estimate that the daily minimum crude protein requirement of an adult in Nigeria varies between 65g and 85g per person, hence, it is recommended that 55g of this minimum requirement should be obtained from animal protein (Joseph and Ajayi, 2002; Omotosho, 2004). However, beef contribute

46.7gm per day of net protein and the average Nigerian consumes 7.5g of animal protein per day which is still below the recommended requirement by the World Health Organisation (Amao et al., 2006). This shows that the problem of malnutrition and malnourishment; particularly protein intake is a serious one in Nigeria as a large proportion of the population including children do not receive enough calories to ensure physical health and development Meat is considered as an essential food product with high rate of consumption (Guerrero, Valero, Campo and Sanudo, 2013), but the demand for meat in most African countries is very low at 25g and the demand is lower in the Southern parts of Nigeria where the quantity of meat available enough to meet the rapid growth in population due to low production (Obi, 2003). Other problems affecting the demand of beef include: inadequate finance, feed stuff, high transportation cost, inadequate modern storage facilities, ineffective information system as well as low producer prices which may arise as a result of poor distribution network and high cost of procuring trucks and equipment needed for easy marketing (Mintert, Schroeder and Marsh, 2001).

This study is designed to bring to limelight the strength and weaknesses of effective demand of beef production in the study area. Therefore, it will serve as a useful source of information to national development planners and policy makers in formulating policies and designing programmes that will solve the problems affecting the demand for beef thereby increasing the net income of the participating stakeholders and improving the livelihood conditions of household consumers. The specific objectives were to:; determine the quantity of beef demanded on monthly basis by the household consumers; determine the factors influencing the household demand for beef in the study area and to identify the problems encountered by beef consumers in their demand for beef in the study area.

Materials and Methods

The study was carried out in Obio-Akpor Local Government Area of Rivers State. Multistage sampling technique was used in the selection of respondents in the study area. In the first stage, three (3) communities were purposively selected because of the presence of abbatoir in the areas. In the second stage, twenty (20) respondents were randomly selected and interviewed from each of the communities through the use of a structured questionnaire, making a total sample size of sixty (60) household heads.

Data were analysed using descriptive statistics such as frequency, mean and percentages Ordinary Least Square Multiple regression analysis. This is expressed as follows:

$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7 \ldots, e)$ ………………………………

Where:

Y = Household demand on beef product (₦)

X_1 = Price per kg (₦)

X_2 = Household size (number of persons)

X_3 = Household income (₦)

X_4 = Gender (Dummy; male = 1, female = 0)

X_5 = Age of household head (in years)

X_6 = Marital status (Dummy; married = 1, single = 0)

X_7 = Education level of household head (years)

e = Error term

Results and Discussion

Household demand for beef.

Table 1: Distribution of respondents according to household demand for beef in the study area.

Quantity of beef consumed	Frequency	Percentages
1 -5	6	10.00
6 – 10	8	13.33
11 – 15	26	43.33
16 – 20	20	33.33
Mean = 12.3kg		
Total	**60**	**100.0**

Source: *Field Survey, 2016.*

Table 1 reveals that 13.33% of the household consumed between (6- 10) kg of beef per month, 10% consumed between (1 - 5)kg, 43.33% consumed (11 - 15)kg while 33.33% of them consumed between (16 - 20)kg. This shows a reasonable consumption of beef in the study area as indicated in the mean (12.3kg) quantity of beef consumed in the area. This could be attributed to the large sizes of their households which has implications for higher consumption of beef.

Factors influencing household demand for beef in the study area.

Table 2: Regression results of the factors influencing household demand for beef in the study area.

	(-0.91)	(0.623)	(-1.124)	(0.551)
Educational Level	23.67	232.0	-0.028	-0.474
(X_7)	(1.533)	(1.745**)	(0.931)	(1.801)**
R^2	0.617	0.547	0.643	0.667
F- Value	10.29	7.712	7.586	12.757

Source: *Field Survey, 2016.* *= significant at 1%, ** = significant at 5%; t-values are the figures in parenthesis

Table 2 shows that the Cob-Douglas functional form was selected as the lead equation based on the statistical significance of the coefficient of multiple determinations (R^2), the significance of F-value, the significance of the coefficient parameters and the conformity with a priori expectations. The results show that the estimated coefficient of multiple determinations (R^2) was 0.67. This shows that 67% of the variations in the exogenous variable was explained by the explanatory variables while the remaining 33% was not accounted for probably due to error term which captures factors not expressed in the model. The F-value of 12.757 was statistically significant at 1% which implies that the model is best fit and hence explaining the variation in quanti2y of beef demanded. Household income, price of beef, educational level and household size were statistically significant at 5% and 1% levels of significance. The coefficients of price and education level were negative and significant at 5%. This implies that the higher the price of beef or/and education level, the lower the quantity dlastic in the study area in that a
unit change in price of beef would reduce the quantity demanded by 0.1%. This observation is in line with the findings of Adetunji and Rauf (2012). Similarly, the negative sign of education level indicates that well educated household head tend to spend less on beef consumption. This is because he is aware of the high calorie content of beef which may have adverse effect on the health status of the individual. The coefficient of household size was positive and statistically significant at 5% while that of household income was positive but significant at1%, implying that the higher the value of these variables the higher the quantity demanded of beef. Therefore, a large household size tends to consume more beef than low household size and increase in household income tend to increase the quantity of beef demanded. This is because there is more mouth to feed in the household, hence more expenditure on beef consumption. This result disagrees with of Mohammed and Eleche (2017) which noted that household size decreases as output increases. Also with respect to income, the income elastic nature of beef signifies that any unit increase in disposable income of household head will result in 0.465 unit increase in quantity demanded for beef.

Problems Encountered by the households

Table 3: Problems encountered by beef consumers in the study area

Problems	*Frequency	Percentage
Poor hygienic condition of abattoirs	35	58.3
High calorie content of beef	26	43.3
Inability to afford beef	30	50.0
Preference differentials of household members	25	41.7
Health reasons	28	46.7

Source: *Field Survey, 2016*
Multiple responses recorded

Results in Table 3 show that majority (58.3%) of the household beef consumers complained that poor hygienic condition of abattoirs is a major challenge. The unhealthy state of abattoirs agree with the findings of Mande (2011) who stated that meat consumers were discouraged owing to the poor hygienic practices of the meat marketers. This was followed by 50% the beef consumers who reported inability to afford beef. This suggests the high cost of beef in the area. This was followed by 46.7% of the households which were limited for health reasons. This could be attributed to the increasing health awareness of beef as having high content of high density cholesterol which is not good for their health. About 41.7% of the respondents reported that preference differentials of household members were the main problem of beef consumption in the household. About 43.3% indicated that high calorie content of beef posed a serious threat to beef consumption,

Conclusion and Recommendations

The study revealed that the beef consumers were mostly married young educated females with large household size in the study area. Level of education, household income and household size are factors that influence the household demand for beef in the study area. The poor hygienic condition of the abattoirs was the major challenge to beef consumption in the study area. The following recommendations were made:

1. Efforts should be made by the government and other relevant stakeholders to reduce the price of beef by providing the beef producers and marketers with the necessary infrastructures, land and modern technologies so that it can be made affordable to all categories of consumers.
2. The beef processors should be educated on the food sanitation process so as to minimize the poor hygienic condition of the abattoirs and
3. The people should be educated on the nutritional value of beef in order to avoid malnourishment from valuable nutrients contained in beef and thereby increasing beef consumption level.

Structure of Tomato Marketing at Yankaba Market in Kano State, Nigeria

***A, Saleh, *Ahmed, B.S. and **S, Adamu**
*Department of Biological Sciences, Kano State College of Arts, Science, and Remedial Studies, Kano State, Nigeria.. E-mail: aminusalehn@gmail.com
**Department of Management Sciences, Kano State College of Arts, Science, and Remedial Studies, Kano State, Nigeria..

Abstract

The paper appraised Tomato marketing at Yankaba Market in Kano State, Nigeria. The specific objectives of the paper were to examine the socio-economic characteristics of Tomatoes marketers and describe the Structure of the Tomato Market in the study area. Primary data were collected from fifty (50) randomly selected Tomato marketers with the aid of well-structured questionnaire. Data collected from the field were analyzed using descriptive statistics. The paper revealed among others that: Tomato marketing in the area was male dominated (100%), 80% *of the respondents belong to the active labour force of the population.The market was found to be a perfect one with free entry and exit characterized by little or no role played by marketer's association in price determination: It was recommended that favourable Market conditions should be provided through cooperative initiatives that will lead to the general empowerment of the Marketers especially those with low capital base in order to make them more competitive and hence generally improve their income.*

Key words: Market Structure, Tomato marketing, Yankaba Market, Cooperative Societies, Kano State, Nigeria.

Introduction

Vegetable production has been playing a vital role in human nutrition, poverty reduction and improving the socio-economic status of the farmers. Vegetables are important items in the daily diet of the Nigerian family (Adeoye et. al, 2011). They are a cheap and easily available source of vitamins, minerals and dietary fiber and are low in fat and calories (Abba, 2004). Tomato (*Lycopersiconlycopersicon* karst) is perhaps the most important commercial Vegetable grown all over Nigeria. Both the Wet and Dry Season Cropping contribute immensely to the National requirement (Shehu, et.al, 2013). However, the bulk of the Production is from the Dry Season Cropping particularly under Irrigation in the Northern States and near perennial river banks in the South (Anon,1989). Tomato can grow in a wide range of Climatic conditions. It requires abundant Sunshine and Cool Weather of 20-27^{0c} day Temperature and 15-21^{0C}Night Temperatures (Aderibigbeet *et al*. 1998). Tomato is highly perishable and therefore makes its Marketing important hence the need for studying its Marketing Structure and the concentration of the Marketers.

Market structure also refers to a set of Market characteristics which determines the economic environment in which a firm operates (Thomas and Maurice, 2011). According to Jema (2014), Market structure consists of the relatively stable features of the environment that influence the behavior and rivalry among the buyers and sellers operating in a market. For example, if the market structure is characterized by high barriers to entry, it may result in only a few traders profitably maintaining the business activities. These few traders may engage in non-competitive behavior such as collusion and exclusionary or predatory price setting behavior. These non-competitive behaviors can result in excessive profits and widened marketing margins for traders.

Analyzing market structure is important in understanding the key structural aspects of the Tomato Market and the distribution of its Marketers. This involves the number and concentration of

Market agents, ease of entry and exit, degree of product differentiation as well as the basic operations of its agents at various levels of the Marketing chain. Several studies have analyzed the market structure of Agricultural products in Nigeria. For instance, Abba (2004) analyzed the marketing of Tomato and Onion in Jigawa State while Shafaatu (2017) analyzed structure and Concentration of Rice Market in Kano state. A Gini coefficient value of 0.2 (20%) was obtained implying inequality in size distribution of the sellers' concentration.
It is against this background that this study was conceived in order describe the Market Structure of Tomato with the view of understanding how it affects the price system as well as the Market participants.

The major objective of this paper is to appraise the structure of Tomato marketing in Yankaba Market located along Hadejia Road in Nassarawa Local Government Area of Kano state. The specific objectives are to:

- describe the socio-economic characteristics of the respondents in the study
- determine the Structure of Tomato market in the study area
- Make relevant recommendations

Methodology

Kano state is largely situated in the Sudan savannah agro-ecological except for its southern border which predominantly shows traces of Northern Guinea Savannah. It lies between latitude 13.53^{o} N and 10.25^{o} N and longitude 7.40^{o}E and 10.53°E, and is about 480km from the edge of Sahara Desert (KNSG, 2006). According to Danyaro (2012) the state is 472.45 meters above sea level. It has a total of fourty four (44) local Government areas and share boarders with Bauchi, Jigawa Kaduna and Katsina States with a total land area estimated at 20,760 square kilometers. The main soil type of the study area is reddish brown vegosols, with mainly sandy to clay loam texture. The soils tend to be slightly alkaline, and soil organic matter content and cat ion exchange capacity are low (pH: 8.0, soil organic matter content 0.26%; CEC. 1.34 Me per 100g soil). The latter indicates a dominance of Kaolinite clay minerals. The state climatic condition has two distinct seasons: the dry and wet seasons. The dry season spans the period between October/November to March/April, while the wet season covers the period between May/June to September/October, with an annual rainfall ranging between 787 to 960mm and a temperature raging between a maximum of 33^{0}c to a minimum of 15.85^{0}c although it can fall even lower during Hamatan to as low as 10°C (Olofin and Tanko, 2002). In an official gazette of the Federal Republic of Nigeria released by the National Population Commission (2006), the state had a population of 9,383,682. million people as at 2006 and projected population figure of fifteen (15) million people by the year 2015 making the state the most populous, not only in the region, but also in the country at large. These factors facilitate the diverse nature of Agricultural activities in the state where most of the people are farmers and are actively engaged in the production and Marketing of Grains like maize, millet, cowpea, groundnut, guinea corn and Vegetables. Vegetable crops especially Tomato is mostly grown along Fadama low land areas where the soil is mainly clay – loam textured as well as irrigated perimeters in the state (Ibrahim *et.al*, 2014). Thus, making the primary activity of the people in the study area to be predominantly farming in the rural areas and Marketing/Business in the urban centers alongside other secondary engagements like animal husbandry and civil service there by making the state to become the major Commercial as well as Marketing center across Northern Nigeria comprising international markets like Dawanau (Grains) and Na, ibawa-Yan-lemo/Yankaba Markets (Fruits and Vegetables) among others.

Sampling Procedure

Yankaba Market located along Hadejia road was purposively selected for the study being the single largest Vegetable Market in Kano State, with high concentration of both wholesalers and Retailers. Primary data were used for this study. The primary data were collected from fifty (50) randomly selected Tomato marketers with the aid of well-structured questionnaire supported with interview method for the respondents in the Market.

The data generated include the socio-economic characteristics of the marketers among which are their age, sex, marital status, level of education and their household sizes. Other data include years of experience in Tomato marketing, sources of income, costs and returns of respondents such as marketing costs (transportation cost, handling cost, fees and levies paid), depreciation cost of marketing equipment used, cost of produce, selling price (₦ /fruit), amongst others. Data on Marketing channel i.e. source of product materials used such as table, basket, bag, knife, trays, buckets, basins and umbrella.

Analytical Tools

The tools used for the analysis of the data collected from the field were: Descriptive Statistics. Descriptive statistics such as frequency distribution and percentages were used to describe the socio–economic characteristics of Tomato marketers, determine the Market structure as well as the constraints facing the marketing of the product in the study area.

Results

Socio-Economic Characteristics of the Respondents

Socio economic characteristics describe the personal characteristics of the respondents in the study area. These include age of the respondents, sex, educational level, marital status, household sizes, and marketing experience of the respondents in the study area. Table 1 revealed that 20% of the respondent's ages between 25 - 31, 39 - 45 and 46 - 52 years respectively while 36% and 4% of the respondent's ages between 32 - 38 and 18 - 24 years respectively, implying that majority (80.0%) of the respondents are still very young and are within the active labor force age of 18 to 45.

The study revealed that all of the respondents (100%) were, male which probably has to do with the Socio- religious belief of the majority of the population where purdah is practiced. This conforms with the findings of Shafaatu on the marketing structure of Rice in Kano State. The distribution of the respondents according to marital status revealed that 8 % of the respondents were single, 80% were married, 4% divorced and 8% were separated. This implied that majority of the respondents were married which might have a positive effect on the availability of family labor and help in decision making which directly contributes to the success or otherwise of the enterprise. The result also revealed that 80% of the respondents had Quranic education 12% of the respondents had primary school education, 4% of the respondents had secondary school education, while the remaining 4% had non- formal education otherwise known as Mass Literacy Classes in the Area. It therefore revealed that 98% of the respondents had one form of education or another which implies that watermelon marketers in the study area were moderately educated meaning that they take better decisions in regards to accepting new innovations and applications for better marketing practices.

The study also revealed that majority (80%) of the respondents had between 6 and 10 years marketing experience, while only 16% of the respondents had marketing experiences between 1 to 5 years and 4% of the respondents had marketing experience of 11 to 16 years. This implies that most of the respondents are new entrants and watermelon marketing is new and growing enterprise as new marketers are being added to it daily.

Table: 1. Socio-Economic Characteristics of Respondents

Socio-economic characteristics	Frequency	Percentage
Age Range in Years 18-24		
	2	4.0
25-31	10	20.0
32- 38	18	36.0
39- 45	10	20.0
46- 52	10	20.0
Total	**50**	**100**
Gender		
Male	50	100
Female	-	-
Total	**50**	**100**
Marital Status		
Single	4	8.0
Married	40	80.0
Divorced	2	4.0
Separated	4	8.0

Market Structure Analysis

The Market Structure is an important Framework that provides crucial insight on how Markets operates especially with regards to a healthy competition among the various actors in the Market (Kang, et al., 2009). Major indicators of Market structure include Entry and Exit, product differentiation, number of buyers and sellers and price determinants which were analyzed below as indicated by the results.

Entry and Exit Behaviour

The result revealed that majority of the Tomato Marketers (84%) believed that there was no any entry restriction whatsoever. While the remaining 16% believed that it was difficult to enter into the Market. Barrier to entry and Exit limits the number of the number of sellers and buyers from entering and exiting the Market thereby affecting competition among and between sellers.

Product Differentiation

Product differentiation is a feature that distinguishes the Market from type of the product being marketed; it is used to gain advantage over and above other competitors (Kang, et al., 2009). The results from table 2 revealed that tomato was found to be differentiated in the Study area according to Grades and majority of the Marketers (44%) were mainly engaged in the marketing of the lowest grade (Taru) probably because of in adequate capital as well as high demand from consumers as a result of its relatively lower price.This is followed by24% involved in the marketing of Grade III and 14% for Grade II respectively. However, only 6% were engaged in the marketing of Grade I by virtue of its relatively high price and therefore implied that only few of the marketers had the capital to invest in it especially when its demand is relatively lower than other Grades In addition, 12% of the respondents were involved in the marketing of all the grades.

Price of Tomato

Prices of tomato in the Market are determined largely by market forces as revealed by the results in table 4. Majority (94%) of the respondents stated that Market forces determined the prices of the commodity in the study area. This implies that sellers are price takers. This showed that a perfectly competitive market structure operates in the retail tomato market. High level of competition allows for the effective operation of the Market forces of Demand and Supply in which case the Price and quantity bought and sold in the Market are at favourable condition for buyers and sellers. In other words this opens more opportunities for potential Marketers to go in to the emerging enterprise.

Table: 2. Market Structure for Tomato (n= 50)

Variable	Marketers Frequency	Percentage
Entry and Exit		
Absence of barrier	42	84
Presence of barrier	8	16
Total	**50**	**100**
Grading		
Grade I	3	6.00
Grade II	7	14.00
Grade III	12	24.00
Others(Taru)	22	44.00
All grades	6	12.00
Total	**50**	**100**
Price of tomato		
Market Price	47	94
Market Officials	0.00	0.00
Comparing Market prices	3	6.00
Total	**50**	**100**

Source: Field Survey, 2017.

Conclusion and Recommendations

The paper revealed among others that: 80% of the respondents belong to the active labour force of the population while the remaining 20% belong to the aged group. It also showed that the enterprise in the Area was Male dominated (100% of the respondents were males). Result showed that 96% of the respondents were literate. The market structure depicts many buyers and sellers and size of the market is large which collectively describes the market as a perfect competitive one. In addition sellers are price takers since price is determined mainly through the interaction between Buyers and Sellers.

It is recommended that more favourable Market conditions should be provided through cooperative initiatives among the marketers that will lead to their general empowerment especially those with lower capital base in order to make them more competitive and hence generally improve their income.

mezinokbe@yahoo.com

Abstract
Road transport is a major means of transporting farm produce from the farms gate to the markets as well as to various urban areas. This research examines the effect of road transport on agricultural development in Ivo L.G.A of Ebonyi State. Primary and secondary data for the study. One hundred and fifty respondents were sampled systematically in the study area. Descriptive and analytical statistical methods were both employed to analyze the data gathered. The result revealed that road transport has both positive and negative effect on agricultural development in the study area. However, the bad conditions of the road affect cost of transportation of agricultural produce which in turn affect the rural farmers' income. This research concludes by suggesting that improvement in road transport system will lead to increased output by farmers. Thus, Community participation in road transport development should also be encouraged in the study area.
Keywords: *Rural development, marketing, transportation, farm size, output, road network*

Introduction
Agriculture generally is important in the life of every nation for its contribution in improving the standard of living of the people through provision of food for man, feed for animal, hides and skin for clothing, raw materials industries, and timber for shelter. Food in Nigeria is critically dependent on transport distribution, it then become obvious that wide variety of Nigerian food would not be available without the complex transportation network system, which serves as stem food industry. Farm produce usually depend upon transportation facilities. Transport is viewed as an important factor involved in agricultural development all over the world. It is the only means by which food crops produced at farm site is moved to different homes as well as markets, Aderamo, and Magaji, (2010). Transport usually creates market for agricultural produce, raise up interaction among geographical and economic regions and creates new areas to economic focus. There are complex relationships that vary both spatially and over time between transport and development. Therefore, for any meaningful development to take place, transport plays a vital role. Ogunsanya (1988) observed that there are three types of paths in the rural areas which may include bush paths, unsurfaced rural roads and surfaced rural roads. However, the bush path is very common but the least developed of all the routes. Bush paths connects villages with farmsteads and they are usually narrow, winding and sometimes overgrown by weeds particularly during the rainy season. Paul *et al.* (2009) pointed out that the effect of road infrastructure on agricultural output and productivity are particularly important in Sub-Saharan Africa for three reasons. Firstly, the agricultural sector accounts for a large share of gross domestic product (GDP) in most Sub-Saharan countries (Paul *et.al* 2009). Secondly, poverty is intense in rural areas. Finally, inadequate road infrastructure and long travel time leads to high transaction costs for sales of agricultural inputs and outputs, and this limits agricultural productivity and growth. Transport affects agricultural marketing because it is the only means by which farmers can transport their agricultural produce to the market. Low level of transportation in the rural areas has resulted in low income level, low productivity, high rate of poverty and a fall in the standard of living of rural residents (Aloba, 1986). Instances where the distance from the farm to the market is far away with rough road network, causes perishable crops to be destroyed and farmers end up running at a loss (Ajiboye, and Afolayan,2009). It is against this background that this study specifically examines the effects of transportation of produce by road on farmers' farm income.

Materials and Methods

The study was carried out in Ivo Local Government Area of Ebonyi State, Nigeria. It has an estimated population of 129,068 people based on the 2006 census (NPC, 2006). The local government area is composed of the following communities: Ishiagu, Ishiaka, Ndiokoroukwu, Nzerem and Obinagu. The people of this area are mostly farmers and some engage in stone crushing to supplement their farm income. One hundred and fifty (150) farmers were selected from 5 communities in the local government area using a systematic sampling method. In each community, a total of thirty copies of questionnaire were administered to the farm families. The data for the study were collected from two main sources, the primary source and secondary source. The primary data were collected through the use of well-structured questionnaire and personal interviews with the farmers. The questionnaire sought information on farm income, cost of transportation and the effects of transport on agricultural production. Interview and discussions were conducted with the transporters and farmers respectively in order to find out their own opinion about the conditions of the roads to each community sampled. Descriptive statistics such as frequency distribution, percentages and means were used for data analysis.

Results and Discussion

Table 1 shows that about 36% of the farmers generate below N50, 000, 21% make (N50, 000-N100, 000), 29% earn (N101, 000- N150, 000) while about 19% of the farmers generate above N151, 000 and N200, 000.

Table 1 Income level of farmers

Income (naira)	Percentage
10,000-50,000	36
51,000-100,000	21
101,000-150,000	29
151,000-200,000	19
201,000-250,000	9
Total	**100**

Field survey data, 2018

Transportation Cost of Agricultural Produce on Farmers' income

Cost of transportation of farm produce from the farm gate to the market has a great impact on production and income of farmers. This is as a result of transport charges on agricultural produce vary with type of crops, the efficiency of the transport and distance travelled. Table 2 revealed that 14 percent spent nothing less than N20, 000 annually in carting their produce to the market, 26.7 percent spent between N21, 000 and N40, 000, 38 percent of the farmers spent between N41, 000 and N60, 000, 21.3 percent spent between N61, 000 and N80, 000annually to transport their farm produce to thevarious towns where demands are high. This means a significant proportion of the farmers' income was spent on transportation and this is as a result of dilapidated roads infrastructures in these areas. Farmers that spent less than N20, 000 annually are those engaged in vegetable production. This is given the fact that majority (86%) of the farmers earned less than N150, 000 annually from their farm produce. High cost of transportation cost implies high selling price and if the price is too high when compared with other farmers from other areas, customers will not buy and this may result to selling below cost of production.

Table 2: Cost of Transportation of Produce to the Town (Market) Annually

Settlements	Less than N20,000	N21,000-N40,000	N41,000-N60,000	N61,000-N80,000	Total
Ishiagu	1	5	15	9	30
Ishiaka	-	5	12	13	30
NdiokoroUkwu	11	7	10	2	30
Nzerem	5	14	6	5	30
Obinagu	4	9	14	3	30
Total	**21 (14)**	**40 (21.7)**	**57 (38)**	**32 (21.3)**	**30**

Note: Percentages are in Parenthesis

Farmers' Agricultural Productivity level in relation to Transportation of Produce

A lot of factors are responsible for the quantity of crops produced by farmers in the study area and these vary from farm to farm and community to community. These factors include availability of transport, markets, farm size and farm input. Thus 59 percent of the sampled farmers produced 100-5000kg, while 41% produced less than 100kg. This is attributed to the small scale production of the rural farmers. Most of them produce for subsistence and only sell the excess from their production. Transportation problems and other agricultural problems they encountered have really reduced their production capacities. Transportation cost especially has limited their production capacities hence they produce only little at a time.

Conclusion and Recommendations

The study had extensively examined the impact of road transport on agricultural production in Ebonyi State. From the study, it was revealed that road transport has a significant impact on distribution of agricultural produce in the study area. It can therefore be concluded that road transport should be improved upon so as to improve agricultural production generally in the study area. This will in turn generate more income and improve the standard of living of the farmers as well as the inhabitants of the communities under study.

Furthermore, community participation should be encouraged in the construction of roads.

Impact Assessment of Some Selected Improved Cassava Varieties on the Socio-economic Status of Farmers in Cross River State, Nigeria

P. Amadi[1], I. Igbojionu[1] and C. Kalu[2]
1Extension Services Programme, National Root Crops Research Institute, Umudike
2Extension Department, Michael Okpara University of Agriculture, Umudike
pearlamadi@gmail.com

Abstract
The study was conducted to assess the impact of selected improved cassava varieties on the socio-economic status of the farmers in cross river state, Nigeria. The data for the study were collected from 180 farmers. An interview schedule with a well-structured questionnaire was used for the study. The data were analyzed by descriptive statistics such as frequency, tables, percentages, mean and likert scale. The result revealed high awareness and adoption of three out of the five selected improved cassava varieties studied, TMS 89/0505, TME 419, TMS 89/0851, NR 8082 and pro vitamin Aamong the farmers.The result also revealed the socio-economic benefits derived from the technologies adopted. The result shows that farmers adopted those improved cassava varieties that have high impact on their socio-economic status, particularly in food production and income earnings. The paper therefore calls for developing strategies that will enhance high adoption of the technologies by organizing more trainings, field days, and workshops, provision of incentives and seminars for women farmers in the state.
***Keywords**: Improved Cassava Varieties, Impact Assessment.*

Introduction
Assessing the impact of some selected improved cassava varieties for their expected performance on the socio-economic status of the farmers is a pre-requisite and basis for the suitability of new varieties in Nigeria. Cassava is suitable to various farming system, available all the year round and produces efficient food energy (Ironkwe *et al,* 2012, Beeching *et al*, 2000). It is an important food staple and industrial crop in Nigeria. Cassava is also important as a major source of income for rural households, enhances food security and livelihood of people in Nigeria. Nigeria is currently the largest producer of cassava in the World with an annual production of over 54tons from an estimated land area of 1.4 million hectares (Chinaka et al, 2013; FAO, 2009). This record was made possible through the successful research efforts of the International Institute for Tropical Agriculture (IITA), Ibadan, National Root Crops Research Institute (NRCRI), Umudike, other partners and that of the farmers who adopted the technologies developed by these institutes and partners. National Root Crops Research Institute, Umudike has developed several improved cassava varieties to increase the productivity and income of the farmers in the country and to enhance their socio-economic welfare (NRCRI, 2014). These technologies have been disseminated to farmers through the Agricultural Development Programmes (ADPs) of various states in Nigeria for adoption and constant use. Thus, after developing and disseminating technologies, efforts should be made to assess the adoption rate and impact of such technologies on the output, income and general welfare of the farmers. Against this background therefore, it became necessary to examine the impact of these selected improved cassava varieties on the socio-economic of the farmers in Cross River State, Nigeria.

Methodology
The study was conducted in Cross River State in South-South agro-ecological zone of Nigeria. The State is made up of three agricultural zones namely, Calabar, Ikom and Ogoja. A multistage sampling procedure was used in this study. Ikom agricultural zone was purposively selected based

on the fact that Ikom was one of the areas where the improved cassava varieties have been disseminated to farmers through the extension agents in the zone. Secondly, three (3) blocks were randomly selected from the selected zone. A random selection of three (3) circles in each of the blocks was done and in each of these circles, twenty (20) cassava farmers were randomly selected from the list of cassava farmers in the area, making it a total number of 180 farmers for the study. Data collected were analyzed using descriptive statistics such as frequency tables, percentages, means and 5 points Likert-type scale rating.

Results and Discussion

Level of Awareness and Adoption of some selected improved cassava varieties

Table 1 shows the levels of awareness and adoption of the some selected improved cassava varieties in the study area. Results reveals high awareness of all the five selected improved cassava among farmers studied as over 71% of the respondents were aware of the technologies. Greater proportion of the respondents adopted three of the five technologies while TMS 89/0851 and pro vitamin A recorded low adoption.

The socio-economic benefits derived from the technologies adopted

Table 2 reveals the socio-economic benefits the farmers derived from adopting the technologies. Majority of the respondents indicated that TME 419 (88.9%), TMS 89/0505 (78.3%) and NR 8082 (61.1%) benefitted them in food production and income earning while smaller proportion indicated that TMS 89/0505, TME 419, NR 8082 and Pro-vitamin A provided employment opportunities for them. This implies that farmers adopt those improved cassava varieties that have high benefit on their socio-economic status.

Extent the selected improved cassava positively impacted on the socio-economic status of the farmers

Table 3 shows that majority of the selected improved cassava varieties had positive impact on the socio-economic status of the farmers in the study area. Improved cassava varieties like TMS 89/0505, TME 419 and NR 8082 had high impact, particularly in availability of food, income earnings and boosting household economy while Pro-vitamin A and TMS 89/0851 recorded moderate and low impact. This finding agrees with the report of Ironkwe (2012) that farmers adopt those technologies that have high impact on their socio-economic status. The grand mean (3.2) indicated that most of the technologies adopted by the farmers had relative impact on their socio-economic status.

Conclusion

The selected improved cassava varieties such as TMS 89/0505, TME 419 and NR 8082 had high awareness and adoption rate among the farmers in the study area. Though, TMS 89/0851 and pro vitamin A cassava varieties had high awareness but recorded low adoption. However, it is imperative to note that the farmers adopted improved cassava varieties that had relative high impact on their socio- economic status. With the adoption of these improved cassava varieties, the farmers were able to increased availability of food and generate more income from the cassava. Hence, the improved cassava varieties transferred to the farmers in the study area helped to enhance socio-economic status of the farmers. However, efforts should be made by the National Root Crops Research Institute and State ADP to develop strategies that will promote, enhance or encourage high adoption of these improved cassava varieties among farmers in order to generally impact positively on their socio-economic status. This could be done by organizing more trainings, field days, workshops and seminars for farmers in the state.

Table 1: Distribution of Respondents according to the level of Awareness and Adoption of some Selected Improved Cassava Varieties Adopted

Selected Improved Cassava Varieties	Unaware	Aware	Not-adopted	Adopted
TMS 89/0505	36.1	63.9	42.8	57.2
TME 419	11.7	88.3	13.9	86.1
NR 8082	47.2	52.8	46.7	53.3

Factors Influencing Income Generating Activities of Rural Women in ensuring Household Food Security in Ikwuano Local Government Area of Abia State, Nigeria

P. Amadi[1], F.N. Nwakor[1], L. Udoh[2] and F.C. Nzeakor[2]
[1]Extension Services Programme, National Root Crops Research Institute, Umudike
[2]Extension Department, Michael Okpara University of Agriculture, Umudike
pearlamadi@gmail.com

Abstract
This study examined factors influencing income generating activities of rural women in ensuring household food security in Ikwuano LGA of Abia State, Nigeria. Data for this study were obtained by the use of structured questionnaire. A total of 60 respondents were interviewed consisting of women involved in income generating activities. Frequency counts and percentages were used to describe the data collected while multiple regression model was used as inferential statistical tool. The result of the analysis revealed that access to credit positively influence the income generating activities of the rural women at 5% level of probability while marital status of the respondents, level of education and membership of cooperative positively influence the income generating activities of the rural women at 10% level of probability. The study recommends that women should be encouraged to attend adult literacy classes as this will help in better organizing and carrying out of income generating activities. In order to improve on their performance. The local government should assist women by linking them with financial institutions so as to acquire loan and women should be encouraged to form cooperative groups for easier access to loans.
Keywords: Income, Rural women and food security

Introduction
The role of women in income generating activities is of paramount importance to economic growth and development in Africa (Yusuf *et al,* 2015). More importantly, recognizing and supporting this is essential and vital for the development and growth of women and the fulfillment of their economic potentials, while they are often hidden, silent and not appreciated, rural women represent probably the world's most powerful untapped natural resources. Income generation simply means gaining or increasing income or money that an individual or business receives in exchange for providing a good or service after investing capital (FAO, 2011). Women farmers engage in diverse income generating activities in order to ensure their household food security, there are four major elements that constitute food security these include availability, accessibility, utilization and sustainability of access to food. Availability connotes the physical presence of food in large amounts, accessibility suggests sufficient purchasing power or ability to acquire quality food at all times while utilization demands sufficient quantity and quality of food intake (Marilee, 2009). This study therefore was carried out to assess the income generating activities of rural women in ensuring household food security in Ikwuano Local Government Area of Abia State Nigeria. This study examine socio-economic characteristics of the rural women in the study area, identify the various income generating activities of the rural women and factors that influence the rural women choice of income generating activities.

Methodology
The study was conducted in Ikwuano Local Government Area of Abia State. It is one of the seventeen LGAs of the Abia state. It was purposively selected based on the preponderance of numerous income generating activities of rural women in the area coupled with the fact that two renowned National Agricultural Institutions namely National Root Crops Research Institute, Umudike and Michael Okpara University of Agriculture, Umudike are situated in Ikwuano Local

Government Area of Abia State. Simple random sampling was used in selecting 60 rural women involved in different income generating activities. Data for the study were collected using well-structured questionnaire to elicit information from the selected respondents. The data collected were analyzed using descriptive statistics such as frequency, percentage and means as well as inferential statistics (multiple regressions). The model is specified implicitly thus:

$Y = F(X_1, X_2, X_3, X_4, X_5, X_6, X_7 + e)$

Y = Income generating activities

X_1 = Age (in years)

X_2 = Marital status (single 1, married 2)

X_3 = Household size (number of people eating from same pot)

X_4 = Education (in years)

X_5= Farm income (in naira)

X_6= Member of cooperative society (Yes 1, no 0)

X_7 =Access to farm credit (Access =1, non=0)

e = Error term.

Results and Discussion

Socio-economic characteristics

Findings in table 1 show that the highest percentages (98.4%) of the respondents were in between the age range of 35-46 years. This implies that majority of women sampled for the study were in their active age and this is expected to influence their income generating activities in supporting the household food security in the area. Majority (70%) of the respondents were married, indicating high level of involvement in income generating activities. The result of the findings show that majority (57.6%) of the respondents had household of 3-5 persons. The size of the household of the respondents may contribute positively to their involvement in the various income generating activities. In terms of educational attainment, majority (96.7%) of the women attended one form of formal education or the other, while only (3.3%) had no form of formal education. This may be the basis for the women in engaging in various income generating activities. Majority of the farmers (63.3%) belong to cooperative society. This implies that there exists a direct relationship between income generating activities and belonging to cooperative society.

Income Generating Activities of the rural women

The results show the various income generating activities performed by the women (table 2) in supporting their household food security and it was indicated majority of the women engaged in crop production/farming(93.3%). This is followed by trading/marketing (75%), livestock rearing (41.7%), and crop processing (45%). This implies that women sampled engaged in different activities so as to ensure household food security. These findings conform to Food and Agricultural Organization of United Nation who reported that significant roles played by women in addition to unpaid labour are aimed at maintaining the household welfare.

Regression Results on factors influencing the rural women choice of income generating activities.

Table 3 shows the result of the regression analysis on factors influencing the rural women choice of income generating activities. The coefficient of multiple determination (R^2) value of 0.72 indicates that about 72% of variations in factors can be explained by the explanatory variables while the remaining 28% was due to other factors not specified in the model. The result indicated that four out of the eight explanatory variables had positive relationship and were significant at 5% and 10% alpha levels. The estimate showed that marital status, educational level and member cooperative society had a positive and significant relationship at 10% level respectively while access to credit had a positive relationship and significant at 10% alpha levels with the income generation by rural women. This means that as the women acquired more formal education, income generation from cassava increased. This agrees with *a priori expectation* and result of Onyebu (2016) that education enhances the potential of women and makes them take advantage of available opportunities that could enhance their income generating activities. The result showed that marital status increased the respondents' income generation. The result also showed that access to credit and member cooperative society enhances their income generating activities.

Conclusion

The study concluded that there exist positive relationships between level of education, marital status, access to credit, membership of cooperative of the rural women and their income generating activities. Sequel to these finding, it is therefore recommended that women should be encouraged to enrol in part time studies in a nearby institution like Michael Okpara University of Agriculture, Umudike or attend adult literacy classes as this will help in better organizing and carrying out of income generating activities. In order to improve on their performance, the local government should assist women by linking them with financial institutions so as to acquire loan and women should be encouraged to form cooperative groups for easier access to loans.

Analysis of Market Orientation Among Sweetpotato Farmers In South Eastern Nigeria

Okoye, A.C[1,2], Mbanasor, J. A [2]. and Okoye, B.C[1] and J.C. Njoku[1]
[1]National Root Crops Research Institute Umudike P.M.B. 7006 Umuahia Abia state, Nigeria
[2] Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
Email: okoyeamalac@yahoo.com

Abstract
The study shows an empirical result on analysis of market orientation among sweetpotato farmers in South Eastern, Nigeria. A stratified sampling design which adopted five stage multi methods that involves purposive and random procedures to select 360 respondents with the use of structured questionnaire Heckit selectivity model were used to analyze the determinants of market orientation respectively. The Heckit results shows that the coefficients for education and native of community were directly related to the probability of being market oriented and coefficients for level of orientation, extension contact and household size were directly related to level of market orientation at 10% level. The coefficients for distance from the farm to market and transportation cost were significant at 5% and 10% respectively and indirectly related to probability of being market oriented. More so, the coefficients for gender were negative and significant at 5% and 1% for probability of being market oriented and level of market orientation respectively. The study calls for policies measures such as increasing farmer's access to farming land, credit, education, infrastructural amenities and encouraging women forum in sweetpotato production.
Key Words: Market Revenue, Comparative Advantage, Sweetpotato and Farmers

Introduction
Market orientation is the extent by which a producer use knowledge about the market, as a basis to make decisions on the three basic economic questions of what to produce, how to produce and how to market (Jaworski and Kohli,1996). In sweetpotato enterprise, market orientation is the degree of allocation of resources (land, labor and capital) to the production of sweetpotato that are meant for exchange or sale (Immink and Aarcon, 1993). Berhanu and Moti (2012) noted market orientation as the relative importance of more marketable crops in the crop mix of the household. Underlying market orientation as the profit motive of households as posited by Pingali, (2001), with the realization of profit depending on market revenues following the study of Gebremedhin and Jaleta (2010).The degree of farmer's level of market orientation has been a major determinant of its competitive advantage (Fritz, 1996). Kahan (2013) noted that market-oriented production begins with an understanding of the market, demand, and involvement in the selection of suitable crop and procedures that can supply the demand and generate profits. Although sweetpotato has contributed significantly towards food self-sufficiency over the last years in Nigeria, farmer's knowledge and understanding to market orientation geared toward sweetpotato root production is the key instrument for its commercialization, smallholder inclusion and increased food and nutrition security. The perishability, low value per unit and bulky nature of sweetpotatoes discourage small scale farmers from accessing high price in markets and limits their level of orientation. A better understanding of variable that affect market orientationwith respect to gender will aid in the identification of interventions to unlock and release benefits associated with marketing agricultural products such as sweetpotato. This study is therefore aimed at establishing factors that commands high market-oriented farming among sweetpotato farmers in South eastern, Nigeria with respect to gender.

Methodology

The Study Area: The study was carried out in South Eastern Geo-Political Zone of Nigeria. The Zone lies within latitude 6°N and 9°S and longitude 4°E and 7°W with a total land mass of 10,952,400ha. It is made up of five states namely: Abia, Anambra, Ebonyi, Enugu and Imo States.
Sampling Procedure: A stratified sampling design was used for the study. The design adopted five stage multi method that involves purposive and random procedures to select sample respondents. Three (Anambra, Ebonyi and Enugu State) out of the 5 states in the South-East Geo-Political zone were purposively selected being the top leading states in the zone in sweetpotato production for the study. For the second stage two agricultural zones per state were randomly selected. They were; Anambra and Onitsha for Anambra state, Enugu North and Enugu East for Enugu State, Ebonyi Central and Ebonyi North for Ebonyi State giving a total of six agricultural zones. In the third stage, two Local Government Areas (LGAs) were randomly selected from each zone in the fourth stage, three communities were selected randomly from each Local Government Area giving a sample of 36 communities. In the last stage, 10 sweetpotato producers were systematically selected, giving a total of 360 respondents for the study.
Data Collection Procedure: the data for the study were collected from primary sources with the use of structural questionnaire.
Analytical Procedures: Descriptive statistics and Heckit selectivity model (Heckman, 1979) following a Double Hurdle procedure. In the first stage, Probit link function was used to estimate if producers are market oriented or not and in the second stage, the level of market orientation was estimated simultaneously by Heckit Estimation. This model has advantage over the Tobit model by eliminating sample selection bias as observed by Gebremedhin *et al.,* (2009); Makhura *et al.,* (2001); Siziba *et al.,* (2011) and Ouma *et al.,* (2010).
The models are as specified thus;

Hectic (MOI)= a0 + aiXi + ui (1)

Where MOI= level of market orientation ($\sum \alpha_i L_i / L_i^T$),

$$\begin{cases} \text{MOI=1 if farmer is market oriented,} \\ \text{0, otherwise} \end{cases}$$

a_o = constant for level of Market Orientation equation
a_i= vector of parameters to be estimated for level Market Orientation
x_i = variables for estimation
u_i= error term

In the specific terms, the Heckit model in the second stage of estimation is stated as

MOI = a0 + a1X1 + a2X2 + a3X3 + a4X4+ a5X5 + a6X6 + a7X7+ a8X8+ a9 X9 + a10X10 + a11X11 + a12X12 + a13X13 + a14X14 + ui (2)

Where,
X_1= age (years)
X_2= educational background (years) ‘
X_3= number of times of extension contacts
X_4= capital invested (Naira)
X_5= household size
X_6= distance to the nearest market (km)
X_7= area of sweetpotato (hectare)
X_8= native of community (dummy variable; yes =1, No=0)
X_9= farming experience (years)
X_{10}= marketing experience (years)
X_{11}= sweetpotato yield (kg/hectare)
X_{12}= transportation cost (Naira/bag)
X_{13}= road condition (good = 1, bad =0)
ui= error term

Result and Discussion

The results in Table 1 show the determinants of market orientation among sweetpotato producers in south eastern, Nigeria. The χ^2 was highly significant at 1.0% level of probability. The inverse mills ratio (lambda) for the level of market orientation was significant, implying that a sample selection bias would have resulted if the level of market orientation was estimated without taking into account the decision to be market oriented. Heckman estimated ρ (rho) as 0.55, the correlation of the residuals in the two equations and sigma (σ = 10.4226), the standard error of the residuals of the market orientation equation. In this case we can reject the null that rho = 0, so indeed we should be using a sample selection model on this data.

The coefficients for education and native of community were significant at 10% and directly related to the probability of being market oriented and level of orientation. This suggests that a 1% increase in level of education will results in 0.0633%, 0.0187% and 0.082% for education and 1.060%, 0.340% and 1.409% for native of community increase in being market oriented, level of orientation and for all producers respectively. Investing in agricultural crop requires skills and information that individuals whom are educated may possess or acquire more easily than others following Rios *et al.,* (2008). Ethnicity reduces barriers to communication and cooperation (Rios *et al.,* 2008). The coefficients for extension contact and household size were significant at 10% level of probability and directly related to level of market orientation. This indicates that any 1% increase in number of extension contacts will lead to an increase in level of market orientation for all the sweetpotato producers.

The coefficient for capital invested was significant and directly related to probability of being market oriented at 5% level. This implies that a 1% increase in capital will result to 0.00001% and 8.49 $\times 10^{-6}$% for being market oriented and for all the farmers respectively. The coefficients for distance from the farm to market and transportation cost were significant at 5% and 10% respectively and indirectly related to probability of being market oriented. This implies that a 1% increase in distance from farm to market is expected to lead to a 0.0465% and 0.0744% decrease in being market oriented and for all the farmers respectively. Consequently, through negative multiplier effects, distance can have severe implications for market orientation following the findings of Omiti *et al*., (2009). Thus, the variable transport costs per unit of distance increases with the potential marketable load size thereby influencing the probability of being market oriented. The coefficient for area of sweetpotato cultivated, farming and marketing experience had a directly related to probability of being market oriented at 1%, 10% and 5% level of probability respectively indicating that a 1% increase in area cultivated sweetpotato will lead to an increase in being market oriented. Experience has been known to lead to perfection in activities. This resultantly manifests in increased knowledge of techniques or otherwise involved in any enterprise. This result is consistent with Agwu (2009) and (Agwu and Ibeabuchi, 2011).The coefficients for gender were negative and significant at 5% and 1% for probability of being market oriented and level of market orientation respectively. This implies that the females tend to increase their probability of being market oriented, level of market orientation and for all the farmers by 0.960%, 0.466% and 1.426% respectively compared to their male counterparts. Female headed households are more likely to be market oriented in sweetpotato production than the male-headed households, and this is in line with the findings of Arega *et al.*, (2007) who studied livestock markets in Kenya and Makhura *et al.,* (2001) in maize markets in South Africa. Having a female headed household increases a household's probability of selling its sweetpotato by a greater amount than due to other factors. This implies that women are more inclined to sell their sweetpotato than men, the result in contrast to the expected outcome, but possibly because women are better at bargaining than men. Female farmers also tend to experience lower transaction costs since they tend to have more credibility following the findings of Okoye *et al.,* (2016).

Conclusion

The study analyzed the determinants of market orientation among sweetpotato farmers in South Eastern, Nigeria. A number of variables were showed to affect market orientation in the study area which includes education, native of community, capital invested, distance from farm market, transportation cost, area of sweetpotato cultivated, farming and marketing experience and gender. Understanding the importance of market orientation towards commercialization and agricultural development is one step to help economies to get back on track and still maintain increased sweetpotato system A This would help to reach the goal and reducing the status of poor rural farmers. The study call for policies in measure es like: increasing farmer's access to farming land, credit, education, infrastructural amenities and encouraging women forum in sweetpotato production.

Abstract
The Study assessed on profitability of cassava production in Ido Local Government Area, Oyo State, Nigeria. It examined cost and returns to cassava production and also determined the factors affecting cassava production in the study area. Data were collected through the questionnaire and analyzed using. Budgetary analysis and Regression model. The results showed to the cost and return to cassava production, the total and Average variable cost is ₦ 27,316,500 and ₦23, 753,478.26, respectively. The total Gross margin and Gross margin per producer is ₦34,536,086.96 and ₦39,716,500 respectively. The Total net income and net income per marketer is ₦43,902,739,13 and ₦50488950 respectively. It is therefore concluded that cassava production in the study area is operating profitably and also material cost was found to have positive significant effect on the cassava production. It is recommended that Government should provide adequate capital inform of loans and subsidized farm input to the farmers to improve cassava production in the study area

Introduction
Cassava is believed to have originated in Northern Brazil and Central America. This popular crop is now grown in almost every tropical country. In Nigeria it was introduced to Warri (in the then Bendel State of Nigeria) by Portuguese explorers from the 16th to 17th century (Yakasai*et al* 2008). Since then Nigerians have accepted cassava as one of their main dish, because of its high demand both locally and internationally, its cultivation should be given more consideration now than ever before. Nigeria is an agrarian society with about 70 percent of over 140 million of her population engaged in agricultural production (CBN, 2006). Nigerian agricultural production is operated by large number of small producers with little capital, who produce more than 90 percent of the total food crops (CBN, 2004). Cassava is one major crop produced by the numerous small-scale farmers in Nigeria and its production has been increasing over the past two decades in terms of the area cultivated and the yield per hectare. The growth in cassava production has been primarily increased due to rapid population growth, large internal market demand complemented by the availability of high yielding improved varieties of cassava, a relatively well developed market infrastructure, the existence of improved processing technology and a well-developed internal market structure(Ajibefun and Daramola, 2003). Nigeria grows cassava more than any other country in the world with an annual production currently put at about 34 million metric tonnes per annum and the total area cultivated for the crop in 2003 was 3.1 million hectares with an average yield of about 11 tonnes per hectare (FAO, 2007). The total area cultivated has risen to 3.8 million hectares with an average of 11.84 metric tonnes per hectare in 2005 (FAO, 2002).The presidential initiative on cassava in Nigeria set in motion the process of achieving economic growth through cassava production. Stressing the influence of the presidential initiative on cassava in Nigeria, in 2005 it was observed that the trade promotion policy of the federal government has created a very strong domestic demand and market for cassava. The need to diversify and expand the uses of cassava such as production of ethanol, starch and livestock feed and household floor is said to be necessary so as to realize the benefits derivable from domestic markets and as raw materials for industries (Nweke, 2004). IITA (2004) noted that poverty reduction can be attained in Sub-Sahara Africa by improving the technical and economic efficiencies of food production in

crops such as cassava. The cash income from cassava proves more egalitarian than the other major staples because of cassava's low cash input cost (Nweke, 2003).

Methodology

The study was carried out in Ibadan atIdo Local Government Area of Oyo State. The sampling procedure involves two stages. The first stage were purposively selection of three wards out of the ten wards in Ido local government, in each of the three wards selected three villages were selected purposively due to the large population of cassava farmer in the areas. The villages include Akufo, Idigba, Araromi, Omi-Adio, Omi-Onigbagbo, Bakatari, Aba Eemo, Alako, Ilaju, making a total number of nine villages. A total number of 123 questionnaires were distributed among the small-scale cassava growing farmers. based on the population size of the cassava growing farmers in each ward, while 115 questionnaires were retrieved.

Results and Discussion

Costs and Returns of Cassava Production

S/n	Items	Price (₦)
1.	Total Variable Cost	27,316,500
2.	Average Variable Cost/Producer	237,534,782.6
3.	Total Fixed Cost	16,544,850
4.	Average Fixed Cost	143,868,260.9
5.	Gross Revenue	582,895,652.2
6.	Gross Revenue/Producer	67,033,000
7.	Gross Margin	345,360,869.6
8.	Gross Margin/producer	39,716,500
9.	Net Income	439,027,391.3
10.	Net income/Producer	50,488,150

Source: Field Survey, 2016

The summary of the cost and returns of the activities of cassava producer in the study area is shown in table above. The result shows that the Total and Average Variable Cost is ₦27,316,500and ₦237,534,782.6 respectively. The Gross Revenue and Revenue per producer is ₦ 582,895,652.2 and ₦67,033,000 respectively. The Total and Average Fixed Cost is ₦16,544,850 and ₦143,868,260.9 respectively. The Total Gross margin and Gross margin per producer is ₦345,360,869.6 and ₦39,716,500 respectively. The Total Net Income and Net Income per marketer is ₦439,027,391.3 and ₦50,488,150 respectively. Cassava production in the study area is thus operating profitably. This is agreement with work done by Muhammad *et al.,* (2012) on economics of improved and local varieties of cassava production.

Factors influencing cassava production

Model	Beta	Standard error	t-value	Sig.
Constant	-75541.714	102492.760	-0.737	0.462 NS
Gender	2529.247	33631.201	0.075	0.940 NS
Age	23913.457	26987.744	0.886	0.378 NS
Marital status	3153.931	28967.535	0.109	0.914 NS
Education	7014.339	27606.044	0.254	0.800 NS
Household	8147.895	17704.987	0.460	0.646 NS
Experience	-15549.196	18439.145	-0.843	0.401NS
Material cost	3.991	0.70	56.710	0.000*

Source: Field Survey, 2016
R^2 = 96%
Prob. (F-stat) - 0.05
* Significant at 5% level of probability
NS - Not significant at 5% level of probability

From the table above, it is shown that material cost as a positive influence on cassava production while age, gender, marital status, education and household size have no significant effect on cassava production in the study area. Adjusted R^2 of 96% however, indicates a good fit for the regression equation.

Conclusion and Recommendation

The results showed that the cassava production is profitable. This can be attributed to the value of the gross margin, gross revenue and net income of the cassava producer in the study area. Material cost was found to have positive significant effect on the cassava production. The following are recommendations based on the research findings:

Government should provide adequate capital, subsidized farm input, modern storage facilities, effective extension service, good road network for free access, available market and implement favourable policies for the farmers to increase cassava production

Abstract
The study examined the profitability of Irish potato farmers in Plateau State. A cross-sectional survey of 80 farmers selected through a multistage sampling effort was done and descriptive statistics and gross margin tool were employed in the data analysis. The study revealed that 62.50% of Irish potato farmers were in the age bracket of 36-45 years and both male and female engaged in Irish potato production in the area. Majority (53.8%) of the farmers were married with mean household size of 9 members. Majority (86.2%) of Irish potato farmers in the area attended school. The production of the crop was found to be profitable with a mean income of ₦48, 400 per ha and returns on investment (ROI) of ₦1.34. The constraints that limit productivity of the farmers were potato blight disease, high input costs and poor infrastructures. The study therefore recommended that policy makers and all stakeholders in the Irish potato value chain should device motivational package that will encourage youths to participate in farming and also more extension specialists should be recruited and trained to guide farmers on the recommended practices of Irish potato production as well as management of diseases for better and improved output.

Keywords: Income, Blight, ROI, Policy

Introduction
Irish Potato (*Solanum tuberosum*), is an important commodity to farmers, traders, and consumers. It is grown to supplement staple crops particularly the cereal crops and also add to the household economy through increased income to farmers. It was first domesticated in the Andes Mountains of South America (IPC, 2015). Irish potato requires an optimum temperature of 15^{o}C for tuber formation (NRCRI, 2015). The crop is a temperate region crop which requires cool climatic conditions to grow. It grows well in temperatures between 15^{0}C to 25^{0}C and high day temperature of 20-25^{0}C is good for vegetative growth while 15-20^{0}C night temperature is good for tuber formation. Tuber formation stops totally when the temperature goes above 30^{0}C (Agriinfo, 2015).

According to FAO (2007), the world three largest producers of potato are China (72,040,000 tons), Russia (36,784,200 tons) and India (26,280,000 tons), incidentally some of the most densely populated countries on earth. In Africa, a total of 1,541,498 ha of land is cultivated annually, producing about 16,706,573 tonnes of potato with an average of 10 tonnes/ha (FAO, 2007).

The enterprise is facing a lot of threat, which includes problem of late potato blight coupled with the ever-increasing cost of procuring inputs and poor marketing of tubers has, to a great extent, limit farmer's productivity. Therefore, this study is designed to determine the income of Irish potato farmers in Plateau state and also describe the socioeconomic characteristics and the constraints faced by farmers therein.

Methodology
Plateau State is located in the North Central geopolitical zone of Nigeria. The State has a land area of 30,913 km^2 with a projected 2018 population of 4,206,969 base on the 2.6% annual growth rate of 2016. The State is about 1230m above sea level, with about 1400mm of annual rainfall which spans from April to October (NRCRI, 2015). The climatic condition of the State is suitable for potato production because they meet the required 15^{0}C for tuber formation. Other crops produced in

these areas include tomato, cabbage, carrots, lettuce, cucumber, green beans and onions. Cereal crops such as maize sorghum and millet are also grown in the area. Over 80% of the potatoes are produced as a sole crop during the dry season and in mixtures during the rainy season.

Sampling Procedure

Plateau State is made up of 17 Local Government Areas (LGAs), and 9 LGAs are known for Irish potato production. Pankshin LGA was conveniently selected because it is safe in terms of security and research could be conducted without exposing the researcher to the frequent ethnic crisis in the State. The villages of Fier, Mile 8, Bwarak, and Tambes were selected purposively because they are among the Irish potato producing sites in Pankshin LGA. Finally a systematic random sampling was used to select 80 Irish potato farmers from the various villages (20 from each village).

Data Collection

Data for the research was collected from primary source through oral interview using structured questionnaire. The data were collected by trained enumerators while the researcher supervised the data collection process.

Tools of Analysis:

Descriptive statistics (such as frequencies and percentages) and Gross Margin Analysis were employed in data analysis: The Gross Margin model is given by $GM = GR - TVC$

Where;

GM = Gross Margin (₦/Ha)

GR = Gross Revenue (Gross Sales) = Total output (kg/ha) x Unit Price (₦/Kg)

TVC = Total Variable Cost (sum total of all costs of buying variable items such as seeds, fertilizer, agrochemicals, labour etc.)

The ratios used to further ascertain the enterprise profitability are;

Gross Ratio: This is given by;

$G.R = \frac{TVC}{GI}$ Where; G. R = Gross ratio TVC = Total variable cost

GI = Gross Income given by; GI = Total Irish Potato Output (kg) x Unit Price (₦/kg)

It shows the proportion of the gross income that goes to pay for the operating costs.

Return on Capital Investment: This is the amount that every capital (Naira) invested will pay back after been committed in a production or business cycle. It is given as;

$ROI = \frac{GI}{TVC}$

Where; ROI = Returns on investment GI = Gross Income (₦) TVC = Total Variable Cost (₦)

This shows the returning power of every naira invested and they altogether determine whether a farmer remains or is removed out of business.

Results and Discussion

The majority (62.5%) of the farmers were male and 37.50% were females. The mean age of Irish potato farmers was 40 years with the majority (62.50%) of the farmers in the 36-45 age group and the least (3.8%) belonging to the 56-65 age group. Majority (53.8%) of the farmers were married followed by the widowed with 22.5% and only 11.3% were found to be divorced. The mean household size was 8 with a larger portion (52.9%) belonging to the 7-10 members. A mean land size of 2.6ha was cultivated by Irish potato farmers, a larger proportion (42.5%) cultivated between 0.1-1.0ha of land, while 22.50% cultivate between 1.1-2.0ha of land. Majority (50.0%) of the farmers had farming experience of 1-10 years. Forty percent (48.00%) attended post-secondary education followed by 18.8% with secondary school education and the least (13.8%) with no formal education. Among the benefits drawn from association membership, over 59.3% benefits through training, 28.8% with production inputs and 11.9% through Loan/Credit.

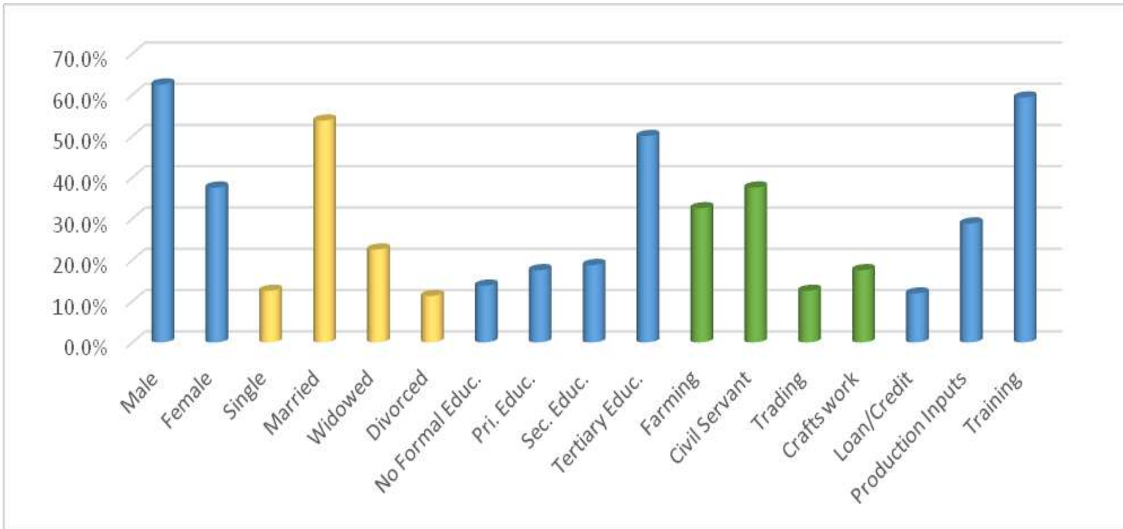

Fig. 1: Qualitative Socioeconomic Characteristics of Irish Potato Farmers
Source: Field Survey, 2017

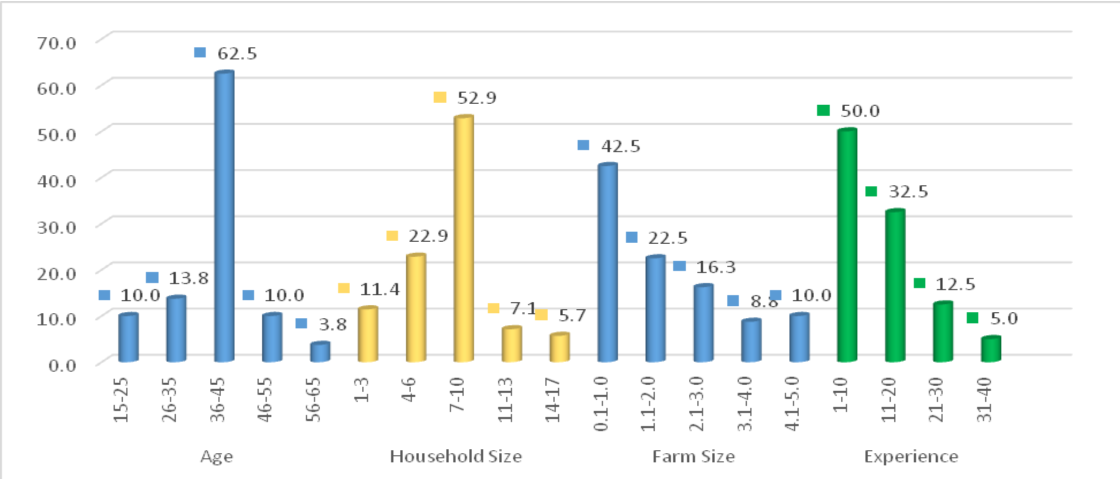

Fig. 2: Quantitative Socioeconomic Characteristics of Irish Potato Farmers
Source: Field Survey, 2017

Table 1 shows that over 29.9% of the total cost of Irish potato production was spent on seed procurement, 25.4% on labour cost, 18.7% spent on purchase of agrochemicals, 18.3% on fertilizer purchase, 4.2% as transportation costs, 1.90% spent on purchase of organic manure and 1.6% for bag costs. A mean gross margin of the farmers was ₦48, 400 per hectare, the returns on every naira invested was 1.34 and a gross ratio of 0.61.
The finding of this study agrees with the results of Jwanya (2014) and Ayodele (2005) where both reported that Irish potato was a profitable venture and that the costs of seeds, labour and fertilizers were the major costs of Irish potato production and hence were the most demanding variable items for the crop in question.

Table 1: Costs and Returns Analysis

Variable Inputs (₦/Ha)	Cost(₦/Ha)	%
Seeds	42,460	29.87
Fertilizer	26,041	18.32
Organic fertilizer	2,656	1.87
Agrochemicals	26,631	18.74
Labour	36,137	25.42
Transportation Costs	5,941	4.18
Cost of bags	2,270	1.60
Total output (kg/Ha)	934	
Unit Price (₦/kg)	204	
Gross Income	190,536	
Total Costs	142,136	
Gross Margin	48,400	
ROI	1.34	
OR	0.75	

Field Survey, 2017

Figure 3 shows the constraints to Irish potato production in the study area. The common problems limiting Irish potato production were potato blight disease (100%), high input costs (100%) and poor infrastructures (83.8%). Other constraints were inadequate credit facility, limited contact with extension agents and poor pricing as reported by 47.5%, 26.3% and 25.0% respectively.

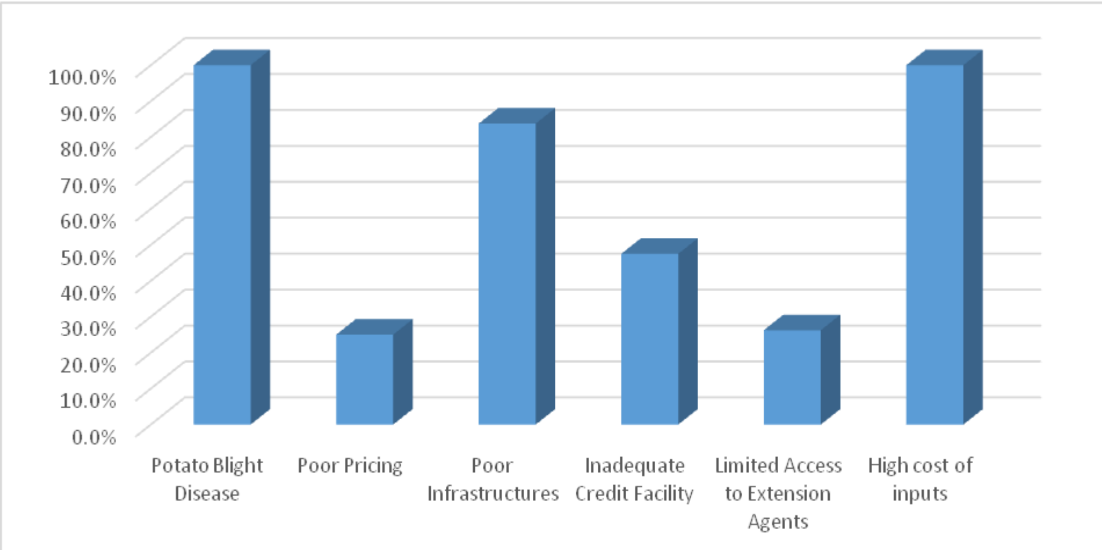

Fig. 3: Constraints Faced by Irish Potato Farmers
Field Survey, 2017

Conclusion and Recommendations

The study described the socioeconomic characteristics of potato farmers, determined the gross margin and constraints of Irish potato production in Plateau state. The study revealed that Irish potato production is a profitable enterprise though farmers are challenged with blight disease, high input costs and poor state of infrastructures. Hence, the study made the following recommendations:

i. There is need for both government and research institutes and all related stakeholders to come up with policies and other motivational package that will awaken the interest of youths to partake in Irish potato farming as a business.
ii. More extension specialists should be recruited and the ones on ground be retrained on how to guide and feed farmers with updated facts about Irish potato production and also on how to counter the deadly blight disease of potato.

iii. Also, efforts should be made to see that group formation among farmers becomes common as this will help them have a mouth on the prices offered and also will be able to counter against all problems that might claim difficult to be addressed individually.

Abstract
This paper examined vegetables and spices research in Nigeria as contained in the publications of Agricultural Society of Nigeria (ASN) conference proceedings (2007 – 2016). The number of technical and symposium papers was compiled, while papers pertaining to vegetables and spices were also determined as present in a total paper per volume. The findings revealed that total of 2,651 technical papers were presented during the period of study and a total of 131 and 65 papers were presented on vegetables and spices, representing 4.94% and 2.45%, respectively. Findings revealed that University had the highest contributors (4.38%), while Colleges of Education had the least (0.036%) contributors. National Root Crop Research Institute, Umudike and Ahmadu Bello University, Zaria had the highest contributors of 42 and 18, respectively. ASN conference of 2016 had the highest contributors on vegetable and spice crops. There was low frequency of publications pertaining to vegetable and spice crops compared to other aspect of production. Capacity building of appropriate personnel to steer the much-needed development in the research on these crops is imperative and is advocated.

Introduction
Vegetables are soft edible plant or plant products such as leaves, petioles, stems, inflorescences and fruits (Balogun *et al*, 2009) and roots. They are herbaceous plant species with various morphological utilized parts. Many types of vegetables grown for their nutritional values in Nigeria include leafy, fruits and root vegetables. According to Ogunniyan and Akinfosoya (2007), vegetables are those horticultural food crops which are not desert fruits, dry pulses, nuts, herbs or large starch crops. They are edible fresh non – toxic succulent plant parts (fruits and leaves) that can be eaten raw or cooked with or without other ingredient. They serve as food for growth and development, and as socio-economic product serving aesthetic and other satisfactory functions. Vegetables are rich in vitamins and minerals and constitute one of the very indispensable items of Nigerian kitchen.

Spices on the other hand, are products from plant seeds, fruits flowers, roots or rhizomes, leaves or bark that are added to food to improve flavor, taste, colour or act to minimize the rate of rancidity and as preservative that suppresses microbial activities. Spices possess phytonutrients, essential oils, anti-oxidants, minerals and vitamins that are essentials for overall wellness of both adults and children (Thomas, 2007, Teye *et al*, 2013). Research have shown that spices such as fenugreek seeds, garlic, onion, turmeric, ginger, mustard, curry leaves and coriander possess potential anti-diabetic agents (Asif, 2011; Xinyan *et al*., 2017; Yahaya *et al*., 2010; Schippers, 2000. Studies have shown that there are diverse plants in Nigeria known as vegetables (Denton and Olafolaji, 2000), but many are not widely utilized and many of these vegetables and spices consumed locally in Nigeria are not reported or documented. The need for relevant and reliable information on identification, evaluation, propagation, production, utilization and patent right issue of Nigerian rich vegetable and spice plants bio-resources however, can only be created through scientific research investigations on these species, apart from indigenous knowledge about their management and conservation in the various localities of natural distribution and adaptation. In a bid to examine how the country's agricultural professionals had fared to harness the great potentials of vegetables and spices, to contribute to national health scheme, socio-economic growth and development, the study was conducted.

Materials and Methods

Information about vegetables and spices research inputs and nature of research were obtained from 10 volumes conference proceedings of ASN across 10 years period that took place in different host cities in Nigeria. Articles published on vegetable and spice crops in the conference proceedings were analyzed. Data collected from the articles included author's affiliation, distribution of articles based on institutional type, vegetable and spice crops whose research involved in-depth study and reports, or mentioned in the survey report were noted.

Results and Discussion

Entries in Table 1 showed that ten cities across Nigeria geo-political zones hosted the ASN annual conference at different times between 2007 and 2016, of which Abuja hosted two times during the period. A total of 2,651 scientific papers were presented in ASN conferences over the years in review. Result showed that between 2007 and 2016 4.94% and 2.45% of the papers dealt with vegetables and spices respectively.

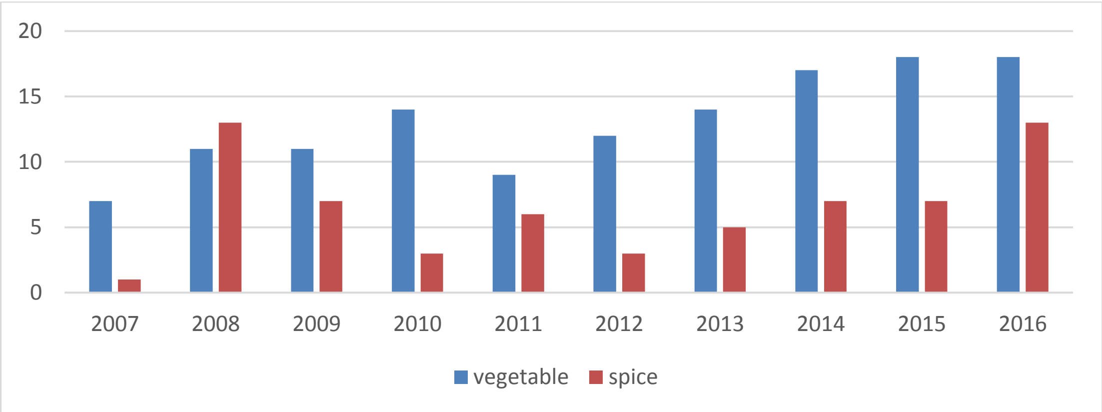

Fig. 1: Vegetable and Spice crops published in ASN Conference Proceedings in ten years

This indicated that vegetables and spices despite its benefits are being ignored in research. There is the need for more research to be carried out on these important horticultural crops. Table 2 shows that the family of Solanaceae recorded the highest researched crop family (5), followed by Cucurbitaceae (3). Crop species of *Abelmoschus esculentus* recorded the highest specie, followed by *Zinger officinale* (300 and *Telfairia occidentalis* (29), while *Lepidium sativum* had the least representation of 1 specie.

Table 2: List of Researched Horticultural Crops Reported in 10 Years ASN Conference Proceedings (2007 – 2016)

Family	Crop Specie	Number of occurrences
Alliaceae (2)	*Allium cepa*	7
	Allium sativum	5
Amaranthaceae (1)	*Amsranthus spp.*	10
Asteraceae (1)	*Veronmia amygdalina*	2
Brassicaceae (1)	*Lepidium sativum*	1
Cucurbitaceae (3)	*Cucumis sativum*	16
	Telfairia occidentalis	29
	Cucurbita pepo	2
Crucifera (1)	*Brassica oleracea*	2
Labiatae (1)	*Ocimum viride*	2
Malvaceae (2)	*Abelmoschus esculentus*	44
	Hibiscus sabdariffa	3
Portulacaceae (1)	*Talinum tringulare*	5
Solanaceae (5)	*Lycopersicon esculentum*	17
	Solanum melongena	8
	Capsicum frutescens	5
	Trichosanthus cucumerina	2
	Capsicum annum	2
Umbelliferae (1)	*Daucus carota*	2
Zingiberaceae (2)	*Zinger officinale*	30
	Curcuma longa	2
12 families	**22 species**	**196**

Figure 2 shows that Universities in Nigeria had the largest representation in the study (4.38%), followed by Research Institutions (2.19%), and followed by Colleges of Agriculture (1.36%). The Polytechnics and Colleges of Education had 0.34% and 0.03%, respectively. The increase in the number of research work on vegetables and spices from the Universities and Research Institutions and Colleges of Agriculture could be attributed to their wide scope of agricultural related courses offered as well as their mandates.

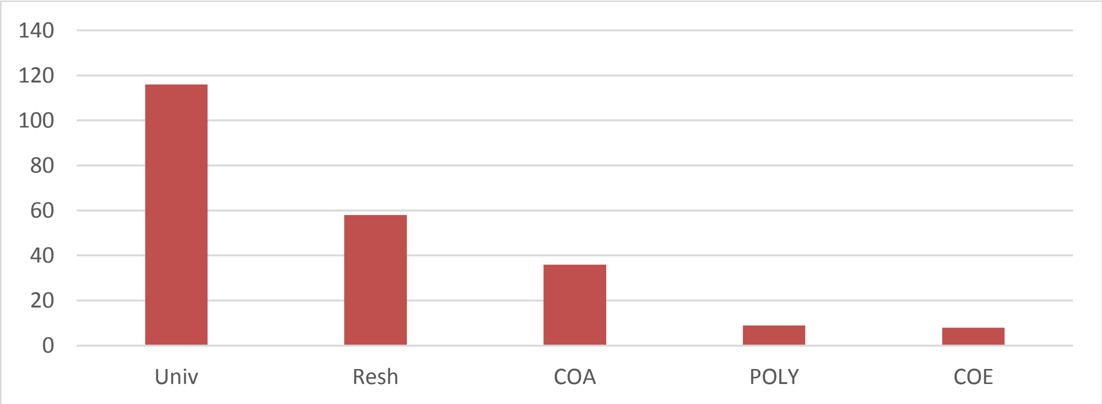

Fig. 2: Vegetable and Spice Crops Published in ASN Conference Proceedings in 10 years by Institutions

Conclusion

This paper examined vegetables and spices research in Nigeria as exemplified in Agricultural Society of Nigeria (ASN) conference Proceedings in a decade publications. There was disproportionate low frequency of publications pertaining to vegetable and spice crops in relation to other aspects of agricultural production. Author's affiliation revealed that Universities in Nigeria have the highest contributions, followed by Research Institutes. Large numbers of research publications within the period were during 2015 and 2016 ASN conferences only. Capacity building of appropriate personnel to steer the much needed development in the industry is imperative and advocated.

ASN 52nd Annual Conference Proceedings

Comparative Analysis of Profitability of Cassava Production in Southern Nigeria

H.N. Anyaegbunam, I.I. Okonkwo, I.N. Nwokocha, and G.N. Asumugha
Extension Services Programme, National Root Crops Research Institute Umudike, Abia State, Nigeria
Email: helenkol8@yahoo.com, hnanyaegbunam@gmail.com

Abstract
The study compared the profitability of cassava production in different cassava producing states of Nigeria namely Anambra, Ebonyi and Ogun States as first set. Others were Benue, Taraba and Niger States as second set. Primary data used were collected from ninety cassava farmers under International Fund for Agricultural Development (IFAD) with the aid of structured questionnaire. The data were analyzed using profitability and Duncan test models. The results indicated that cassava production is more profitable in second set of States – Benue, Taraba and Niger than in the first. The result further showed no significant difference among Anambra, Ebonyi, Taraba and Ogun, but showed significant difference among Ebonyi, Taraba, Ogun and Niger at 10% and also among Taraba, Ogun, Niger and Benue at 10% levels. It was concluded that cassava production in Nigeria is a profitable venture but labour cost is the major challenge facing the farmers.

Introduction
According to Onyemauwa (2010), cassava has the potential to increase farm incomes, reduce rural and urban poverty and help close the food gap. As a cash crop, cassava generates cash income for the largest number of households, in comparison with other staples, contributing positively to poverty alleviation (Obisesan, 2012). Reports have shown that a higher proportion of cassava farmers, in Nigeria get a higher income from its production more than they get from most of other major staples (Ezeibe, *et al.,* 2015). Okonkwo, *et al*. (2016) noted that cassava would yield higher revenue if cassava farmers are encouraged in areas like loan and credit facilities. Cassava is reported to be grown in 24 of the country's 36 States, but dominates in the southern part of the country, both in terms of area covered and number of farmers growing the crop (Okonkwo and Nwaru 2017). The crop's ability to provide a stable food base and thrive in different parts of the country is a function of its flexibility in terms of planting and harvesting strategies and because of its relative tolerance to poor soil and pests/diseases problems. However, the profit base of cassava farmers would be attributed to different market forces and price differentiation of cassava and its products in different location of the country. Therefore, this study focused on comparing the profitability of cassava production in some selected States of the southern part Nigeria

Methodology
The study was purposively carried out in Anambra, Ebonyi, Ogun, because they are among the six cassava-producing States under the Federal Government of Nigeria (FGN) / International Fund for Agricultural Development (IFAD) and also selected for cassava value chains for sustainable Agriculture. A multi stage random sampling technique was employed in the selection of LGAs and respondents within these States. Eighteen (18) Local Government Areas (LGAs) were selected for the study and from the LGAs, 45 cooperative societies were selected and from each of the cooperatives, one farmer was chosen. Data were collected from the selected farmers with the help of structured questionnaire and this was based on the costs and returns of cassava production. Profitability analysis was analyzed using net income analytical model while the profitability result of each of the States was compared using Duncan multiple range test model.
The models are derived mathematically as follows:

Net Income (NI) = Total Revenue (TR) – Total Cost (TC)
where
TR = cassava output x price in Naira
TC = Total Variable Cost (TVC) + Total Fixed Cost (TFC)

Duncan multiple range test model is as follows:
$DMRp = Qp\sqrt{MSE} / r$
where
DMRp = Duncan Multiple Range
Qp = Shortest Significant range
$\sqrt{MSE}$ = Mean Square Error
r = Number of states
The depreciation method used was the straight line method, which is: (Price of product – Salvage value of product) / Life span of the product. However, it was assumed in this report that the salvage value of the farm tools is zero, since most of the farm tools may not have any useful value after its useful life. This is in line with Dillivan (2014).

Results and Discussion

Profitability Results for One Hectare of Cassava Production in Anambra, Ebonyi and Ogun States

Table 1 shows the estimated profitability results of one hectare of cassava production. The pooled result shows that total cost for the production of one hectare of cassava in the Southern Nigeria was ₦312, 672.82 while the total revenue from the hectare of cassava was ₦487, 288.89. This shows that if a total of ₦312, 672.82 is spent in producing one hectare of cassava, a net income (profit) of ₦174, 616.07 would be realized and this suggests that cassava production in the region is profitable. This agrees with Okonkwo and Nwaru, (2017) who noted that cassava production is profitable to both male and female farmers. Also Obisesan, (2012) noted that cassava as a cash crop, cassava generates cash income for the largest number of households, in comparison to other staples hence contributing positively to poverty alleviation.

Table 1: Estimated Profitability per Hectare of Cassava Production

Source: FGN/VCDP/IFAD, 2017 Survey.

Furthermore Ezeibe, *et al.,* (2015) reported that higher proportion of cassava farmers in Nigeria get a higher income from cassava production than they get from most other major staples. However from the result, high cost of planting material (14.67%) and land acquisition (12.86%) were the major challenges facing the production of cassava in the region. The high cost of planting material and land is an indication that they are in short supply. The scarcity of planting material could be attributed to the infestation of cattle into cassava farm as at the time of the study or that majority of people are now into cassava farming due to the economic recession in Nigeria.
The result indicates that a one Naira invested on cassava production in Anambra and Ebonyi States would yield N0.12 and N0.42 respectively. This is an indication that farmers in Anambra and Ebonyi have low return on investment unlike farmers in Ogun State who could earn N1.04 for every one Naira invested on cassava production. This could mean that there is strong market outlet in Ogun State than Anambra and Ebonyi States. Generally, the pooled result indicated that cassava production would yield N1.79 for every one Naira invested on cassava production in the area under study. This implies that cassava production has the capacity to increase farmers' income and also reduce poverty. According to Onyemauwa, (2010) cassava has the potential to increase farm incomes and reduce rural and urban poverty.
Table 2 shows the comparative results for the profitability of cassava production for the three States in under study.
From the Table, Anambra is not significant different to Ebonyi, and Ogun States while Ebonyi is significantly different at 10% level to Ogun State. The implication of the results is that there are differences in the profitability levels across the States, perhaps due to differences in management decision on sale, level of investment and the use of innovation. The results conform to the earlier study by (Alsyouf, 2004).

Table 2: Duncan Test Analysis

States	Net Income
Anambra	172071.428
Ebonyi	358875.0000
Ogun	700750.0000
p-value of Duncan multiple test analysis	**0.203**

Summary and Conclusion

Cassava production in Nigeria is a profitable venture and that labour cost gives the highest cost incurred by farmers in production. The foregoing, therefore suggested that cassava production in the study areas is a profitable venture that needs to be developed and built upon in Nigeria quest to be food secured and to alleviate rural poverty through cassava seed multiplication. This conforms to earlier studies of Zakari *et al* (2016), Enimu *et al* (2016), Okoh (2016) and Toluwase and Abdu-raheem (2013).

Constraints Militating Against the Supply of Cocoyam to Consumers in Umuahia North LGA of Abia State

Mgbeahuru C.C, Anyaegbunam, H.N. and Nwokocha I.N.
Farming Systems Research Programme, National Root Crops Research Institute, Umudike.
PMB 7006 Umuahia, Abia State

Abstract

This study was conducted in Umuahia North Local Government Area of Abia State which is noted for farming and trading of cocoyam. Purposive sampling technique was used in selecting Oriendu and Nkwoegwu communities for the study because of high production of cocoyam in the communities. About 30 respondents were selected randomly from each of the communities. Structured questionnaire was used in data collection and data were 96nalysed using descriptive statistics such as frequency distribution, percentage and mean. From the result obtained, female farmers dominate male farmers in cocoyam supply, and farmers within the age range between 40-51 years had the highest percentage in the supply of cocoyam in the study area. The result also showed that 80% of the respondents had formal education. Constraints encountered by the respondents were mainly lack of fund (22.98%) followed closely by lack of access to land (19.70%). This is expected because women are mostly involved in cocoyam production. Polices should be advocated in the areas of granting soft loans to the women to rent land to increase cocoyam production in the study area since lack of land is also one of the major challenges faced by the respondents.

Introduction

Cocoyam (*Xanthosomana maffafa* and *Colcocasia esculanta*) is one of the major tuber crops in which Nigeria is the largest producer in the world, producing about 5.39 million metric tons per annum (FAO, 2008 and 2009). Nigeria accounts for an average production figure of 37 percent of total world output of cocoyam, but the average production rate is still low. Two major species of cocoyam, cultivated in Nigeria are *Xanthosoma maffafa* and *Colcocasia esculanta*. The production of cocoyam in Nigeria however, had stagnated in the last few decades due to several production constraints among which are various pre-harvest and postharvest challenges (Nwakor *et al;* 2015). The average yield has remained relatively low ranging between 5.0 and 7.5 tons/ha in Nigeria. The discrepancy is a clear indication the current yield of cocoyam is currently far below its potential yield of 15-20 tons per hectare in farmers field (Onyeka, 2014). There is problem of diseases including the taro, leaf blight caused by fungi *phytophoraclocasine*. The cultivation of cocoyam in most African countries including Nigeria is essentially in the hands of resource poor farmers with minimum input (NRCRI, 2011). Okoye *et al*. (2009) established that cocoyam have yield potential of 30-60 tons per hectare which indicates that there is much room for improvement on the farmers output through research and development of the crop. Cocoyam is grown extensively in the eastern States but it does best in places with high humidity, good water supply and good soil throughout the growing period (Okereke *et al*, 2009). Before the civil war, Imo State was the largest producer of cocoyam in South-eastern Nigeria, but now the output of this crop has declined (Eze and Okorji, 2003). The management practices of the past are no longer in use in the cocoyam growing communities as supposed, due to emphasis on modern agriculture, yet the output decline of cocoyam has continued to decline in the face of modern technologies. High cost of labour, poor extension of modern agricultural technologies and many other factors may have contributed to the poor output of cocoyam in the recent years. The demand for cocoyam has continued to increase with increase in population. In spite of considerable increase in hectare cultivation of the crop so as to increase the output, yet the poor average yield of about 170,000 tons per annum continue to prevail (Ohajianya, 2005). It was against the background that it becomes imperative to assess constraints militating against the supply of cocoyam to consumers in Umuahia North Local Government Area of Abia State.

Methodology

This study was conducted in Umuahia North Local Government Area of Abia State which is noted for farming and trading of cocoyam. Purposive sampling technique was used in selecting Oriendu and Nkwoegwu communities for the study because of high production of cocoyam in the communities. Thirty respondents were selected randomly from each of the communities. Structured questionnaire was used in data collection from primary source and data were analyzed using descriptive statistics such as frequency distribution, percentage and mean.

Results and Discussion

Socioeconomic Characteristics of the Respondents

The results in table 1 show the socioeconomic characteristics of the respondents. It indicates that there were more females (76.7%) than males in cocoyam production than males. Women are the custodian of cocoyam farming in most African countries, thus improving cocoyam production should have a direct impact on the most economically vulnerable groups (Onyeka, 2014).

Table 1: Socioeconomic Characteristics of the Respondents

Variables	Frequency	Percentages
Sex		
Females	46	76.7
Male	14	23.3
Total	60	100
Age		
21-30	2	3.3
31-40	10	6.7
41-50	28	46.7
51-60	14	23
71 and above	4	6.7
Total	60	100
Marital Status		
Married	40	66.7
Widowed	15	25
Single	5	8.3
Total	60	100
Religion		
Christianity	57	95
Traditional	3	5
Total	60	100
Level of education		
No education	15	25
Primary education	25	41.7
Secondary	16	26.7
Above secondary	4	6.7
Total	60	100
Household size		
1-4	6	10
5-8	40	66.7
9-12	12	20
13 and above	2	3.3
Total	60	100

Source: Field survey, 2014.

Most of the respondents were married (66.7%) while (95%) were Christians. About 42% had basic education. The result also showed that 47% of the respondents were within age range of 41-50 years which implies that the respondents were within the productive and active age. Majority

(81.7%) of the respondents were literates. This agrees with the findings of Agbanu and Atoma (2010) that level of education influences participation in agricultural productive activities, adoption Transfer and application of innovations.

Problems Faced by Cocoyam Producers in the Study Area

Table 2 shows the constraints encountered by the respondents. The most common problem was lack of fund (22.98%), followed by access to land (19.70%). This is expected because women are mostly involved in cocoyam production. Some areas in the South east, women do not have access to land. Other constraints were high cost of fertilizer (16.50%), lack of extension contact (14.89%), pest and diseases (13.59%) and bad road network (6.79%). The least constraint is high cost of labour (5.59).

Table 2: Problems faced by cocoyam producers in the study area

Constraints	Frequency	Percentage
Lack of fund	71	22.98
Lack of access to land	61	19.70
High cost of fertilizer	51	16.50
Lack of Extension contact	46	14.89
pest and Diseases attack	42	13.59
Bad road network	21	6.79
High cost of labour	17	5.59

Source: Field survey, 2014
*Multiple responses accounted for this number

Conclusion

The study revealed that more women are involved in cocoyam production that fall within active production age. The respondents (cocoyam farmers) are constrained by many factors which include lack of fund and land among others. Polices should be advocated in the areas of granting soft loans to the women to rent land to increase cocoyam production in the study area since lack of land is also one of the major challenges faced by the respondents.

Consumers' Willingness to pay for the Primary Products of Maize in Aba Agricultural Zone of Abia State, Nigeria

S.I. Ogbonna[1] and C.O. Emerole[2]
[1]Department of Agricultural Economics and Extension, National Open University of Nigeria
[2]Department of Agricultural Economics and Extension, Abia State University, Uturu- Nigeria
Corresponding author: E-mail: ogbonna101@gmail .com

Abstract
The study analysed varieties and primary products of maize supplied, and willingness of consumers to pay for them in Aba Agricultural zone of Abia State, Nigeria. The specific objectives include to identify the varieties and primary products of maize supplied to consumers in Aba Agricultural zone of Abia State; estimate consumers' willingness to pay for maize; and determine factors that influenced demand for maize in the study area. Data generated from survey of consuming stakeholders were subjected to descriptive analysis, consumer willingness to pay estimation and probit regression analyses. The demand for maize was influenced by size of household, number of feed millers in the area, and price of rice (close substitute to maize). There was good market for maize as consumers on the average were willing to pay a price not more than ₦125.00 per kilogramme weight. We recommended that traders should supply more maize and local farmers increase own production to help bring down maize price and further enhance it.

Key Words: Maize, own production, willingness to pay, demand

Introduction
Maize (*Zea mays, L.*) is the most important commercial cereal in the World after wheat and rice on which many agro-based industries depend for raw material (Iken and Amusa, 2004). Different varieties of maize with unique grain structures and colours are supplied in local markets and are purchased by processors and consumers for food, livestock feed and other industrial uses. Matured green maize are cut fresh on the cobs and sold to consumers who eat them as roasted, parched, baked, or boiled nutritious delicacies that help in quenching hunger. Maize is rich in carbohydrate (80.0%), protein (10.0%), fibre (3.5%), minerals (2.5%) and vitamin B and oil (4.0%) on dry weight (IITA, 2001).The primary products of maize include pap, flour, moimoi; *agidi* and popcorn consumed as food or used as raw material in pharmaceuticals.

A consumers' willingness to pay for a commodity shows the monetary value he attaches to the commodity. His willingness to pay for one more unit of the commodity actually is the monetary measure (naira or dollar) of the benefits the extra unit of the commodity gives him. This otherwise is the marginal benefit derivable from the commodity. It gives a guide that could help estimate actual commodity price in the market. This price of the commodity will be at a point somewhere between the buyer's willingness to pay and trader's willingness to accept. For maize, it is a maximum price at or below which maize consumers definitely will buy one unit of maize package. Consuming households, individuals, processors and even farmers who buy maize as planting material make effective demand for it and its primary products (Nwaigbo, 2011). They all need to be supplied with adequate stock of maize according to their choice in our local markets within determinable range of prices. To achieve this, it becomes imperative to specifically: (i) identify varieties, forms and primary products demanded by consumers in Aba Agricultural zone of Abia State;(ii) estimate consumers' willingness to pay for maize in the area; and (iv) determine factors that influence demand for maize in the study area.

Materials and Methods

This Study was carried out in Aba agricultural zone of Abia State Nigeria. Aba Agricultural zone is one of the three agricultural zones in Abia State. The constituent LGAs of the zone are Aba North, Aba South, Ugwu-na gbo, Ukwa East and Ukwa West. Amongst these LGAs, Ukwa West and Ukwa East are essentially rural and agrarian with the other three being cosmopolitan and host many industries, households and individuals consume maize and its primary products.

Stratified random sampling was used in selecting respondents. The respondents were from the strata of housewives, street buyers, feed millers/industrialists and farmers. Four respondents on each of the four strata were chosen at random from each of the five constituent LGAs. This gave a sample of 80 maize users involved in this study.
Data were collected on variety/form of maize and primary products demanded by buyers (green cobs, roasted and dry cobs/maize grains, pap (*akamu*), and *agidi*). The data collected were presented descriptively in a frequency distribution Table. The demand factors for maize were estimated with the following Probit regression demand model:

$$Y= \alpha + \beta_1 X + \beta_2 B + \varepsilon \quad (1)$$

Where
Y= Bought maize (yes=1), did not buy maize (no=0);
B = Bid price or Price of a unit form (fresh/dried cob/grain) of maize bought (₦);
X_1= Price of one Kg of rice as close substitute (₦);
X_2= Household size (number);
X_3= Number of livestock feed industries known around by respondent (number);
X_4= Monthly income used for maize/product(s) purchases (₦'000);
εi= Error term.

Mean Willingness to Pay (MWTP) was derived from the expression $((\sum(\beta_1 * X^a)/\beta_2)^{*}\text{-}1 \quad (2)$
X^a = Mean value of the X variables

It is true that maize is a commodity traded at a price, but veracity of its forms and products and the fact that farmers in the area consume much of own products, necessitates that we estimate its economic value. The willingness to pay was thus estimated with model of consumer willingness to pay.

Results and Discussion

Maize Varieties and Primary Products Purchased

Table 1 shows maize varieties/forms and primary products of maize by types of buyers in Aba Agricultural zone of Abia state Nigeria. The Table revealed that respondents consumed maize in fresh green cobs; dry white cobs; dry yellow cobs; roasted, boiled, or as prepared into pap, flour, moi-moi; *agidi* and popcorn by housewives (25.0%), farmers (25.0%) and street buyers (35.0%). These consumers and members of their households ate maize to derive from the rich vitamin A, C and E, carbohydrates, dietary fibre, sulphur amino acid, and about 9.0% protein present in it(IITA, 2001; Khawar *et al.* 2007).Farmer consumers of maize feed on the maize and use the carefully selected viable seeds as planting material on their plots. The millers/livestock feed producers constituted 15.0% of the maize buyers who bought maize mainly as whole yellow grains, flake grits, and flour. The maize grits are the larger pieces of broken maize endosperms freed of husk and germ which they used as feed stuff.

Table 1: Distribution of Maize varieties/forms and primary products of maize by types of Buyers in Aba Agricultural zone of Abia state Nigeria

Type of Maize Buyer	Variety/Form/Primary Product of Maize bought	Number of Buyers	Percentage
Housewives	Green cobs; dry white cobs; dry yellow cobs; pap, flour, moi-moi; pop corn, *agidi*,	20	25.0
Street buyers	Roasted maize cobs; boiled maize cobs, Pap, flour, moi-moi, pop corn, *agidi*,	28	35.0
Feed millers/ industrialists	Whole yellow grains, Isolo (yellow), Ns-1 (yellow), Western yellow 1096BP6 (yellow), flake grits, and flour.	12	15.0
Farmers	Whole grains, dry cobs, pap, flour, moi-moi, pop corn, *agidi*, Bende local (white), TZPB (white), TZB (white)	20	25.0
Total		**80**	**100.0**

Source: Field Survey, 2016.

Willingness to Pay for Maize

The consumer's willingness to pay for one unit of maize is his derivable marginal benefit from the commodity. Willingness to pay and Marginal benefit are thus the same and can thus to be used interchangeably. Precisely, the willingness to pay is the maximum amount of money an individual is willing to hand over to procure a product or avoid something undesirable (Table 2.0). The Table shows that maize consumers in the study area were willing to pay any price less than ₦125.00 per kilogramme since the mean WTP was ₦124.460.00.

Table 2: Probit estimates of determinants of consumers' willingness to Pay (WTP) for Maize

Variable	Coefficient	Mean	Coefficient * Mean
Mean price of maize forms (B)	-0.7023		
Unit (kg) price of rice	0.0322	147.215	4.740323
Household Size	0.8571	7.211	6.1805481
Number of known feed Industries/millers	4.112	5.612	23.076544
Income spent on Maize	0.005	4,200.00	21.000
Constant	32.411		32.411
Total			**87.4084151**

Source: Field Survey, 2016.

Mean WTP= (87.4084151/-0.7023) *-1 = 124.46022369

Demand for Maize

The factors that influenced quantity of Maize bought by units consuming maize were estimated with Probit Regression estimates as shown in Table 3. The demand for maize was very highly determined by population of the consumers' proxies by size of households. Other factors that influenced its demand in descending order were number of feed millers in the area, mean price of maize forms and unit price of rice (close substitute to maize).

Table 3: Probit Regression Estimates of Factors Influencing Demand for Maize

Conclusion and Recommendations

There was a good market for maize in Aba Agricultural zone of Abia State, Nigeria. Maize consumers in the study area were on the average willing to pay any price less than ₦125.00 per kilogramme. To meet the demand for maize without tolerating gaps in its supply, we recommended that traders should buy more maize from areas of maize production in the country. In addition, the local farmers should strive to increase maize yield to help increase supply of more maize and bring down the price. This will further enhance the demand for maize.

Constraints Facing Male and Female Households in Ware Yam Marketing in Abia State, Nigeria

[1]E.O. Nze and [2]C.I. Ezeh
[1]Department of Agribusiness and Management,
Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
[2]Department of Agricultural Economics, Abia State University, Uturu
E-mail: nzeedith3@gmail.com

Abstract
The study analyzed constraints facing male and female households in ware yam marketing in Abia State, Nigeria. Multi stage random sampling technique was employed in the selection of 120 female and male ware yam sellers from twelve community yam markets in the area. The tool used for data collection was a structured questionnaire and descriptive statistics was used in realizing results. The result showed that 61.67% of the household heads had between 1 and 5 persons in their households. With respect to constraints, transportation cost was the most common constraint as 95.00% of female-headed households and 88.33% female-headed households confirmed it. To sustain strategies for enhancing food security and livelihoods in Nigeria, it is recommended that adequate transportation facilities should be provided by the government and the ministries of agriculture, especially in the rural areas where the produce are being produced, for ease of movement of the produce.
Keywords: Households Heads, Ware Yam, Constraints, Yam Marketing

Introduction
Ware yam is a primary agricultural commodity in Nigeria. It is the big sized and the marketable yam. The tuber can grow up to 2.5 meters in length and weigh up to 70kg (150 pounds). Depending on variety, its flesh may be of various shades of off-white, yellow, purple or pink, and the skin from off-white to dark brown. The tuber has a rough skin which is difficult to peel, but which softens after heating (Walsh, 2003). Its importance requires that it should be available all through the year, but regrettably, there is a problem of glut in supply of yam at the harvest period and scarcity thereafter leading to high cost of the produce at off season. Supply shrinks as scarcity lasts and this leads to decline in the incomes of men and women in the marketing process (FAO, 2006). Ware yam marketing is of considerable importance in the food economy/security of Nigeria. Ware yam is a major source of cash income to the producer and marketer irrespective of scale of operation. It is very important in local commerce in Africa and accounts for about 32 percent of farm income earned from crops as a source of foreign exchange (Chukwu and Ikwelle, 2002). The importance of ware yam cannot be over emphasized (Igwe *et al*, 2006). The activities of marketing of ware yam in Abia State involve both men and women and the activities involve various exchange points (markets) and the number of exchange points depends on the distance between the yam production and that of consumption. Interestingly, women's involvement in ware yam marketing is gradually increasing. Selling of foodstuffs is seen as a work mainly for women, and most of these women have built up businesses from trading of foodstuffs. Some of these women go to rural rotating markets to buy these foodstuffs and sell at the street side tables (IITA, 2004; Madueke, 2007).
Marketing appears to be the crux of the whole food and agricultural problems (Nwachukwu *et al*., 2007). Ware yam marketing is probably fraught with several macro and micro-economic problems which hinder its efficiency in distribution (Igwe *et al*, 2006). In Abia State, ware yam is becoming more expensive and relatively unaffordable as production has not kept pace with population growth leading to rise in price of the available ones. The State still depend on the northern Nigeria and other south-eastern States for its yam supply since local production is not enough to feed its

populace. A lot of problems such as high transportation cost, theft, perishability, and others, militate against moving this product from the points of production to consumption areas. This affects the final price, quality and income (IITA, 2007). In most south-eastern States of Nigeria, yam production and marketing is seen as men's business because of the energy requirement in its farming activities as well as in its trade. Nowadays, many people are after the white collar jobs, and there has been neglect in yam production (farming) and distribution (marketing) as it is seen as the un-educated and rural people's career (Okwuokenye, 2006). The study therefore analyzed constraints facing male and female households in ware yam marketing in Abia State, Nigeria

Materials and Methods

The study was conducted in Abia State, Nigeria. Abia is in south eastern Nigeria. It is located within latitudes 4^0 45' and 6^0 07' North and longitudes 7^0 10' and 8^0 10' East. It is bounded on the north and north east by Anambra, Enugu and Ebonyi States. To the west is Imo State, to the east and south east are Cross River and Akwa Ibom States, and to the south is Rivers State (Independent National Electoral Commission, 2008). There are three agricultural zones in Abia State, namely Aba Zone, Umuahia Zone and Ohafia Zone (Abia State Planning Commission, 2001).

Multistage random sampling technique was employed. In the first stage, two agricultural zones, Aba and Umuahia were randomly selected. Secondly, four Local Government Areas (LGAs) were selected across the two zones, and three markets from three communities were selected from each Local Government Area from which five female-headed and five male-headed households ware yam marketers were selected to give a total of 120 ware yam marketers for the study.

The researchers collected data with the aid of a structured questionnaire. Data collected include socio-economic characteristics of the respondents and the constraints of ware yam marketing. Descriptive statistics was used to analyse the data.

Results and Discussion

Socio-economic Characteristics of Ware Yam Marketers in Abia State

The socio-economic characteristics of the respondents is shown in Table 1. The table revealed equal number of men and women in ware yam marketing. This is purposive in order to give both gender equal opportunities for participation. This result does not agree with the opinion of Tewe (2002) that men look down on agricultural commodity marketing as petty trade meant for women. About 16.67% of the traders had household size of 11 persons and above. Few (21.67%) had fewer years of experience. This implied that people with little or insufficient ware yam trading experience were discouraged from going into the trade since they were likely to encounter a lot of risks associated with the trade. This agrees with Awoniyi and Omonona (2006) that experienced ware yam traders have higher bargaining power than new entrants. Majority (85%) of the marketers earned less than ₦8,000 per heap of ware yam sold, and this suggests that they were low income earners. The reason could be that most of the traders depended on the ware yam supplies from the northern part of Nigeria whose prices are exorbitant due to the inbuilt transportation expenses.

Table 1 Distribution of ware yam marketers in terms of socio-economic characteristics

Variables		**Frequency**	**Percentage (%)**	**Mean**	**Std. Deviation**
Sex:	Male	60	50.00		
	Female	60	50.00		
Household Size (Number):	1-5	74	61.67	5.2	1.83
	6-10	26	21.67		
	11 and above	20	16.66		
Trading Experience (Years):	1-10	26	21.67	15.5	3.94
	11-20	49	40.83

Constraints encountered by male and female household heads in ware yam marketing

Constraints encountered by male and female household heads in ware yam marketing is shown in Table 2. Transportation cost was the most common constraint as 95.00% of female-headed households and 88.33% female-headed households confirmed it. This may be due to inadequate transportation facilities in most rural areas in Abia State where motorable roads are lacking, and the available ones are in state of disrepair. This constraint affected the female household heads more (95.00%) than the male household heads (88.33%) due to the fact that men can afford to use head-loads and wheel barrows in transporting their goods unlike women (Echebiri and Mejeha, 2004). Losses in transit accounted for the second highest constraint to household heads' ware yam marketing in Abia State. This is because some ware yams were damaged in the distribution system and also as a result of other activities involved in distribution system such as loading, off-loading and transportation before reaching the final consumer. Inadequacy of funds was another constraint in ware yam marketing in the area. This implied that majority of ware yam traders in Abia State, Nigeria had little funds for the business. This might be as a result of their high dependency on personal savings, funds from friends and relatives (Awoniyi and Omonona, 2006). Perishability of ware yam tubers was ranked as the third and fourth most common constraints to ware yam marketing in male and female-headed households respectively. This may be as a result of low storability and low sales of ware yam in Abia State. Nze (2008) equally confirmed that low sales and storability of yams lead to high perishability. Seasonality constituted the least constraint in thearea. This might be because, although seasonality creates surplus at the harvest periods which must be sold at low prices leading to low income, a large amount of the produce is still available during the off-season (Nze, 2008).

Table 2. Constraints to Gender household heads in Marketing of Ware Yam in Abia State

	Female Household Heads			Male Household Heads		
Constraints	*Frequency	Percentage (%)	Rank	*Frequency	Percentage (%)	Rank
Transportation Cost	57	95.00	1st	53	88.33	1st
Losses in Transit	55	91.66	2nd	49	81.67	2nd
Inadequacy of Funds	48	80.00	3rd	43	71.67	4th
Perishability	33	55.00	4th	47	78.33	3rd
Inadequate Storage Facilities	29	48.33	7th	36	60.00	5th
Lack of Bank Credit	31	51.67	6th	24	40.00	6th
Tenancy/Storage Cost	32	53.33	5th	18	30.00	7th
Seasonality	22	36.67	8th	16	26.67	8th

Source: Field Survey; 2012.
*Multiple responses recorded

Conclusion and Recommendations

Ware yam marketing is a low-income yielding business, as a heap (100 tubers) of ware yam gives only ₦9,000 as profit, and transportation cost is a very big constraint challenging the business for men and women alike. Based on the findings, the researchers recommended that adequate transportation facilities should be provided by the government and the ministries of agriculture, especially in the rural areas where the produce are being produced and marketed. This will entail the construction, expansion and maintenance of urban-to-rural, rural-to-rural and rural-to-urban roads. Government should put up effective transportation schemes, such as good rail ways, roads, etc., that can assist in reducing the cost on transportation by ware yam marketers.

Evaluation of Wealth Status of Rural Farm Households in Abia State, Nigeria

E.O. Nze and J.G. Ekeleme
Department of Agribusiness and Management,
Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
E-mail: nzeedith3@gmail.com

Abstract
The study evaluated the wealth status of rural farm households in Isiala Ngwa North Abia State, Nigeria. Random sampling technique was adopted in the selection of sixty farm households in the area and a questionnaire was used in gathering data from the households. Data were analyzed with descriptive and inferential statistical tools. Results revealed that most (38%) of the respondents saved little, below ₦11,000.00 per year, very few (2%) earned between ₦200,001.00 – ₦300,000.00 per year, and majority (74%) spent below ₦50,000.00 on monthly basis. Regression result showed that age, household size, savings, credit amount, years of farming and expenditure were the major factors affecting wealth status. The study also found that the wealth status of farm households could be improved through so many ways such as the use of improved farming implements and infrastructures, availability of accessible roads and transport facilities, availability of credit facilities, etc. It was recommended that farmers should device means of increasing savings like forming savings groups and participating in credit and thrifts societies.
Keywords: Wealth Status, Rural Farm Households and Isiala-Ngwa Abia State.

Introduction
Wealth status is one of the most important variables in social science research because it plays a significant role in the planning and execution of development programs (Tiwari *et al*, 2005). Wealth is the accumulation of resources (Agesa, 2005; Bellon, 2001). Rural farmers are said to be wealthy when they are able to accumulate many valuable resources such as improved seedlings, farming tools/ machine, to mention but a few. A rural household's wealth status could mean the ranking of household in the milieu, to which it belongs, in respect of defined variables, like physical assets such as land, warehouse / storage facilities, farm inputs and outputs, economic status, education, occupation, social position, political influence, caster, among others (Tiwar, *et al,* 2005). The traditional approach to measurement of household wealth status has been through the use of standardized household interview surveys (Worrall *et al*, 2003; Akanke and Atkinson, 2002). An alternative has been the possession of properties such as agricultural lands, building and other valuable assets as proxy for income and expenditure. In Isiala-Ngwa North Local Government Area of Abia State, wealth status is determined based on the accumulation of valuable asset such as labour availability, money to expend on purchasing inputs such as seedlings, fertilizers, herbicides, pesticides etc., investment decisions, and amount used in growing crops. It also includes the number and variety of animals a livestock farmer could keep, as well as, their management tactics which should be used in farming.

However, farmers in Isiala-Ngwa North are currently faced with problem bordering on inadequacy of lands for cultivation of crops and rearing of animals. Other problems associated with the wealth status of rural household in Isala-Ngwa North include lack of access to most basic social amenities such as electricity, well and motor able roads, good water supply, lack access to improved varieties of farm inputs, inadequacy of financial institutions in the rural areas for farmers to save money generated from the sales of their farm produce, etc. High level of illiteracy among the farmers has also led to the inability of rural farmers to apply modern farming techniques in their production processes. The consequences of these have brought about low production of crops and productivity by farm animals. Furthermore, Nigerian performance in the agricultural sector in recent times especially in the rural area suggests that farmers are yet to absorb most of the

mechanized ways of farming due to inadequate credit facilities such as bank loans which could be used in importing machines, improve seedlings to mention but a few.
The study therefore evaluated the wealth status of rural farm households in Isiala Ngwa North Abia State, Nigeria. The specific objectives include examining the wealth profile of the farm households in the study area, determining factors influencing the wealth status of the rural farmers, and ascertaining the possible ways of improving the wealth status of the rural farmer's household.

Methodology

The study was conducted in Isiala-Ngwa North Local Government Area of Abia State, Nigeria. Its headquarters is at Okpuala-Ngwa approximately 30 kilometers away from Umuahia town the State Capital (Census, 2006). It is made up of seven towns which include Ngwa Ukwu, Ama-Asa, Umuohia, Ihie, Amasa-Ntigha, Amapu-Ntigha and Nsulu. The main occupation of Isiala- Ngwa people is farming. The major food crops grown by Isiala-Ngwa people includes cassava, yam, maize, melon, local beans and various vegetables and the cash crops grown under plantation include oil palm, plantain and banana. Piggery, poultry, sheep, goat and fishery form the major livestock enterprise in the study area. The agricultural production is mainly on a small scale.
Six communities were purposively selected based on proximity and accessibility. These communities included Amaorji, Abayi, Eziama-uratta, Ikputu, Umuosu and Mbawsi, and 10 farmers were randomly selected from each community with the use of questionnaire which contained information on their household wealth status among others to give a total of sixty respondents for the study. Data collected were analyzed using both descriptive and inferential statistical tools. In realizing objectives 'i' and 'iii', descriptive statistics such as tables, frequency distributions and percentages were used. Objective 'ii' was analyzed using ordinary least square regression.

Model Specification

The regression model that explained the factors influencing wealth status of rural farm households was implicitly stated as; $\mathbf{Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, e)}$

Where;

Y	=	Wealth status of respondents proxied by the value of farm assets (₦)
X_1	=	Age of respondent in (years)
X_2	=	Household size (number of persons living in a household)
X_3	=	Years of education (Years)
X_4	=	Average family monthly savings (₦)
X_5	=	Credit amount (₦)
X_6	=	Amount of interest (₦)
X_7	=	Years of experience in farm business (years)
X_8	=	Average household monthly expenditure (₦)
e	=	Error term

Results and Discussion

Wealth profile of rural farm households in Isiala-Ngwa North Local Government Area of Abia State, Nigeria

The wealth status of the rural farm households in Isiala-Ngwa North Local Government Area of Abia State, Nigeria is shown in Table 1. The **t**able showed that majority (60.0.0%) of the rural farm households in Isiala-Ngwa North's average income was below ₦51,000, while only 8.3% had an average income of ₦300,000 and above per month. This implied that most of the farmers in the study area were very low income earners. Few of the respondents (13.3%) saved above ₦55,000, 11.7% saved within the range of ₦41,000- ₦55,000, and majority (38%) saved below ₦11,000 on monthly bases. This implied that farmers saved little. Majority (33.3%) obtained credit of below ₦51,000 while only 8% of them obtained credit of ₦200,001 and above. The implication is that these households do not rely on much credit for their sustainability, and this is plausible. Majority (74%) of the respondents' monthly expenditure was below ₦50,000 in a month. The implication is that the monthly expenditure of these farmers is low and this can help to increase the wealth status and encourage the farmer to invest more capital into the farming business.

Table 1: Distribution of respondents according to their wealth status

Wealth status	Frequency	Percentage
Average monthly income		
Below ₦51,000	36	60.0
₦51, 000 – ₦100,000	10	16.6
₦100, 001 – ₦200,000	6	10.0
₦200, 001 – ₦300,000	3	5.0
₦300, 001 and above	5	8.3
Monthly savings		
Below ₦11,000	19	31.6
₦11,000 – ₦25,000	10	16.7
₦26,000 – ₦40,000	16	26.7
₦41,000 – ₦55,000	7	11.7
₦56,000 and above	8	13.3
Credit amount		
Below ₦51,000	20	33.3
₦51,000 – ₦100,000	17	28.3
₦100,001 – ₦200,000	6	10.0
₦200,001 – ₦300,000	11	18.3
N300,001 and above	6	10.0
Amount of interest (N)		
Below ₦10,000	15	25.0
₦10,100 – ₦300,000	20	33.3
₦30,001 – ₦60,000	15	25.0
₦60,001 – ₦90,000	0	0.0
Above ₦90,000	10	16.7
Average monthly expenditure (N)		
Below ₦50,000	37	61.7
₦50,100 – ₦150,000	9	15.0
₦150,001 – ₦300,000	8	13.3
₦300,001 and above	6	10.0
Total	**60**	**100**

Factors influencing wealth status of the rural farm households

Regression result on factors influencing wealth status of rural farm households is shown in Table 2. Age, household size, savings, credit amount, years of farming and expenditure were all statistically significant at different levels of probability with different signs. The coefficient of age (113638.929) was significant at 1% level of probability and positively related to wealth status of rural farm households. This implied that older farmers were wealthier than younger farmers. This conforms to *a priori* expectation as higher age must have led to accumulation of wealth. Household size was also significant at 1% level of probability and positively related to wealth status. This means that the higher the number of people in the household the higher the wealth status, because the amount of money spent in hireling farm labor could be saved by using members of the family as farm labor. Saving was significant at 10% level of probability and positively related to wealth status. The implication is that high savings encouraged high wealth status. Credit amount was significant at 1% level of probability and positively related to wealth status, thus implying that higher farm households' access to credit increased their productivity which in turn improve their wealth status. Years of farming experience was significant at 1% levels of probability with a positive sign which implied that the more farm households stay in the farming business, the more experienced and tactical they become and the resulting outcome will increase the family wealth status. Expenditure was significant at 1% level of probability and negatively related to the wealth status, implying that an increase in the household's expenditure reduced their wealth status. This conforms to *a priori* expectation because the higher the expenditure, the lower the savings.

Table 2: Regression result on factors influencing wealth status of rural farmers in the study area

Parameters	Coefficient	Standard error	T-values
Constant	1.142E6	1.574Eb	0.726

Ways of improving wealth status of rural farmers' household
From Table 3, 27.35% of the respondents indicated that for rural farm households to have sustainable strategies for enhancing livelihoods the use of improved farming implements and infrastructures should be adopted to reduce low productivity and remove tedious activities found in agriculture while 17.96% of the respondents suggested that there should be accessible roads and transportation facilities. About 16% of the respondents indicated that if credit facilities and financial institutions should be accessible that it will increase their wealth status, and 13.06% of the respondent suggested that planting of improved seedlings will help to increase productivity.

Table 3 Distribution of respondents' response on possible ways of improving wealth status

Ways of improving wealth status	Frequency	Percentage	Rank
Improved farming implements and infrastructures	57	27.35*	1st
Accessible roads and transport facilities	44	17.96*	2nd
Accessibility of credit facilities and savings	39	15.91*	3rd

Conclusion and recommendation

Based on the findings of the study, rural farm households in Isiala Ngwa North, Abia State are very low income earners, and they equally spend low on monthly basis. Household size, income, savings, household monthly expenditure influenced their wealth status which could be enhanced through the use of improved farm implements and infrastructures. It is recommended that farmers should device means of increasing savings like forming savings groups and participating in credit and thrifts societies; modern farm equipment should be provided for the local farmers and that government should help in making credit easily accessible to the rural farm householders to enable their embrace the modern ways of farming that will lead to greater productivity and hence improve their wealth status.

Analysis of Inorganic Fertilizer Use on Sesame Production in Awe Local Government Area of Nasarawa State, Nigeria

Onuk E.G., Salau E.S. and Girei A.A.
Department of Agricultural Economics and Extension, Faculty of Agriculture, Nasarawa State University, Keffi, Shabu-Lafia Campus

Abstract
The study examined inorganic fertilizer usage among sesame farmers in Awe local government Area of Nasarawa State, Nigeria. A purposive sampling procedure was used to select a total of 80 sesame farmers. Data was collected with the aid of a questionnaire. The result showed that 65.5% of the respondents cultivate sesame as a sole crop while 34.5% cultivate it as a mixed crop. The result revealed that 65.5% of the respondents do not apply inorganic fertilizer to sesame while 34.5% applied inorganic fertilizer to the Crop. The mean quantity of the respondents apply NPK and urea fertilizer were 6.5bags/ha and 3.7bags/ha respectively. The result further showed that the regression coefficients of farm size were significant at 1%. The R^2 *value was 0.7899 indicating that 78.99% of the variation on inorganic fertilizer was used in sesame production. The major source of fertilizer application information is by radio. the research concluded by calling on extension agents to create awareness to sesame farmers in the study area through establishment of Small Plot Adaptive Technique (SPAT) by demonstrating sesame respond to inorganic fertilizer.*

Introduction
Fertilizer use is crucial for sustainable intensification and for raising farm productivity under increasing land constraints and decline soil fertility. Fertilizer is one of the critical inputs used in improving smallholder food and agricultural productivity. Trends in fertilizer use are very important because without significant increases in the use of chemical fertilizers it will not be possible for the production of sesame to keep up with the demand from a rapidly growing population and agro-industries. Traditionally Nigeria farmers have been using fertilizer primarily on commercial/export crops, but in recent years, an increasing quantity of fertilizers is being used on such food crops as rice, maize, wheat, Yams, Cassava and sesame (RMRDC Survey 2004).
Sesame (*Sesamum indicum L.*) belongs to the family *Pedaliaceae.* The genus consists of about thirty six species of which the most commonly recognized is *Sesamum indicum L.,* popularly known as beniseed in Nigeria (Alegbejo *et al*., 2003). It is an erect, flowering annual plant which grows 50 to 250 cm tall or more, as determined by the soil or environmental conditions and varieties (Sharma, 2005). Sesame is usually propagated by seeds and matured in 70 - 150 days after sowing, depending on the varieties (Indu and Savithri, 2003).
Fertilizer application among sesame growers in Nigeria (particularly in the north central part), has not been a common practice because it is considered as a minor crop and can do well even on poor soil (Haruna and Usman, 2008). In Nasarawa State, sesame is grown mainly as a sole crop. Farmers have no definite fertilizer recommendations for the production of sesame as a sole crop. The crop is grown in a mixture with sorghum or millet (RMRDC Survey, 2004).
Fertilizers are not always applied to sesame in major growing areas of Nigeria. The crop benefits only from the fertilizer applied to other crops grown earlier in the year. Unfortunately, growth and yield of the crop are generally low compared with the growth and yield obtained when fertilizer is applied. Reports of nutrition studies carried out in Nigeria and elsewhere have shown significant increase in growth and yield of the crop (Haruna and Abimiku, 2012). Low fertilizer use has been identified as a major challenge that must be overcome in order to increase Nigeria's agricultural productivity. However, there are several factors that contribute to low fertilizer use that are not addressed by direct price subsidies. First, the extension service system generally plays a critical role in driving demand for fertilizer through its transmission of information about fertilizer

technology to farmers. In Nigeria, the extension service is also instrumental in providing farmers access to fertilizer. Based on interviews with extension agents, Banful, (2010) found that the primary constraint to fertilizer use in Nigeria is the physical absence of the product at the time that it is needed, rather than problems of affordability or farmers' lack of knowledge about its importance. Therefore, there is an immediate need to conduct a study on the analysis of fertilizer application among sesame farmers in Nasarawa State.

Methodology

The study was carried out in Awe local government Area of Nasarawa State. The average rainfall is between 1000-1400mm with a high daily temperature range between 28^0C-31^0C which is favorable for agricultural production (NIMET, Station, 2014). The Area has a population of about 112,574 people inhabitants with Jukun (from Kwararafa Kingdom), people who constitute 95% of the ethnic groups in the area, while other minority tribes are Hausa, Tiv and Fulani (NPC, 2006). The local government share boundary with Taraba State and Benue State. It has an estimated land area of about 2521km^2, the major crop grown in commercial quantities are Rice, Sesame, Cassava, Groundnut and Millet (NADP, 2014).

Method of Data Collection and Analysis

Primary data were collected with the aid of a questionnaire. A simple random sampling technique was used for the study. Five villages namely Kekura, Tunga, Kanje, Baure and Mahanga were randomly selected for the study area. Sixteen farmers were randomly selected from each village making a total of 80 farmers that were used for the Study. Data were analyzed using simple descriptive statistics and regression analysis.

Regression model

$\text{Log}Y = \beta_0 + \beta_1\text{Log}_{(}X_{1)} + \beta_2\text{Log}_{(}X_2) + \beta_3\text{Log}_g(X_3) + \beta_4\text{Log}_{(}X_{4)} + \beta_5\text{Log}_{(}X_{5)\ldots} + e$

Where Y = Yield of sesame (kg)

X_1 = Labour (Man day)

X_2= Seed used (Kg/ha)

X_3 = Fertilizer (kg)

X_4 = Farm size (ha)

X_5= Agro chemicals used (liters)

β_0 = Constant term

β_1–β_5 = regression coefficient

e = error term

Results and Discussion

Socio-economic Characteristics of Sesame Farmers

The socio-economic characteristics of the respondents are presented in Table 1. The result showed that 53.2% of the respondents were between the age of 22-31years while 30.1% were between the age of 32-41years. The majority (71.4%) of the farmers were males while 28.6% were females. This implies that men engage more in sesame production than women in the study area. The result revealed that 93.7% of the respondents were married while 6.3% are single. The result further revealed that 46.7% of the respondents had primary education, 12.0% had secondary education, 3.1% had tertiary education, and 38.2% had no formal education. This indicates that majority 62.8% can read and write. The implication of the level of education of farmers is that it increases farmers' awareness on modern agricultural technologies and also the level of adoption of such technologies.

The result also showed that 20.6% had household size of 10-14 persons, 49.2% had household size of 15-19 persons, and 28.6% had household size of 20-24 persons. The implication of household size is that high household size discourages the use of hired labour in production. The result further showed that 80.1% of the respondents acquired their land through inheritance, 14.3% purchased the land, and 5.6% rented the land. Land holding through inheritance is common among rural farmers probably as a result of the social structure of the rural people.

Majority 60.1% of the respondents had farm size between 1 and 10ha, while only 20.5% had farm size greater than 10ha. The result further show than 6.3% of the respondents between 1-10 years had farming experience, and 41.3% had between 11-20 years, farming experience and 52.4% had between 21-30 years of farming experience. Farmers with much experience have some managerial skills that contribute to the overall productivity. In addition 65.5% of the respondent cultivate sesame as a sole crop while, 34.5% cultivate it as a mixed crop.

Factors influencing inorganic fertilizer use by farmers for sesame production

The factors influencing inorganic fertilizer decision by the respondents were described in Table 2. The result showed that 37.5% of the respondents indicated that their reason for applying inorganic fertilizer to sesame was to obtain higher yield. Furthermore, 12.5% of the respondents indicated that they applied inorganic fertilizer because soil fertility was poor. Fifteen per cent indicated that they applied inorganic fertilizer based on advice by extension agents, while 2.5% indicated that fellow farmers advised them to apply fertilizer.

Meanwhile, 12.50% of the respondents reported high cost of inorganic fertilizer as the reason for not applying the fertilizer. From the result obtained the major reasons for farmers to apply inorganic fertilizer to sesame was because they wanted to obtain high yield while unavailability and high cost of inorganic fertilizer featured as the main reason for not applying the fertilizer.

Table 2: Factors influencing inorganic fertilizer use by farmers in sesame production

Reason for applying fertilizer to sesame	**Frequency**	**Percentage**
To obtain high yield/ effectiveness of fertilizer	30	37.50
Because of poor soil fertilizer	10	12.50
Based on advised by extension agents	12	15.00
Based on advice from other farmers	02	02.50
Reason for not applying fertilizer to sesame		
High cost of fertilizer	10	12.50
High soil fertility	05	06.25
Unavailability of fertilizer	07	08.75
Availability of organic manure	04	05.00

Estimation of input and output relationship in sesame production

The result revealed that the f-value (2.436) was significant at 1%. The R^2 value of 0.723 implies that 72.3% of the variation in output of sesame production was explained by the inputs. Two of the explanatory variables, labour (mandays/ha) and farm size (ha) were both significant at 1% while the remaining explanatory variables, seed (kg/ha), fertilizer (kg/ha) and chemical (litre/ha) were significant at 5%. The positive value of the coefficients implies that the explanatory variables had positive influence on the dependent variable. The result indicated that as the variable inputs are increased the output will also increase.

Table 3: Estimates of the input and output relationship in sesame production

	Unstandardized Coefficients		**Standardized Coefficients**		
	B	**Std. Error**	**Beta**	**T**	**Sig.**
Constant	-12982.985	7904.469	0.000	-1.642Ns	0.104

Note: R = 0.781; R square = 0.723; Adjusted R square = 0.723; F-value =2.436 ;*** = Significant at 1%; ** = Significant at 5%, Ns = Not significant

Information sources on inorganic fertilizer application for sesame production Information source of inorganic fertilizer to sesame production is presented in Table 4 below. The result showed that about 51.5% of the sesame farmers obtain fertilizer application information from Radio programs, while 25.5% of the respondents obtain their information from extension agents. This shows that the major source of information to the farmers in the study area is by Radio.

Table 4: Information sources on inorganic fertilizer application for sesame production

Information sources	**Frequency**	**Percentage**
Radio	45	51.5
Extension agents	20	25.5
Other Farmers	10	13.5
NGOs	5	9.5
TOTAL	**80**	**100**

Sources: Field Survey, 2015

Conclusion

The study revealed that majority of the respondents used radio as their source of information on the use of inorganic fertilizer. Their decision on inorganic fertilizer used is to obtain higher yield due to poor in soil fertility. Despite the benefit of fertilizer to the productivity, some farmers still do not use fertilizer as found in this study. It can be concluded that high cost of fertilizer hinder farmers from using fertilizer.

Extension agents should create more awareness in the study area through established of small plot Adaptive technique (SPAT) demonstrating on sesame response to inorganic fertilizer. The E-wallet scheme should be employed by the state and local government to ensure that fertilizer gets to sesame farmers in the state. The complementary application to organic and inorganic fertilizer for sesame production should be perfected in terms of application rate for sesame production in the state. Government should improve on the use of radio medium for disseminating fertilizer application information to the farmers.

Food Price Volatility and Food security in Nigeria: Current Issues and Possible Measures

***H. Egwuma, Y.U. Oladimeji, O.A. Ojeleye and A. Gomina**
Department of Agricultural Economics, Ahmadu Bello University, Zaria, Nigeria
*Corresponding Author's email: ***henry4him@gmail.com***

Abstract
The prices of food commodities globally have been characterized by increased volatility in recent years, generating a growing concern with regards to food security especially in developing countries. This paper focuses on food price volatility as it relates to food security in Nigeria and also discusses some policies and strategic measures to address price volatility in the food market. It is shown that volatility in food prices is caused by both demand and supply-side factors and that these factors are expected to persist such that high and volatile food prices will continue. Suggested possible measures for reducing food price volatility include the building of stock reserves, addressing climate change issues, increasing agricultural investments, and provision of social protection.
Keywords: Price volatility, Food security, Food deficit, Net importer

Introduction
Historically, agricultural product markets have been characterized by price volatility and recent market events have heightened the feeling that agricultural commodity price volatility will continue to increase in the future. Beginning from September 2006, world agricultural markets witnessed considerable fluctuations with prices rising to an unprecedented level by early 2008. These sharp upswings were most noticeable in maize, rice, wheat and dairy products. However, by mid-2008 through 2009, food prices declined sharply and rose again in 2010 and by 2011 prices rose to the peak of the price increase in 2008. Again, since 2012 food prices started falling in the global agricultural markets and then rose again markedly by 2017 (Figure 1). Thus, within the past ten years many agricultural commodity prices fluctuated sharply, rising and falling at different periods. Such rather exceptional volatility in world food prices generates considerable uncertainty for all market participants, makes both short and longer term planning very difficult, and poses serious threats to the food security of vulnerable people especially in developing countries (Saris, 2013).

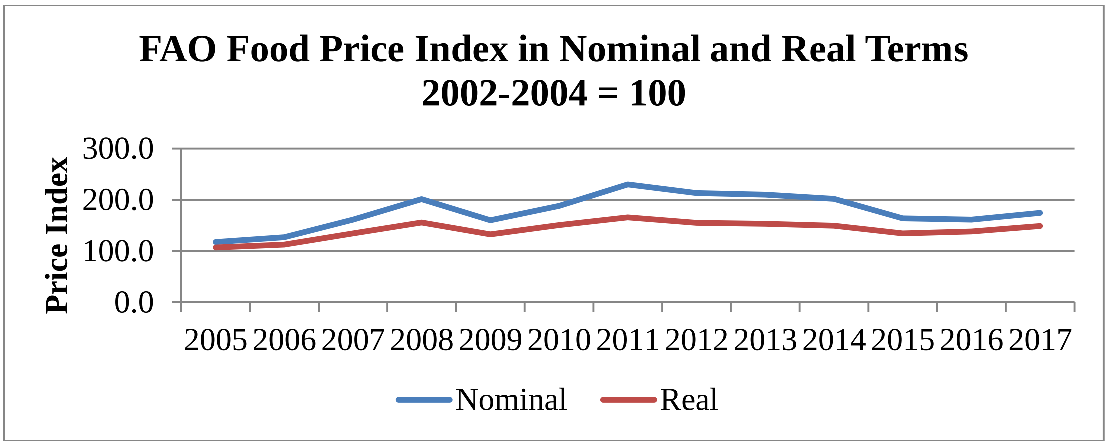

Figure 1: Food Price Index
Source: FAOSTAT, 2018

Previous research has identified and strongly debated on a variety of structural and temporary factors that are responsible for such unpredictability in food prices (Mitchell, 2008; Abbott et al., 2009; Gilbert & Morgan, 2010; Harrigan, 2014; Woertz et al., 2014; Kalkuhl et al., 2016). On the demand side, volatile food prices are caused by population growth, shifts in diets in emerging markets, stronger interlinkages between the food, feed, energy and financial markets. Supply-side factors include harvest shortfalls, declines in productivity, climate change and ecological constraints, high cost of inputs such as fuels and fertilizers, low inventory levels, and global catastrophes. As noted by Harrigan (2014), the causes behind the global food crisis are expected to persist such that high and volatile food prices will continue.

Food price volatility generates significant concerns that border on food security and has a significant impact on the welfare of poor individuals or countries who are net buyers of food. The impact of price volatility extends to farmers, market actors, consumers, and governments in many countries. The share of food consumption in total household consumption is substantially high for many developing countries and as such food price volatility can bring about significant hardships for consumers and even trigger riots (Gilbert & Morgan, 2010; Arezki et al., 2016). Existing evidence (Table 1) shows that food insecurity is a pressing issue in many developing countries and Africa is the continent most subject to food insecurity in the world, thus making food price stabilization and food security a major objective of governments in these countries (Gouel et al., 2016; McCorriston & MacLaren, 2016).

Based on the Global Food Security Index (GFSI) which considers the core issues of food affordability, availability, quality and safety across 113 countries in 2017, Nigeria is ranked 92 with a score of 38.4. With this pathetic situation, it becomes very crucial to understand the food security situation in Nigeria with a view to providing possible policy measures that could help address market instability, reduce hunger and enhance food security. This then is the major motivation of this paper.

Table 1: Food Insecurity in Selected African Countries

Country	Score/100	Rank
Benin	39.6	90

The State of Food Security in Nigeria

The FAO crop prospects and food situation released in June 2018 reveals that Nigeria is among the 39 countries in need of external assistance for food (FAO, 2018a). Food insecurity has continued to be driven by persisting conflicts and weather shocks which have adversely impacted access and availability of food stuff. Based on a three-year average (2014-2016), the number of undernourished in Nigeria is about 14.3 million with a 7.9% prevalence of undernourishment while the depth of food deficit is 48kcal per capita per day (FAO, 2017).

As one of the potentially food insecure countries in the world, Nigeria is a net importer of food despite its enormous agricultural potential. Nigeria has a large food deficit and is a net cereal importer with cereal import projected to reach 7.8 million tonnes in 2018. Furthermore, the country is the largest importer of rice in Africa with an average of about 2.6 million tonnes of rice import annually (FAO, 2018b). Its food imports as a share of total imports in 2017 is 16.3%, representing about double the world average of 8.3% with the food import bill in 2016 standing at 1.1 trillion naira (National Bureau of Statistics (NBS), 2018).

The huge food gap in Nigeria, revealed by the large food imports is due to the inability of the country to realize an increase in agricultural production to meet the growing food demand. The high rate of population growth is partly to blame for this situation as the average annual growth rate of population in the last decade is about 2.6%. Nigeria is currently the seventh most populous country globally with a more than 6.5% average annual growth rate of the urban population. Other causes of the food gap include decades of underinvestment in agriculture, local conflicts and climate change which have led to the displacement of a significant segment of the population and an increase in poverty and diseases. With poverty levels exceeding 50% of the population, most people in Nigeria are vulnerable to food price fluctuations.

Measures for Reducing Food Price Volatility

Addressing food price volatility is very crucial given the fact that price instability has adverse impact on the poor and poses a threat to the attainment of food security. The adoption of a broad approach that encompasses storage policies, marketing, stocks, trade, climate change, conflict management, and social protection to target food price stabilization can help in managing excessive food price volatility in Nigeria. Collective storage and marketing strategies can be used by producers and farmers organizations to prevent over-commercialization which arises due to lack of storage capacity and household liquidity constraints during harvest season. The use of national food reserves (based on collaboration between the public and private sectors) can also help to overcome temporary disruptions in food supply considering that low grain stock levels can potentially exacerbate food price instability. Thus, there is need to increase the capacity to stock food in Nigeria in case of price volatility. Because food price volatility and food security are strongly linked to climate change, government policies should be designed to address greenhouse gas emissions and facilitate increased productivity boosting investments in climate change adaptation and resilience to shocks. In addition, safety nets also play a critical role in relieving the effects of short-term food price instability on food insecurity arising from local conflicts. In this light, social protection and protective measures such as cash transfers and employment programmes can be used to address short term risks associated with food price fluctuations.

Conclusion

Food price volatility is a major concern in Nigeria, affecting the most vulnerable in the society and threatening the food security target of the country. High rate of population growth, low investments in the agricultural sector, conflicts and climate change have contributed in creating large food deficits in Nigeria, leading to agricultural market volatility. Dealing with food price volatility requires a combination of different approaches including the building of stock reserves, addressing climate change issues, increasing agricultural investments, and provision of social protection.

Analysis of Household Demand for Beef in Adamawa State, Nigeria

H.B. Inyang
Department of Agricultural Economics and Extension,
National Open University, Kaduna
hinyang@noun.edu.ng

Abstract
This study analysed the household demand for beef in Adamawa State using AIDS model. The AIDS model result revealed that five coefficients of the variables were statistically significant. These include the age of the household head (5%), marital status of the household head (5%), occupation of the household head (1%), educational level of the household head (10%) and the child dependency ratio (10%). The coefficients of the household head; age, occupation, secondary education and the child dependence ratio were negative. While the coefficients of marital status showed a positive coefficient. The expenditure elasticities of beef, poultry and fish revealed that all the coefficients were positive and statistically significant at 1% level. The study recommends reduction on income taxation for low income salary earners, investment in livestock production, provision of credit facilities to livestock farmers and improvement on educational attainment.
Keywords: Analysis, Household, Demand, Beef and AIDS Model

Introduction
Beef is the term used to designate meat from different types of cattle; it is usually applied to meat of cattle over one year old. Beef contains 15-20 percent protein of outstanding nutritive value. It is also an excellent source of some of the vitamin B complex and a good source of iron and phosphorus; it also contains sodium and potassium. The vitamins and minerals are found in the lean portion of the meat. Meat (beef) is rich in most of the nutrient required by man. This is to be expected since the tissue and body fluid of man are very similar to those of animals. Meat (beef) is rich in protein and contains all the essential amino acids, which are very good for the maintenance and growth of human tissue. It is also rich in minerals and vitamins. Moreover, phosphorus, copper and iron are present in significant amount in meat (Khader, 2001 and Manay and Shadakshoraswamy, 2001).

World demand for meat has risen sharply during the last few decades. The key reason for these increases in meat demand are increasing population, improving technology and increasing incomes. However, despite the overall improvement in technologies and per capita income consumption of meat has lagged especially in the less-developed countries of the world because protein is the most costly food item (Goliath, 2005). The increase in meat consumption is a universal desire to diversify diet and eat meat, dairy products and fish when income per capital increases. Today, the increasing human population in the face of inelastic production strategies appears to have widened the demand-supply gap and accentuates society's demand of meat product (Igwe and Onyekwere, 2007).

The global beef consumption is expected to rise gradually by about 1.6% per year in average in the Food and Agricultural Policy Research Institute (FAPRI) projections in relation to income growth, notably in the emerging economies. In many developed countries, the per capita consumption of beef is expected to stagnate or to fall, since consumers continue to substitute beef meat with pork and poultry meat. The declining beef meat consumption is influenced mainly by the decreasing purchasing power and the occurrence of the Bovine Spongiform Encephalopathy (BSE) disease. The elasticity estimation result revealed that the beef meat is price and income inelastic (Hupkova, Bielik and Turcekova, 2009).

Bastian (2008) reported that, consumer concerns with beef were related to cholesterol, calorie content, artificial ingredient, convenience characteristics (Microwaveable and storage), how it is displayed in the store, and price (too expensive). Each of these factors exhibited a statistically significant negative effect on the quality perception of beef compared to other meats. Wohlgenant (1985) attributed the decline in beef consumption to increased nutritional consciousness of consumers and changes in relative prices as well as real income. However, the change in elasticity relationship between beef and fish from substitutability to complementarity might reflect a desire on the point of consumers, in response to health concerns about red meat, to expand their diets to include fish. Moreover, the decrease in the consumer demand for beef is due to age related sicknesses such as heart disease and arthritis (Kudi *et al.,* 2008).

Beside, the decline in consumer demand for beef as compared to other sources of animal protein such as pork, poultry, fish and sea food are due to many factors. The numerous factors that jointly influence beef demand over time can be broadly categorized as (i) relative prices (or quantities), (ii) consumer incomes, (iii) health/nutrition concerns, (iv) food safety concerns, and (v) consumer preferences for meat product attributes. Beside aging population is one of the factors that are causing changes in meat consumption. Older people of nearly 50 years and above tend to consume more poultry and less beef (Schroeder and Mark*,* 2000).

Moreover, animal protein consumption in developing nations is low because animal products are more expensive than other food and their consumption is closely related to the level of income, which are generally low (Murtala *et al.,*2005). Animal protein consumption is closely related to the level of income because animal products are more expensive than plant protein and other foods. As the level of real income improves, people tend to substitute high quality foods, notably animal products for carbohydrates in their diet plan. Per capita animal product consumption is a good indicator of the gross domestic product and standard of living of a country (Amoo, 2005).

Methodology

The research was carried out in Adamawa State of Nigeria. Multi-stage random and systematic sampling techniques were employed for the selection of one hundred and ninety six (196) households used for the study. The analytical tool used was AIDS model. The AIDS model suggested by Deaton and Muellbauer (1980) has enjoyed great popularity in applied demand analysis starting from the Gorman polar cost (expenditure) function. The AIDS demand functions in expenditure (budget) share is given by:-

$$\omega_i = \alpha_i + \sum \gamma_{ij} \ln \mathrm{P_j} + \beta_\mathrm{i} \ln\left(\frac{x}{p}\right) + \mathrm{U_i} \quad (1)$$

Where:-

wi = the budget share for good i

α_i = The constant Coefficient in ith share equation

γ_{ij} = The slope coefficient associated with the jth good in the ith share equation (Price Coefficient)

P = the price of commodity (Price Index)

β_i = Expenditure Coefficient

U_i = The disturbance/Error term

The AIDS model needs to satisfy the adding up, homogeneity and symmetry conditions.

The adding up restriction is:-

$$\sum\alpha_j = 1, \sum\gamma_{ij} = 0, \sum\beta_i = 0 \text{ (adding up)} \quad (2)$$

Some socio-economic/demographic variables other than price and income were incorporated into the model by allowing the intercept in equation (1) to be a function of demographic variables as:-

$$\alpha_i = p_{io} + \sum_{j=i}^{S} P_{ij} d_j \quad (3)$$

Where dj = jth demographic variables of which there are S.

The new model, including the demographic variables and an error term u_i is then defined as: -

$$\omega_i = p_{io} + \sum_{j=1} p_{ij} d_j + \sum_j \gamma_{ij} p_j + \beta_i \text{In}\left(\frac{\text{x}}{\text{p}}\right) + u_i \quad (4)$$

The adding up requirement under the specification with the demographic variable now requires that:

$$\sum_j p_{io} = 1, \ \sum_i p_{ij} = 0 \ (j = 1, \dots \dots \dots, S) \quad (5)$$

Elasticity was also incorporated in the model as follows:-
The price elasticity in the AIDS model is given by:-

$$\epsilon_{ij} = -\delta_{ij} + \frac{\gamma_{ij} - \beta_i(\alpha_i + \sum \gamma_{ij} \ln p_i)}{\omega_i} \quad (6)$$

Note: In practice the term given by ($\alpha_j + \sum \gamma_{ij} \ln p_i$) may sometimes be replaced by the equivalent $\left(\text{wj} - \beta\text{jln}\left(\frac{\text{y}}{\text{p}}\right)\right)$in elasticity expressions.
Expenditure (income) elasticity is given by:-

$$\epsilon_{iy} = \frac{\beta_i}{\omega_i} + 1 \quad (7)$$

Results and Discussion

The analysis of the determinants of household demand for beef obtained from the Almost Ideal Demand System (AIDS) model is presented in Table 1. The result revealed that five explanatory variables used in the model, namely; age, marital status; main occupation, secondary education and child dependency ratio significantly affect households' demand for beef. The result revealed that the coefficients of age of household head, main occupation, secondary education and child dependency ratio were negatively related to the budget share on beef, meaning that an increase in these variables would decrease budget share allocated to beef.
However, the coefficient of marital status was positively related to the budget share on beef, implying that households that are married increase their budget share on beef. The statistical significance of age of household heads at 5% level indicates that as the age of household head increases, the budget share (expenditure) on beef decreases. This may be attributed to the linkage between beef consumption and age related sicknesses such as heart disease and arthritis as discovered by (Kudi *et al.,* 2008). Hence, households that have attained certain age decrease the consumption of beef because of the associated health hazards. This is in line with Schroeder and Mark (2000) who found a link between cholesterol and heart disease.

Table 1: AIDS Parameter Estimates for Beef in Adamawa State

Parameter	Beef
Constant	0.558**
	(2.38)

Source: Computed from Result of AIDS Model
Figures in parentheses denote Z-values. *** denotes significance at 1% level
** denotes significance at 5% level * denote significance at 10% level

The coefficient of main occupation is statistically significant at 5% level and negatively related to expenditure on beef implying that respondents whose main occupation is farming tend to decrease their expenditure on beef. This may be attributed to their low income status where respondents rely more on cheaper protein sources instead of spending the meager resources on beef. This is in line with Hupkova *et al* (2009) who opined that, the declining beef meat consumption is due to the decreasing purchasing power of the consumer.

The statistical significance of secondary education at 10% level indicates that household heads that has attained secondary level of education decreases their budget share (expenditure) on beef. At that level of education, respondents are not expected to have good Jobs that can earn them better income so as to increase their demand for beef. This might be the reason why majority of them are farmers. The coefficient of child dependency ratio is statistically significant at 5% level and negatively related to expenditure on beef implying that respondents with high child dependency ratio tend to decrease their expenditure on beef. This is a deviation from *apriori* expectation where high child dependency ratio is expected to increase demand for beef, although low income could result to this situation. This is in confirmation with Murtala *et al.* (2005) findings that animal protein consumption in developing nations is low because animal products are more expensive than other food and their consumption is closely related to the level of income, which are generally low. The statistical significance of marital status at 5% level indicates that household heads that are married tend to increase their budget share (expenditure) on beef. Household size tends to be higher among households that are married than unmarried households, and this tends to increase the expenditure on beef.

Table 2 shows the expenditure elasticities of beef, poultry and fish. It reveals that all the coefficients were positive and statistically significant at 1% level, implying that all of them are normal goods, whose consumption will increase with increase in income. Of the normal goods, beef and poultry have fallen under luxury goods by virtue of their elasticity coefficients (>1). Thus, a 1% increase in household expenditure (income) will increase the demand of beef by 1.07% and that of poultry by 1.56%. However, the household demand for fish is inelastic (0 < e < 1) and can be considered as a necessity. Thus, a 1% increase in household expenditure (income) will increase the demand of fish by 0.75%.

Table 2: Household Expenditure Elasticities of Beef, Poultry and Fish in Adamawa State

Parameters	Elasticity coefficient	Elasticity
Beef	1.065*** (17.01)	Elastic
Poultry	1.563*** (9.07)	Elastic
Fish	0.753*** (10.51)	Inelastic

Conclusion and Recommendations

This study analysed the consumer demand for beef in Adamawa State using AIDS model. The results of this study will add to the existing literature on consumers demand and expenditure using AIDS model. The estimated results may be useful to researchers working on the related topics in future. The AIDS model result revealed that five coefficients of the variables were statistically significant. These include the age of the household head (5%), marital status of the household head (5%), occupation of the household head (1%), educational level of the household head (10%) and the child dependency ratio (10%). The coefficients of the household head; age, occupation, secondary education and the child dependence ratio were negative, meaning that the variables were inversely related to the budget share allocated to beef. While the coefficients of marital status showed a positive coefficient indicating a direct relationship to the budget share. It reveals that all the coefficients were positive and statistically significant at 1% level, implying that all of them are normal goods, whose consumption will increase with increase in income.
Based on the findings of the study, the following recommendations are hereby proffered:
Government should reduce income taxation for low income salary earners as well as subsidizing farmer's farm inputs for increase production, so as to raise their disposable income which will enhance households demand for beef as well as other animal protein sources for healthy living.
Individuals, government and non-governmental organization should invest in livestock production in order to make beef and other animal protein products not only available in large quantity for consumption but also affordable since price is the major determining factor for consumer demand.

Credit facilities through banks and other financial institutions should be made available to farmers and with simplified procedures in order to boost livestock production in the study area and the nation as a whole, thereby, reduced the prices and enhance consumption of beef other animal protein products.

Since majority of the respondents were secondary school leavers. That the statistical significance of secondary education at 10% level indicates that household heads that has attained secondary level of education decreases their budget share (expenditure) on beef. There is need for them to improve on their educational attainment to attract good jobs and earn better income to enhance high demand for beef and other animal protein sources.

Transactions Cost of Market Participation for Cassava in Nigeria: Implications for Agricultural Trade

Abstract
In Nigeria, strong demand and the fact that most of the nation's more than 180 million people are in the hands of smallholders provides a tremendous opportunity for cassava farmers to participate in the cassava market and increase rural incomes. Unfortunately, recent output has not kept pace with increasing demand, suggesting that barriers prevent rural farmers from participating in the market. Increased transaction costs deter entry of small farmers into the market. This review looks at interventions aimed at reducing transaction costs to encourage increased farmer participation in competitive markets. The study raises policy issues which, when attended to, might reduce fixed and proportional transaction costs, particularly by enhancing access to credit, extension and providing market outlets and bulking centers for farming households and rural infrastructure, especially good road networks. Some constraints require direct policy measures dealing with education, and then there are those that require stable policy environment for small-scale traders to promote significant farmer response. The conceptual and empirical evidence suggests that interventions aimed at facilitating rural smallholder cooperatives, by reducing transaction costs are central to stimulating market participation.
Keywords: Fixed Costs, Proportional Transactions Costs, and Cassava

Introduction
Two broad categories of transaction costs, proportional and fixed transaction costs, have been identified in literature (Key *et al*., 2000). Others have distinguished transaction costs between tangible (transportation costs, communication costs, legal costs, etc.) and intangible (uncertainty, moral hazard, etc.) costs (Holloway *et al*., 2000 and Birthal *et al*., 2005). Key *et al*., (2000) introduced a distinction between fixed or lump sum transaction costs, on the one hand, and variable, proportional or per-unit transaction costs on the other hand. They show that both fixed and variable transaction costs impact on market participation whereas supply decisions (amount sold), conditional on market participation, only depend on proportional transaction costs.

Proportional transaction costs change according to how much a household sells or buys (e.g., per unit transportation costs and price premiums deriving from bargaining capacity). Fixed transactions costs are independent of the quantities sold or bought (Vakis *et al*, 2003). It is the bundle of transaction costs that farmers face that determines market participation. Interactions between the unique features of food system participation and other household- and location-specific characteristics can further exacerbate transaction costs. Farmers will not enter markets when the value of participating is outweighed by the costs of undertaking the transaction (Sadoulet and *de* Janvry 1995).

Cassava is a staple food crop in South-Eastern Nigeria and it contributes about 15% of the daily dietary energy intake of most Nigerians and supplies about 70% of the total calories intake of about 60 million people in Nigeria (Ezulike *et al*., 2006). Nigeria is the world's largest producer of cassava; with about 54 million metric tonnes and average yield of 14.03tonne/ha (FAOSTAT, 2012).

Fresh cassava roots, with about 70% water content, are bulky and therefore expensive to transport especially over long distances. The roots are also perishable, and begin to deteriorate soon after harvest. These features are expected to have profound bearing on the trade network for the roots. For instance, the bulky nature of the roots makes the market for fresh roots more localized around the producing areas than the market for processed cassava products. Also the perishability factor makes the marketing process considerably shorter for fresh roots than other cassava products (Ezedinma *et al*., 2007).

Promoting market-orientation among agricultural producers, more so the smallholder farmers, in developing countries is pivotal for development of effective agribusiness value chains that could supply adequate food. This will involve improving the production and marketing processes as well as capacity for income generation among resource-poor farmers (Otieno *et al.,* 2009).

One variable that can be used to access the trend in Cassava commercialization at the rural farm level is the proportion of cassava output that farmers sell after harvest from their fields. Cassava roots can either be sold (in roots or processed form) or consumed at home in the South-South and South-Eastern Nigeria (Ezedinmma *et al*., 2007). The proportion sold suggests a higher degree of commercialization of the commodity. The Collaborative study on Cassava in Africa (COSCA) had used these variables along with others as indicators of cassava commercialization to show that on the average, Nigerian farmers were willing to sell about 45% of their cassava output 15 years ago (Nweke, 1994).

Transaction Costs Economics is especially relevant for agricultural market analysis in developing countries because many of the institutions, or formal rules of behaviour, that are taken for granted in developed countries which facilitate market exchange are absent in low-income countries. The frequent occurrence of market failure and incomplete markets (i.e. caused by higher transaction costs and information asymmetries) in developing countries requires an institutional analysis. This could help to determine what types of institutions are needed (either formal or informal) to improve the economic performance in developing countries (Makhura, *et al.,* 2001).

Methodology

Review of literature for transactions cost and mitigating factors were highlighted. The country Nigeria lies between the geographic co-ordinates, latitudes $4^01'$ $13^09'$N and longitudes $20^02'$ and $14^030'$E. The nation borders the Gulf of Guinea on the south, Cameroon and Chad on the east, Niger on the north and Benin on the west. With a total of 923, 768 square Kilometers of space, the country has an estimated population of 140, 003, 542 inhabitants and a population growth of 2.5% annually (NPC, 2006). The nation Nigeria has six Geo-political Zones viz. North-East, North-West, North-Central, South-East, South-West and South-South.

Results and Discussion

Farmer's decision to participate in the market at any time is influenced by the combined (simultaneous) effects of fixed and proportional transaction costs factors.

Transaction Cost Determinants

Information and search costs related

Frequency of Extension contact: Agricultural extension services provided by the ADPs are the major source of agricultural information in the study area. Frequency of contact with extension workers will increase farmers' likelihood of participating in the market as a result of decreased fixed cost of participation.

Membership of Cooperative societies: Social networks are expected to reduce fixed costs of participation because members may be able to access information about price asymmetries and markets etc within the network.

Access to Communication facilities: Information is acquired through phones, internet, radio, television, extension guides and bulletins etc. It is important that this information be reliable, consistent and accurate. Thus, the right mix of information properties is needed for effectiveness in participation decisions.

Education: Exposure to education should increase a farmer's ability to obtain, process, and use information for market participation. Education thus is thought to increase the probability that a farmer will participate more in the market as a result of decrease in fixed costs associated with education.

Bargaining and Negotiation Costs related

Sex: It is expected that the relative role women play in 'effort' in terms of bargaining suggests that women participate more than their male counterparts in cassava marketing as a result of reduction in fixed costs emanating from bargaining power.

Age: Age is a latent characteristic in the participation decisions. Farmers who are younger may be expected to have more bargaining strength for better prices than their aged counterparts. Dialogue has to take pace between buyer and seller and this demands negotiating skill on both sides in order to arrive at the most advantageous 'deal'.

Native of Community: Natives of the community culturally have more credibility among their kinsmen and members of the community. This lowers the fixed cost of participation as a result of more bargaining power. Therefore they are expected to participate more in the market than their counterparts who are migrant farmers.

Farming experience: A farmer's experience can generate confidence. With more experience, a farmer can become more credible and vast in terms of prices, thereby leading to better bargains and reduction in fixed costs of participation.

Monitoring and Enforcement Costs related

Time to get paid in days: This fixed cost occurs ex ante since the transaction has already taken place. Default in payment as at when due/agreed extending the time of payment increases fixed costs of participation

Number of times asked for payment: Increase in the number of times asked for payment is expected to increase fixed cost of participation in the market making farmers opt out of markets.

Have trust in Buyer: This is expected to lead to a reduction in fixed cost leading to increased participation. Trust in buyer will reduce the length of monitoring.

Proportional Transaction Costs Related (PTCs)

Personal Means of Transportation: Farmers with means of transportation are expected to have lower proportional costs leading to increased market participation.

Distance from the farm to the market: Farmers' who travel long distances to the market experience high proportional transaction costs constraining them to buyer conditions selling in the farm because of the bulky nature of cassava as well as the road conditions.

Distance to the nearest town: Farmers' with long distances to the nearest town are constrained accessing information and markets in these towns as a result of huge PTCs associated with traveling.

Distance from the house to the Market: Farmers' with long distances from the house to the market may prefer to sell cassava at the farm gate as a result of huge proportional transaction costs associated with market participation.

Distance from the house to the farm: Farmers' with long distances from the house to the farm may be constrained to sell at the farm gate to mitigate the proportional transaction costs of traveling again from the farm to the market to sell.

Volume of Credit: Credit will lead to decreased proportional transaction costs leading to increased market participation. This is measured in naira

Crop transportation costs: Increase in crop transportation costs will lead to increase in proportional transportation costs. This will increase the cost of traveling to the market either from the farm or the house to make sales.

Household Size: Because larger households are more likely to provide the labor that might be required to move cassava to the market, a larger household size would be expected to increase market participation thereby leading to a decrease in proportional transaction costs.

Dependency ratio: Increase in dependency ratio is expected to lead to a decrease in market participation because the aged and the children may not be able to give any support in terms of labour reduce proportional transportation costs.

Marketing experience: Marketing experience is expected to reduce the proportional transaction costs of participation.

Farm income: Farm income is expected to reduce the proportional transaction costs of market participation.

Road conditions to the nearest town: If road conditions to the nearest town are good more farmers are expected to participate in the market because of reduction in proportional transaction costs.

Yield: Yield is expected lead to increased farm gate sales as a result of the bulky nature of cassava. This will lead to increased proportional transaction costs of market participation as a result of increased distances from the farm to the market and road conditions.

Non-farm income: Non-farm income is expected to lead to increased market participation as a result of decrease in proportional transaction costs.

Conclusion

Smallholder cassava is characterized by low levels of market participation. The results support previous studies that existence of transaction costs constrains households from selling. While transaction costs are difficult to measure, understanding the impact they have on behavior is crucial as it can inform policy design aimed at reducing them. This review shows how different types of transaction cost influence decisions and outcomes for farm-households in South-Eastern Nigeria. Collectively, these results demonstrate the importance of allowing for non-negligible fixed costs in market participation studies. When these costs are ignored but are non-negligible, a significant bias in participation and level of sales estimation appears to exist. Policies that reduce transaction costs through improved transportation, promotion of organizations for marketing, improving rural infrastructure (e.g., access roads), credit access, encouraging the younger marketers especially women to increase marketed output will lead decrease in transactions cost of marketing cassava

Abstract
This paper reviewed the place of agriculture and agricultural policies in Nigeria's quest for economic development and growth. Agriculture long before and after independence was the base of our economy and held the forte until petroleum was discovered in commercial quantity. Agriculture has a high propensity for inclusive growth. It ensures food security, provides raw materials for industrial production and development. It is a panacea to the problem of a mono product economy and a shift from dependence on oil to a diversified economy. Being labour intensive, it has the capacity for massive job creation, thus reducing the present high unemployment rate in the country. Agriculture has the potential to raise GDP, reduce unemployment, accelerate industrialization, increase foreign exchange and arrest the rampaging poverty. Unfortunately, it has been ignored by successive governments in Nigeria. Empirical evidences have shown that agriculture for now is the cheapest and easiest way out from the present economic predicament of the Nigerian economy.
Key words: Agriculture, economic, development, food security, unemployment, poverty.

Introduction
Nigeria though battling with huge external debt has tried exploiting and exporting her natural resources for sustenance these years. However, contemporary international debt issues have become increasingly challenging in generating enough resources for sustenance without increased pressure on resources (monetary in particular) for the production of goods for local consumption and agricultural products for export. In order to meet its obligations in the face of the mounting economic challenges (especially foreign and local debts), economic policies and programs have been introduced. These include self-sufficiency in food and raw materials production, employment generation, increases in exports, rural development etc. these are reflected in the objectives of the structural adjustment program (SAP) of years gone by. Agriculture, many scholars believe, can be an easier and cheaper alternative among other options to getting out of debts and growing the economy.

Development of the Agriculture sector appears a most probable option and would imply sustained increases in production and productivity and improvements in the wellbeing of the farmers and the general populace who will experience higher per capita income. Agricultural development will not only include sustained increases in production and productivity but also lead to sustained social and economic improvement in rural communities. To achieve these goals through agriculture, there should be a systematic improvement in institutional, physical and social infrastructures (Tunji, undated blog).

Notably, the agriculture sector's performance from political independence has been declining steadily from a 75 per cent contribution to Nigeria's GDP in the 1960s to less than 50 per cent in 1990s. For 2nd quarter 2017, agriculture contributed 28.08 percent to nominal GDP and 24.44 percent in the 3rd quarter. The factor responsible for this is the exploration of oil and gas and the attendant boom in the 1970s. Other reasons for the decline are the poor funding in the budget and the poor implementation of agriculture-focused policies. Notwithstanding these, agriculture is believed to be the easiest routes to structural changes and economic diversification since the country is richly endowed and agricultural production and processing do not require complex technology and, there is the propensity for increased productivity from the adoption of appropriate technology for varieties of improvements and fiscal incentives (Ogunleye, 2017).

Olajide *et al*., (2012) argued that for development to take place especially economic development, a nation has to pass through some stages such as a traditional stage necessary for industrial take-off, the take off stage itself needed to drive the nation to maturity and finally a high mass consumption stage. Agriculture played crucial roles in stages one to three and the agricultural sector is very necessary for the industrial and economic springboard a country needs for development to take off. Agricultural activities normally are concentrated in the rural areas where the need for rural transformation, redistribution, poverty alleviation and socio-economic development is critical.

From contemporary realities, possessing natural resources like petroleum, natural gas and other forms of mineral resources does not automatically guarantee economic growth for a country. Many crude oil bearing economies witnessed significantly stagnated economic growth in the 1970s and 1980s. From Gylfason (2001) studies, natural resource–rich countries which includes Nigeria, struggle to attain long-term investments of more than 25% of Gross Domestic Product and, per capita income growth of more than 4 percent per annum on the average from 1970 to 1998. Many countries like Nigeria, Angola, Sudan, Congo etc are rich in natural resources such as crude oil, diamond, and other minerals; yet they have a very low per capita income (Amini, 2018). From empirical literature, the link between natural resources, human capital development and economic growth has been consistent among countries and, it has been observed that economic growth has an inverse variation with natural resource abundance, human capital development measured by educational inputs or participation; however economic growth varied directly with education (Akpan et al, 2014).

Table 1: Regression Results: Natural Resource Abundance vs Economic Growth and Human Capital Development

Dependent Variable	Constant	Natural Capital	Human Capital Accumulation	Investment	Per Capita Income	R^2
Economic Growth	30.55 (0.75)	-1.55 (-3.12)***	4.19 (0.72)	4.29 (1.1)	6.46 (2.71)**	0.71
Human Capital Accumulation	15.08 (6.32)***	-0.29 (-6.46)***			0.59 (1.43)	0.53

T-statistics are shown within parentheses. *** And ** indicates significance at the 1% and 5% levels respectively
Source: (Akpan *et al.,* 2014)

Empirically, the relationship of natural resource availability, human capital development and economic growth in Nigeria indicated an inverse relationship between natural resource availability and economic growth. This relationship is strong both statistically and through econometric evaluation; all pointing to a negative influence on growth and has a coefficient that is significant at 1% level of confidence. A one percent increase in earnings from natural resource exploitation (petroleum oil mineral) resulted in a retardation of economic growth by 1.55%. The result also shows that resource-human capital equation results pointed to the fact that natural resource availability also had an inverse relationship to human capital development in Nigeria implying that as the share of natural resource rises in national income, there is the likelihood for the government to pay more attention to her natural resource assets and neglecting other assets (Akpan *et al*., 2014). Amini (2018) also reported that all countries that had access to oil wealth or other natural resources displayed similar behaviour compared to their contemporaries without such advantages. This may be because the presence of these resources can crowd-out human and physical capital accumulation. Therefore the assertion should be carefully studied because of its implications on other sectors of the economy such as agriculture, education and development policy (Akpan *et al*., 2014).

The Impacts of Government Policies on our Agricultural Development Continuum

Olajide *et al.,* (2012) reported that agriculture is of great importance to a nation's development process and provides the ingredient for most of the world's great civilization in times past and recalled that the increase in agricultural productivity in ancient England paved the way for and initiated the industrial revolution. This kind of transition and progress through agriculture is only possible through good and sustainable policies.

Agricultural development therefore will need good and viable policies to remain supportive and sustainable in any economy. Policies should mainly target economic adjustments: the macroeconomic and structural adjustments. The former refers to policy changes aimed at reducing or eliminating disequilibrium in the economy and may involve changes and short-term remedies for immediate problems and influence demand in the economy. Agricultural policies should depend on a resource base that is both sustainable and productive. The challenge today will be how to increase productivity while at the same time enhancing the productive capacity of resource bases. Policy interventions by successive Governments in Nigeria targeted improvements in agricultural productivity. Yet, the country made very little progress. These policy interventions have aimed largely at enhancing productivity and jobs creation specifically (Ogunleye, 2017) without targeting a sustainable resource base.

Government policies on agricultural development may need to shift from the contemporary emphasis on low-rent resources like artisanal activities and even crude exploration to alternative income sources which agriculture offers. Countries with low rents in their natural resources, some scholars have advised, should develop alternative economic sources with high potentials for wealth creation that can aid the provision of public goods and incentives for investments in both economic and social infrastructure and agriculture fits into the picture. These alternative activities will induce the development of the manufacturing sector that may boost government revenue (Akpan *et al.,* 2014). In this concept, changes and redirection of government investment will be a single important policy instruments that many developing countries can use to promote inclusive growth in agriculture through equitable resource distribution (Ebere *et al*, 2014).

Government organs responsible for instituting policy interventions to promote agriculture for inclusive growth must sit up if agriculture must be sustainable and support economic growth. Some of the policy interventions that should be provided should include the following, outlined by Ogunleye (2017):

Import substitution: this will discourage importation of products which Nigeria may have comparative advantage in their production and processing, save foreign exchange, encourage the local alternatives and hasten the attainment of self-efficiency. Nigeria should not be importing products like tomato paste/concentrate, tropical fruit concentrate, cassava derivatives, etc. Nigeria spends an estimated N18 billion annually on products like these. Import substitution policy should cater for investment in agriculture to the advantage of local production. Import substitution, as events presently suggest, is in the shadows because Nigeria still significantly imports even what it can produce locally with reasonable advantage.

Tariff and surcharge: when levied on some imported agricultural commodities will limit their importation and encourage domestic production and processing. Commodities like rice, sugar, maize, etc fall into this category. The tariff regimes will exert positive effect on the agriculture economy enhancing local production. These types of policies will falter if our borders remain as porous as it is today because smuggling and black market activities will negate whatever these policies aims to achieve. Moreover, the policies must be intelligently executed though to avoid a trade war that may impact the economy.

The Policy of Zero Duties on Agricultural Equipment and Machines will facilitate importation of needed agricultural equipment, machines and other accessories like tractors that are not produced and manufactured locally. This will reduce production and processing costs.

Contemporary realities suggest the acquisition of these tools remain prohibitive and out of the reach of the farmers that need them. Agricultural inputs to support the farmers especially the small scale farmers should be subsidized. This will reduce cost of production for the small holder farmers who plausibly are resource poor. The suggested inputs should include seeds and seedlings, agro chemicals, loans and credits.

The Place of Agriculture in Nigeria's Economic Growth and Development

Development economists have always considered how agriculture will contribute to a nation's economic growth. Some laid emphasis on agriculture in economic development and believes the development of an economy may depend on agriculture because agricultural productivity surpluses can diffuse throughout the entire economic system and networks of transactions. They see the agriculture sector as a base in the productive sector of an economy upon which all others depend (Olajide *et al*., 2012). In our own clime, we can see that Agriculture contributes to the development of the economy through industrial raw material provision, factor (input) availability, market contribution and foreign exchange (Kuznetz 1961; Mackie 1964; Abayomi 1997; Abdullahi 2002; World Bank 2007 in Olajide et. al., 2012). Agriculture is the largest economic sector in Nigeria with a dominant share in the GDP, employing more than 70% of the labour force and generating about 88% of non-oil foreign exchange (Olajide *et al*., 2012). Agriculture's primary relevance is the provision of food and manpower to the industrial economy. In Nigeria, it is a key sector and will remain crucial in our development continuum. Economic history confirms agriculture is fundamental and a pre-condition for economic growth, in many developing and developed countries.

Olajide *et al*., (2012) citing Iganiga and Unemhilin (2011), stated that using Cobb Douglas Growth Model with variables such as commercial credits to agriculture, consumer price index, annual average rainfall, population growth rate, food importation and GDP growth rate proved that federal government capital expenditure was positively related to agricultural output. Also Oji-Okoro (2011) employed multiple regression analysis to study the contribution of agricultural sector to the economic development and found a positive relationship between GDP, domestic saving, government expenditure on agriculture and foreign direct investment from 1986 to 2007. Further, using a time series data, the team reported that Lawal (2011) verified federal government's expenditure on agriculture for a thirty year period 1979 – 2009. The study also showed significant statistical evidence that the contributions of the agricultural sector to the nations GDP was in direct relationship. The empirical table below lays much credence to the report of the three some.

Table 2: Relationship of agriculture investment and Nigeria's GDP

Variable	Coefficient	Std. Error	t-Statistic	Prob.
Constant	13106.28	27745.31	0.472378	0.6393
OUTPUT	0.344909	0.007552	45.67056	0.0000
R-squared	0.991381		Mean dependent var	1571964.
AdjustedR² squared	0.991160		S.D. dependent var	2758148.

F-statistic	4485.789		Durbin-Watson stat	1.267931
Prob(Fstatistic)			0.000000..................	

Source: Olajide et. al.,

The empirical results of the regression show a positive relationship between GDP and the Agro-outputs. From the result, a unit change in agricultural output caused a 34.4% change in GDP. The F-ratio of the study was about 4485.789 at 5 percent level of significance implying that the agricultural sector for the period under study had significant influence on the macroeconomic performance. From the ongoing it is evident that agriculture is one of the most important sectors in the economy. The capacity of agriculture to initiate economic growth and a sustainable development of the economy cannot be overemphasized. Agriculture can pave way for economic growth, guarantee employment opportunities, foreign exchange earnings and poverty reduction in the economy.

Conclusion

It is obvious that the agriculture sector can significantly contribute to Nigeria's GDP, grow and develop the economy. Literature, contemporary and empirical evidences are compelling enough to change our perceptions and orientation about the agriculture sector, it is no longer the ''ordinary farming business''. Though recent regimes have highlighted interests in agriculture in recent times yet, this is a far cry from what is adequate, more so, agriculture has all that it takes to turn the economy around (release of labour to the industries, provision of raw industrial materials, increased income earning capacity, access to foreign exchange, infrastructural development, etc) on a sustainable bases because it is inexhaustible unlike petroleum and other mineral and natural resources. Further, the multiplier effect on the economy is perpetual so long as the industry exists. Based on the findings, the study recommends a well articulated vision for the agriculture industry; it should be a front burner in our economic planning. Agriculture should be repositioned through mainstreaming for sustained growth and development. Easy to acquire credit should be made available to the smallholder farmers who are the main players in the agriculture industry. This is necessary to assist them to deal with the challenges associated with inadequate access to credit as this will affect production and output.

Agripreneurship as a Tool for Improving the Agricultural Sector for Economic Development in Nigeria

R. A. Oke, O. P. Oyetunji, O. A. Fadele, G. O. Akinyemi and A. A. Kareem
Onigambari Research Station Forestry Research Institute of Nigeria
Razaq_Ok@Yahoo.Com

Abstract
This paper reviews and highlights problems facing the agricultural sector and agribusiness in Nigeria and in turn the overall economic growth and development. It further identifies agripreneurship as a remedy to current situation of underperformance plaguing the agricultural sector which will in turn lead to an overall economic growth and development. Agripreneurship will attract youth to the agricultural sector, create agribusiness growth and expansion, provide better options for farmers and improve the standard of living of farmers. Trend analysis was employed in terms of current and historical perspectives as well as descriptive analysis to evaluate the effects of agripreneurship on the agricultural sector. The paper made relevant recommendation that will enhance the creation of favorable business environment for agripreneurship in Nigeria.
Key Words: *Agriculture, Economic Growth and Development, Agripreneurship, Agribusiness*

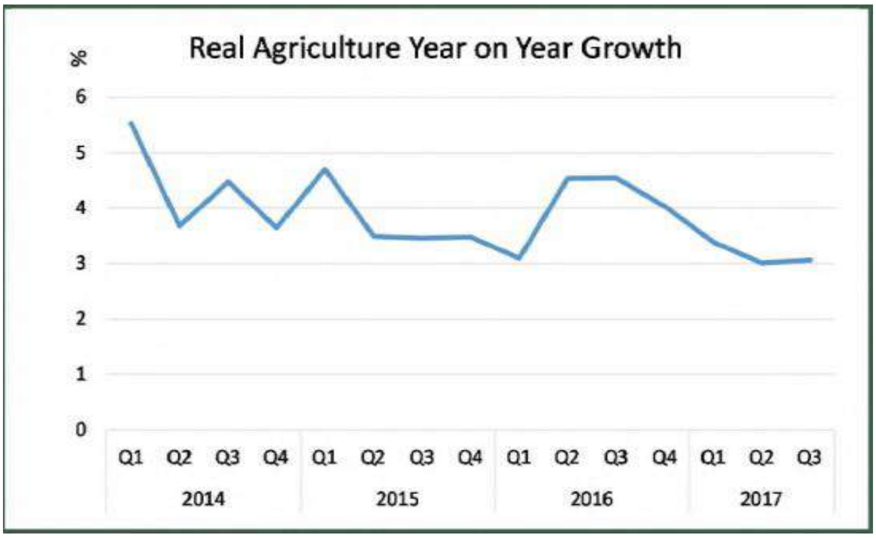
Introduction
Agriculture is very crucial to the Nigerian economy and the livelihood of the rural populace. It was the mainstay of the nation's economy prior to the discovery of crude oil. One of the sectors governments and policy makers turn to with regards to economic diversification is the agricultural sector; this is because of the numerous benefits and potentials inherent in the sector. Chukwuma and Uju (2013) stated that agriculture contributes the largest to non – oil foreign exchange earnings and can ensure output income and food security. Adeniran and Sidiq (2018) also described agriculture as one of the tools for pulling the Nigerian economy out of economic recession. According to the NBS, the agricultural sector is made up of four (4) subsectors namely: Crop Production, Livestock, Fisheries and Forestry. The sector is heavily dominated by Crop Production contributing for 91.27% of the overall nominal growth of the sector. Agripreneurship has been identified as the new solution to unemployment and food insecurity especially in developing economies. Uche and Familusi (2018) described agripreneurship as the combination of entrepreneurship and agriculture and that an agripreneur like an entrepreneur must be able to detect and create business opportunities that he or she can exploit. Bairwar *et al,* (2014) explaind that agripreneurship refers to agribusiness establishment in agriculture and allied sector. They also described an agripreneur as someone who undertakes a variety of activities in agriculture sector in order to be an entrepreneur.

Problems Facing the Agriculture Sector in Nigeria
In terms of economic development and contribution to industrialization, the Nigerian agricultural sector is still far from reaching its expected potential due to its failure to produce food beyond subsistence level despite the sector contributing 24.44% to the nominal GDP in the third quarter of 2017 (NBS, 2017). It still reflects a lot more work to be done in the sector. The underperformance of the agricultural sector can be attributed to the following (Yusuf, 2014),

- Overdependence on the Oil Sector - Yusuf (2014) affirms that the after the discovery of oil in Nigeria, the contribution of agriculture to the overall GDP fell from about 75 – 80% to about 40%. The discovery of oil gradually turned Nigeria into a mono – economy, heavily dependent on the sales of crude oil. The Nigerian economy was plunged into an economic recession in 2016. During the third quarter of 2016, the nation's GDP contracted by -2.24% (year-on-year) in real terms according to the NBS Report (2016). The NBS report stated that among other factors, a significant drop in the sale of oil was responsible for the drop in the real GDP leading to economic problems for the country.

- High Interest Rates and Poor Credit Facilities – The agricultural sector is usually faced with high interest rates making lending almost impossible. Furthermore, the collateral often asked by financial institutions is beyond the capacities of the rural farmers. The inability of farmers to access loans and credit facilities prevents them from expanding and growing their agricultural ventures.
- Environmental Issues – As environmental degradation occurs, agricultural activities take a steady decline. Furthermore, oil refining activities in the Niger Delta have resulted in oil spillage causing environmental damage. This has affected farming and fishing activities in the region.
- Poor Infrastructure – The absence of storage facilities has affected agricultural output due to the perishable nature of several agricultural produce. Furthermore, poor transportation facilities, poor electricity has not only disabled farming activities but also prevented the growth and expansion of the sector.
- Insecurity – Agricultural activities have been put to a standstill in regions affected by unwarranted killings and loss of properties. This has led to a remarkable drop in crop production and livestock practice in Nigeria.

Figure 1: Graph showing agricultural performance from Q1 2014 TO Q3 2017.



Source: National Bureau of Statistics Q3 Report

Eze (2017) added that the shift of attention from the agricultural sector to the oil sector led to problems and consequences such as food insecurity, import dependence, inadequate supply of raw materials to industries, excessive borrowing, high inflation and unemployment rates etc in the country.

Agripreneurship as A Way Forward in the Agricultural Sector

Agriculture as an enterprise is going through a transition globally, assuming a new shape and has gone beyond mere cultivation of crops and rearing of animals or an enterprise of the rural population (Uche and Familusi, 2018). They further added that agripreneurship will help in achieving Nigeria's Agricultural policy whose objectives includes job creation, food security, foreign exchange conservation and earnings as well as the enhancement of economic diversification. It is therefore important to employ more productive techniques into the agricultural sector in Nigeria.

Uneze (2013) stated that the need for agripreneurship stems from increasing demand of organic and quality food, competitive advantages for many primary production activities in agriculture, private sector willingness to enter into agribusiness at all levels of operation, to reduce malnutrition in women and children and to ensure household and national food security.

Agripreneurship views farming as an important venture, sees farmers as investors, provide opportunities for the growth of Small and Medium Scale Enterprises (SMEs), allow urban – rural intra and inter population participation in agribusiness, brings about sustainable and healthy business environment and its innovative approach increases effectiveness and efficiency in agribusiness. Agripreneurship is a viable tool for revitalizing the agricultural sector in Nigeria. This is also very important given the subsistent nature of farming being practiced by many farmers especially those in rural areas and the heavy emphasis being placed on entrepreneurship as an option for alleviating problems of unemployment in Nigeria.

Adeniran and Sidiq (2018) mention that the older population is the ones who are still heavily involved in agriculture as most youths leave rural areas to urban areas in order to find employment. Agripreneurship involves the use of modern farming techniques and machinery as well as an exposure into a vast agricultural value chain which allows for more output and income. These may attract more youths to venture into agribusiness. As more youths begin to join the agricultural sector and agripreneurship models are employed, rural – urban migration is curtailed, employment opportunities will further be created and the overall agricultural sector will improve. Most agricultural practices currently being used are restrictive and as such can only reach limited markets. However, with agripreneurship farmers can sell their products to a wider and bigger market. Farmers will also have increased farming options and may have better access to credit facilities that would otherwise have been absent or unavailable with subsistent farming. Agripreneurship further gives farmers the options of exploiting other points on the value chain and as such achieve expansion and growth of their agribusiness.

Nwibo, *et al,* (2016) maintain that at input production level, there are many potential agripreneurial opportunities such as bio-fertilizers, bio-pesticides, soil amendments, plants of different species of fruits, vegetables, ornamentals, roots media for raising plants in pots, mineral mixture and complete feed. There are also agripreneurial opportunities to support sericulture, fishery and poultry. Agripreneurship can also serve as a means of improving the standard of living of farmers especially those in rural areas. By employing agripreneurship techniques, farmers will be able to create a wide range of products and services from their agribusiness. This will lead to an increase in income and earnings leading to a rise in standard of living. This may eventually lead to the development of such rural areas.

The application of entrepreneurship skills and principles in agriculture may give rise to more agro-allied firms that will create new products using agricultural output as raw materials. These new products will make Nigerian exports compete better in the international market therefore creating foreign exchange earnings. Entrepreneurship breeds competition and as such employing these techniques in agriculture will create healthy competition among farmers leading to better agricultural output at lower prices ensuring food security.

Recommendations and Conclusion

Given the already existing and potential roles agripreneurship can play in revitalizing the agricultural sector, governments and policy makers need to create specific policies aimed at promoting agripreneurship in Nigeria. By actively conducting trainings in schools and other institutions in Agripreneurship Education, providing credit facilities to existing and potential agripreneurs, creating better infrastructure that will support the growth and development of the agricultural sector and tackling insecurity, government can create a good environment for agripreneurship to thrive in Nigeria. Hence, the agricultural sector would be revived and in turn contribute positively to economic growth and development Nigeria.

Socioeconomic analysis of Processors and Users of Camel (*Camelus Dromedrius*) Products in Yobe State Nigeria

Hamisu Abubakar Mahraz
Federal College of Education, Kano –Nigeria PMB 3045
Email- Mahrazhamis@yahoo.com

Abstract
The research was conducted to evaluate camel production, the different products obtainable from camel (Camelus dromedrius) and their utilization in Yobe State. A design questionnaire was used to collect the required information. Stratified random sampling technique was used to sample 113 respondents from the study area. The results showed that over 95% of the total respondents consumed camel meat and about 82% of the respondents were engage in marketing of camel meat. About 54% believed that cooking is the most common method of processing camel meat. Over 70% of the respondents consumed camel milk and about 64% of the respondent involve themselves in marketing of camel milk. 33% of the respondents do not consider camel urine for medicine or any consumption but about 51% used it for medicinal purposes. Furthermore, the result indicates that 77% of the respondents used camel hide domestic purposes and over 50% of the respondents were involved in the marketing of camel hide. Meat, Milk, hide and Urine are the major products obtained from camel in the study area and they are extensively utilized in the area.
Key words: *Camel, meat, market, processing, milk, hides*

Introduction
Camels are pseudo ruminant animals that have either one hump (Arabian camel) or two hump (Bacterian camel), which play an important socio-economic role within the pastoral and agricultural system in dry and semi dry zones of Asia and Africa (Berhanu et al., 2013 and Gwida et al., 2011). Global population of camel was estimated to be around 20million of which 15million are found in Africa and 4million in Asia (Farah 2004 and Jaji *et al.,* 2017). Rearing of camel in Nigeria is for various purposes like carrying farm products, milk, meat, and hides production and to some extent camel is used for racing especially in the Middle East countries (Jaji *et al.,* 2017). They are also a reliable source of milk during dry season and draught when milk from other animals like goat, sheep and cattle become scarce and there products play a vital role in nutrition and medicine for the people in eastern Africa (Farah 2004, Farah et al., 2007 and Jaji *et al.,* 2017). Camels are known to be drought tolerant animal due to their unique physiological features that help them to survive and produce under harsh environmental conditions by regulating the body temperature to changes in ambient temperature (Berhanu et al., 2013). Camelus dromedrius are mostly found in arid and semi-arid areas of Africa, found in the countries like Somalia, Sudan, Ethopia, Kenya and Djibouti (Gebisa, 2015). Camel are also found in Nigeria mostly in the northern part of the country including Borno, Yobe, Kano Jigawa, Katsina, Sokoto Kebbi and Zamfara state. An increase in camel population within Nigeria was reported to be about 90,000 in 1994. The increase in camel population was believed to be due to the disease outbreak in cattle range that decrease the supply of cattle meat in the country and may also be due to the affordability, as camel meat is cheaper than cattle meat (Jaji *et al.,* 2017 and Abubakar *et al.,* 2010).

The casual use of the camel as draught animal was reported by Musa (1990). The camel is, however increasingly becoming important in primary land preparation and secondary field operations during the rainy season (Jaji *et al.,* 2017). Farmers in the Northern States are exploiters of camels rather than producers, since the camels are an essential part of the pastoral daily life. They are important for the pastoralists to be recognized as a true member of the community (Kaufman and Binder, 2002). Camels not only sustain life on a day-to-day basis for many people living on the fringe of subsistence, but also serve as depository of wealth and a security against unknown future

(Wilson, 1998). Meat is importantly required by all human beings to have enough supply of animal protein in their body as deficiency can lead to certain nutritional diseases and reduce disease resistance (Olusiyi *et al.,* 2014). Camels are also considered as good meat producers in Sub-Saharan Africa (Kurtu, 2004) and in areas where the climate adversely affects other animals and cannot provide the required amount of meat needed. The male dromedary carcass can weight 400kg or more (Knoess, 1977). The carcass of a male Bactrian can weigh up to 650kg. The carcass of a female camel weighs 250 and 350kg.

Tasfemariam *et al.,* 2017, reported that, camel milk contain higher whey protein to casein ration compared to bovine milk which is responsible for a soft and easily digestible curd in the gastrointestinal tract. Camels are good producers of milk in the dry regions. Apart from their use for luggage, their milk is good for child health improvement (Yagil and Etzion, 1980; Wilson, 1988). Camel milk is staple food of desert nomad tribes and is richer in fat cow milk. Camel milk cannot be made into butter in the traditional churned method. It can be made if it's first churned, and then a clarifying agent is added, at 24-25° C, but times will vary greatly in achieving results. The milk can be made into yoghurt. Butter or yoghurt made from camel milk is said to have greenish tinge. Camel milk has many healthful properties and is used as a product; some tribes believe that camel milk has great curative powers if the camel`s diet consists of certain plants (Nowak, 1991). Despite the numerous advantages drawn from camel, there is still need to carry out research on processing and utilization of camel products in northern Nigeria. Therefore the current study was aim to assess the processing and utilization of camel products in Yobe State Nigeria.

Methodology

The study was conducted in Yobe state, a Muslim dominated state. The state lies between longitude 12° 00' and a latitude of 11° 30'. The annual rainfall varies from 500 mm to 1000 mm and the rainy season is usually from June to September, with flooded pastures towards Lake Chad and Montane regions in the extreme southeast (Jaji *et al.,* 2017). Three LGAs (Damaturu, Geidam and Yunusari) out of seventeen were purposively selected due to their high level of engagement in processing and utilization of camel products. A total of 113 respondents were selected after a pre-test, using stratified random sampling technique for the study (Gupta, 2002; Pagano and Robert, 1990). Data was collected with a questionnaire administered by trained field staff and analyzed using descriptive statistics.

Result and discussion

Socioeconomic analysis

The results revealed that 80% of the people engaged in processing of camel products were males (Figure 1) with only 19% of female respondents. Less female members were involved in the activities of processing and marketing of camel products. This is attributed to culture and religion of the people in the area, which restrict female participation to household chores. This is supported by the findings of Hassan *et al* (2006) who found that most of the people engaged in poultry processing in the northern part of the country were males.

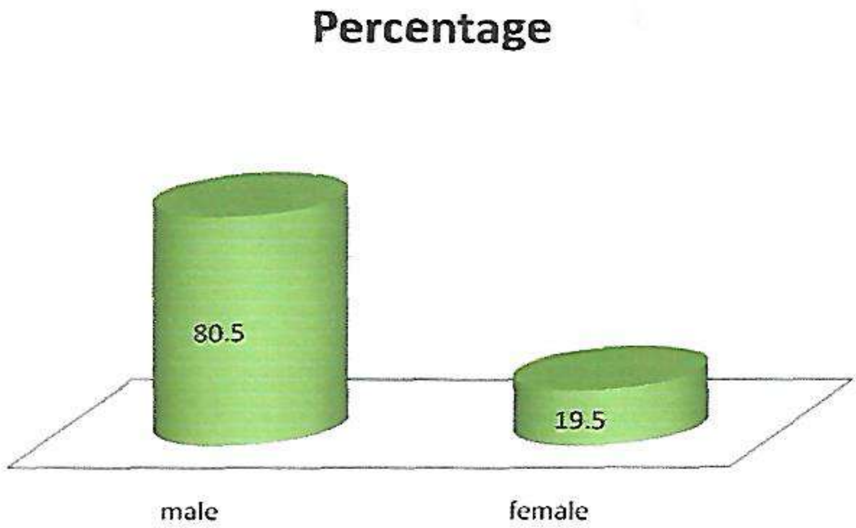

Figure 1: Distribution of respondents by sex

Majority (93%) of the respondents fell within the range of 20 to 40 years. Only 7.07% of the respondents fell within 41 to 50 years. This is in line with the report of Muhammad and Kibon (2006) of age range between 28 and 61 years for respondents in Borno. This indicated most (93%) of the respondents were in their active age, that is, they are energetic enough for the processing of camel products. Older people are likely to participate in community development projects and farm practices due to old age, but the youth are stronger, they can participate in all agricultural activities. This supports the findings of Yusuf *et al.,* (2002)

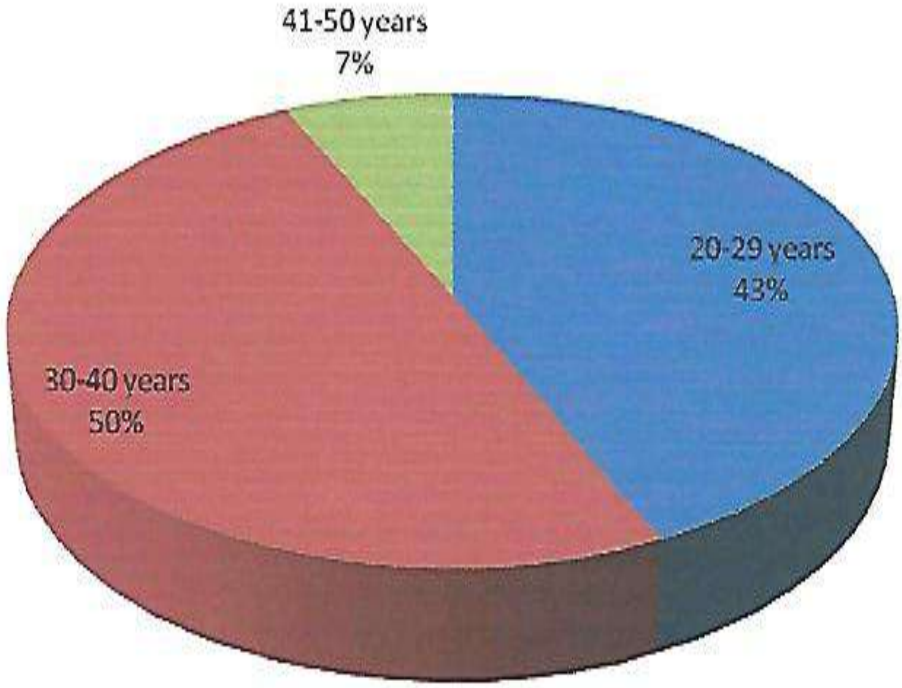

Figure 2: Age distribution

About 32.74% of the respondents were single, 44.2% married, 13.2% widowed and 10% divorced. These results indicated that most of the respondents in processing and utilization of camel products were married men and women in a stable family system. Only a few were widowed and divorced, which exert social pressure on family members. The findings were similar to the reported values of Muhammad *et al.* (2006). Most (49.55%) of the respondents had families with only 1-3 children, 12.38% had between 4-6 children, only 6.19% had 7-10 children. The results indicated that majority of the respondents in the study area had newly established families. Family size is a very important factor in the individual economy and it characterizes the expenditure and labor for most activities (Yusuf *et al.* 2002). The results showed that the majority (51.3%) of the respondents were butchers and 12.4% farmers. The civil servants among the respondents were 16.8%, while 19.5% were meat processors. Female respondents mostly process meat at home and later convey it to the markets. Camel farmers were involved in activities of camel products processing and often utilized the products. The civil servants among the respondents were mostly meat inspectors and veterinarians at abattoir.

Table 1: Distribution of the respondents by marital status, family size, occupation with Sources and preferred sexes of camels

Table 1 also shows the distribution of the respondents based on their sources of camels. Majority (53.1%) of the respondents sourced their camels from Bulaburin *market* while 31.0% were from Gumsa market and 15.9% were from Niger Republic. Also, the results showed that the most preferred camel for slaughter by the respondents were male camels (49.63%), while 44% showed no preference to sex of camels for slaughter, only 6% of slaughtered Camels were females. Majority of the people living in the study area (77.9%) required the services of others to achieve efficient processing of the camel products, especially in the processing of camel meat for hiring meat handlers (62%). However 20% did not require aid from the third party to conduct their activities. The services of butchers and relatives were sought by 14% and 24% of the respondents, respectively. The use of family members and friends provide cheaper source of labor to camel producers (personnel communication, 2008).

Table 2: Use of hired services, Camel meat consumption & marketing, Use and marketing of camel hide by the respondents

Hired services			**Camel meat consumption & marketing**			**Camel Hide**		
Parameters	Fre	%	Parameters	Fre	%	Parameters	Fre	%

Total	113	100	Total	113	100	Yes	67	59.3
						No	46	40.7
						Total	113	100

Most (96%) of the respondents consumed camel meat as shown in table 2 only 4% reported none consuming camel meat, which they associated with ill-health. The results indicated that camel meat is highly consumed in the area and was related to availability and high protein content (Kurtu, 2004). Majority (54.9%) of the respondents considered cooking as the common method of camel meat processing.

About 27% of the respondents considered frying as the most common method, while 17.7% considered roasting as the most common method. These three methods are the commonest means of food processing in the study area. The results indicated that majority of the respondents in the study area considered cooking as method of processing camel meat due to ease of cost compared to roasting and frying, heat treatment effects a number of nutrients contents of meat especially protein. The results further showed that majority of the respondents (82.3%) were involved in marketing of camel meat. Only 6.2% of the respondents were involved in other activities than camel meat marketing. The result indicated that camel meat marketing is a highly valuable activity in the study as it provides good source of income (Personal Communication, 2008)

Again, majority of the respondents (76.8%) used camel hide for one product or the other, of which 38.1% used it for food. About 22% did not use camel hide at all. Likewise, 59.3% of the total respondents were involved in marketing of camel hide while 40.7% were not. Majority (38.1%) of the respondents used camel hide as food. Hide is a valuable commodity used for making a number of products by the respondents; these include bags (12.3%); shoes, belts, whip, saddles (26.55), in the study area. EI-Amin (1979) was of the opinion that in general camel hide provides a good source of income and used for shoes and sandals among other useful materials.

Table 4 shows the distribution of the respondents based on camel milk consumption, marketing and Urine use. Majority (74.3%) of the respondents consumed camel milk while 25.7% did not due to one reason or the other. The results further showed that the most common milk products consumed by the respondents were fresh milk (52.2%) and cheese (47.7%). Majority of the respondents (64.6%) were involved in the marketing of milk. Most of the respondents were involved in the milk marketing to generate more income.

Table 4: Camel milk, marketing and Urine

Camel milk and marketing			Camel Urine		
Parameters	**Freq.**	**%**	**Parameters**	**Freq.**	**%**
Camel milk consumption			**Utilization of camel urine**		
Yes	84	74.3			
No	29	25.7	Yes	33	29.20
Total	113	100	No	80	70.80
Camel milk products			Total	113	100.00
Fresh milk	59	52.2			
Cheese	54	47.7	**Use of camel urine**		
Total	113	100	Medicine	16	51.60
Marketing of camel milk			Spiritual activity	15	48.40
Yes	73	64.6	No response	82	72.50
No	40	35.4	Total	113	100.00
Total	113	100	**Camel urine processing**		
			Yes	17	15.00
			No	96	85.00
			Total	113	100.00

Approximately, 70% of the total respondents were not using camel urine for any purpose. However, 29.2% used camel urine for medicinal (51.6%) and spiritual activities (48.4%). Almost all 85.0% of the respondents reported not processing the camel, while 15.0% claimed that the urine is subjected to some processing before use.

Conclusion

The socio-economic environment of the study area was homogenous. The camel meat, milk, hide and urine were the products used extensively. The male camels were most preferred for slaughter and marketing of the camel meat and hide was a major engagement in the study area. Also, fresh camel milk was mostly used for cheese making while the camel urine was used for medicinal purposes. Therefore great benefit could be achieved through improving the processes of utilizing camel products in the study area. It is an important source of protein as well as a beast of burden. It is therefore recommended that further investigation into the method of processing and utilization of camel products should be conducted. The nutritional and chemical qualities of products should be evaluated and Camel producers and consumers of the products should be encouraged to form User Group and Cooperating Societies for maximum benefits.

E-mail:carobinedo@yahoo.com

Abstract

The study investigated marketing of cassava flour for poverty alleviation among rural people in Emohua Local Government Area of Rivers State, Nigeria. Primary data were collected through structured questionnaire. A total of 50 respondents were purposively selected and employed for the study. Data collected were analyzed using mean scores and percentage. The results showed that majority (42.00%) of the respondents were within the age range of 41 to 50 years, married (80.00%) and are females (64.0%). More (38.0%) had secondary education, have been involved in cassava flour business for 6-10 years (46.0%), and are full time farmers (88.0%). A good proportion (37.31%) of the respondents accepted that buns were the major product produced from cassava flour in the area. A total variable cost (TVC) of N1, 560 was needed to realize total revenue (TR) of N2, 800 giving a profit of N1, 240. The ways cassava flour marketing alleviate poverty are: it served as additional source of income (20.0%) and a source of livelihood (26.0%) to rural people. The constraints to marketing of cassava flour are: longevity (x=3.18), method of preparation (x= 3.20) and non-acceptability of the product in the market (x=32). The study recommends that government should popularize the use of cassava flour in baking and confectionary products
Keywords: *Cassava flour, poverty alleviation, rural people*

Introduction

Cassava is one of the most productive root crops in the tropics in terms of yield per hectare. It belongs to the genus *Manihot* of the natural order *Euphorbiacea*. It is said to have been introduced from Brazil as its original home to West Africa by the early Portuguese explorers (Kassan, 2001). The two main kinds of cassava commonly grown in West Africa are the sweet cassava (*Manihot palmet*) and bitter cassava (*Manihot utilisima*). The bitter cassava contains a bitter juice that must be extracted before it is considered safe for food. The varieties of cassava differ in their stem, skin, leaf, petals, colour and time it takes to mature and in quantity of the tuber. Apart from being a staple crop in both rural and urban households, cassava is a major source of income to cassava farmers and processors in the rural areas. Cassava production alone contributes about 45% of agricultural GDP in Nigeria for food or domestic purposes (IITA, 2005). However, its industrial processing and utilization has been very limited. Cassava is recognized as one of the staple foods in Nigeria. Most farmers in Emohua Local Government Area of Rivers State are cassava producers due to the massive land and the soil suitable for cassava production. Cassava tubers can be processed to cassava flour which can serve or be used as a substitute for wheat flour which is used to prepare bread, meat-pie, cake and other flour related food products. The use of cassava flour will reduce the price of bread, meat-pie and other by-products of flour in the market.

Recently, the price of wheat flour is high which has affected the prices of bread, doughnut and other food products from flour. Flour for baking is mostly imported into the country from other neighbouring countries. The ban on importation affected the price of wheat flour and its related products. Therefore, cassava flour can be used by rural people as substitute for wheat flour to produce bread, meat-pie, cake, Chin-chin, buns etc and it becomes a source of livelihood to them since cassava is common in the area, and it could easily be processed into cassava flour. It is on this note that this paper seek to find out how marketing of cassava flour would help to alleviate poverty among rural populace with the following objectives:

(i) describe the socio-economic characteristics of the respondents;
(ii) identify the different types of products from cassava flour;
(iii) determine the profitability of cassava flour of some products;
(iv) ascertain benefits from cassava flour and how it will reduce poverty; and
(v) identify the constraints to the use of cassava flour among rural people in the study area.

Methodology

The study was conducted in Etche ethnic nationality. The Etche ethnic group is made up of two Local Government Areas, namely Etche and Omuma, respectively. Etche is made up of five clans while Omuma is made up of four clans. They are predominantly rural and agrarian in nature. The respondents in the study were selected using multi-stage sampling techniques. Firstly, the study area was divided into five clustered (clans). Secondly, two communities were purposively selected from each clan, giving a total of ten communities. Thirdly, five cassava processors/ users of cassava flour were purposively selected from each community because they are few, giving a total of 50 respondents which was used for the study. Primary data were gathered through the administration of structured questionnaire for those who could not fill the questionnaire. The data collected from the field were analyzed and interpreted through the use of percentages and mean statistics. Gross margin analysis was used to determine the cost and returns on cassava flour of buns/doughnut. Gross margin is given as:

$$GM = TR - TVC$$

Where:
GM = Gross margin
TR = Total revenue
TVC = Total variable cost

Results and discussion

Socio-economic Characteristics of the Respondents

The age of the respondents as shown in Table 1 reveals that a higher number (42%) of the respondents were within the age bracket of 41 to 50 years with a mean age is 46.3 years. Majority (64%) of the respondents were females. This shows that there are more female involved in cassava flour processing business than men in the area. This also agrees with the findings of Albert *et al* (2017) that women are mostly involved in cassava processing business. Majority (80%) of the respondents were married. Also marriage gives people the sense of responsibility to provide the basic needs of the family (Albert *et al* 2014). All the respondents attained a level of education. This indicates that the respondents were literates, they can read and write.

Table 1: Socio-economic characteristics of the respondents

Characteristics	Frequency	Percentage	Mean
Age (years)			
21-30	3	6.00	
31 – 40	9	18.00	46.3 yrs
41 – 50	21	42.00

Products from Cassava Flour

The types of products from cassava flour as shown in Table 2 shows that most (37.31%) of the respondents accepted that buns was the major product they produce from cassava flour in the area. About 22.39% and 14.92% produced doughnut and chin-chin, respectively from cassava flour. An equal percentage (8.95%) of the respondents produced bread and cake from cassava flour. The implication is that majority of the respondents produce buns from cassava flour as a source of business. This is because buns are cheap and accepted by both adults and children who buy it as snacks.

Table 2: Types of products from cassava flour (Multiple Responses)

Types of Products	Frequency	Percentage
Bread	6	8.95
Chin-chin	10	14.92
Doughnut	15	22.39
Cake	5	8.95
Meat pie	5	7.46
Buns	25	37.31

Source: Field data, 2017

Profitability of Buns from Cassava Flour

The result in fig 1 shows that the variable cost (TVC) needed to produce 56 buns was ₦1, 500.00. The total revenue (TR) realized from it was ₦2,800 indicating a gross margin (GM) of ₦1,240.00 indicating that cassava flour business is profitable.

Total Variable Cost (TVC)		
Cassava flour	1 Custard rubber	700.00
Groundnut oil	1 Small Eva rubber	350.00
Sugar (grinded)		50.00
Nutmeg	1 sachet	50.00
Yeast		100.00
Butter	1 packet	100.00
Salt	1 wrap	10.00
Firewood		200.00
Total Variable Cost (TVC)		₦1,560.00
Total Revenue (TR)		
1 rubber of cassava flour will produce 56 buns at ₦50 per buns = 50x56		
Total = ₦2,800		
GM = Total Revenue (TR) – Total Variable Cost (TVC) = ₦2,800 – ₦1,560		
GM = ₦1,240		
Total Revenue (TR) = ₦2,800 – ₦1,560 = ₦1,240		

Fig 1: Profitability ratio of buns from cassava flour

Perceived ways cassava flour alleviate poverty in the study area

Table 3 shows that most (26%) of the respondents accepted that cassava flour was a source of livelihood. This implies that when the products are marketed it can be used to pay children's school fees, pay rent and improve the livelihood of the people in the study area. About 20% also went into cassava flour as it serves as additional source of income. This indicates that apart from other agricultural activities, going into cassava flour business was an added advantage to the people in the area. Cassava flour business as a source of livelihood for rural women, employment opportunity for those selling and an additional source of income to people involved in it, reduces poverty in the area.

Table 3: Ways cassava flour alleviate poverty in the area

S/N	Effects	Frequency	Percentage
1.	Reduces the money use to buy wheat flour	6	8.00
2.	Source of livelihood for rural women	20	26.00
3.	Additional source of income	15	20.00
4.	Provides easy snacks at home for rural people	7	9.33
5.	Source of employment for those selling	10	13.33
6.	Low in calories, fat and sugar	5	6.67
7.	In expensive, sustainable and easy to grow	12	16.00

Source: Field data, 2017 **Multiple Responses**

Constraints to the use of Cassava Flour

Among the various constraints to the use of cassava flour in the study area, non acceptability of the product in the market, method of preparation, storability, non availability of product in the markets, taste and fear of consumption of bread and confectionary products made from cassava flour appeared more prominent as shown in table 4 below.

Table 4.5: Constraints to the use of cassava flour among rural people

S/N	Constraints	Total Score	Mean Score (x)
1.	Taste	150	3.00
2.	Method of Preparation	160	3.20
3.	Longevity	159	3.18
4.	Non-availability of cassava flour in the market	152	3.04
5.	Non-acceptability of the product in the market	166	3.32
6.	Fear of consumption of bread and confectionary products made from cassava flour	150	3.00
7.	Government not adequately popularizing the use of cassava flour in baking and confectionary products	146	2.92

Source: Field data, 2017 $\geq$ 2.50 = Serious Constraints

Conclusion and Recommendations

High proportion of the respondents had buns/doughnut as their major product produced from cassava flour in the study area while few of the respondents produced meat pie from cassava flour. Cassava flour business was very profitable in the study area. It helped to reduce poverty in the area, as rural people have enough money to pay their children's schools fees, provide the basic needs of life for their households. Based on the findings of this study, it is recommended that government should popularize the use of cassava flour in baking and confectionary products through trainings for the rural women.

ASN 52nd Annual Conference Proceedings

Investigating acceleration, deceleration and stagnation in rice production, import and consumption in Nigeria (1970-2016)

D.O .Onu, J.B. Simonyan and U.R. Oke
Michael Okpara University of Agriculture, Umudike, P.M.B 7267 Umuahia Abia State, Nigeria
Email: dononu@yahoo.com

Abstract
The study was carried out to examine acceleration, deceleration or stagnation in rice production, import and consumption in Nigeria from the period 1970 -2016. Secondary data were collected from the USDA, FAO, IRRI and CBN. Exponential trend equations were fitted to examine their patterns of growth. The results show that over the period of 1970 – 2016, the production, importation and consumption of rice in Nigeria increased at compound rates of growth were 5.55%, 12.30% and 6.40% respectively within the period under review. However, the quadratic time trend equation indicated a declarative growth in rice production, import and consumption. It was recommended that the process of deceleration in rice production be revised by intensifying research in order to improve rice production technologies significantly in a way that the rate of growth would achieve the needed self- sufficiency in domestic rice production and thereby reducing the amount of money spent in rice imports in this country.
Keywords: *Growth Rate, Rice, Production, Import, Consumption*

Introduction
Rice is a leading staple crop in Nigeria cultivated and consumed in all parts of the country. Its domestic supply therefore has a great implication for food security and self-sufficiency in the country. Rice production rose gradually over the years with area expansion to surpass major rice producing countries like Cote d'Ivoire and Sierra Leone (Ayanwale *et al*, 2011). The reality is that Nigeria has not been able to attain self-sufficiency in rice production despite increasing hectares put into production annually (CBN, 2012). On the other hand, the demand for rice has been soaring over the years (Ayanwale *et al*, 2011). Since mid-1970s, rice consumption in Nigeria has risen tremendously growing by 10.3% per annum, a result of accelerating population growth rate, increasing per capita consumption, rapid urbanization, increased income levels, and associated changes in family occupational structures (Ayanwale *et al*, 2011; Akpokodje *et al*., 2001; Akande, 2002). About 3 billion people eat rice everyday with Nigerians consuming over 3.5 million metric tons per annum (Ayanwale *et al*, 2011)

Based on an estimated annual rice consumption of 6 million metric tons, an average Nigerian consumes 32 kg per annum, which is consistent with the USDA estimates from the early 2000s (USDA, 2000). This consumption is higher in the urban areas, averaging 47kg/annum, (USAIDS, 2012) representing 9% of annual calorie intake (IRRI, 2012). The recognition of rice as a major source of calories for the urban poor in Nigeria stimulated an increase in consumer demand above domestic production. Paradoxically Nigeria is also the second largest importer of rice in the world (Binuomote *et al*., 2012). The annual demand for rice in the country is estimated at 5 million tons, while production level is 3 million tons of milled rice resulting in a deficit of 2 million tons. The per capita household consumption of rice in Nigeria ranges between 3.5kg and more than 14kg per year (Nkang *et al,* 2005). Akpokodje *et al,* (2001) contended that the resultant effect of the increase in consumer demand is the massive importation of the commodity in the pre-devaluation (1975–1985) period, thus lowering the price of domestically produced rice with its attendance on poor farmers who now see reasons why they shouldn't go into rice production. Over the years the country had resorted to imports to bridge this deficit as reported by Ayanwale *et al* (2011).

However, several governments in Nigeria in the past and present have put in place quiet a number of progammes (Back to farm, Green Revolution, Operation Feed the Nation, etc) in a bid to improve agricultural productivity and encourage domestic production of her food. It is worrisome to note that in Nigeria, food demand have not kept pace with supply in virtually all the food types
.
This study empirically investigated the hypothesis of growth rates in rice production, import and consumption in Nigeria, 1970-2016. Specifically, this study analyzed (1) the trend in rice production, imports and consumptions in Nigeria within (1970 – 2016) ;(2) estimated the compound (over period of time) rate of growth of rice production, imports and consumptions in Nigeria within the reference period and (3) investigated the hypothesis of acceleration or deceleration or stagnation in the growth processes of rice production, imports and consumption in Nigeria within the period under study

Methodology

This study was carried using available secondary data for Nigeria from USDA, FAO, IRRI and CBN. Data on milled rice production, import and consumption were collected from the United States Department of Agriculture Foreign Agricultural Service (USDA, 2014). The data covered a period of fifty four years, 1970 to 2016. Objectives were realized with exponential trend or log-linear trend in line with Onyenweaku (2004) and Diebold (2004) exponential trend or log-linear trend equation for the quantity of rice production, imports and consumption in Nigeria is modeled as follows;

$$InRp_t = \beta_0 + \beta_1 t + \mu_t \quad (1)$$
$$In\ Ri_t = \beta_0 + \beta_1 t + \mu_t \quad (2)$$
$$InRic_t = \beta_0 + \beta_1 t + \mu_t \quad (3)$$

Where,
$InRp_t$ = quantity of domestic output of rice (measured in metric tons) at period t.
$In\ Ri_t$ = quantity of rice imports (measured in metric tons) at period t.
$In\ Ric_t$ = quantity of quantity of rice consumption (measured in millions of naira) at period t.
β_0 = the constant in the regression line, β_1 = the trend coefficients. t = trend variable measured in years. μ_t = the error term.

Objective 2 was realized using instantaneous growth and compound growth models. The models are specified as:

The instantaneous (at a point in time) growth model is given as;
$$\text{Growth rate} = \beta_1 Yt \times 100 \quad (4)$$

Where,
$\beta_1 \overline{Y}$ = relative change in quantity of rice output, imports and consumption respectively (trend coefficient);
t = trend measured in years

By multiplying the relative change in quantity of rice output, imports and consumption respectively by hundred, we obtained the percentage change or the growth rate in quantity of rice output and imports for an absolute change in time. After the estimation of equation (4) for instantaneous (at a point in time) growth rate of rice production, imports and consumption, the compound rate of growth was computed in line with Onyenweaku (2004), Gujarati and Porter (2009) as:

$$r = (e^{\beta} - 1) \times 100 \quad (5)$$

Where,
e = Euler's exponential constant (2.71828) (Sawant, 1983).
β = estimated coefficient in equations (1), (2) and (3) respectively

Objective 3 was realized using log quadratic trend equation. The log quadratic trend equation is fitted as;

$$InRp_t = \beta_0 + \beta_1 t + \beta_2 t^2 + \mu_t \quad (6)$$
$$InRi_t = \beta_0 + \beta_1 t + \beta_2 t^2 + \mu_t \quad (7)$$
$$InRiv_t = \beta_0 + \beta_1 t + \beta_2 t^2 + \mu_t \quad (8)$$

Where,
β_2 = estimated parameter.
All variables as previously defined.
A positive significant value of β_2 indicates acceleration while a negative significant value of β_2 entails a deceleration. Stagnation in the growth process is explained by a non- significant value of β_2. i.e If $\beta 2 > 0$ and statistically significant, then there is acceleration in growth, If $\beta 2 < 0$ and statistically significant, then there is deceleration in growth. If $\beta 2$ is positive or negative but not statistically significant, then there is stagnation in growth (Oyenweanku, 2004)

Results and Discussion

Graphical Presentation of Trend in Rice Production, Imports and Consumption in Nigeria between 1970 and 2016
is shown in Figure 1

Rice Output, Imports and Consumption (1970 -2016)

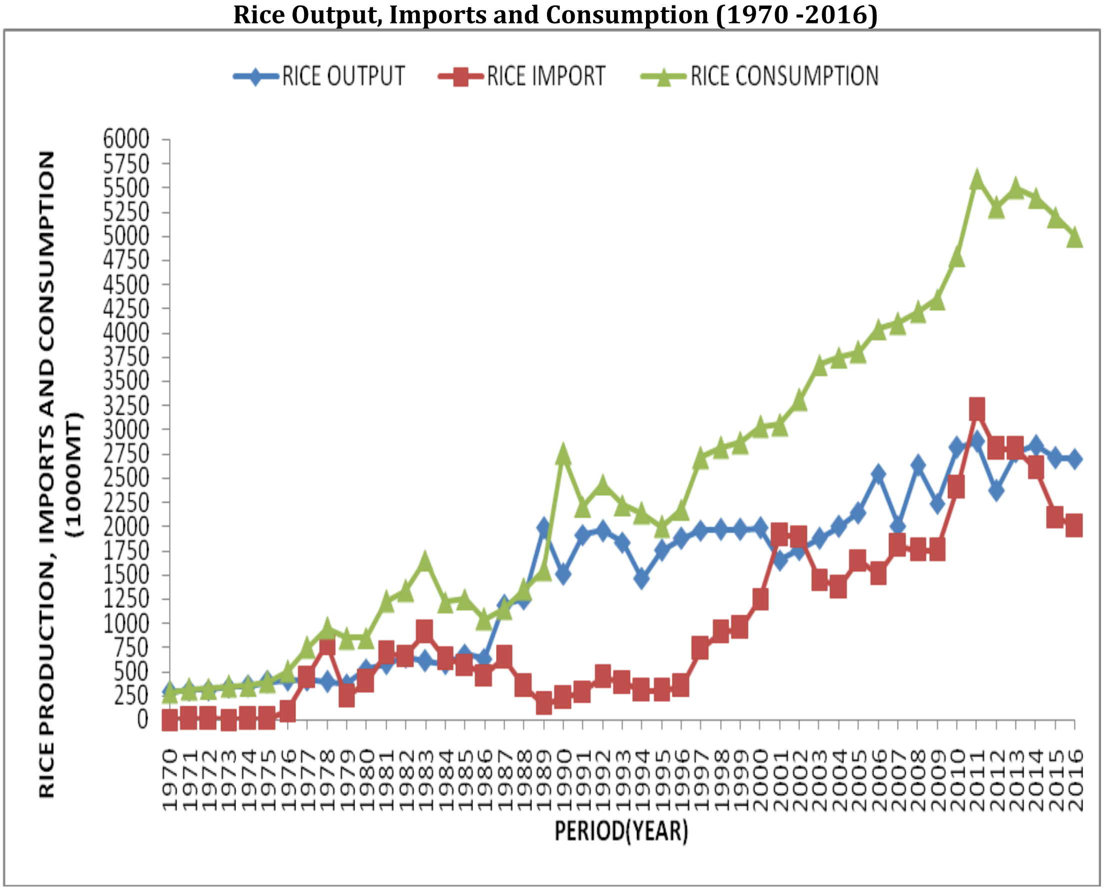

Figure 1: Trend in Rice Production, Imports and Consumption in Nigeria between 1970 and 2016

The trend lines and data for rice production, imports and consumption in Nigeria from 1970 to 2016 are presented in Figure1. It could be seen from Figure 1 that the estimates are not consistent as they do not show steady increasing or decreasing trend over the period. This confirmed that between 1970 and 2016, the quantity of rice production and imports increased and decreased severally overtime except for that of consumption that somewhat had a seemly increasing trend. The inconsistent trends of the rice production, import and consumption over the period under study could be among other things, due to the interest of the Government ruling at any particular period. It implies that there was no consistency and continuity of programmes of action by the successive Governments in this direction. The expectation is to see a pattern that will show an increasing trend over the period as an indication of a growing economy. The inconsistency and lack of continuity of various Government programmes in most cases according to Okolo (2004) accounted for the poor outcome of the programmes.

Trend equations for quantity of rice produced, imported and consumed in Nigeria (1970 - 2016)
Data were subjected to analysis using the exponential growth equations to examine the holistic percentage change in rice production and importation within the reference period. The result is presented in Table 1 below.

Table 1: Estimated exponential trend equations for quantity produced and imported of rice in Nigeria (1970 -2016)

Dependent Variable	β_0	β_1	R^2	F-ratio
Rice output	5.832 (73.151)***	0.054 (17.931)***	0.877	321.513***
Rice imports	3.351 (9.398)***	0.116 (8.651)***	0.625	74.842***
Rice consumption	6.066 (82.793)***	0.062 (22.750)***	0.920	517.558***

Source: Computed from time-series data, 1970-2016 Note: *** implies statistically significant at 0.01probability level.

Table 1 shows that quantity of rice production, quantity imported of rice and quantity consumed in Nigeria exhibited significant growth during the period under review. The results show that time variable was significant in influencing rice production, rice imports and rice consumption all at 1%. This is because, the coefficient of the time variable was positively signed and statistically significant at 1% with respect to quantity of rice production, quantity imported and quantity consumed of rice indicating a general increase in yield of rice, quantity imported and quantity consumed of rice in Nigeria within the period under review. This implies that quantity of rice production, import and consumption in Nigeria within the period under study depended on time trend variable. Table 1 shows further that the coefficient of multiple determination is high (R^2=0.877 for rice production; 0.625 for rice imports and 0.920 for rice consumption) and significant ($p<0.01$). This implies that87.7%, 62.5% and 92.0% of the total variations in rice production, rice imports and rice consumption was due to time trend variable. This also implies that growth in rice production, imports and consumption is highly time dependent.

The F –ratio is statistically significant at 1% alpha level which implies the model gives a good fit, has a sound explanatory power, confirmed the overall significance of the regression (trend) model and as such can be used for forecasting purposes.

Compound Rate of Growth of Rice Production and Imports in Nigeria (1970-2016)
The computed compound rates of growth in quantity produced, imported and consumed of rice in Nigeria within the study period are presented in table 2.

Table 2 Compound growth rate for quantity of rice produced, quantity imported of rice and quantity of rice consumed

Variables	Parameter (β1)	Exponential compound Growth rates (%)
Quantity of rice produced	0.054	5.55
Quantity of rice imported	0.116	12.30
Quantity of rice consumed	0.062	6.40

Source: Calculated from the Estimated Exponential Trend Equations in Table 1

The annual compound growth rate in rice production, imports and consumption in Nigeria over the study period were 5.55%, 12.30% and 6.40% respectively. This finding is in line with Ojoehemon *et al.,* (2009), who noted that both rice production and consumptions have vastly increased with rice demand outstripping rice production thus spurring rice importation. The 6.4%per annum rice consumption growth rate estimate in this study is closely related to the 7% per annum used to make a projection of rice demand of 35 million tons in 2050 (Ayanwale and Amusan, 2012). The result of this study indicates that the rice demand-supply gap scenario have been an existing trend that would continue if appropriate measures are not taken to salvage the situation. The compound growth rate in the quantity imported of rice in Nigeria was fastest (12.30% per annum) while the compound growth rate in the quantity produced of rice in Nigeria was slowest with a compound growth rate of 5.55% per annum. As noted by Bamba *et al.,* (2010), the cost of rice imports represents a significant amount of lost earnings for the country in terms of jobs and income.

Acceleration, Deceleration or Stagnation in Quantity Produced and Imported Of Rice (1970-2016)

Table 3 shows the results of the quadratic equation in time variables fitted for quantity produced of rice, quantity imported of rice and quantity consumed of rice

Dependent Variable	β_0	β_1	β_2	R^2	F-ratio
Quantity of rice produced	5.427 (65.223)***	0.107 (12.824)***	-0.001 (-6.647)***	0.939	337.090***
Quantity of rice imported	2.013 (4.847)	0.294 (6.519)***	-0.004 (-4.092)***	0.728	58.888***
Quantity of rice consumed	5.677 (78.319)***	0.114 (15.683)***	-0.011 (-7.361)***	0.964	591.758***

Source: Computed from time-series data, 1970-2016 Note: *** = significant at 1% alpha level. Figures in brackets are t-values.

To investigate for the existence of acceleration or deceleration or stagnation in growth of rice production, import and consumption, the quadratic equation in the time trend variable were fitted according to the equation. Results in Tables 3 show that the statistically significant negative value of the coefficient of time variable (β_2) for quantity of rice produce, imported and consumed revealed deceleration in the growth rates of this variable, thus, indicating that quantity of rice produced, imported and consumed in Nigeria increased at a decreasing rate during the entire period (1970 -2016). This conforms to the findings of Tanko *et.al* (2010) who observed a deceleration in production and productivity of rice for the period 1985-2006 but not in tandem with those of Ibrahim *et.al*. (2010) who realized accelerated growth in rice for the period 1983-2003 and Onyenweaku (2004) who discovered a stagnated growth in the Nigerian agricultural production for the period 1970-2000.

Conclusion and Recommendations

Quantity of rice production, quantity imported and quantity consumed in Nigeria all exhibited significant deceleration in growth during the period under review. The time variable was significant in influencing rice production, rice imports and rice consumption and the annual instantaneous rates of growth in quantity of rice production, import and consumption in Nigeria within the period under study were 5.4%, 11.6% and 6.2% respectively while their annual compound rates of growth within the same study periods were 5.55%, 12.30% and 6.40% respectively. The study recommends that the process of deceleration in rice production should be revised by intensifying research in order to improve rice production technologies significantly in a way that the rate of growth will achieve the needed self- sufficiency in domestic rice production and thereby reducing the amount of money spent in rice imports in this country. Also, rice production needs to be stepped up through the implementation of output scheme policies that would help boost the growth of domestic rice production. Technological research on early maturing, easy soil acclimatization and disease resistant rice seedling will have a multiplier effect on domestic rice production and thereby reduce rice importation in Nigeria. Effort should be made to grow rice production level geometrically to maintain pace with population growth if food security is to be ensured in Nigeria. This can be pursued through adequate and timely financing of rice production activities.

Abstract
This stud□□□□□□carried out in the Niger Delta region of Southern Nigeria where the bulk of Nigeria's crude oil is being extracted. The study employed both qualitative and quantitative perspectives in accessing people's awareness of the consequences of crude oil exploration and extraction in oil producing rural communities. The qualitative aspect of the study involved the focus group discussion consisting a total of 31 participants, while the quantitative aspect involved a questionnaire survey on 446 respondents. The result indicates that only a negligible percentage (9.7%) of the focus group participants indicated awareness of the oil and gas industry's support for agricultural development in rural communities. On the other hand, an overwhelming majority (100%) of the participants indicated awareness of pollution and pipeline explosion among the major negative consequences of the oil and gas industry. Other negative effects of the industry indicated include; food safety issues (74.2%), damage to forest resources (87.1%), loss of farmlands (83.9%), low of crop yield (77.4%), social crisis (90.3%) and high cost of living (93.5%). The ordered probit results indicate that with a P-value of 0.01, farmers more than fishermen and those in other occupational groups, perceived that the oil and gas industry affects agriculture in oil producing areas. Also, with P-value of 0.01, fishermen more than other occupational groups indicated that the industry has very high impact on water resources. These suggest that rural farmers and fishermen are comparatively more vulnerable to the negative consequences of oil and gas exploration and extraction in the region. By inference, oil and gas operations affect human livelihoods and food security in oil producing areas in Nigeria. Thus, the study recommends that oil and gas companies should improve on their support for agricultural development in the rural areas by sponsoring trainings of rural farmers, support for extension services, and funding for research in agriculture among others.

Keywords: *Crude oil, rural communities, agriculture, oil and gas industry, Niger Delta, Nigeria.*

Introduction
Human livelihood depends largely on the natural environment, thus the health condition of the environment determines to a large extent, the quality and efficiency of ecosystem services. In oil and gas producing areas, the ecosystem suffers persistent distortions that affect the biological and physical nomenclature and potential of environmental resources. These changes affect human livelihood (Ukpong *et al*., 2017). In other words, the oil and gas (O&G) industry comes with a cost to the natural environment and human livelihood (Bhau & Ukpong, 2018). One of the major costs comes from oil spills and facility explosions which result in pollution that affects ecosystem services and environmental resources including land, air, forest and water resources (Ukpong *et al*., 2017). Pollution from the O&G industry includes mainly; land pollution, air pollution and water pollution. Air pollution is one of the inherent risks of O&G extraction, mostly triggered by gas flaring, and Nigeria flares more gas than any other country in the world (Emoyan *et al.,* 2008). Gas flaring is a routine practice by the O&G industry where 'excess gas' is being flared into the environment under a supposedly controlled medium, to relieve dangerous equipment overpressure conditions. However, gas flaring contributes to climate change and global warming,

and remains one of the major sources of air pollution (ERA, 2005; Kan *et al.,* 2012, Zhang *et al.,* 2012). Land pollution affects the fertility and productivity of the land, hence affecting the volume and quality of crop yields (Pegg & Zabbey, 2013). This might contribute to high food prices, food safety issues and food insecurity. Food safety is a global issue and millions of people across the globe are reported to have either died or fallen ill as a result of consuming unsafe food (Ordinioha & Brisibe, 2013). Evidently, the O&G industry has both direct and indirect consequences on agriculture and food safety, result from a range of activities involving crude oil (oil and gas) exploration and extraction. These activities affect farmlands, for instance, a large mass of land can be occupied by oil and gas facilities such as pipelines. Also, crop yield is often affected especially in the event of an oil spill resulting in soil pollution (Ekpebu & Ukpong, 2013). This affects the quality of food crops, resulting in poor yields or outputs, hence high food prices, which affect the quantity of food available in the markets and accessible to rural households. Under such conditions, poor households are not able to afford the high-cost food, resulting in food insecurity and hunger. In other words, the processes of crude oil exploration and extraction affect food security in oil producing areas. It is therefore important that the industry's social responsibilities should be more focused on these issues, especially to promote agricultural production to enhance food security and affordable food prices in the rural markets.

The O&G industry also affects water resources, causing contamination of valuable aquatic organisms, including fish and other seafood, especially during crude oil spills (Cunha *et al.,* 2014). Besides the effects on air, land and water resources, the activities of the O&G industry during exploration and extraction of crude oil, have direct impacts on the forests on which most of the rural population also depend for their food and means of livelihood. The forest is an integral part of the natural environment which offers essential ecosystem services, and remains a critical economic resource in the rural areas serving as a major source of livelihood for rural people in terms of provision of food, income and employment (Mmom & Arokoyu, 2010). However, there is high concern over forest degradation (forest clearance) in recent years as a result of O&G exploration and extraction (James *et al*., 2007; Kuenzer *et al*., 2014). In particular, crude oil pollution poses a hindrance to ecological performance and resilience of the environment, and the impacts of oil pollution on the forest and other ecological resources, mainly as a result of oil spills and facility explosions have also raised global concerns (Giri *et al.,* 2011; Hong *et al.,* 2014). In view of this background, this study seeks to; assess awareness of the consequences of crude oil exploration and extraction in oil producing rural communities in Nigeria, determine the influence of socioeconomic characteristics on people's perception of the consequences of crude oil exploration and extraction in oil producing rural communities in Nigeria and make suggestions and recommendations based on findings of the study.

Materials and Methods

The study was carried out in selected oil producing rural communities in the Niger Delta region of Southern Nigeria, where majority of the rural population depend largely on agriculture and the natural environmental resources. The region is made up of a large terrain of mangrove forest supported by rivers and rivulets, and the coastal linings of the Atlantic Ocean, with high economic value for the rural community (Kuenzer *et al*., 2014).

Both qualitative and quantitative data were used for the study to access people's awareness of the consequences of crude oil exploration and extraction in oil producing rural communities in Nigeria. The qualitative data were collected through three focus group sessions involving thirty one (31) participants. The quantitative data were collected through the use of survey questionnaires administered to 446 respondents, selected from fifteen (15) communities in the region. The study also involved site visits carried out within the study area to observe and obtain pictorial data related to the subject matter.

Results and Discussion

Results of the analyzed FGD are presented in Table 1. From this result, the participants identified seven major positive impacts of the O&G industry in the Niger Delta. The result shows that the majority (74.2%) of the participants identified provisions of employment by the industry. Over 58% mentioned provision of borehole water, and support for skills acquisition, with as low as 12.9% and 16.1% indicating awareness of provision of road construction and electricity.

Participants' knowledge of the industry's support for agriculture was comparatively negligible, with only 9.7% of the participants indicating awareness. The result suggests that the majority of the respondents may not have been aware of the industry's contribution to agriculture or support to farmers, yet agriculture is among the economic activities mostly affected by crude oil exploration and extraction in the region. The comparatively low percentage of awareness suggests that the supposed industry's support for agricultural development may not have been widely distributed. Improved support for skill acquisition would help create employment, hence helping to address insecurity and socioeconomic issues. On the whole, the varying proportions of awareness suggest that most of these benefits are either not adequately provided or not widely spread across various communities.

Table 1 Summary of Focus group participants' Awareness of Positive Impacts of the O&G Industry in the rural communities in the Niger Delta region

S/N	Positive contributions	Percentage of Respondents
1	Agriculture support	9.7
2	Skill acquisition	58.1
3	Road construction	12.9
4	Scholarship	48.4
5	Boreholes	58.1
6	Electricity	16.1
7	Employment	74.2

Note: Multiple responses recorded

The results in Table 2 indicate high percentage of awareness of high impacts on farmland (83.9%), and low crop yield (77.4%) suggesting that agriculture in the region has been seriously affected. As much as 77.4% of the respondents indicated awareness of the impacts of the industry on crop yield.. Oil pollution affects soil fertility and crop yield which is a direct threat to food security. In communities such as rural oil producing communities in the Niger Delta where most people depend largely on farming, persistent negative impacts on crop yield can result in severe cases of hunger and poverty. Samy *et al*. (2015) reported that most people in the Niger Delta depend largely on farmlands for their livelihood. As also shared by Evangelou *et al. (*2015), pollution from oil spills have a statistically significant effect (negative impacts) on crop yield' in oil producing areas. Other areas of livelihood that are negatively affected include: Water resources (74.2%), forest resources (87.1%) and high food prices (93.5%). Access to affordable food and price stability can contribute to equity and poverty alleviation by helping to reduce the vulnerability of poor people to changes in food prices (Timmer, 2000). Food price fluctuation can reduce economic growth with implications for the living standards of rural households (Myers, 2006). Food price is therefore a critical issue in addressing socioeconomic problems in the region.

Table 2: Summary of Focus group participants' awareness of the negative impacts of the O&G industry in the Niger Delta

S/N	Negative issues	Percentage of respondents
1	Acid rain	22.6
2	Gas flaring	83.5
3	High cost of living	93.5
4	Social crisis	90.3
5	Moral degeneration	41.9
6	Pipeline explosion	100
7	Damage to water sources	74.2
8	Loss of farmland	83.9
9	Low crop yield	77.4
10	Loss of forest resources	87.1
11	Food safety issues	74.2
12	Roof top corrosion	51.6
13	Pollution	100

Multiple responses recorded

An ordered probit regression analysis was carried out to assess the influence of socioeconomic characteristics on people's rating of the consequences of O&G exploration and extraction. The levels of consequences were designated as levels of impacts labelled as follows: no impact, low impact, moderate impact, high impact, and very high impact. The results are presented in Tables 3 below.

Table 3: Ordered Probit estimates of people's awareness of the negative impact of O&G exploration and extraction

Variable	Negative impact on water resources	Negative impact on Agriculture
	Coefficient (S.E)	Coefficient (S.E)
Educational level	0.091 (0.090)	0.0541 (0.080)
Family size	-0.021 (0.041)	0.032 (0.036)
Age	0.025** (0.010)	-0.006* (0.009)
Income	-3.7E-6* (4E-6)	-1.6E-6* (3.4E-6)
Gender = Female	0.095 (0.144)	0.082 (0.127)
Marital Status		
Single	0.380 (0.340)	-0.151 (0.330)
Married	0.512*** (0.289)	0.050*** (0.284)
Occupation		
Farming	-4.644* (0.358)	0.996* (0.579)
Civil servant	-5.186* (0.312)	-0.987*** (0.468)
Oil company workers	-5.408* (0.340)	-2.059* (0.483)
Other company worker	-5.962* (0.300)	-1.297* (0.488)
Self employed (Business)	-5.383* (0.254)	-0.990** (0.438)
Unemployed	-5.263** (0.259)	-0.566 (0.475)
Student	-5.716* (0.000)	1.018** (0.477)
Likelihood Index (*P*)	0.000	0.000
Pseudo R^2		
Cox & Snell	0.117	0.209
Nagelkerke	0.154	0.237
McFadden	0.087	0.110
Number of observations	446	446

Figures in parenthesis are standard errors (S.E). The variable 'fishing' is a reference variable in the model.

The results indicate the significance of model coefficients at various levels including age, income, marital status and occupation. The significance of the Age coefficient at p=0.05 confidence level suggests that older people more than young people might be comparatively more concern about water resources. On the other hand, the coefficient of Age at p=0.01 confidence level indicates that young people's are comparatively more concern about the negative impact of the O&G exploration and extraction on agriculture. The result suggests that there might be comparatively more young people engaged in agricultural activities in the area, while there might be comparatively more older people engaged in water related activities such as fishing. Thus, a reduction in the negative impacts of the O&G industry would enhance agricultural development, and allow for gainful fishing, thus helping to improve the livelihood of both young and old people in the area. The significance of income variable suggests that people with comparatively low income are more concerned and perhaps more affected by the effects of O&G exploration and extraction on agriculture and water resources. The significance of the coefficient of marital status indicates that married people more than single people viewed the impact of O&G exploration and extraction as very high, thus suggesting that married people might be more worried about the impacts compared to single people. This might confirm comparatively high dependency of married households on agriculture and water resources which are the main sources of livelihood in those areas.

Conclusion and Recommendations

Owing to the wide dependence of rural population on natural resources, the growing negative impacts of oil exploration and extraction remain a serious threat to people's livelihood and survival in oil producing areas. In particular, the Niger Delta region as an agrarian society is characterized by farmers who engage in crop and animal production, as well as those engaged in various off-farm activities including sales and marketing of agricultural products. Hence, mitigation of negative consequences of the O&G industry would promote improved livelihood, food safety and household income in oil producing rural communities in the region. Among the major findings of this study is that rural farmers and fishermen are more vulnerable to the negative consequences of oil and gas exploration and extraction. Again, poor support for agricultural development by oil and gas firms impact negatively on the rural people in the study area. Based on these findings, it is recommended that oil and gas companies should improve on their support for agricultural development in oil producing rural communities by sponsoring trainings of rural farmers, support for extension services and provide adequate funding for research in agriculture and improved fisheries technology.

Abstract
The study assessed the market level characteristic factors influencing coffee marketing in Kogi State. Three towns within Ijumu Local Government Area (Iyamoye, Kabba and Ilogun-bunu) were purposively sampled. These areas are known for the cultivation, production and marketing of this crop. Twenty eight traders (farmers) were randomly sampled from each of the towns. A total sampling frame of eighty four respondents was used. Structured interview schedules were used for data collection from respondents. Data were analyzed using descriptive statistics (frequency and percentages). Farm size, variety of coffee, marketing channel, trading experience, membership of association, price satisfaction and selling method constituted major socio economic variables influencing coffee marketing in the study area.
Key Words: Coffee, Marketing, Cobb Douglas, Variety, Policies

Introduction
The vast majority of coffee production has its roots in colonialism, during which missionaries or colonialists usually imported the plant. Coffee then became a "cash crop, planted and harvested by serfs or wage laborers on large plantations, then exported to imperial countries" (James, 2000). Consequently, governments, ethnic relations and general ways of life were changed in these countries because of the shift to the new reliance on coffee production. However, with the growth of the United States economy, the market for exporting coffee also expanded. Therefore, coffee became a major source of income for many countries in Central and South America, Africa, and South Asia where colonialism was present and the environment was ideal for coffee trees (Cleland, 2010). Meanwhile, the coffee plant originated in Ethiopia. However, coffee-drinking habits had spread to Europe by the 17th century.
According to Milford (2004) the coffee tree can be grown only in warm areas without frost or sudden temperature shifts, and it also needs plenty of rain. This explains why it is a common export commodity for countries in tropical areas, and an unsuitable one for the rest of the world. Commercially grown varieties are *Coffee Arabica* and *Coffee Robusta*. *C. Arabica* has a mild taste, it is more fragile, and its best growing conditions are found in warm zones or in the highlands of tropical zones. Contrastingly, *C. Robusta* is more resistant and can be grown between sea level and 800 metres above sea level (Milford, 2004).

However, the producers of these coffee beans are often small-scale farmers who are reliant on faceless consumers, large corporations and an ebbing market for their income and resources. Meanwhile, empirical studies reveal that smallholders in developing countries face numerous constraints due to the pervasive imperfections of markets. Increasing evidence shows that through collective action smallholders can reduce transaction costs of accessing input and output markets, adopt efficiency-increasing and value-adding technologies, and tap into high-value markets associated with certification and labeling (Kersting and Wollni, 2012; Wollni and Zeller, 2007; Gruere *et al.,* 2009; Devaux *et al*., 2009; Narrod *et al*., 2009). In the early 2000s, a historic world market price slump hit millions of coffee farmers hard, especially smallholder producers in Africa and Latin America (Ponte, 2002). The volatility of coffee markets in combination with poor production infrastructure and services have sunk the majority of coffee producers in developing countries in low-input-low-output cycles and structural poverty. Similarly, coffee is a traditionally worldwide traded cash crop with new emerging markets; many coffee-producing developing countries such as Nigeria are struggling with production and marketing of the crop (Jena *et al*., 2012). In addition, smallholder coffee growers face high transaction cost, lack of market information, poor infrastructure, and weak capital markets (Anteneh, *et al.,* 2011**)**. Moreover, imperfect competition in which farmers are getting paid less for their produce than they would in a competitive situation occurs among the smallholder coffee growers in Nigeria. This loss of income may have a serious effect on the life situation of a trader who is living close to absolute poverty. When this effect is added to the other aforementioned factors that are characteristic of the coffee industry, we can perhaps understand why many of these farmers see this situation to be unfair. The objective of the study was to profile the socio economic characteristics of the coffee traders in the study area.

Methodology

The study was conducted in Kogi State, Nigeria. The state is in the middle belt region and falls in to the guinea savannah agro ecological zone of the country. Three towns within Ijumu Local Government Area (Iyamoye, Kabba and Ilogun-bunu) were purposively sampled. These areas are known for the cultivation, production and marketing of this crop. Twenty eight traders (farmers) were randomly sampled from each of the towns. A total sampling frame of eighty four respondents was used. Structured interview schedules were used for data collection from respondents. Data were collected on socio economic characteristics such as age, educational status, marital status, gender and membership of farmers' group, respectively. Additional information was gathered through informal discussions with the farmers and by personal observations of the crop in some of the farmers' fields. Data were analyzed using descriptive statistics frequency, percentages and mean.

Results and Discussion

Table 1 shows the socio-economic characteristics of Coffee farmers/traders. The table reveals that all the farmers (100%) were men.

Table 1: Socio economic characteristics of Coffee Farmers in Kogi State

Variables	Frequency	Percentage (%)	Mean

Source: Field Survey, 2016

This result is in conformity with Adinoyi and Attanda (2016) who reported that majority (94.4%) of groundnut farmers are male. Similarly, Girei *et al* (2013) reported that in Africa, men are more in a crop that is perceived to have commercial value. The implication of this is that coffee trading in the study area is largely dominated by male gender. Moreover, the mean age of the traders is 64 years. The implication of this is that coffee traders in the state are ageing and almost out of their productive years and this perhaps may be responsible for the average farm size (5ha) put into cultivation of the crop by farmers in the study area. Similarly, the table reveals that about 60% of the farmers had no access to former education with average years of educational level being about 2 years. The implication of this is that the farmers may perhaps not have access to market information system (MIS) with respect to both production and marketing of the crop. Furthermore, the table reveals an average household size of 8 persons. This is in conformity with the result of Ibitoye *et al* (2012). They reported an average household size of 8 persons in their study on the socio economic variables of and their profitability levels in maize production in Kogi State. This implies that the farmers may perhaps utilize members of the household as labour for some operations relating to production and marketing of the crop. This may reduce some transaction costs that may be incurred on the crop. Mean trading experience was about 29 years. This means that the farmers have adequate knowledge of marketing the crop. This perhaps may influence the choice of marketing channels as the farmers sell to preferred buyers.

Conclusion

The study assessed the socio economic variables of coffee traders in Kogi State. Farm size, variety of coffee, marketing channel, trading experience, membership of association, price satisfaction and selling method constituted the socio economic characteristic factors influencing coffee marketing in the study area. More efforts should be made to assess variety of coffee that is more preferred by the buyers. In addition, farmers should be trained on the variety of the crop that has higher market demand with a view to increasing its production in the study area. Similarly, farmers should be given incentives to increase their farm holdings for higher productivity. In addition, there is need to maintain or improve on the price satisfaction existing between the farmers and the buyers of the commodity to avoid imperfect market in the study area. Farmers that are members of association should be encouraged to improve on their participation as this will go a long way in price determination for increased profit. This will encourage and improve coffee traders' access to market information and as such will be able to sell the crop for more profits.

Influence of credit accessibility on households' food security among Farmers in South-Western Nigeria

Wasiu Olayinka Fawole
National Open University of Nigeria (NOUN), Kaduna - Nigeria
wasiufawole@gmail.com

Abstract
Food security and factors influencing it have been topics of interest in developing countries in recent years. This study is coming to further reiterate the importance of credit facilities on food security by investigation the nexus that exists between the two. The study used multistage random sampling technique to select 161 households from the nine selected local government areas from Osun and Oyo states in South Western Nigeria. Primary data collected with the aid of structured questionnaires were used for the study. The findings of this study revealed that majority (53.4%) of the households investigated had access to one or more forms of credit facilities to meet the dietary needs of their members and also utilize the accessed credit facilities principally on direct consumption in their respective households. The findings also indicated that households with access to credit facilities constituted majority of food secure households in the study area thereby underscoring the key role access to credit plays on food security at household level. The findings of the study implied that much could be achieved in achieving the zero hunger targets as being envisaged by SDGs by 2030 if credit facilities are made available for agricultural production and business enterprises to guarantee sustainable income for households to meet their dietary needs.
***Key words**: Food security, credit, household, farmers*

Introduction
Food insecurity is currently considered as a development challenge in the world particularly in developing countries including Nigeria where food production is not commensurable with the prevailing growth rate in the affected countries (Fawole and Ozkan, 2018). Food insecurity has been attributed to many factors such as low income, population growth, livelihoods and access to productive factors of production such as credit facilities among other things (Babatunde *et al.* 2007a). Agriculture is undoubtedly the largest components of the rural economy in Nigeria and most sub-Sahara African countries (Ogundari, 2017). Among all the known factors that have contributed to food insecurity in Nigeria lately, decreasing fortunes of agricultural production has taken the lead (Fawole *et al*. 2016). The decreasing fortune of agriculture has been aided principally by lack of access to credit facilities by smallholder farmers who constitute the bulk of food producers in developing countries (Fawole and Ozkan, 2018). FAO (2002) defined food security as "availability at all times of adequate world food supplies of basic foodstuffs to sustain a steady expansion of food consumption and to offset fluctuations in production and prices". Africa has not been able to feed herself since 1970s and may be unable to do so soon and this is the greatest reality that stakeholders in the food sub-sector in sub-Sahara Africa often sigh away from but it is real (Martin, 2004). Similarly, Wu *et al*. (2011) posited that African countries may face decline in per capital food availability in coming years a position that has not been countered by superior policy actions. In many or most African countries, food security at both national and household levels is still not encouraging. The per capita growth rate in food production in some of these countries is still far lesser than corresponding growth in population which is not enough to meet the rising demand for food at household level leaving many undernourished thus creating an embarrassing gap between food supply and demand. For instance, the Nigerian population annual growth rate is around 3.5 percent with accompanying 2.7 percent growth rate or less in agriculture which is largely insufficient to meet food needs of the entire population (Ogundari, 2013). Before

now, agriculture especially food production used to be an important sector of the Nigerian economy because of its significant contribution to national economic growth. As of 2000, it constituted 30% of the annual GDP, 70% of the labour force, 70% of the non-oil exports and 80% of the food requirements of the nation (Adegboye, 2004). Of the Nigerian total GDP, as of 2014 according to the Central Bank of Nigeria (CBN) data as obtained, agriculture constitutes 20.24 percent; of this percentage crop production constitutes 87.76 percent, livestock 8.73 percent, forestry 1.15 percent and fishing 2.36 percent (CBN, 2014).

From the above illustrations, it is evident that any factor that affects the fortunes of agriculture on one hand would definitely affect food security situation on the other hand. Therefore, this study was carried out to investigate the nexus that exists between food security in households and the accessibility of households to credit facilities either to support their food production or other business enterprise that would thereafter improve the income of the household to meet their dietary needs.

Materials and Methods

This study was conducted in the South-Western Nigeria. Primary data collected from 161 households with the aid of structured questionnaires were used for this study. Similarly, multistage sampling technique involving four stages was used to select the households for the study (Iorlamen et al. 2013). The first stage involved purposive selection of two states (Osun and Oyo) followed by the second stage which involved selection of four and five local governments from the two states respectively based on their population. The third stage of the sampling was the random selection of towns and villages from the selected local governments and last stage was the random sampling of at least 15 households from each of the selected local governments in the two states. The data were analyzed using both descriptive statistics and inferential analysis as collected from the survey as explained earlier while the prevailing food security at respective households were based on total calorie consumption with minimum per capita calorie consumption pegged at 2300kcal/day/AE (Amaza et al. 2008). Households whose calorie consumption was above the minimum were categorized as food secure while those with lower than minimum were food insecure. This procedure was carried out for households with and without access to credit facilities.

Results and Discussions

The findings of this study as shown on Table 1 revealed that majority (53.4%) of the households investigated had access to one or more forms of credit facilities to meet the dietary needs of their members. Conversely, the remaining (46.6%) had no access to any form of credit facilities thus relying solely on their income to meet their dietary needs. Furthermore, majority of the sampled households were food secure based on the quantity of calories consumed in those households. In other words, majority of the households consumed above the minimum recommended daily allowance of 2300kcal/day/AE. Majority (63.6%) of the food secure households were those with accessibility to one or more forms of credit facilities. However, food insecure households were majorly accounted for by those without access to any form of credit facilities.

Table 1: Distribution of households according to food security and credit accessibility

Credit access/Food security	Food secure	Food insecure	Total
With credit access	56	30	86
Without credit access	32	43	75
Total	**88**	**73**	**161**

Source: Field survey, 2017

Furthermore, the findings of the analysis of the food data as presented on Table 2 showed that strong and positive correlation exists between credit accessibility and food security among households in the study area.

Table 2: Correlation between food security and access to credit among households

		Food security	Access to credit
Food security	Pearson Correlation	1	0.690**
	Sig. (2 – tailed)	-	0.05
	N	**161**	**161**
Access to credit	Pearson Correlation	0.690**	1
	Sig. (2 – tailed)	0.05	-
	N	**161**	**161**

** Correlation significant at the $p < 0.05$ (2 – tailed)

The findings based on the utilization of accessed credit are presented on Table 3 indicated that majority of the households utilized their credit on direct households' consumption including foods and this accounted for 41% of the entire households while some expended the credit facilities on agricultural production to provide food and sometimes income to meet other needs of their households some expended the credit of other business enterprises to generate income that were in turn utilized to procure foods of their choice to meet the dietary needs.

Table 3: Distribution of households according to credit utilization

Utilization	Number of households	Percentage
Agricultural production	40	24.8
Direct consumption	66	41.0
Business enterprises	45	28.0
Others	10	6.2
Total	**161**	**100**

Source: Field survey, 2017

Similarly, majority of the investigated households relied on cooperative societies to which they belonged to access credit facilities based on the findings as presented on Table 4 subsequently. Therefore, these findings implied that food security in the households increased with accessibility to credit facilities.

Table 4: Distribution of households according to sources of credit

Credit source	Number of households
Bank	52
Cooperatives	71
Government	34
Relatives	41
Money lender	25

Source: Field survey, 2017; Note: Some households accessed credit from more than one source

Finally, these findings as outlined above are in congruent with Muche et al. (2014), Obayelu (2012) but are however in contrast with those of Babatunde et al. (2007b).

Conclusion

The findings of these studies have shown that for the attainment of food security in the country as a whole, credit accessibility will play a key role. This is so because when food security in households with and without access to credit facilities was compared, it was clear that those households with access to credit facilities showed high rate of food security. Therefore, for Nigeria to achieve zero hunger as being envisaged by SDGs in 2030 the stakeholders must ensure unhindered access to credit facilities for citizens particularly to those engaged in food production and businesses in such a way that even when the households are not engaged in direct food production to meet the dietary needs of their respective households they could be provided with credit facilities to enable them engage in other activities such as small and medium scale enterprises that could enable them garnet resources that would enable them acquire their needed food items from the market. The import of this study is to sensitize the concerned stakeholders on the importance of credit on achievement of food security in the country particularly through indirect intervention to agriculture to stimulate indirectly food availability and access among households in the country with a view to achieving a completely food secure nation.

E-mail: osonducharles87@gmail.com

Abstract
This study identified coping strategies and determinants of food insecurity among farm households in Isiala Ngwa North Local Government Area of Abia State, Nigeria. Multistage random sampling technique was employed in collecting data from 90 farm households using semi structured questionnaire. Data were analyzed using descriptive statistics, food security index, and Probit regression model. Result showed that 59% of the farm households were food insecure. Various strategies such as eating less expensive food (73.58%), and allowing children to eat first (69.81%) were adopted by the farm households to cope with food insecurity. Probit regression result showed that gender, household size, non-farm income activity, educational level, membership of cooperatives, extension access and farm income were significant determinants of farm households' food insecurity status. There is need to boost income generating potential of food insecure farm households. To this end, heads of farm households should be trained by relevant agencies on improved farming technologies and skill acquisition so as to boost their farm and non-farm income earning capacity and subsequently reduce household food insecurity.
Key words: *Coping strategies, farm households, food insecurity*

Introduction
Food security and insecurity are terms used to describe whether or not individuals, households or an entire nation have access or not to sufficient quality and quantity of food (Osei *et al.,* 2013). Food security is defined as a situation that exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for a healthy and active life (FAO, 1996). Food insecurity on the other hand, is the inability of a household or individuals to meet the required consumption levels in the face of fluctuating production, price and income (Maharjan and Chhetri, 2006). A food insecure household has inadequate food available to it to ensure minimum intake for all members (usage) and does not have adequate capacity to effectively demand for more food if there is such need. Maintaining food security at the household level and individual level is still a major challenge for many developing countries including Nigeria. FAO (2012) estimated that about 900 million people globally are undernourished (food insecure). Vast majority of these undernourished people (about 852 million) live in developing countries, with the most vulnerable region being sub-Saharan Africa.

The average amount of food available per person per day in the region was 1,300 calories compared to the world wide average of 2,700 calories (FAO, 2012). Ayodeji (2010) asserted that the number of hungry people in Nigeria is over 53 million, which is about 33% of the country's total population of roughly 160 million. The Global Food Security Index (GFSI) of the Economist Intelligence Unit ranked Nigeria among countries with low food affordability, availability and quality (Ahmed *et al.,* 2015). These are matters of grave concern largely because Nigeria was self-sufficient in food production and was a net exporter of food to other regions of the world in the 1950s and 1960s. Although, successive Nigeria governments in an attempt to alleviate the food insecurity problem in the country have made efforts to achieve national food security through setting up of a number of agricultural development institutions, and special programmes and projects which include: the National Agricultural Development Fund, NADF (2002); National Special Programme on Food Security, NSPFS (2002); National Food Crisis Response program [NFCRP] and Food Security Thematic Group [FSTG] in 2009, an overwhelmingly large proportion of Nigerians are still food insecure (Abimbola and Kayode, 2013).

Among Nigerian households, rural farm households are the most vulnerable to food insecurity even though they produce the bulk of food eaten within the country. Most foods produced by farming households in Nigeria are consumed, or sold for cash only to be repurchased when household barns run short with supplies. This cyclic and unstable condition most times leaves affected farm households in a state of food insecurity (Emerole *et al.,* 2014). According to Osondu *et al.* (2014) Nigerian agriculture is characterized by numerous smallholder farmers using mostly crude tools and low level technology, which results to low productivity, output and farm income. This hampers ability of affected farm households to achieve the minimum requirement of food nutrition. In view of the foregoing this study intends to: profile food security status of farm households in the study area; identify coping strategies adapted by food insecure farm households in the study area; and identify determinants of food insecurity among farm households in the study area.

Methodology

The study was conducted in Isiala-Ngwa North Local Government Area (LGA) of Abia State. The LGA has an area of 283km^2 and a population of 153,734 persons (NPC, 2006). The LGA is bounded to the North by Umuahia South LGA, to the South by Isiala-Ngwa South LGA, to the West by Imo River and to the East by Ikot-Ekpene and Abak LGAs of Akwa Ibom state. The climate is essentially tropical humid with annual rainfall of 1500-2600mm distributed evenly throughout the wet season (April to October). Mixed cropping system is mainly practiced. Food crops such as cassava, yam, maize, and melon, and cash crops such as oil palm, plantain and banana are most widely cultivated crops in the LGA. Animals reared include poultry, goats, sheep and pigs.

Population for the study comprise of all farm households in the area. Multi-stage random sampling technique was adopted. First, six communities were randomly selected. Secondly, three villages were randomly selected from each of the selected six communities. Lastly, five farm households were randomly selected from list of farm households in each of the selected 18 villages. Thus, 90 farm households were selected for the study.

A pre-tested semi structured questionnaire was used to collect primary data from the selected farm households through survey involving household heads and their spouses. The pre-test helped to standardize the questions in structure, instructions and ease of flow of response. The questions thus addressed what they ought to address (validity) and gave consistent answers from the same respondents in a test retest trial (reliability). The survey was conducted on daily basis for a period of two weeks. Data were collected on amount of food/calories consumed (24 hours recall method), age of household head, gender of household head, household size, household resource endowment, farm size, off farm income activity, level of education of household head, credit access, membership of cooperative, extension access, farm income and food insecurity coping strategies.

Food security index was used to profile food security status of the farm households. Frequencies and percentages were used to identify coping strategies adapted by the farm households against food insecurity and Probit regression model was used to identify determinants of food insecurity among farm households.

Two objective methods of food security measurement have been widely used in most food security studies (Maxwell 1996; Babatunde *et al.,* 2007). One method is to estimate value of household consumption and purchases of food items over time. The other method is to undertake food consumption recall for individual members of a household or entire household and analyze each type of food mentioned for calorie content. This second method is more often used by Food and Agricultural Organization (FAO) in food security measurements. In this study, a 24 hour recall method was used. The food security line was FAO recommended daily per capita calorie intake of 2260kcal. From data collected, quantity of every food item consumed by the households in the 14 days period were estimated. The quantities were converted to gram and the calorie content was estimated by using the nutrient composition table of food commonly eaten in Nigeria. Per capita calorie intake was calculated by dividing estimated total household calorie intake by the household size after adjusting for adult equivalent using consumption factors for age-sex categories. To get the households average daily per capita calorie intake, the sum of the household's per capita calorie intake was divided by fourteen. A farm household whose average daily per capita calorie intake is up to 2260Kcal was regarded as food secure and those with per capita calorie intake below 2260Kcal were regarded as food insecure farm households. The food security index was computed thus:

$$Zi = \frac{Yi}{R} \ldots \quad (1)$$

Where:
Zi = Food security status of ith farm households which takes values 1 for food secure farm households or 0 for food insecure farm households;
Yi = Daily per capita calorie intake of ith farm household;
R = Recommended per capita daily calorie intake (2260 kcal).
Zi = 1 when Yi greater than or equal to R and Zi = 0 when Yi less than R

Additionally, the food insecurity gap, surplus index and headcount ratio of food security were calculated for the sampled farm households based on the food security line following Babatunde *et al.* (2007) approach. The food insecurity gap (FIG) measures extent to which food insecure households are food insecure and the surplus index (SI) the extent by which food secure farm households exceed the food insecurity line food and the headcount ratio (HCR) measures percentage of the population of farm households that are food insecure.

$$Food\ insecurity\ gap\ (FIG)\ = \frac{1}{M}\sum_{i=1}^{m} Gi \quad (2)$$

M = Number of food insecure farm households
Gi = Per capita calorie intake deficiency for ith farm household

$$Gi = (\frac{Yi-R}{R}) \ldots \quad (3)$$

$$Headcount\ index\ (HCR)\ = \frac{M}{N} \quad \ldots \quad (4)$$

N= Number of sampled farm households

Based on the household food security index (Zi), the Probit model was used to identify determinants of food insecurity among farm households. The implicit form of the model was expressed as: $Y = \Sigma\beta x + \varepsilon i$ (6)
Where
Y= Food security status (food secure households = 1, food insecure households = 0);
$\beta_1 - \beta_7$ = Unknown coefficients value of factors;
β_0 = Constant; X = Vector of explanatory variables;
εi = Error term

The independent/explanatory variables included in the model are:
X_1 = Age of household head (years)
X_2 = Gender of household head (male = 1, female = 0)
X_3 = Household size (number)
X_4 = Household asset endowment (Naira)
X_5= Household Farm size (hectare)
X_6 = Non- farm income (Naira)
X_7 = Level of education of household head (schooling years)
X_8 = Credit access (access =1; no access = 0)
X_9 = Membership of cooperatives (member = 1; not member = 0)
X_{10} = Extension access (Number of extension contacts)
X_{11} = Farm income (Naira).

Results and Discussion

Food Security Status of the Farm Households

The summary of the food security status of the farming households is presented in Table 1. It was observed that food insecurity incidence of the farm households was 0. 59. This implies that 59% of the farm households were food insecure because their per capita calorie intake fell short of the recommended daily per capita calorie consumption used as food security line. Table further shows that the average per capita calorie intake of the farm households in the area was 2165kcal.The food insecurity gap/surplus index which measures the extent of deviation from the food security line, show that the food insecure households fell short of the calorie requirement by 38%, while the food secure households exceeded the calorie requirement by 29%. Average household size was 6 persons, while it was 4 persons for food secure households and 7 persons for food insecure households. Babatunde *et al*. (2007) obtained a similar result with respect to food insecurity incidence and gap in North Central Nigeria.

Table 1: Distribution of the farm households based on food security status

Food Security Indices	Food Secure	Food Insecure	All
Number of households	37	53	90
Household size	4.28	7.44	5.86
Per capita daily calorie intake	2924	1406	2165
Food security index (Z)	1.29	0.62	0.96
HCR (head count ratio/ incidence of food insecurity)	0.41	0.59	-
Food insecurity gap (FIG)/Surplus index (SI)	0.29	0.38	-

Coping Strategies of the Farm Households against Food Insecurity

Coping strategies of the food insecure farm households against food insecurity is shown in Table 2. The table shows that 73.58% of the food insecure farm households ate less expensive food as strategy against food insecurity. This agrees with Kuwornu *et al.* (2013) finding that when households are faced with food shortage, the predominant strategy they adopt is to eat less preferred and less expensive food. Meanwhile, 69.81%, 64.15% and 56.60% of the farm households allowed children to eat first, reduced proportion of meal size and used savings to buy food respectively as coping strategies against food insecurity. More so, 45.28%, 37.73%, 30.19% and 26.41% of the households reduced number of meal time, borrowed money to buy food, consumed seed stocked for next planting season and bought food on credit respectively. Although the study area is endowed with natural forests and one would have expected households to resort to searching for wild fruit when faced with food shortage, it was one of the least practiced strategy by the farm households with only 11.32% of the farm households practicing it. According to United Nations (2002) food insecure households adapt a variety of coping mechanisms against food insecurity.

Table 2: Distribution of the farm households based on Coping strategies against food insecurity (n = 53)

Coping strategy	*Frequency	Percentage (%)
Allowing children to eat first	37	69.81
Eating less expensive food	39	73.58
Reduction of meal size	34	64.15
Using savings to buy food	30	56.60
Working in exchange for food	15	28.30
Reducing number of meal time	24	45.28
Consuming seed stocked for next planting season	16	30.19
Sending household members to eat elsewhere	13	24.53
Buying food on credit	14	26.41
Borrowing money to buy food	20	37.73
Sale of livestock	1	24.53
Selling personal belongings	11	20.75
Eating wild fruits	06	11.32

Factors influencing Food Security of the Farm Households
The result of the probit regression is presented in Table 3. The model correctly predicted 73.6% of the variations in dependent variable and posted a significant goodness of fit chi-square value of 37.316. The table revealed that seven out of the eleven factors variedly determined food insecurity of the farm households.The coefficient of gender of household head was negative and significant at 5.0% alpha level. This implies that male headed farm households had lower probability of being food insecure. According to Nwachukwu *et al.* (2014) female heads of farm households in Abia State generally have fewer years of formal education, lower access to credit, extension services and land compared to male farm household heads and consequently, female headed farm households have higher probability of being food insecure. The coefficient of household size was observed to be positive and significant at 5.0% alpha level. This implies that increase in household size increased farm households' probability of being food insecure. All things being equal, increase in household size results to more people eating from the same resources; leading to reduction in food intake. The likely explanation for this is that increasing household size results to rising demand for food. This demand, however, when not matched with higher food supply from own production or purchase, ultimately lead to the household becoming food insecure. This result consolidates finding of Babatunde *et al.* (2007).

The coefficients of non- farm income activity and level of education were negative and significant at 1.0% alpha level, implying that increase in both variables decreased probability of the farm households being food insecure. Non-farm income generating activities help to diversify sources of farm households' livelihoods and reduce the risks of food shortage during periods of unexpected crop failures. Also, income from non-farm activities can be invested in agriculture to increase farm output, farm income and food availability at the household level. The negative impact of level of education on food insecurity could be due to the fact that years of formal education are a major factor in wage earning opportunities and determination in Nigeria where the higher the academic qualification, the higher the wage/salary (Olabisi and Olawamiwa, 2014). In addition, formal education improves human capacity and technical know-how which aids rate of adoption thus improving productivity level and farm income of such households. The result supports findings of Babatunde *et al.* (2007) and Ahmed *et al.* (2015) but differs from finding of Sulaiman *et al.* (2015).

Membership of farmers association had a negative coefficient and was significant at 5.0% alpha level, implying that membership to farmers' association decreased farm households' probability of being food insecure. According to Babatunde *et al.* (2007) access to cooperative loans by a farmer depends on membership to the association and such accessed credit are expected to boost household's income, own food production and food consumption. This result is consistent with findings of Babatunde *et al.* (2007); Arene and Anyaeji (2010); Kuwornu *et al.* (2013); and Ahmed *et al.* (2015) which revealed positive and significant relationship between membership to association and households' food security status. The coefficients of extension access and farm income were negative and significant at 5.0% alpha level, implying that the probability of the farm households being food insecure decreases with access to extension services and rising farm income. Access to extension services tends to enhance chances of a household having access to better production techniques, improved inputs, as well as other production incentives that positively affect farm production and thus household food security (Sulaiman *et al.*, 2015). Income generated from the farm can be used to finance investment opportunities and consumption of other food items not produced by the household, thus increasing the household's overall food intake and food security status. This finding compares favourably with result obtained by Ahmed *et al.* (2015) but contradicts findings by Ojeleye *et al.* (2014) that farm income had a significant positive effect on household food insecurity status.

Table 3: Probit regression estimates of factors influencing food security status of the farm households

Variable	Coefficient	Standard error	Z-statistic

** And *** significant at 5.0% and 1.0% alpha levels respectively

Conclusion

The study showed that 59% of the farm households were food insecure. Various factors such as gender of household head, household size, non-farm income activity, educational level of household head, membership of cooperatives, extension access and farm income were significant determinants of farm households' food insecurity status. Coping mechanisms embarked upon by the food insecure farm households have short term effect. There is need to boost income generating potential of food insecure farm households. To this end, heads of farm households should be trained by relevant agencies on improved farming technologies and skill acquisition so as to boost their farm and non-farm income earning capacity. Male headed farm households had lower probability of being food insecure, thus, female headed farm households should be targeted more in future programmes aimed at reducing farm household food insecurity. Farm household heads should be encouraged to participate in cooperative societies in order to have improved access to productive resources such as seed input, information dissemination and credit facilities so as to enhance their productivity level which will invariably improve their household food security status. Policies that will make extension services accessible to heads of farm households will go a long way in improving household food security in the LGA. Enlightenment programmes on family planning should be directed at farm households, in order to educate them on benefit of having manageable household size.

Economic Analysis of Banana Fruit Marketing in Ivo Local Government Area of Ebonyi State, Nigeria

Anozie, R.O, Okelola, O.E and Ivoke, G.E
Federal College Of Agriculture, Ishiagu, Ebonyi State, Nigeria
E- Mail: Rofalink415@Gmail.Com

Abstract
Economic analysis of banana fruits marketing in Ivo Local Government Area of Ebonyi State, Nigeria was studied. Data were collected through structured questionnaire from 120 respondents (60 retailers and 60 wholesalers). The data was analyzed using percentages, gross margin analysis and multiple regression analysis. Majority of the retailers (66.6%) and wholesalers (71.7%) were within the ages of 31 -50 years, about 83.3% of retailers and wholesalers (79%) attended formal education,. majority of the retailers (58.3%) and wholesalers (65%) had household size of at least persons, Most of the retailers (75%) and wholesalers (65%) do not belong to any marketing association, majority of the retailers (81.7%) and wholesalers (93.3%) have had more than 5 years marketing experience, only 1.7% of retailers and wholesalers (9.2%) acquired capital from the bank. Banana marketing is a profitable enterprise in the study area. It gives a benefit cost ratio of 1.4 and 2.7 for retailers and wholesalers respectively. Age of the marketers, their education level, marketing experience, cost of transport and access to credit were the factors that significantly affect retail banana fruit marketing in the study area, while age of the marketers, their educational level, marketing experience, cost of transportation and membership of co-operative association were the factors that significantly affect wholesale banana marketing in the study area

Key words: *Economics, Banana, Marketing, Ivo, Area*

Introduction
Banana (*Musa* spp) is a major starchy staple in the sub-Saharan Africa, providing more than 25% of the carbohydrates and 10% of the daily calorie intake for more than 70 million people in the continent (IITA, 2000). Yields are highest in western Africa estimated at 26.4 tons per hectare and lowest in Central region where it is estimated at 5.5 tons per hectare. A greater percentage of banana fruit harvested is lost to spoilage and infestations on transit to consumers (Njoku and Nweke, 1996). In developing countries, where tropical weather and poorly developed infrastructure contribute to the problem, losses are sometimes of staggering proportions (Echebiri and Mejeha (2004). However, relative attention given to banana is focused on its production technology while little is done on its marketing. Obasi (2008) noted that serious inefficiencies characterized the operation of the marketing system in most developing countries as a result of so many socioeconomic, political and other constraints militating against marketing efficiency.

Banana marketing activity in Ivo LGA has been deficient of relevant quantitative and qualitative information. This has made it difficult for the government, research institutes, policy makers, individuals and marketers to obtain holistic, relevant and reliable marketing information to work with. Availability of information is essential for deciding measures to prevent post- harvest losses of the fruit. Such measures may have to be taken by the small farmers, the private traders, the cooperatives, handlers and transporters, wholesale and retail marketers etc (Lynam *et al*., 2002). . It is therefore against this background that this study was undertaken to determine the effect of socio-economic characteristics of marketers on their income and estimate costs and returns to banana friut marketing in the study area

Methodology

The study was carried out in Ivo Local Government Area of Ebonyi State, Nigeria. The area is located between latitude $5^0 56^1$ and $6^0 59^1$ North of Equator and longitude $7^0 35^1$ and $7^0 4^1$East of the Greenwich Meridian. Its rainfall ranges from 1500 -2500mm, temperature of 28-45^{0}c and moderate Relative Humidity of 75%. Ivo Local Government Area has an area of 350,659km^2 with population of 220,919 people (NPC, 2006). It comprises five (5) autonomous communities namely, Ishiagu, Ihie, Okue, Umuihe and Akaeze. Ivo people are mainly agrarians, prominently in the production of rice, plantain, banana, okra, yam, cassava, sweet potato, cocoyam and vegetables. Data was collected from respondents by the use of structured questionnaires and oral interview. Multi-stage random sampling procedure was used to select respondents for this study. This was done in the following stages; Stage1involved random selection of two (2) markets in the area. In stage 2, thirty (30) wholesalers and thirty (30) retailers were randomly selected from each of the two markets making a total of 120 respondents who formed the sample size for the study. Descriptive statistics (Tables and Percentages) was used to analyze socio-economic characteristics of respondents. Gross margin analysis was used to estimate costs and returns of banana fruit marketing. Multiple regression analysis was used to determine the effect of socio-economic characteristics of respondents on their income.
The multiple regression model is stated thus:

$$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, , ei).$$

Four functional forms of the model are explicitly represented as follows:
Linear: $Y = a_0 + a_1X_1 + a_2 X_2 + a_3 X_3 + a_4X_4 + ei.$
Semi log: $Y = a0 + a_1 \log X_1 + a_2 \log x_2 + a_3 \log x_3 + a_4 \log x_4 + ei.$
Double log: $\text{Log } Y = a0 + a_1 \log X_1 + a_2 \log x_2 + a_3 \log x_3 + a_4 \log x_4 + ei.$
Exponential: $\text{In}Y = a0 + a_1 X_1 + a_2 x_2 + a_3 x_3 + a_4 x_4 + ei.$

Where
Y = Output of banana marketing (kg)
X_1 = Age of the marketers (years)
X_2 = Household size (No in the family)
X_3 = Educational level (years)
X_4 = Marketing experience (years)
X_5 = Transportation (N),
X_6 = Membership of Association (Member = 1, Non-member =0)
X_7 = Credit (N)
ei = Error term.

Gross margin Model: GM = TR –TVC (GI –TVC)
Where
GM = Gross margin
TR = Total Revenue
GI = Gross income
TVC = Total variable cost

Results and Discussion

The socioeconomic characteristics of the respondents studied were Age (years), Gender, level of education, marital status, Household size among others. Table 1 shows distribution of respondents according to their socio-economic characteristics.

Table 1: Distribution of the Respondents According to Age (years)

	Retailers		Wholesalers	
Variable	Frequency	Percentage	Frequency	Percentage
Age (years)				
Below 30	39	32.5	30	25.0
31 -40	58	48.3	53	44.2
41 – 50	22	18.3	33	27.5
51 – 60	1	0.8	4	3.3
Level of Education				
No formal education	20	16.7	21	17.5
Primary education	16	13.3	27	22.5
Secondary education	69	57.5	60	50

Source: Field survey, 2017

Result shows that majority of the retailers (66.6%) and wholesalers (71.7%) were within the ages of 31 -50 years. This implies that both the retailers and the wholesalers of banana in the study area were still within their youthful and active age. This is in line with the findings of Nwaru (2004), who noted that the ability of a farmer to bear risk, be innovative and be able to do manual work decreases with age .On educational attainment of marketers, majority of retailers (83.3%) and wholesalers (79%) attended formal education. Their level of literacy could enhance adoption of new technologies in marketing. Result is in consonance with findings of Nwaru *et al* (2011), who stated that, education helps for product management and easy access to information. Majority of the retailers (58.3%) and wholesalers (65%) had household size of at least 7 persons. The relatively large family size of banana marketers is to enhance availability of labour needed in banana marketing. Result supports finding of Effiong (2005). Most of the retailers (75%) and wholesalers (65%) do not belong to any marketing association. This implies that marketers do not take membership of marketing association seriously. Marketing associations are important especially in acquiring loans from formal financial institutions. Table I also shows that majority of the retailers (81.7%) and wholesalers (93.3%) have had more than 5 years marketing experience. Long years of involvement in marketing expose the marketers to marketing ideas that will help them to overcome marketing intricacies (Okoye *et al,* 2010). Retailers identified their source of capital to include personal savings (55.8%), friends (26.7%(, thrift (15.8%) and loan from bank (1.7%) while the wholesalers identified theirs to include personal savings (45.8%), thrift (31.7%), friends (13.3%) and loan from bank (9.2%). This implies that the wholesalers have more sources of capital than the retailers in the study area. This may be due to the quantity of their sales. Anozie *et al* (2016) opined that capital is an important factor in production and marketing of products.

Source: field survey, 2017 NB:***, ** and * indicates levels of significant at 1%, 5% and 10% respectively. Values in bracket represent the t – values.

The result showed that double log model was chosen as the lead equation in both retailers and wholesalers. The choice was based on the econometric criteria such as the highest R^2 value (0.655), F-value (3.77) and the highest numbers of independent variables that were significant for the retailers. However, R^2 value of 0.655 implies that about 65.5% of the variation in the income of the banana retailers were influenced by the combined effect of the independent variables included in the regression model. On the other hand, R^2 value of 0.801 for the wholesalers indicates that 80% of the variation in the income of the wholesalers is influenced by the combined effect of the independent variables included in the model.

However, age of marketers, their education, experience, cost of transportation and access were the independent variables that influenced banana marketing by retailers in the study area. The coefficient of Age (X_1) was negative and significant at 1% level of probability. This implies that an increase in the age of the marketers will reduce their income by –₦0.106. Education (X_3) was also negative and significant at 1% level. This also indicates that increase in the level of education of the retailers increases their income in the study area. Marketing experience (X_4) was positive and significant at 1% level. The implication is that a unit increase in the experience of retailers in banana marketing will increase their income by N0.093. Cost of transportation (X_5) has negative coefficient implying that increase in cost of transportation reduces the income of the retailers by N0.129. Access to banana (X_7) has a positive coefficient which implies that the more access a retailer has to the goods could increase his/her income by N0.948 in the study area. On the other hand, age, education and cost of transportation were the factors that influence the income of wholesalers in the study area. The coefficient of age (X_1) was positive and significant at 10% level. This implies that the older a wholesaler marketer is, the better he performs in the business. Coefficient of education (X_3) was negative and significant at 1%level, this implies that the more educated a wholesaler marketer is, the greater his income. Cost of transportation (X_5) was positive and significant at 5% level. The implication is that the higher the cost of transportation, the higher the income of the wholesaler in the study area. The coefficient of membership of association (X_6) was positive and significant at 5% level implies that banana wholesalers that belongs to association has more income than those who do not belong to any.

The overall, confidence of the model was confirmed by their f-value which is statistically significant at 1% level. Therefore, socioeconomic characteristics of banana marketers influenced their income in the study area.

Table3: Gross Margin Analysis of Banana fruit Marketing in Ivo Local Government Area of Ebonyi State.

Items	Retailers(N)	Qty	Wholesalers (N)
Purchase price/15kg of banana	2050	375kg	225,000
Transport	150		56,250
Marketing expenses	20		1,000
Miscellenous	100		2,000
Total variable cost	2,320		284,250
Selling price/unit	3,200	2050	768,750
Gross marketing margin (TR – TVC)	880		484,500
Benefit cost ratio (BCR) = TR/ TC	1.4:1		2.7:1

The table 3 shows that the wholesalers purchases 375kg of banana fruits from the producers or their agents at N225,000 and resells to the retailers at N2,050 per 15kg. The retailers resells their 15kg of banana at N3,200. The total variable cost for the retailers was N2, 320 while that of the wholesalers was N284, 250. Gross margin for the retailers was N880 while that of wholesalers was N484, 500. Their Benefit Cost Ratio was N1.4 and 2.7 for the retailers and wholesalers respectively. The implication is that for any N1.00 spent in banana marketing, the retailers get N1.4 and wholesalers get N2.7, indicating that the business is profitable.

Table 4: Distribution of the respondents according to the constraints to banana fruit marketing

Constraints	Retailers Frequency	Percentage	Wholesalers Frequency	Percentage
Inadequate storage facilities	33	27.5	36	30.0
Perishable nature of the product	60	50	30	25.2
Pest and diseases attack	27	22.5	50	42.0
Poor transport system	-	-	30	2.5
Poor access to credit	-	-	1	0.8
Total	120	100	120	100

Source: Field survey, 2017

Table 4 shows that the major problems identified by the retailers as their constraints to banana fruits marketing in the area includes perishable nature of the fruits (50%), lack of storage facilities (27.5%) and pest and diseases attack (22.5%) while the problems encountered by the wholesalers are; pests and diseases (42%), inadequate storage facilities (30%), perishable nature of the fruits (25.2%), poor transport system (2.5%) and poor access to credit (0.8%). This implies that banana marketing is hindered by the identified factors which need to be solved for efficient marketing.

Conclusion

Banana marketing is a profitable enterprise in the study area. Wholesalers and retailers made gross margin of N 484, 500 and N888 respectively per 15kg of banana sold. Their Cost returns analysis show that for every N1 invested N1.4 and 2.7 for retailers and wholesalers were realized respectively. Age of the marketers, their education level, marketing experience, cost of transport and access to credit were the factors that significantly affect retail banana fruit marketing in the study area, while age of the marketers, their educational level, marketing experience, cost of transportation and membership of co-operative association were the factors that significantly affect wholesale banana marketing in the study area. Based on the research findings, the following recommendations were made: The banana marketers (wholesalers and retailers) should form cooperatives to enable them generate a strong source of credit for improved marketing. The government on their own should provide the infrastructure, such as good road, proper storage facilities for the banana marketers in the study area. There is urgent need for the research institute to develop more effective and non-contaminant pesticides that could reduce or solve the problem of pests and diseases as encountered by the banana marketers in the study area.

Abstract
The study examined the rice farmer's productivity in Wase Local Government Area of Plateau State, Nigeria; the objectives were to estimate profitability of rice farming in the study area and determine the socio economic factors affecting rice farmer's productivity. Primary data was used for this study with the aid of well- structured questionnaire. A multi-stage sampling technique was used in selecting rice farmers in the study area. Three major rice producing districts were purposely selected from the Local Government Area followed by the random selection of the villages from each districts. In all 153 rice farmers were randomly selected from six village's.Gross margin analysis revealed that the production of rice is profitable with the gross margin of ₦216,576.The multiple regression estimates for determinant of productivity among rice farmers reveals that the coefficient of age, educational level and farm size were negatively significant at 1% level while the quantity of seed and fertilizer were positively significant at 5%.Based on the findings of the study, recommendations are necessary for more sustainable rice production in the study area.
***Keywords**: Rice Farmers, Productivity and Gross-margin*

Introduction
Agriculture is the mainstay of the majority of Nigerian rural poor, producing major crops comprising cereal such as sorghum, maize, rice; tubers such as yams, cassava, legume such as groundnut and cowpea as well as vegetables.Rice is cultivated in all regions of Nigeria. It ranks sixth after sorghum, millet, cowpea, cassava, and yam (5). It accounts for about 12 percent of the total cereals produced in Nigeria (6). Five major production systems have been identified, these are the upland rain fed, inland shallow swamp, deep water, floating lowland and irrigated rice production systems (15). In 1990, rice yield in Nigeria was 2.07 tonnes/hectare, this reduced to as low as 1.3 tonnes/hectares in 2007 and in 2012, Nigeria rice yield was 1.88 tons/hectare (11). The land area under rice cultivation in Nigeria in 2005 was about 2.708 million hectares. But the estimated area planted with rice in 2012 stood at 2.685 million hectares (11). This figures indicated a reduction in area cultivated for rice over the period 2005 – 2012.Rice is a major staple food in Nigeria, but its domestic production has never been able to meet the demand; (9,10) observed that the demand and supply gap in rice production is widening, resulting in huge import bill on rice. Rice imports have affected the domestic production and marketing of Nigeria's local rice. This is due to the decreased demand for local rice by Nigeria as opposed to the imported ones. Also, as a response to the prevailing rice supply deficit situation in Nigeria, successive Nigerian governments intervened in the rice sector through the establishment of parastatals and policies since 1970; all these were aimed at encouraging, boosting local rice production and enhancing strategies on food security and livelihoods of Nigerians. First, government established the Federal Rice Research Institute (NCRI) in 1974; National Seed Service (NSS) in 1975; and Operation Feed the Nation (OFN) in 1976. Other Government programmes were the River Basin Development Authority (RBDA) 1977; Agricultural Development Projects (ADP) 1975; The Structural Adjustment Programmes (SAP) 1986; (4). The National Special Programmes on Food Security (NSPFS), National Rice Development Strategy (NRDS) 2009 and Presidential Initiative on Rice (2001), aimed at attaining food sufficiency in local production of rice in the short term (2005) and increase export in the medium term (2007), with targets of 3 million hectare cultivation, and 15 million tons of paddy rice or 9 million metric tons of rice (8). Despite these efforts, rice production

potential has not yet been realized, as small holder (small-scale, subsistence and fadama farmers) output is inadequate and paddy rice processing is still substandard. Also, Nigeria is still the world largest importer of rice (10). In a bid to achieve rice self sufficiency in Nigeria, a rice transformation action plan was set up in 2011 under the umbrella of the Agricultural Transformation Agenda (ATA) and the target was 6.0 million metric tons per annum of locally produced and internationally competitive milled rice by 2015 (7). The importation of rice to bridge the demand-supply gap is worth ₦365 billion (2). The cost of these rice imports represents a significant amount of lost earnings for the country in terms of jobs and income (3).Therefore the main objective of the study is to analyze rice productivity among farmers in Wase Local Government Area of Plateau State, Nigeria.While the specific objective are to:estimate the cost and return of rice producers and to determine the socio-economic factors affecting rice productivity in the study area.

Methodology

The study was conducted in Wase Local Governments Area of Plateau State, Nigeria. It is located about 216 kilometers away from Jos, the State capital, with an estimated population of 209, 311 in 2015 (12). The land covers an area of 4,587 square kilometers.The annual rainfall is 1083mm and 27.4^{o}C average temperature. Major crops grown are food and cash crops as maize, sorghum, rice, groundnut, cotton, vegetables and beans. The major livestock are cattle, sheep, goat, poultry, and pigs.

A multi-stage sampling technique was conducted in three (3) district of Wase Local Government Area. The three (3) districts areKadarko, Lamba and Wase town. The Primary data in the study were obtained from153 rice farmers.This structured questionnaire was used to collect data from the farmers during2014/2015 season. Data were analyzed using gross margin and multiple regressions.

Model specification

Gross Margin Analysis.

Gross Margin is simply the difference between the total revenue and the total variable cost of each unit.

GM =TR-TVC,Where;GM=Gross Margin,TVC=Total Variable Cost,TR = Total Revenue.The variables to be used are:Seed (₦/kg),Fertilizer (N̲/Kg),Agro chemicals (N̲/Kg),Labour (mandays),Transportation (N̲/km).

Total Factor Productivity (TFP)

The Total Factor Productivity is measured as the inverse of the average unit cast of production. It is defined as the inverse of the ratio of total variables cost to total output. The model is approximated by a linear relationship.

(i) Total Factor Productivity Model

(ii)

$$TFP = \frac{Q}{TVC} \quad \text{or} \ \frac{1}{AVC} \qquad (1)$$

where, TFP = total factor productivity, Q = output(yield) and TVC = total variable cost.

$$TFP = F(Z_i, Z_2, Z_3 ...., Z_m) \qquad (2)$$

$$TFP = d_o + d_i z_i + d_2 Z_2 + d_3 Z_3 + ... + d_{10} Z_{10} \qquad (3)$$

Multiple Regression Model

This model was used to determine the socio economic factors influencing the productivity models (total factor).The model is as specified below;

$$Y = F(Z_1, Z_2, Z_3, Z_4, Z_5, ei). \qquad (4)$$

$$Y = b_o + b_1 Z_1 + b_2 Z_2 + b_3 Z_3 + b_4 Z_4 + b_5 Z_5 + Ui \text{ (linear)} \qquad (5)$$

Where Z_1 = age of farmers (yrs);Z_2= level of education (yrs);Z_3 = farm size (ha);Z_4 = seed(₦/kg);Z_5 = fertilizer (₦/kg);Z_6 = labour(mandays);u = error term; β= parameters to be estimated.

Results and Discussion

Gross Margin Analyses of Respondents

The total variable cost consist of seed, labour, fertilizer, chemicals, transportation, land rent,,the total variable cost stood at ₦179,424. Gross Income was ₦ 396,000and the gross margin was ₦ 216,576, while the return per naira increased was 0.83. This means that for every one naira invested, there was a return of 0.83kobo. This implies that production of rice is profitable in the study area.This means that the income generated would help farmers to have a sustainable livelihood.

Table 1: Gross Margin of Rice Productivity in the Study Area

Items	Cost/ha(₦)	Percentage
A: Gross Income (GI)	**396,000**	
B: Variable Cost (VC)		
Seed	9,600	5.4
Fertilizer	32,000	17.83
Agro chemicals	8,752.90	5.0
Transportation	9,750	5.4
Labour:		
Weeding	16,500	9.19
Harvesting	11,540	6.4
Land preparation	40,000	22.29
Sowing/plating	8,350	4.65
Processing and storage	33,431.40	18.6
Land	10,000	5.6
Total variable cost (TVC)	**179,424**	**100%**
C:GrossMargin (GM)	**216,576**	
D: Net Return (NR)	**0.83**	

Source Field survey, 2016

Socio Economic Factors Affecting Rice Farmer's Productivity in the Study Area

The multiple regression shows that R^2 (the coefficient determination) was 0.645. This shows that the variation in the dependent variable Y (output) was influenced by the combined effects of the independent variable (z_1-z_6). This implies that 36% of the variation in rice productivity was accounted for by the inputs included in the model.

Age: This variable is negatively significant at 5%level. This implies that an increase in the age of the farmers would lead to a decrease by the value of -0.584. This support the finding of (1) and (13) which found that age has a negative influence on productivity.

Educational level: This variable is negatively significant at 5% level. This implies that an increase in the education of the farmers would lead to a decrease by the value of -0.426. This support the finding of (1) which found that education has a negative influence on productivity

Farm size: The variable is negatively significant at 5%level. This implies that an increase in the farm size would lead to a decrease by the value of -0.604.

Quantity of seed: The variable has a positive coefficient(0.114) and significant at 1%level. This implies that a unit increase of input will lead to an increase in output.This suggests that the more use of certified seed the more productive the rice farmer.

Quantity of fertilizer: This variable has a positive coefficient(0.664) and significant at 1% probability level. This implies that the higher the use of fertilizer the more productive the rice farmer become.This support the finding of (14) which observed that the use of fertilizer increased agricultural productivity of crop farming in the dry savannah and humid forest agro-ecological zones of Nigeria.

Table2: Multiple Regression Rice Productivity in the Study Area

Variables	Coefficient	Standard error	t- ratio
Constant	0.395	0.461	0.856
Age	-0.584	0.226	-2.464**
Education	-0.426	0.189	-2.25**
Farm size	-0.604	0.297	-2.023**
Seed	0.114	0.042	2.704***
Fertilizer	0.664	0.232	3.136***
Labor	0.635	0.529	-1.200^{NS}
R^2	0.645		

Conclusion/Recommendations

On the basis of findings, it was concluded that rice production in WaseLocal Government Area of Plateau State is profitable given improved seed, available climate and soil requirement. It was recommended that more revenue can be made by farmers if availability of agricultural inputs are subsidized which could help them to have a sustained livelihood.

Economic of Sorghum Production in Kachia Local Govrnment Area of Kaduna State, Nigeria

Ademiluyi,I.O , Okeke-Agulu,K.I and Agbajie,J.O
Federal College of Forestry, Jos, Plateau State, Nigeria
E-mail: bukkyinkus@yahoo.com

Abstract
The study examined the economics of sorghum production in Kachia Local Government Area of Kaduna State. A multistage sampling technique was used to select 80 respondents used in the study. The analytical tools used include, Farm budgeting technique, production function and resource use efficiency. The result shows that sorghum production is profitable with the total cost of production (TC) being ₦ 47459.9 per/ ha while total Return (TR) was ₦ 78093.2. Per/ha, net income stood at ₦ 30633.3 while the return to investment was ₦ 1.64. The R^2 was 0.81% Coefficient of input shows that labour, and fertilizer were positively significant at 1 percent each, while seed was negatively significant at 1 percent. The study also revealed that seed is less than (<) the MFC. This indicates that seed is over utilized. This can be attributed to the variability of seed in the production of sorghum, while on the other hand, the MVP of labour, fertilizer and herbicide are greater than (>) as MPC. This indicates that labour and herbicide inputs are under-utilized, which implied that labour, fertilizer and herbicide inputs need to be used. The underutilization of purchased inputs might be due to improper management practices. It is recommended that with time and policy change these small scale farmers will improve their production income and they will grow to become major producers in order to sustain livelihood.
Keywords: *Sorghum, Farmers, Production, Kaduna State.*

Introduction
Sorghum (*Sorghum bicoloi*) is one of the most important staple crops in Nigeria and is the most important cereal food in the northern state that covers the guinea savannah ecological zone (FAO, 2005). In term of food contribution, Sorghum is the major cereal consumed by the majority of the population (NAERLS, 1997)). In the northern state about 73% of the total calories intake and 52.3% of the per capita protein intake are contributed by sorghum alone (Samm 2009). Some sorghum varieties are rich in antioxidant and all sorghum varieties are glutan free, an alternative for wheat allergy (Annon2, (2010). It is one of the most drought cereal crops currently, under cultivation. It offers farmers the ability to reduce cost on irrigation and other farm expenses. It requires an average temperature of at least 25^{o}c to produce maximum yield. In general is a very competitive crop and does well in competing with weed in narrow rows (FAOSTAT, 2010). Nigeria have resulted in the development and release of sorghum varieties suited to specific ecological (Aba et al (2004). Agricultural contribution to the National economy has been dwindling, this is so given that Nigeria has varied and complex constraint militating against the realization of increased agricultural output, among which are low crop yield, use of no improve crop varieties, inconsistent micro-economy policy, poor input and pests outbreak have also contributed to this situation (12). This makes sorghum the second most important cereal grain in Africa after maize.

According to (Akinleye, 2006) the production of commodities is not given consideration due to decline in output of the commodities in the savannah zone. Sorghum is grown and estimated as 4.5 million per ha with an annual production output of about 6 million tons (NAERLS, 1997)). Therefore to increase sorghum productivity, there is a need to understand the efficiencies of production since increase in production is directly related to productivity of the farmers which could help them to enhance food security and livelihoods in Nigeria. These require knowledge of aggregate farm level resource availability and difference in the productivities of these resources. This paper attempts to provide some useful information on policies towards increase in sorghum productions. Therefore, the broad objectives of the study are to analyze the economics of sorghum production in Kachia Local Government Area of Kaduna State. While the specific objectives are to: estimate the cost and return of the sorghum production in the study area; determine the resources-use efficiency of sorghum production in the study area.

Methodology

The study was carried out in Kachia Local Government Area of Kaduna State. It has land mass area of 4,632 kilometer square and estimate the total population of 350,275 people according to 2014 estimate population census. The Local Government is situated between latitude $9^0$25W and $10^0$20W and longitude $7^0$45E and $8^0$40E.The area has a temperature of 10^0C with severe cold in the month of December, January and early February. Rainfall distribution ranges from 550 – 900mm. Subsistence farming is the main source of livelihood in the area and crop cultivated include, maize, groundnut, ginger, soya beans, millet and guinea corn.

A multistage sampling technique was used in the study. Four (4) out of eight (8) districts were selected due to the high production of sorghum in the area. Two villages were chosen from each of the four (4) district selected. The villages' include: Dackham, Gidan Jibir, Tunga, Jaban Kogo, Fadan, Gidan Mana, Dangyolmi and Sabon Sarki. Based on the population of the villages 15% of the population was used to determine the number of respondent to avoid bias. 80 farmers were randomly selected.. Primary data was used in the research. The primary data were open and close ended type of questionnaire and oral interview. Data were analyzed using net farm income and resource use efficiency.

Model Specification

Net Farm Income

The farm budget techniques were used in this study. The net farm income is expressed as follows:

NFI = GFI – TC.

Where;

NFI = Net farm income,
GFI = Gross farm income
TC = Total cost
TC = TFC + TVC
TVC = Total variable cost,
TFC=Total fixed cost
The variable to be used includes:
Seed (₦/kg)
Labour (man per/day)
Fertilizer (₦kg)
Herbicides (₦/litters)
Land rent (₦)
Depreciation on equipment (₦)

Production Function Model

Production function model was used to examine in the input-output relationship in sorghum production and it was given as:

$$Y = f(X_1\ X_2\ X_3 \ldots\ldots\ldots\ldots\ldots Xn)$$

Where;

Y= Output of sorghum in kg
,x_1= Seed (kg)
x_2=Labour (man per/day)
x_3= Fertilizer(kg)
x_4= Herbicide(litters)
E=Error disturbance term.

The relationship was expressed in explicit cob- Douglas production form (double log) as follow:-

$$\text{Logy} = \log a0 + b_i \log x1 + b_2 \log x\ 2 + b_3 \log x\ 3 + b_4 \log X4$$

Resource use Efficiency
Resource use efficiency was used to satisfy objective (iii) of the study. The efficiency of resource use was determined by the ratio of marginal value product (MVP) to marginal factor cost (MFC) of input based on the estimated regression coefficient following (Mohammed, 2008) efficiency of resource, r, is give as:

$$MPP = \frac{bi\,y}{X_1} \quad MVP = bi\,\frac{y}{x}.Py$$

$$r = \frac{MVP}{MFC}$$

The rule provides that when r = 1 there is efficient use of a resource; r > 1 indicates under-utilization of resource while r < 1 means over utilization of resources. The equation is stated as follows:

$$MVP = MPP \times PY.$$

Where
r = efficiency ratio
MVP=Marginal Value Product
MPP=Marginal Physical Product
MFC=Marginal Factor Cost
Pxi (unit price of input x1)
Y=Arithmetic mean value of output
X_1=Arithmetic mean of input considered
Py= Unit price of output.

Result and Discussion

Net Farm Income
The total cost of production include; the variable and fixed cost. The total variable cost consist of seed, labour, fertilizer, chemicals, land rent, while total fixed cost consist of depreciation of equipment. The total variable cost stood at ₦39959.9 while the total fixed cost stood at ₦ 7500. Fertilizer cost constituted the highest fraction of 62%, followed by land rent at 13% while seed, labour, chemicals at 3% each. Total revenue was ₦ 78093.2, total cost of production was ₦ 47459.9, and the net farm income was ₦ 30633.3, while the return per naira increased was ₦ 1.64. This means that for every one naira invested, there was a return of 1.64kobo. This implies that production of sorghum is profitable in the study area, which means that through sorghum production the farmers could improve their food security status and their livelihoods.

Table 1: Cost and Return of Sorghum Production in the Study Area

VARIABLE COST (VC)	VALUE (₦ /HA)	PERCENTAGE (%)
Seed	1444.7	3.04
Labour	1422	3.00
Fertilizer	29527.7	62.22
Chemicals	1565.5	3.30
Land rent	6000	12.64
Total Variable Cost (TVC)	39959.9	
Fixed cost (FC)		
Depreciation of equipment	7500	15.80
Total fixed cost (TFC)	7500	
Total cost of production (TC)A	47459.9	100
Total returns (TR)B	78093.2	
Net Income B-A	30633.3	
Return per naira invested (TR/TC)	1.64	

Source: Field Survey, 2014.

Production Function of Sorghum Production

The R^2 which is the coefficient of determination was 0.81% this means that 0.81% of the variation in output of sorghum production was determined by the explanatory variables included in the model. The coefficient for labour, fertilizer, herbicide are positively significant, this implies that an increase in units of the same input will result in increase in output but in the case of herbicide it was found not to be significant. Amongst all the variables used, seed is the only variables with a negative co-efficient which agrees with (14) in the project titled economic of sorghum production in Bauchi Local Government Area of Bauchi State with seed having negative signs. This implies that, in any increase in unit, production lead to the total decrease in the output to about – 0.333kg.

Table 2: Production Function of Sorghum Production in the Study Area

Variables1	Coefficient	Standard Errors	T-Radio
Constant	1.555	1.218	1.276
Seed	- 0.333	0.118	-2.822 ***
Labour	0.505	0.135	3.749 ***
Fertilizer	0.063	0.024	2.625***
Herbicide	0.085	0.448	0.190NS

Source: Field Survey, 2014

R^2 = 0.81
*** = Significant at 0.01 % (P<0.01
NS = Not Significant

Resource Use Efficiency

From the below table, the MVP of seed is less than (<) the M.F.C. This indicates that seed is over utilized in the study area. This can be attributed to the variability of seed in the production of sorghum in the given area. While on the other hand, the MVP of labour fertilizer and herbicide are greater than (>) as MPC. This indicates that labour, fertilizer and herbicide inputs are under-utilized in the study area. This implied that labour, fertilizer and herbicides inputs need to be used.

Table 3: Resource Use Efficiency in Sorghum Productionin the Study Area

Variables	MPP	MVP	MFC	MVP/MFC
Seed	1.244	-99.52	100	-0.99
Labour	13.02	1301.5	500	2.60
Fertilizer	1.68	252.65	150	1.68
Herbicide	20.45	24540	1000	24.54

Source: Field Survey, 2014

Conclusion/Recommendations

Sorghum production in Kachia Local Government Area is a profitable venture as shown in this study. Moreover, like other agro-business, it is faced with a lot of challenge or constraints that need urgent attention to be tackled to improve the situation of sorghum production. It is however believe that with time and policy change these small scale farmers will improve on their performance and grow to become major producer of sorghum in Kaduna State and in Nigeria at large in order to enhance sustainable livelihood and food security.

Gender and Agricultural Land Access: a Discriminant Function Analysis Approach

C. N., Onunka.[1], C. C., Olumba [2], J. E., Ihemezie [1], N. Uche[2]
[1]University of Nigeria, Nsukka
[2]Ebonyi State University, Nigeria

Abstract
In the developing world, while many people lack secure land right and access to adequate land resources, women have been found to have less access to land than their men counterpart do. This study investigated the factors that best predict how access to land was gained by farmers in the area. This study was particularly carried out with a view to engendering appropriate policy response towards female access to land in the area. Multistage sampling technique was used in selecting 120 respondents used for this study. Data collected were analysed using discriminant function analysis. The result showed that the means of gaining access to land in the study area include community, purchase, lease/rent, inheritance, and gift. Discriminant function analysis was used to determine which socio-economic variables were the best predictors of how access to land was gained. The study found gender of the farmer amongst the best predictors of how access to land is gained in the area. The study therefore concluded that gender biasedness with regards to land access exists in the area, and in favour of the male farmers. It is therefore recommended that the redesigning and redeveloping of the structure of land policies to be more gender sensitive and inclusive.

Key words: land, gender, agricultural, access, farmers.

Introduction
In the discourse of agriculture and its related activities, there is one major factor that cannot be ignored- land. Land is crucial resource for the production of biomass, ensuring food, fodder, renewable energy and raw materials for the sustenance of human and animal life (Adekola *et al*., 2013). In many developing countries, land is a valuable form of asset, given its economic, political symbolic and ritual importance (Bioye *et al.,* 2006). In the agrarian communities of Nigeria, land is not just a factor of production but a major determinant of the people's livelihoods. Land provides the rural household the basic means for the subsistence production of their food need and for market production to generate income. Consequently for the poor rural households land access is an important basis for their economic and social development.

However, in past few years, access to and equitable distribution of land, and other land tenure issues are points of serious controversy in Nigeria. Increasing farmers are faced with the challenge of accessing available land. The constraints is multiplied for the women, as existing rules and traditional practices in relation to land acquisition are biased in the favour of males (Lasterria-Cornhiel & Gracias, 2009). For example, some cultures in Nigeria, through marriage and inheritance practices, discriminate against women from owning or accessing land. Emeasoba, (2012) reports that due to legal or cultural restrictions women usually have very little or no control over resources, particularly land.

This is regarded a major challenge to sustained agricultural production, when considering that women constitute a large proportion of farm labour and agricultural workers. Also these women are responsible for the production of the bulk of the country domestic food. Afolabi (2008), reports that in some Nigerian states, rural women are majorly responsible for production and processing of arable crops, producing as much as 80 % of the staple food items. The sustainability of the cultivation and production of these staple food crop depends on the enormous availability of land to the women. With the constrained access to farmland for the women, it is expected that domestic food production levels would reduce drastically, consequently affecting the food security of the country.

Therefore, for the success of any meaningful agricultural development, ownership or sustained access to land is paramount. Given the potential role of women in sustaining the agricultural sector of the country and the consequences of inequality on land access across gender. This study therefore sought to identify the socio-economic factors determining the means through which land is accessed in the area, with gender being a variable of interest. This is necessary in order to identify issues that must be resolved in the fight against gender biasedness in access to agricultural resources. Moreso, the study is undertaken so as to sharpen the focus of advocacy for equitable integration of women and men in agricultural land access and for the sustained agricultural production in the country. The specific objectives for the study was to analyse the factors that best predict how access to land is gained, with a view to engendering appropriate policy response towards female access to land in the area.

Methodology

The area for the study was Ekiti State, Southwest Nigeria. Ekiti State lies South of Kwara State and Kogi State, East of Osun State and West of Ondo State. The state enjoys tropical climate marked by two major seasons. The seasons include the rainy season which last from April to October and the dry season from November to March. The state provides home to a population of 2,801,161 people (National Bureau of Statistics, 2012). The indigenes of the state belong to the Yoruba ethnic group. Agriculture is the main occupation, providing income and employment for majority of its population. Cocoa, coffee, kolanut, cashew and oil palm are the major cash crops grown in the state. Examples of arable crops grown in the state include yam, cassava, maize, cowpea and cocoyam (Ekiti State Government, 2008). The study used multi-stage sampling technique to draw a sample for the study. At the first stage, 6 local government areas were purposively selected from the sixteen local government areas that constitute the study area. This local government areas were purposively selected based on their degree of involvement in farming. In the second stage, two communities were randomly selected from each of the six local government areas selected, giving a total of 12 communities. In the final stage, ten respondents with equal number of male and female were randomly sampled from each of the communities. This gives a total of 120 respondents for the study. Primary data were collected for the study with the use of a structured questionnaire. Data obtained was analysed using discriminant function analysis.

Discriminant Function Analysis Model

The model was employed in order to determine the variables that are best in discriminating between groups of people based on how they gained access to land. The predictors (independent variables) were the socio-economic characteristics of respondents including: sex, marital status, educational status, income level and occupation. The grouping (dependent variable) was the means of gaining access to land namely community, purchase, lease/rent, inheritance, and gift.

Mathematically, the model is expressed as:

$D = a + b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4$

Where:

D= Discriminant score

a= constant (intercept)

b= Discriminant coefficients

x_1= Sex

x_2= Membership of cooperative

x_3= Monthly farm income

x_4= Age of farmers.

Result and Discussion

Discriminant function analysis was employed to determine the best predictors of access to farm land in the study area. The result of the statistical test of significance of the model is presented in table 1. The table shows the efficacy of the discriminant function.

Table 1. Statistical Parameters of the Correlation

Eigenvalues

Function	Eigen value	% of Variance	Cumulative %	Canonical Correlation
1	1.091[a]	97.5	97.5	.770
2	.291[a]	1.8	99.2	.475
3	.123[a]	.7	100.0	.331
4	.004[a]	.0	100.0	.062

a. First 4 canonical discriminant functions were used in the analysis.

The canonical correlation of 0.770 for Function 1 suggests the model explains 97.5% of the variation in the grouping variable that is whether a farmer accesses land through community, purchase, lease/rent, inheritance, or gift. Function 2 and 3 having canonical correlations of 0.475 and 0.331 suggests the model explains 1.8% and 0.7% of the variation respectively. This shows how good the model is in explaining the variation in the grouping variables. Moreso, the table indicated eigenvalues of 1.091, 0.291, 0.123 and 0.004. A low eigenvalue obtained is an indication of near linear dependence in the data obtained for the study. Thus the model is free of multi-co linearity. This agrees with the work of Nto *et al*., (2014) that got Eigen value of 3.116. However, when eigen value is less than 8, the result is considered as excellent.

Moreover, the Wilks' Lambda indicates the significance of the discriminant functions and provides the proportion of total variability as explained in Table 2. It tests how well each level of independent variable contribute to the model. The scale ranges from 0 to 1, where 0 means total discrimination and 1 means no discrimination.

Table 2: Wilks' Lambda

Wilks' Lambda

Test of Function(s)	Wilks' Lambda	Chi-square	df	Sig.
1 through 4	.040	753.548	16	.000
2 through 4	.687	87.913	9	.000
3 through 4	.887	28.078	4	.000
4	.996	.901	1	.343

In Table 2, function 1, 2 and 3 indicates a highly significant function ($p < .000$) and provides the proportion of total variability not explained. Function 1, 2 and 3 are closer to zero than function 4 which means they tend towards total discrimination, 0, than no discrimination, 1. The smaller the lambda for an independent variable, the more that variable contributes to the discriminant function and it varies from 0 to 1. Hence, it could be concluded that there was a relationship between the dependent variable and the independent variables.
Furthermore, the structure matrix table as shown in Table 3 reveals the correlations of each variable with the discriminant function.

Table 3: Structure Matrix

Structure Matrix

	Function			
	1	2	3	4
Membership of cooperative group	.224	.894*	.024	.387
Sex	.351	-.762*	-.116	-.531
Age of farmers	.161	.294	.114	.935*
Monthly farm income	.031	.472	.612	.633*

Pooled within-groups correlations between discriminating variables and standardized canonical discriminant functions
Variables ordered by absolute size of correlation within function.

*. Largest absolute correlation between each variable and any discriminant function

Identifying the largest loadings for each discriminant function gives an insight into how to name each function. The table, however, shows that in function 1, sex has the largest absolute correlation,

in function 2 membership of cooperative has largest absolute correlation, in function 3 monthly farm income, while in function 4 it is age of farmers. This means sex, membership of cooperative, monthly farm income, and age of farmers are the best predictors of how access to land is extended in Ekiti State Nigeria.
Overall, the result of the discriminant function analysis confirms that sex of the farmers is an important factor that predicts how access to land is extended in Ekiti state. The study findings confirms the assertion of Adekola et al., (2013) of the prevalence of gender differences in land accessibility in South west Nigeria, as male were found to have more access to agricultural land than their female counterparts. Also, the study finding is in line with the study of Ekenta et al., (2012) in South east Nigeria, who reported that land holding in hectares favours males than females in the area. Similarly, the study findings is in agreement with the study of Onumadu and Onuoha (2015), who found that male farmers had more land holding in hectares than females in the study area.

Conclusion and Policy Implication

The study looked into the factors that determine how access to land is gained by both male and female farmers. The Discriminant function analysis was used to determine which socio-economic variables were the best predictors of how access to land is gained in the area. Sex, membership of cooperative, age and monthly income emerged as the best predictors. The result of the discriminant function analysis confirms that gender of the farmers is an important factor that predicts how access to land is extended in Ekiti state. Consequently, the result of this study reiterates the importance of gender mainstreaming in agriculture. There is the need for the restructuring of land tenure policies in such manner that will ensure that both genders have equal access to agricultural land. Improving women access and tenure security over land is considered a strategically important step in combating food insecurity prevailing in the country.

Based on the study findings, it is recommended that governments at all levels should consider gender in agriculture by revisiting the system of land holding in order to include the vulnerable group such as women farmers. Both male and female farmers should have equal access to agricultural land especially for perennial crops and the farmers should be able to obtain land on a more permanent basis. This will have a significant effect on food production in Ekiti State and in Nigeria at large.

Furthermore, there is a need for enactment of law that will abrogate all traditional and customary practices that disadvantaged women in the ownership of landed properties. Enactment of such laws should not be as a written paper document only but it should be backed up by effective implementation. Financial incentives should be given to the farmers, especially the women folk to enable them access more land and expand their scale of production. Farm inputs and other appropriate types of technology to cater for the labour intensive farm activities, should be available to farmers at affordable and subsidized rates as and when needed. Also, government agricultural policies and programs should not be gender biased.

Economic Analysis of Maize Marketing in Kiru Local Government Area of Kano State, Nigeria

H. A. Yusuf and I. G. Ibrahim
Ahmadu Bello University, Zaria, Kaduna State, Nigeria
hagiwa69@gmail.com

Abstract
The study analyzed maize marketing in Kiru Local Government Area of Kano State, Nigeria. Data for the study were collected using structured questionnaire which was administered to 120 maize marketers out of which 115 were retrieved. Descriptive statistics were used to analyze the data. The result indicated that majority of the maize marketers in the study area were men, with the age range of 41-50 years. Also most of the respondents had 1-10 people in their household. The result indicated marketing margin of 26.78%, which implies that 26.78% is the difference in the price incurred as the produce moves from one stage to another in the marketing channel. The main constraints faced by maize marketers in the study area include large number of middlemen, inadequate capital, high transportation cost and inadequate storage facility. The study showed that large number of middlemen was a major (80.9%) constraint. Thus the study recommends that government should create policy that will reduce the number of middlemen in maize marketing system. It is also recommended that marketers should be linked with financial institutions through the help of extension agents in order to secure loans so as to expand their business.
Keywords: Economic analysis, maize, marketing, Kiru, Kano State.

Introduction
Maize (*Zea mays L.*) is a member of the grass family (gramineae). It originated from South and Central America. It was introduced to West Africa by the Portuguese in the 10th century (Iken and Amusa, 2004). Nigeria is currently the tenth largest producer of maize in the world, and the largest maize producer in Africa, (International Institute of Tropical Agriculture (IITA), 2012). It was estimated that 70% of farmers were smallholders accounting for 90% of total farm output (Cadini, and Angelucci , 2013). Marketing is often concerned with all the stages of operations which aid the movement of commodities from the farms to the consumers (Akanni, 2011). These stages include assembling of goods, transportation, processing, grading and financing of all these activities. He also defined marketing as the process of planning and executing the concept, pricing, promoting and distribution of ideas, goods and services to create exchange that satisfies individual and organizational objectives.

Majority of agricultural markets in Nigeria are inefficient and poorly integrated (Onyuma,*et al.,* 2006). The development of an efficient marketing system is essential in the allocation of scarce resource for production and distribution of commodities among consumers (Acharya and Agarwal, 2011) and ensures stable and remunerative incomes to farmers (Ikudayisi and Salman, 2014). Moreover, remoteness, scarce and poorly maintained roads, inadequate transport and storage facilities, and difficulties in accessing reliable information on products and prices prevent the smallholder farmers from participating in competitive markets, often restricting them to non-contestable markets dominated by a few, powerful purchasers (World Bank, 2007). Also middlemen intervention raise price for consumers, which showed that famers encounter high production but hardly get fair pricing of their product from the middlemen, the bulk farm gate buyers. The real profit goes to the middlemen who buy up the farm products at almost give away prices. Based on this background, the study seeks to describe the socio-economic characteristic of maize marketers in Kiru Local Government Area, determine the marketing margin and identify the constraints faced by maize marketers in the study area.

Methodology

The study was conducted in Kiru Local Government Area of Kano State, Nigeria. Kiru Local Government Area (L.G.A.) has land area of 927 km^2, and has estimated population of 264,781 based on 2006 census, (National population commission (NPC, 2006), The projected population for 2017 using annual population growth rate of 3.5 % is 288,840. The people of the community are predominantly farmers, the common crops grown in the area include: maize, sorghum, rice, millet, cowpea and groundnut. The area has two main seasons, wet and dry, the wet season starts at the end of May and ends in September- October and the dry season starts in October and ends in April. Dry cold and dust wind (Harmattan) is experienced between November and February and weather is always cold. Heat is more severe in March and April. The climatic condition is Guinea savannah with grassland vegetation and scattered trees (KNARDA, 2011). Kiru Local Government has 4 major functioning markets. Based on the information collected from maize marketers union, the following information were obtained : Kafin-maiyaki (Kwanar dangora) with 82 maize marketers, Rahama rawun, 66 maize marketers, Yako 47 maize marketers and Kiru 55 maize marketers, making total of 250 maize marketers within the four markets in the study area. The four markets were selected purposively due to high concentration of maize marketers. A total sample size of 120 respondents was selected randomly which represents 48 % of the sample frame (250).

Primary data were used for the study. Data were collected using structured questionnaire complemented with interview schedule. Descriptive statistics such as frequency distribution, range and percentages were used to achieve all the objectives of the study. Marketing margin refers to the difference between the retail price and farm level price. According to Ajala and Adeshinwa (2008) it is expressed as follows:

$$\text{Marketing margin} = \frac{Conumer\ price - Producer\ price}{Consumer\ price} \times 100$$

Where:

Producer price = is the price at which the producer is giving out his produce for sale.
Consumer price = is the price incurred at different stage of time, place, form and possession.

Results and Discussions

The result in Table 1 revealed that 88.7 % of the respondents were male, while 11.3 % were female. This could be because of the socio-cultural belief of the people in the study area. This is in line with studies carried out by Faith *et al.,* (2011). Men were the highest participants (89.24%) in maize marketing in Kano State. Most (41.7%) of the respondents were found to be within the age range of 41 – 50 years, then 30.4 % were within the age range of 31 – 40 years. This implies that most of the marketers were at their active production years. And this is similar to the age range of 30 to 50 years which was found by Onu and Iliyasu., (2008) among maize marketers in Adamawa State. In addition, 91.3 % of the respondents were married while that 8.7 % of the respondents were single. This indicates the ability to take household responsibilities. It also corresponds to the study carried out by Oladopo *et al.* (2007) which indicated that maize marketers in Nigeria were mostly married. The study also shows that 52.2 % of the respondents had no formal education.

Table 1: Socio-economic characteristics of the respondents

Variables	Frequency (N=115)	Percentage (%)
Sex of Respondents		
Male	102	88.7
Female	13	11.3
Age Distribution		
21-30	16	13.9
31-40	35	30.4
41-50	48	41.7
51-60	16	13.9
Marital status		
Single	10	8.7
Married	105	91.3
Household size		
1-10	60	52.2
11-20	50	43.5
21-30	3	2.6
31-40	2	1.7
Level of education		
No formal education	60	52.2
Primary	27	23.5
Secondary	24	20.9
Tertiary	4	3.5
Years of experience		
1-10	72	62.6
11-20	38	33.0
21-30	4	3.5
31-40	1	0.9
Cooperative membership		
Yes	80	69.6
No	35	30.4
Sources of capital		
Formal credit institution	18	15.7
Informal credit institution	28	24.3
Personal savings	69	60.0

Education is very important as it helps the respondents in adopting new marketing strategy, and increases their access on marketing information. This could have effect on the adoption of new marketing strategies. This is contrary to the findings of Onu and Iliyasu (2008) who indicated in their study that majority (56%) had formal education. The study reveals that 62.6 % of the respondents had been involved in Maize marketing for 1 – 10 years, 33 % had of marketing experience, 11 – 12 years, 3.5 % had 21 – 30 years, while 9 % had 31 – 40 years of experience in maize marketing in the study area. (Table1). This shows that majority (62.6%) of the respondents had experience in maize marketing. Also 69.6 % of the respondents belong to co-operative group, while 30.4 % do not belong to any co-operative group (Table 1). This could be an avenue for the marketers to interact with one another through which information diffuse among them. It also implies that the marketer, have opportunity to access loan from bank which will help them to raise their marketing. The result also shows that 15.7 % of the respondents sourced their capital from formal credit institutions, 16.5 % sourced their capital from informal credit institutions, 60 % sourced their capital through personal saving, while only 7.8% sourced their capital from Co-operative society (Table 1) this indicated that most of the marketer (60%) were used personal saving, for their business. This could limit the expansion of their business.

Marketing Margin

Marketing margin for a particular commodity has been defined as the difference between what the consumer pays for the final product and the amount the producer receives, at each intermediary level, it is the difference between price received on resale and the purchase price (Gabre and Madhin, 2001).

Determination of marketing margin

The following formular was used to calculate the marketing margin according to Olukosi *et. al*. (2008).

$$\text{Marketing margin} = \frac{Consumer\ price - Producer\ price}{Consumer\ price} \times 100$$

ΣPP = ₦ 505, 480
ΣCP = ₦ 690, 320

Where:

Σpp = Sum of producer price
Σcp = Sum of consumer price
₦ = Naira

$$\text{Average producer price} = \frac{\Sigma pp}{N} = \frac{₦\ 505{,}480}{115} = ₦\ 4{,}395.48$$

$$\text{Average consumer price} = \frac{\Sigma cp}{N} = \frac{₦\ 690{,}320}{115} = ₦\ 6{,}002.78$$

Where: Σpp = Sum of producer price Σcp = Sum of consumer price N =Number of respondents.

$$\text{Marketing margin} = \frac{Average\ cp - Average\ pp}{Average\ c} \times 100$$

$$\text{Marketing margin} = \frac{₦\ 6002.78 - ₦\ 4395.48}{₦\ 6002.78} \times 100 = 26.78\%$$

This implies that 26.78% is the difference in the price incurred as the produce moves from one stage to another in the marketing channel.

Constraint in Maize Marketing

The main constraints faced by maize marketers in the study area include large number of middlemen (80.9%), inadequate capital (79.1%), high transportation cost (77.4%), and inadequate storage facility (67.8%). Other constraints include inadequate market information (55.7%), price fluctuation (54.8%), Grading and standardization (50.4%), and others which include inadequate good roads and inadequate processing facilities (50.4%). (Table 2)

Table 2: Distribution of respondents according to their constraints

Constraints	Frequency*	Percent (%)
Large number of middlemen	93	80.9
Inadequate capital	91	79.1
High transportation cost	89	77.4
Inadequate storage facilities	78	67.8
Inadequate market information	64	55.7
Price fluctuation	63	54.8
Grading and standardization	58	50.4

*= Multiple responses

Conclusion and Recommendations

The study revealed that the difference between the producer's price and the consumers was 26.78%. This implied that maize marketing in the study area was profitable. The major constraints faced by maize marketers in the study area were: Large number of middlemen, inadequate capital, and high transportation cost, inadequate storage facilities and inadequate market information. Based on these findings it is recommended that Government should implement policy that will reduce number of middlemen involved in maize marketing. This can lead to high cost of maize in the market as long chain of middlemen take a large amount from the consumer's income. Also, the study recommended that marketers should be encouraged by extension agents to secure loans from financial institutions in order to expand their business. Local Government can assist the marketers by providing good road networks as this could reduce transportation cost. Based on the findings, inadequate market information was among the main (55.7%) constraints. It is recommended that Government should set up a Market Information System (MIS) in order to improve the availability and accessibility of market information. Better market information services would enable market agents to read price signals more accurately and promptly, and therefore to make more reliable price forecasts that would aid them in making correct marketing decisions.

Food Insecurity Status of Farm Households during Post-Planting Season in Oru East Local Government Area of Imo State, Nigeria

J.C. Ijioma, C. K. Osondu and V. U. Okoronkwo
Abia State University, Umuahia Campus, Abia state, Nigeria.
E-mail: yokel4life@gmail.com

Abstract
This study was conducted in Oru East Local Government Area of Imo State, Nigeria. Specifically the study assessed food insecurity status of farm households during post-planting season in Oru East LGA and determined factors influencing food insecurity of the farm households during post-planting season. Multistage random sampling technique was employed in selecting 84 farm households from whom data were collected using semi structured questionnaire. Data were analyzed using descriptive statistics, food security indices, and Probit regression model. The farm households posted food insecurity line and food insecurity incidence of 1811.68 Naira and 0.466 respectively and food insecurity gap and severity of 0.418 and 0.291 respectively. Probit regression result showed that gender, level of education, amount of credit accessed, farm income, household size, remittances and off-farm income were significant determinants of farm households' food insecurity status. Efforts to improve access to credit by farm households and the promotion of off-farm activities as alternative livelihood options should be pursued by both the local and state governments.
Key words: Farm households, food insecurity, post-planting season

Introduction
Food security is defined as a situation that exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for a healthy and active life (FAO, 1996). Temu and Msuya (2004) stated that food security is the guarantee of the physical availability of and economical accessibility to sufficient food (produced with bioenvironmental and sustainable social methods) in terms of quantity (amount, distribution, calories) and quality (safe, nutritious, balanced). Food security has been identified to incorporate food availability, food accessibility, utilization and stability of food access as its elements (Bonnard, 1999). The international community has long been concerned about eradication of hunger and undernourishment especially of vulnerable groups. Despite resolution to enhance food security globally, report on world food insecurity highlighted that number of people suffering from hunger globally has increased every year since 1996 (Abimbola and Kayode, 2013). According to FAO (2010) about 925 million people worldwide still suffer from chronic hunger, in which 235 million hunger sufferers are from sub-Sahara Africa. Available evidence indicates that on almost every indicator such as per calories intake, export earnings, per capita income and food imports, Nigeria exhibits high levels of food insecurity (Akpan, 2009).

With more than 60% of Nigerians engaged in agriculture either as a primary or secondary occupation and producing farm products for their own use and market sales, food security is closely tied to agricultural productivity. This is because higher production on one's own farm improves the food security status of the household and vice versa (Abimbola and Kayode, 2013). Most foods produced by farm households in Nigeria are consumed, or sold for cash only to be repurchased when household barns run short with supplies (Emerole *et al.,* 2014). This cyclic and unstable condition most times leaves affected farm households in a state of insecurity with food supplies especially during the post planting season. The problem of food insecurity during the off season period among farm households in Nigeria is long standing (Obamiro *et al.,* 2005). This is because immediately after harvest most farm households are food secure as they have enough food from own production. However, owing to inadequate processing and storage facilities and the fact that these households have other important needs, they usually end up selling their excess produce at low prices during the harvest period only to require them during off-season. This leads to inconsistent food availability and accessibility thus contributing to household food insecurity during the period. An investigation of the food insecurity status and factors that influence food insecurity status of farm households during the post-planting season in the study area will provide clear information about what needs to be done to ensure food security among farm households particularly after planting season when they are most vulnerable to food insecurity.

Methodology

This study was carried out in Oru East Local Government Area (LGA) of Imo State, Nigeria. The LGA has an area of 136km^2 and a population of 111,822 persons (NPC, 2006). The LGA is bounded to the West by Oru West LGA, to the East and South-east by Njaba and Mbaitolu LGAs respectively, to the North by Orsu LGA and to the South by Oguta LGA, all in Imo State. It lies approximately within latitudes 06^0 45′ and 07^0 15′ north of the Equator and longitudes 06^0 50′ and 07^0 25′ east of the Greenwich meridian. The population for the study comprise of all farm households in the study area. Multi-stage random sampling technique was adopted in selection of sample. First, four communities were randomly selected. Next three villages were randomly selected from each of the selected three communities to give twelve villages. Lists of farm households in each village were formulated with the help of extension agents and village secretaries. This list served as the sampling frame from which seven farm households were selected randomly. Thus, eighty four farm households were selected for the study

.

Data were collected with a pre-tested semi structured questionnaire administered through interview method. The survey was conducted in October, 2017 and data were generated on socio economic characteristics of farm households and value of household monthly food expenditure and consumption. Descriptive statistics was used to examine socio-economic characteristics of the farm households in Nigeria and to profile the food insecurity status of the respondents by selected socio-economic variables. The descriptive tools used include means, frequencies and percentages. The need for such analysis is predicated on the fact that a households‟ food security status is largely a function of social and economic characteristics. A Probit model was employed in determining factors influencing the food insecurity status of farm households in Oru East LGA during post-planting season.

Food security status was estimated as the two-thirds of the mean per capita monthly food expenditure of all farm households. The farm households were classified into either food secure or food insecure households based on the food security line. A food insecure household is that whose per capita monthly food expenditure falls below two-thirds of the mean monthly per capita food expenditure while a food secure household is that whose per capita monthly food expenditure is above or is equal to two-thirds of the mean per capita food expenditure (Sulaiman *et al.,* 2015).

Adopting the method of estimation of the Foster, Greer and Thorbecke poverty index, the food security index was estimated as:

$$P\alpha = \frac{1}{N}\sum_{i=1}^{q}\left(\frac{z-Yi}{z}\right)^{\alpha} \ldots \qquad (1)$$

Where:
$P\alpha$ = Food security index
z = Food security line (2/3 mean per-capita household food expenditure)
yi = Per capita household food expenditure (i = 1, 2 ....q);
N = Total number of farm households;
q = Number of food insecure farm households;
α = is the aversion parameter that takes values of 0, 1 or 2 that is $\alpha \geq 0$

When $\alpha = 0$, the FGT index P_0 measures food insecurity incidence. This represents proportion of the farm households that are food insecure i.e. the proportion of farm households that fall below the food security threshold (line). When $\alpha = 1$, the FGT index P_1 measures food insecurity depth of the farm households. This denotes the proportion of food security line that the food insecure farm household require to get out of food insecurity. When $\alpha = 2$, the FGT index P_2 measures the severity of food insecurity status. It measures how far away the food insecure households are from the food security line.

The probit regression model is considered appropriate when dependent variable (Y) takes one of only two possible values representing presence or absence; the model was adopted as used by Gujarati (2003):
Pi [y=1] = [Fzi] … (2)

Where
$Zi = \beta 0 + \beta_1 X_1 + e$
$Y_i = \beta_1 + \beta_2 X_{2i} + \ldots\ldots + \beta_k X_{ki} + \mu$
Yi^* is unobserved but $Yi = 0$ if $y_i^* < 0$,1 if $Y_i^* \geq 0$
$P(Yi = 1) = P(Yi^* \geq 0)$
$P(\mu\, i \geq -\beta_1 + \beta_2 X_{2i} \ldots\ldots\ldots\ldots\ldots -B_k X_{kL}$…(4)

Where i = 1, ……………84
Where Y_i = Food insecurity status of farm households (food insecure = 1, food secure = 0)
β_1 = Unknown coefficients value of factors
X_1 = Age of household head (years); X_2 = Gender of household head (male = 1; female = 0); X_3= Extension access (number of contact); X_4= Level of education (years); X_5 = Amount of credit accessed (Naira); X_6= Farm income (Naira); X_7 = Monthly expenditure (Naira); X_8 = Household size (Number); X_9 = Farming status (full time = 1; part time = 0); X_{10} = Membership of cooperative (1 if member; 0 if otherwise); X_{11} = Remittances (Naira) and X_{12} = Off farm income (Naira).

Results and Discussion

Table 1 shows distribution of the farm households according to socio-economic characteristics. The table shows that mean age of the heads of the farm households was 49 years. This indicates that the heads of the farm households were still active adults capable of withstanding the physical labour and stress associated with farming. The farm households had mean farm size of 0.84 hectares. Farm size is positively associated with the amount of crops grown (Musinguzi, 2000). The larger the farm size of a household, the higher the expected level of food production. Table 1 also shows that the farm households had mean household size of 6 persons. This is good because in face of labour scarcity household members could help in works in the farm enterprise reducing cost of hired labour and increasing farm productivity. However, according to Sikwela (2008) household size has a serious implication on food security and large households have higher propensity of being food insecure. The farm households posted mean annual farm income and non-farm income of 209,520.08 Naira and 122,163.57 Naira respectively. The incomes households earn have positive implications on their adoption of innovations, welfare and economic access to food. The value of food consumed monthly by the farm households was 17337.78 Naira.

Table 1: Distribution of the farm households based on socio-economic characteristics

Variables	Mean
Age (years)	49.26
Farm size (Hectares)	0.84
Household size (number of persons)	6.38
Annual farm income (Naira)	209,520.08
Annual non-farm income (Naira)	122,163.57
Household monthly expenditure on food	17337.78

Source: Field survey, 2017

Estimates of indices of food insecurity in the observed farm households in Oru East LGA during post planting season are shown in Table 2. The food insecurity line defined as two-thirds of the mean per capita food expenditure of the total households stood at 1811.68 Naira. This implies that a farm household whose per-capita food expenditure was below 1811.68 Naira was classified as food insecure while a farm household whose per-capita expenditure equalled or was above this amount was classified as food secure. The degree of food insecurity in Oru East LGA was assessed using the three food insecurity indices: incidence of food insecurity (P_0), depth of food insecurity (P_1), and severity of food insecurity (P_2), following the Foster, Greer and Thorbecke poverty measure. The food insecurity incidence showed that 46.6% of the farm households were food insecure, while the food insecurity gap which measures the extent by which food insecure households were below the food insecurity line was 0.338. This implies that on the average, a food insecure household will require additional per capita food expenditure of 757.28 Naira to exit food insecurity. The value of food insecurity severity was 0.291, implying that there was 29.10% inequality among the food insecure farm households. These estimates are comparable to food insecurity estimates obtained by Egbeogu (2016) in Abia State, Nigeria.

Table 2: Computed food security indices of the farm households

Food security indices	Farm Households
Mean monthly household food expenditure	17337.78
Mean per capita household food expenditure (MPCHHFE)	2717.52
Food security line (2/3 of MPCHHFE)	1811.68
P_0 (Incidence of food insecurity)	0.466
P_1 (Gap or depth of food insecurity)	0.418
P_2 (Severity of food insecurity)	0.291

Source**:** Field survey, 2017

The estimates of the probit regression model which was used to determine factors that influenced food insecurity status of farm households in Oru East LGA of Imo State, Nigeria is presented in Table 3. The model posted a log likelihood value of -87.270, Mcfadden R^2 value of 0.772 and a goodness of fit LR statistic value of 51.615 which was statistically significant at 1.0% alpha level. Seven factors (gender of household head, level of education, amount of credit accessed, farm income, household size, remittances, and off-farm income were revealed to be significant determinants of food security status of the farm households during post-planting season.
The most significant ($P < 0.01$) of the seven factors that determined food insecurity of farm households during post-planting season were level of education (-0.845) and off-farm income (-1.389). The coefficients of both variables were negatively signed, implying that the higher the level of education and off-farm income, the lesser the probability of a farm household being food insecure during post-planting season. Higher education level impacts positively on farmers' productivity and ability to secure higher off-farm income, which invariably increases household food security status. This finding is in agreement with results obtained by Ayantoye *et al.* (2011) among rural households in South Western Nigeria.

The coefficients of gender of household head (-0.054) and amount of credit accessed (-1.00E-05) were significant at $P < 0.05$, implying that male headed farm households that accessed higher amount of credit had relatively lower probability of been food insecure during post-planting season. This finding is understandable because male heads of farm households have relatively better access to land, credit and extension services with which to boost farm productivity, income and household welfare. Nwachukwu *et al.* (2014) and Osei *et al.* (2013) had earlier found that having male head and access to credit reduced food insecurity among farm households. Farm income (0.618) and household size (0.711) posted variedly signed coefficients that were significant at $P < 0.05$. This implies that an increase in farm income decreased the probability of a household being food insecure, while an increase in household size increased the probability of a household being food secure. All things equal, farm households with higher farm income can afford to buy relatively more food items when their barns run short, while, increasing household size means more mouth to feed and lower per capita consumption. The finding agrees succintly with result obtained by Abu and Soom (2016) among farm households in Benue State, Nigeria but disagrees with finding of Emerole *et al.* (2014) in Abia State, Nigeria.

The coefficient of remittances (-0.806) was significant at $P < 0.10$. The negative sign of the variable suggests inverse effect on household food insecurity. This could be attributed to the fact that remittances increase household gross income and could lead to increased per capita income and per capita food expenditure.

Table 3: Probit regression estimates of factors influencing food insecurity status of farm households

Conclusion

This study assessed food security status of farm households during post-planting season in Oru East LGA of Imo state. The study showed that 46.60% of the farm households in the area were food insecure during post-planting period. The study also identified key determinants of food insecurity as gender, level of education, amount of credit accessed, farm income, household size, remittances, and off-farm income. Based on results of the study the following recommendations suffice: Efforts to improve access to credit by farm households and the promotion of off-farm activities as alternative livelihood options should be pursued by both the local and state governments. Female headed farm households should be targeted more in future food security programmes. There should be intensification of enlightenment programmes and campaign on family planning directed at farm households, in order to educate them on the benefits of manageable small household size.

Abstract
The study examines sources of micro-credit, interest rates and adequacy of credit advanced to arable crop farmers in Edo State, Nigeria. Multi stage random sampling procedure was used in selecting 150 arable crop farmers in the study area. Data were collected with the pre-tested questionnaire and analyzed using descriptive techniques such as mean, frequency distribution, percentages and t- test statistic. The study revealed that micro-credit lending from friends attracted interest rates ranging from 2% to 5%. Credit from family members did not attract any interest rate. Osusu charged interest rates that ranged from 2% to 3%, while Micro-finance Banks charged between 5% to 9% interest. Co-operative societies charged interest rates of between 2% and 3% while Commercial Banks charged the highest interest rate of between 20% and 24% on micro-credit. With the exception of commercial banks whose micro-credit term may extend up to 24 months all others had 12 months. Shortness of repayment time and selling off farm products even when prices are low in order to repay loan are the major problems facing farmers in acquiring and managing credit obtained. The study recommends the need to shore up the capital base of informal credit providers to improve their capacity to disburse high loan sums to farmers. This is expected to improve farmer's ability to generate high annual turnover and hence break the vicious cycle of poverty. International agencies targeting poverty alleviation among rural populace can channel such assistance through informal micro-credit providers. Attempt should be made by micro-credit providers to extend the loan term from 12 months to 2 years as it would give farmers sufficient time to sell their farm products off at remunerative prices. Effort should also be made by farmers in efficiently utilizing credit so as to boost their productivity and income as it will go a long way to improve their loan repayment performance and hence livelihood.

Keywords: *Micro-credit, farmers, credit, interest rate, arable crops*

Introduction
The efforts of government towards mobilizing and supporting the agricultural sector of the economy so as to improve standards of living of the farmers are more pronounced now than ever. This is against the increasing awareness that the farmers are capable and willing to pull themselves out of poverty if a conscious effort is made to ease their access to credit. This will increase the level of farm output / income thereby solving the problems of production, consumption and nutrition among farmers. The accessibility of a good financial service is considered as one of the engines of economic development. Governments of less developed countries have frequently practiced the policy of providing cheap credit to the agricultural sector through financial intermediaries. This cheap credit, it was hoped, would lower the dependence on the rural money lenders (Pinaki, 1998). The provision of credit has increasingly been regarded as an important tool for raising the incomes of rural populations, mainly by mobilizing resources for more productive uses. As development takes place, one question that arises is the extent to which credit can be offered to the rural poor farmers to facilitate their farm operations, all things being equal. Thus, the usefulness of any

agricultural credit programme does not only depend on its availability, accessibility and affordability but also on its proper and efficient allocation and utilization for the intended purpose by beneficiaries (Oboh, 2008). However, credit diversion, poor repayment rate and loan default among farmers continue to be a challenge. The extent, to which this is true among arable crop farmers in Edo State in terms of rate of credit allocation to the farm sector and the factors affecting it, is not known.

A number of researches have attempted to explain the factors affecting credit accessibility by farmers in Edo State (Izekor and Alufohai, 2010; Alufohai, 2006; Alufohai and Ahmadu, 2005). Also, Asekome and Ogbechie (2011) posited that credit is not easily accessible and if accessible from moneylenders, they charge rates too high for micro enterprises to pay. The high rates contribute to the cost of capital and further negatively impacts on the annual turnover of the farm enterprise. Asekome and Ogbechie (2011) further posited that farmers buy inputs at exorbitant rates because they cannot buy in wholesale markets, thereby reducing their profit margins. According to Ikhelowa (2011), the foregoing underscores the need to make adequate loanable fund available to farmers at the right time and at such rate that will make returns on investment more attractive. But, there is lack of clarity on the relationship between the volume of loan received and farmers' annual turnover among arable crop farmers in Edo State. Despite the centrality of micro-credit for investment in farm enterprise, Ikhelowa (2011) asserted that banks are often very reluctant to give loans to farmers because of the risky nature of agricultural enterprises. This is due to many unforeseen and uncontrollable factors like weather problems, flood, pests and diseases. The irreversibility of investment made in agricultural enterprise may have reinforced the reluctance of banks to give credit to farmers. According to Onietan and Afolayan (2010), the foregoing factor is closely connected to the biological nature of agricultural sector which includes long gestation period, seasonality of production and perishability of raw products.
Past studies by scholars, including Umoh (1981), Idachaba (1985) and Ikhelowa (2011) stressed that commercial banks do not respond adequately to the needs of the farmers especially the small – scale farmers. The poor responses include delayed processing of application, lack of or poor supervision of funded projects, inadequate amount of money compared to the requirements of the farmers (Ikhelowa, 2011). Hence the choice of micro-credit sources by farmers which include traditional savings associations, cooperative societies, micro finance banks, friends, family and relations (Osagie, 2006). But the interest rates, adequacy and timeliness of the different sources of micro-credit patronized by arable crop farmers are not known.

This study analyzes the sources of micro-credit, ascertains the interest rates, adequacy and timeliness of the different sources of micro-credit patronized by the arable crop farmers. It also examines the problems associated with the different sources of micro-credit delivery for arable crop farmers and proffer solutions. A study of this nature will assist farmers in realizing their potentials for increasing output and incomes. Secondly, it will show the adequacy and timeliness of micro–credit intermediaries both formal and informal and help to strengthen their operations. Thirdly, international donors and financiers will be provided local information in order to maximize existing facilities.

Methodology

The study was conducted in Edo State, Nigeria. It lies roughly between longitudes 05° 04′E and 06° 43′E and latitudes 05° 44′N and 07° 34′N. The state had a population of 2,159,848 (National Population Commission 2007) and made up of 18 Local Government Areas (LGAs) grouped into three agricultural zones. The climate of Edo State is equatorial in nature. It is characterized by humid conditions in the southern parts and sub-humid conditions in the northern parts (Okoro, 2002). The rainfall pattern, which is bimodal, varies from 200cm a year in the southern part to 115cm a year in the north spanning about eight months of the year (Azeke, 2002). The temperature is about 27°C on the average with a monthly range of 22°C to 35°C and relative humidity of 79% to 90%. The vegetation zones distinguished the agricultural zone.

Three Local Government Areas (LGAs) were purposively selected from each of the 3 agricultural zones of the state. In each LGA, two communities were randomly selected. A sample frame consisting of the names of the farmers was obtained from the extension agents. A simple random sampling technique was used in selecting eight (8) respondents among the identified arable crop

farmers in each of the selected communities in Edo north and Edo central. In Edo south, nine (9) arable crop farmers were randomly selected. This brought the sample size of the study to one hundred and fifty (150) respondents. A pre tested structured questionnaire that elicited information on micro-credit sources, interest rates, loan term, timeliness and adequacy of loans obtained as well as constraints facing crop farmers in obtaining loans was used for the study. Data were analyzed using frequency descriptive techniques such as mean, frequency distribution and percentages, as well as other appropriate statistical tools such as t-test statistic.
Comparison of differences in the means between amount of micro-credit applied for and amount obtained from the different sources was facilitated using t-test statistics for independent samples. The t-test statistic is given as:

$$t = \frac{X_1 - X_2}{SE^2{}_1 + SE^2{}_2}$$

Where:
$\bar{X}$ = Means of 2 independent samples
SE^2 = Standard errors
S^2 = Sample Variance

Results and Discussion

Table 1 shows micro-credit sources, interest rates and loan term. In this table, micro-credit lending from friends attracted interest rates ranging from 2% to 5% with a loan term of 12 months. Micro-credit from family members did not attract any interest rate. While Osusu charged interest rates that ranged from 2% to 3%. Micro-finance Banks charged between 5% - 9%. Co-operative societies charged interest rates of between 2% and 3% while Commercial Banks charged the highest interest rate of between 20% and 25% on micro-credit. The interest rate charged on micro-credit from the different sources depends to a large extent on the relationship between the borrower and the lender. This accounts for why people obtain loan from the same source at different interest rates. With the exception of commercial banks whose micro-credit term may extend up to 24 months, all others had 12 months. Short micro-credit term may pose repayment problems for arable crop farmers. To this end, Aligbe (2016) suggests an extension of micro-credit term from 12 to 24 months.

Table 1: Micro-Credit Sources, Interest Rates and Loan Term

Sources of Micro-credit	**Interest Range (%)**	**Loan Term**
Friends	**2-5**	12 months
Family /Relations Contribution	Nil	12 months
Osusu	2-3	12 months
Micro-finance Banks	2-3	12 months
Co-operative Societies	5-9	12 months
Commercial Banks	20-25	12-24 months

Source: Field Survey, 2013

In determining the adequacy of micro-credit received by arable crop farmers, the means of the amounts applied for and the amounts obtained were compared. Results obtained in Table 2, shows that in all the sources, farmers got lower amounts of micro-credit than the amounts they applied for. The difference in means as revealed by the t-test result is statistically significant at the 1% level of probability. This implies that the amount of loan applied for from all the sources within the period covered by the study is significantly greater than the amount obtained and therefore inadequate to meet the needs.

Table 2: Difference in the Means between Amount of Micro-Credit Applied For and Amount Obtained from the Different Sources

Statistics	Osusu	Co-operatives	Micro-Finance Banks	Family Contribution	Friends	Commercial Banks

Source: Computed from survey data, 2013
Note: *Significant at P≤ 0.01

Farmer's perception of problems associated with various sources of micro-credit is presented in Table 3. Majority of the farmers (66) are of the opinion that the one year duration of the loan is too short. They opined that an additional 12 months would suffice them to harvest their crops and sell them at good prices rather than sell them at harvest. This is closely followed by those respondents (60) who were of the opinion that they were forced to sell farm products even when prices were not encouraging in order to repay loan. This phenomenon makes most farmers' to forfeit good prices if their farm products were sold at a time there was no glut (off season). The implication of flooding the market with farm products at harvest is that there will be food scarcity at off-seasons with prohibitive prices. This has serious consequences for national food security. Moreover, selling farm products at poor prices at harvest will limit the amount of income generated from farming, standard of living and ability to invest. This phenomenon could aggravate the poverty status of farmers. Fifty respondents were of the opinion that the loan amount obtained was inadequate to carry out their farming activities the way they would have preferred. This is because in almost all instances, the amount of micro-credit applied for was lower than that approved. The implication of this result is that business expansion and growth is thwarted with no respect for progress. This may pose serious problems for agricultural development and food security. Twenty-eight respondents were of the opinion that high interest rate and surcharge on repayment default constitute constraints of borrowing from the various sources. It is the attempt at avoiding the payment of surcharge upon default of repayment that may have driven most of the respondents to sell their farm products immediately after harvest at poor prices. This calls for the extension of loan term from 12 to 24 months.

Table 3: Farmer's Perception of Problems Associated with Different Sources of Micro – Credit

Problem	Friends/ Relations	Family contributions	Osusu	Microfinance Banks	Cooperative societies	Commercial Banks	Total
Short loan term	6.06%	3.03%	46.96%	25.7%	18.2%	-	66
Inadequate loan amount	16%	8%	40%	36%	-	-	50
High interest rate	12.5%	5%	30%	22.5%	-	30%	40
Sur – charge on repayment default				35.7%	28.6%	35.7%	28
Forced to sell farm products even when price is not encouraging in order to repay loan	-	-	-21.7%	41.66%	23.3%	13.3%	60

Source: Field Survey, 2013

Conclusion and Recommendations

Even though interest rate from the various micro-credit sources is moderate and loan is disbursed on time, the loan amount obtained by arable crop farmers from micro-credit providers is inadequate to meet their production needs. This suggests that with higher loan sums, farmers have the potential for generating higher annual turnover. The study recommends the need to shore up the capital base of informal credit providers to improve their capacity to disburse high loan sums to farmers. This is expected to improve farmer's ability to generate high annual turnover and hence break the vicious cycle of poverty. International agencies targeting poverty alleviation among rural populace can channel such assistance through informal micro-credit providers. The performance of the informal micro-credit sub-sector as it presently stands cannot be relied upon to achieve these objectives. This calls for urgent and pragmatic steps to be taken to improve the systems performance. It is imperative to grant farmers the required amounts of loan to enhance their loan repayment performance. There is an urgent need for increase in the rate of agricultural credit allocation to the farm sector to ensure increased productivity of crops grown for increased welfare and livelihood of these farmers and the citizens of the State as a whole. Attempt should be made by micro-credit providers to extend the loan term from 12 months to 2 years as it would give farmers sufficient time to sell their farm products off at remunerative prices. Effort should also be made by farmers in efficiently utilizing credit so as to boost their productivity and income as it will go a long way to improve their loan repayment performance and hence livelihood.

Social Diversity among Cassava Producing and Processing Communities in Imo State

Amadi, G. and Ewuziem, J. E.
National Root Crops Research Institute Umudike, PMB 7006, Umuahia Abia State
genevieveamadi@yahoo.com

Abstract
This study investigated social diversity among cassava producing and processing communities in Imo State with a view to describing the sources of diversity and identifying differences between communities. A purposive and multi-stage sampling technique was used in selecting a sample size of 240 respondents consisting of 20 cassava farmers/processors (10 males, 10 females) from each of 12 communities namely Logara, Umuohiagu, Egbeada-Ubomiri, Ihite-Isi-Mbieri (Owerri Zone), Abba, Umunakara, Umueze-anoruo, Eziama-obaire (Orlu Zone), Amuro, Isieke-agbaogwu, Mbara-okwe and Okeohia (Okigwe Zone). Data was elicited using semi-structured pre-tested questionnaire. Descriptive statistics such as mean, percentage, and frequency distribution; and analysis of variance (ANOVA) were used to analyze the data. Results from this study showed that there were significant differences (P<0.05) among communities in some socioeconomic attributes including Age, Education, Marital status, and Income from cassava business implying that the communities were socially diverse with respect to these attributes. New and extant policies should be tailored towards mitigating the gaps amongst communities covered in the study.
Keywords: Socioeconomic attributes, Cassava farmers, Age, Education, Marital status, Income

Introduction
Cassava (*Manihot esculenta* Crantz*)* is an important staple food and cash crop in several tropical African countries especially Nigeria where it plays a principal role in the food economy (Agwu and Anyaeche, 2007). Wide adoption of high-yielding cassava varieties, better pest management and value addition technologies have resulted in a sharp rise in its production, processing and consumption.

Social diversity refers to differences between categories of people in their access to and control over livelihood assets, relative wealth, livelihood security, social status, and sense of belonging to different social groups and cultural norms and beliefs (FAO, 2011). Diversity describes differences in age, gender, language, values, attitudes, cultural perspectives, beliefs, nationality, ethnic background, sexual orientation, abilities, impairments, skills, knowledge, level of education, life experience, to be found in a group of people. While the age and gender dimensions are present in everyone, other characteristics vary from person to person and context to context (GICHD, 2014). Stine, (2017), posits that social differentiation is common to most facets of human social life. Social stratification, the systematic ranking of categories of people, especially in their access to livelihood and power is, both "pernicious" and "pervasive". Categories become imbued with specific, negotiated cultural meanings, and as such, become powerful forces in social life. Sources of social diversity include age, sex, religion, culture, ethnicity, disability, castes, poverty which influence the delivery and impact of development programs to improve livelihood and income of farmers involved in the production of crops like cassava.

There is also lack for data on social diversity which could help in understanding differences and influence of diverse groups, contributions and challenges faced by diverse groups in cassava production and processing. In addition, there are poor planning, monitoring and evaluating development programmes targeted at different social groups to increase productivity due to scarcity of necessary social diversity specific data. This scarcity of empirical data on social diversity necessitated this study on social diversity analysis among cassava root producing and processing farmers in Imo state Nigeria.

Methodology

The study was carried out in Imo State of Nigeria. The state lies within latitudes 4°45'N and 7°15'N of the Equator and longitudes 6°50'E and 7°25'E of the Greenish Meridian with an area of 5,100 sq km. The state has a population density of 712 persons per square kilometer (NPC, 2006). The language spoken in Imo State is Igbo though as part of Nigeria, English is the official language. Culturally Ibos of Imo State operates a patriarchy i.e. systemic societal structures that institutionalize male physical, social and economic power over women.. A purposive and multi-stage sampling technique was used in selecting a sample size of two hundred and forty (240) respondents consisting of 20 cassava farmers/processors (10 males, 10 females) from each of 12 communities namely Logara, Umuohiagu, Egbeada-Ubomiri, Ihite-Isi-Mbieri (Owerri Zone), Abba, Umunakara, Umueze-anoruo, Eziama-obaire (Orlu Zone), Amuro, Isieke-agbaogwu, Mbara-okwe and Okeohia (Okigwe Zone). Data was elicited using a pre-tested semi-structured questionnaire. The primary data gathered included socio-economic attributes like age, education, occupation, marital status, income from cassava business and membership of cooperative societies. Descriptive statistics such as mean, percentage, and frequency distribution; and analysis of variance (ANOVA) were used to analyze the data.

Results and Discussion

Sources of Social Diversity among Cassava Producers and Processors in Imo State

The distribution of male and female cassava producers and processors in Imo state Nigeria according to their socioeconomic attributes is presented in Table 1. Respondents can be stratified into young (<20-29 years), middle aged (30-59 years) and aged (>60 years). 75.85% of the male and 79.16% of female respondents was middle aged. Age is an important source of social diversity as it creates differences in perceptions and abilities which influence the delivery and impact of development programs to improve livelihood and income of farmers involved in the production and processing of crops like cassava in the study area. Further subdivisions into age grades are also prevalent in Imo and other south eastern states. Age grades champion social, cultural, political, infrastructural and economic development of communities. Age grades contribute towards the development of their communities through communal labour, constructing and maintaining roads, building bridges, providing portable water and among other efforts protect their communities from military attacks or invasions from their neighboring communities (Okodo, 2012). Communal labour, good local roads and security provided by age groups are incentives for cassava production and processing.

Result shows that most (97.0% of males and 95.5% of females) of the respondents were literate at various levels with only a small proportion (3.0% for males and 5.0% for females) having no formal education. Level of education forms a milieu which stratifies a community into socially diverse groups with different abilities which affects their probability and intensity of participation in cassava production and processing. Table 1 also show that 72.5% of males and 65.8% of females did not go beyond secondary school. This excludes them from the membership and mentorship of graduate associations within their communities. These associations are known to wield some influence which affects agricultural production and processing in their communities. FAO, (2011), and GICHD, (2014) reports that level of education varies from person to person and context to context and influences people in their access to and control of livelihood assets, relative wealth, livelihood security, social status, sense of belonging to different social groups.

Distribution of respondents according to their occupation is shown in Table 1. In addition to farming for which they were purposively selected, 18% of both male and female respondents were government workers. A slightly higher percentage of females (8.0%) compared to males (4.0%) were traders. Adebayo *et al*, (2016) reported an almost similar percentage of civil servants amongst the respondents in their study in Ibarapa area of Oyo State. This result supports the growing tendency of public servants to engage in agricultural activities especially in the Southeast of Nigeria where workers salaries are not paid regularly. Farming is a common option for workers who seek to genuinely diversify their sources of income amidst uncertainties associated with wages in the Nigerian contest. Occupation also provides a means of stratifying a people and therefore is a source of social diversity. Some occupations wield more influence and social recognition while some are looked upon with disdain. During the oil boom era, cassava was seen as a woman crop (Okorji, 1983) and its cultivation and processing looked upon with disdain. But these perceptions are changing now as cassava is becoming an important source of cash and not just a staple food.

The distribution of respondents according to their marital status is also presented in Table 1. The results presented show that majority (74.0% males and 77.0% females) were married. The preponderance of the married people could create potential for increased farm labour supply which would contribute positively to cassava production and processing. However, 12.5% of the female respondents were widows. This implies that women tend to work harder when their husbands are no more, so this group sees cassava production and processing as a viable venture that could provide for their families. Oni, (2016) also found that majority (87.0%) of those involved in Cassava production were married. Amadi *et al*, (2016) observed that the married class does have access to extra financial, moral and physical supports from their spouses that could go a long way to improve their production activities. Furthermore, Nze *et al*., (2017) reasoned that married women engaged themselves in cassava production and processing in other to utilize the different end products of cassava which can serve for both household and commercial uses. Emerole, *et al*., (2014) argued that majority of cassava entrepreneurs being married suggest that activities involved in the enterprise generates attractive returns enough to help households cushion effects of food and financial insecurity associated with married life. Marital status is a significant source of social diversity as it may lead to social inclusion or exclusion in societal groupings. Marriage comes with responsibility and social expectation which influences participation in agricultural activities including cassava production and processing. Married people are obligated to provide food for their homes and the most common way to do that is by engaging in agricultural activities like cassava production and processing. However, 12.5% of the female respondents were widows. Widows are a disadvantaged group especially in patricidal societies like Imo State because many are disinherited of assets belonging to their husbands and are subjected to different forms of social exclusion.

Table 1 also shows the distribution of respondents according to their monthly income from cassava business. From data presented in the table, it is evident that most of the respondents (66.63% males and 63.32% females) earned between ₦ 10,000 – ₦ 50,000 monthly. The mean monthly earnings for males (₦44, 445.83) and females (₦44, 410.00) were similar. Okpara, (2015) reported that men earned more income than females from cassava processing in Enugu State. Damisa *et al*., (2007) theorized that the higher the level of income, the greater is the level of participation of the woman in agricultural production. More income would be made to her disposal to meet her technical and logistic needs in production. Income provides a mean of stratifying people into rich and poor; lower, middle and upper class with different influences and opportunities in the society.

Distribution of respondents according to their membership of cooperative societies is shown in Table 1. Only 20.0% males and 18.0% females belonged to cooperative societies indicating that majority of the respondents did not. This finding is consistent with the report of Onyemauwa, (2012) which showed that about 72.0% of the respondents do not belong to, and take part in, cooperative activities. Incidentally, most agricultural technologies are provided to farmers who belong and take part in cooperative activities. Their non participation in cooperative activities will likely constrain their production and processing activities. In spite of the availability of cooperative societies and efforts of government and Non-Governmental Organizations (NGO's) at various levels to support these organizations, it appears that a significant proportion of rural farmers are either unaware of the existence of such co-operative societies or are lacking in the basic socioeconomic characteristics that form the prerequisite for participation in such activities (Idrisa *et al*., 2007). Farmers communicate most frequently and effectively with those who are most similar to them. These farmers are more likely to obtain information from and be influenced in their farming practices and adoption decision by other farmers (Murphy, 1993; Bamire *et al*., 2002; Tahirou *et al*., 2015). The respondents who are non members may be missing out on the many advantages of belonging to cooperative societies including increasing member's production and incomes by helping better link up with finance, agricultural inputs, information, and output markets (EATA, 2012; FAO, 2012; Tahirou *et al*., 2015).

Table 1: Distribution of male and female Respondents according to sources of social diversity

Socioeconomic characteristics	Male		Female	
Age (yrs)	**Frequency**	**Percent**	**Frequency**	**Percent**
Young (<20-29)	20	16.66	15	12.48
Middle Aged (30-59)	91	75.85	95	79.16

Differentials in respondents' socioeconomic attributes among selected communities in the study area

The mean values of different socioeconomic attributes of the respondents according to communities are presented in Table 2. Significant differences (P<0.05) were observed amongst communities in some attributes implying that the communities were socially diverse with respect to these attributes. The mean age of respondents from Isieke agbaogwu was significantly higher than that of respondents from Egbeada-Ubomiri while mean ages of respondents from other communities were similar. Respondents from Abba and Egbeada-Ubomiri spent more years in school compared to those from Okeohia, Umuohiagu, Umueze-Anoruo, Umunakara and Mbara-okwe. Most of the respondents were either married or widowed but there were more married or widowed respondents in Umunakara, Isieke agbaogwu and Okeohia compared to Ihite Isi Mbieri, Abba, Umuohiagu and Egbeada-Ubomiri. Respondents from Logara earned more from Cassava business compared with those from other communities. Those from Isieke agbaogwu earned the least but did not differ significantly (P<0.05) from those from 7 other communities. The trend for membership of cooperative societies was similar for most communities as most respondents did not belong. At Okeohia, all respondents were not members of any cooperative society.

Table 2: Differentials in respondents' socioeconomic attributes among selected communities in the study area

	Socioeconomic attributes				
Communities	**Age**	**Education**	**Marital Status**	**Monthly Income**	**Membership Cooperatives**
Okigwe Zone

Source: Field survey, 2017

Conclusions and Recommendation

This study investigated the social diversity amongst cassava producers and processors in Imo State, Nigeria with a view to describing the sources of diversity and identifying differences between communities. Findings from the study showed that Social diversity was evident between some communities in some attributes such as age, educational level, marital status, and monthly income from cassava business. Significant diversity between communities was evident in most of the attributes. In line with the finding of this study it recommended that new and extant policies should be tailored towards mitigating the diversity gaps amongst communities covered in the study.

Abstract
The study aimed to examine the effects of climate change on the livelihood of farmers in Oluyole Local Government area of Oyo state. The objectives of this work was to determine the socio-economic characteristics, source of income of the farmers, determine the level of awareness of climate change and the effects of climate change on health of the farmers. The study used primary data through a well-structured questionnaire and scheduled interview, fifty respondents were randomly sampled. The use of frequency count and simple percentage were used to analyze the data. The study revealed that the male population makes up 76% of the farmers while female population is 24%. 70% of the farmers are married, 10% are divorced and 20% widowed. The study also indicated that 54% had non-formal education, 20% of the farmers had quranic education while 12% and 8% of the farmers had secondary and tertiary education respectively. It was further revealed that 90% of the forest zone has been degraded as a result of deforestation. Research institute which represents 60% appeared to be the respondents major source of information on climate change, only 30% heard from radio/Television station (TV), none of the farmers got their information through the newspaper. The common ailment is malaria (66%) while headache constitute only 12% of health risk experienced by the respondents. Their major source of water supply during dry season is stream 76%, which is scarce during dry season (68%).The farmers main livelihood activities is trading of forest products (firewood & bush meat-58%) ,sales of farm products and medicinal herbs represent 30% of their source of income. This study recommends more awareness strategies on climate change be opened-up to the farmers to curb the effect of deforestation. Good water supply should be provided in the area to eradicate the effects of prolong drought.

Key words: Climate change, Global warming, deforestation, livelihood

Introduction
Inter-Governmental panel on Climate Change (IPCC 2007) Links it to the changes in global average temperature between (0.74+_ 0.18). The world health organization (WHO) also considers the consequences of global warming as the most pressing problem of the 21st century. The implication of climate change on human health could be direct or indirect. According to Building National Response to Climate Change (BNRCC) the direct consequences of climate change in Nigeria include cerebra-spinal meningitis, cardiovascular respiratory disorder of the elderly, skin cancer, high blood pressure, malaria and cholera. There is much danger to child and maternal health (UNDP, 2005).From ancient times, early naturalists and philosophers theorized on a possible climate change, for instance Theophrastus a pupil of the famous Greek philosopher, Aristotle (384-322BC) speculated that lands became warmer when the clearing of Forest exposed them to sunlight; hence significant changes In global warming are not strange in earth's history. Renaissance scholars including Vitruvius were of the opinion that deforestation, irrigation and grazing had effects on the local weather around the world (Neuman, 1985). Climate change is a complex interaction between earth's atmosphere- stratosphere and troposphere on one hand and land biosphere (Allen, 2004; Solomon et al'2008). Carbon dioxide and other greenhouse gases are generated as waste by products by human activities; this traps heat from escaping from the troposphere thereby causing global warming. Global warming is the term used to describe the gradual increase in the average temperature of earth's atmosphere and its ocean, a change that is permanently changing earth's climate forever. Global warming is caused by increase in the emission of GHGs through the burning

of fossil fuel (oil, natural gas, and coal), burning of wood products and solid wastes, bush burning and deforestation. All these human activities (anthropogenic) contributes to alter the balance of the equilibrium between the natural GHGs (water vapour,CO2, methane and nitrous oxide) and the man-made GHGs (sulfur hexane fluoride-SF6), hydroflourocarbons-HFC and per fluorocarbons-PFC In earth's atmosphere and the ocean since they are heat trapping gases.

Climate change has been found to have several negative consequences cutting across nearly all spheres of life particularly urban livability and human health either directly or indirectly (Aisha and Sasilata ,2016; Malikabood et al,2016 ; Sarry El-Din et al,2012). This follows from its effects on environmental determinants of health such as clean air, effluents discharge from homes and industries, melting glaciers, rising sea levels and their effects on flooding make water unsafe for drinking. Changing rainfall pattern and rising temperatures as well as deforestation impact food production with resulting effects on health. According to the world health organization (WHO) around 250,000 additional deaths are projected to occur annually between the year 2030 and 2050 due to malnutrition, malaria ,diarrhea and heat stress occasioned to climate change (WHO,2015). Deforestation is the removal of a forest or stand of trees where the land is thereafter converted to a non-forest use (dictionary of forestry, 2008). Odjugo, 2010 inferred that for 105years there has been increase in temperature by 1.1oc and decrease in rainfall by 81mm, this was attributed to high rate of deforestation leading to increase in desertification (inyang and Esohe, 2014). Deforestation has been implicated in Flooding cases which affects farm lands leading to food shortages and ultimately the source of livelihood of rural farmers, health risk as also been implicated in flooding resulting in disease such as cholera and diarrhea. There have been reported cases of cholera outbreak in several parts of Nigeria-the south; including Rivers, Cross river states in the Niger Delta (NIMET, 2010) .It is important to note that deforestation activities increase the amount of carbon dioxide released into the atmosphere through wood smoking kiln, firewood burning, charcoal production and forest degradation. All these post deforestation activities release carbon dioxide into the atmosphere thereby contributing to the greenhouse gases consequently causing global warming which is a precursor to climate change with concomitant negative impact such as increase temperature, rise in sea level, flooding, famine, ecosystem collapse and ultimately death. Livelihood refers to means of making a living. People adopt various lifestyle and ways of meeting their needs. Livelihood depends on the availability of various resources, skills, education, socio-economic factors, agro-climate and agro-ecology as well as gender (Akinwale, 2010; Porter et al, 2007). The specific objective of this study is to determine the effect of climate change agents on the livelihood of farmers in Onigambari.

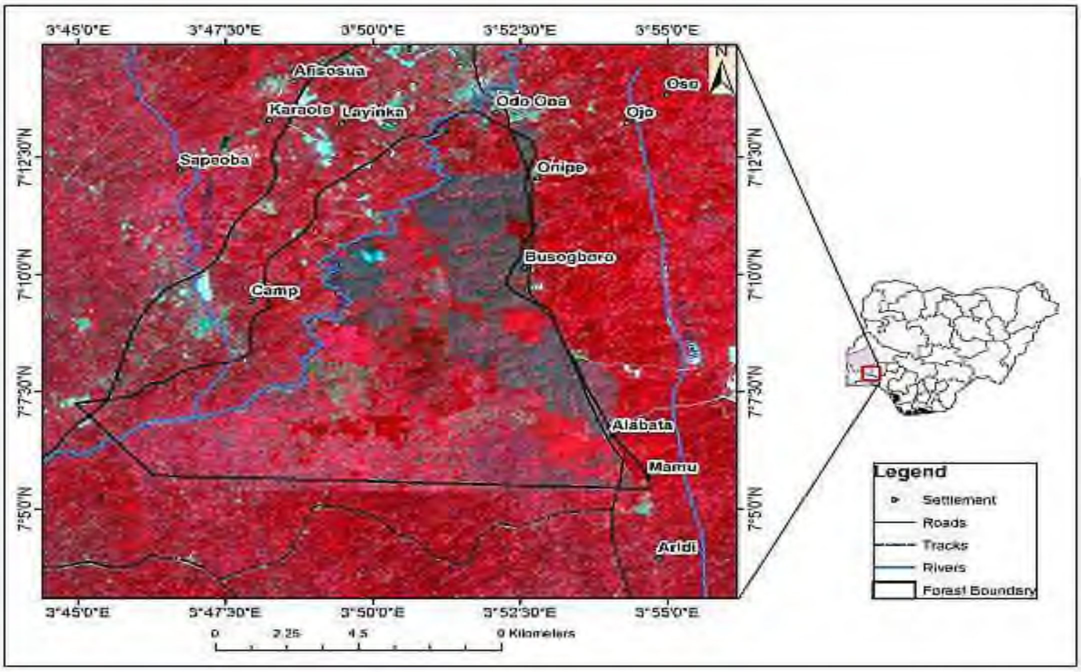

Fig1: Map of Onigambari Forest Reserve.
Source: Field work.

Methodology

Oluyole is a Local Government area in Oyo state, South West Nigeria. It was established in 1976 and occupies a land mass of 4000 square kilometer with a population of 202,725 (Census 2006).The study was conducted around Gambari Forest Reserve, 5 villages which include Odo-ona ,Busogboro, Mamu, Alabata and Onipe where purposively selected. This village was selected based on the high concentration of farmers in the area. Maize, coco –yam, cocoa and cassava are the major crops grown in the area. Questionnaire was randomly administered to 50 farmers out of 102 farmers identified. Frequency and simple percentage method of data analysis was used to examine the test variables and the generated results.

Results and Discussion

Age, gender, marital status, level of education, family size, livelihood activities were the socio-economic parameters analyzed. Tab 1. Revealed that majority of the respondents were male (76%) while only 24% were female. 10% of the farmers are widows, 20% divorced and 70% are married. This is in agreement with the works of Adesiji *et al* (2013), Ojo and Mohammed (2008) who had revealed that 53.1% and 96% respectively of their respondents were married. The implication of this is likely to result in respondents having more children which directly increase the population and other human activities (Anthropogenic). Deforestation, one of the causative factors of climate change is extremely high in this area; this was confirmed by the present study where the rate of forest degradation as a result of deforestation has increased to an alarming rate of (90%) in this area. It was also discovered by the present study that the rural farmers are predominantly illiterate, majority of who had non-formal education 54% as compared to 12% secondary education, 20% had Quranic education, 6% had Adult education, 8% had tertiary education with 0% primary education . This is in agreement with the findings of Ndanitsa. (2005), TSOHO (2005) who separately reported in their studies that rural farmers are characterized with low level of literacy. The study further shows that the main source of income of the farmers is trading of Bush meat and firewood 58%, while sales of medicinal herbs and other farm products represent 30% of the farmer's income source while only 12% utilizes their farm products for personal use .Family size of 5-10 represent 60%of the respondents, 1-4 represents 30% while 10 and above represents 10%.

Tab.2. shows that 86% of the respondents are aware of climate change, only 14% of them are not aware, the table also indicates that 60% of those aware got their information through Research institute while 30%got their information through Radio/TV station. None of the farmers got their information through Newspaper 0%, 6% got their information from Non- government organization (NGO) while 4% heard from farmers association. 90% of the farmers believed that the forest has been degraded as a result of deforestation activities, 10% believed that the forest is still intact.

Tab.3. revealed that malaria is the most common ailment experienced by the farmers 66%, followed by cholera 18% headache 12%, Headache & cholera 2% and typhoid, headache &malaria represents 2%. Result in Tab.4. Shows that the farmer's source of water during dry season is the Stream which account for 76% of their water supply during the dry season, well and borehole water accounts for 12% each. 68% of the farmers said that water was not available during prolong drought /dry season while 32% agreed that water was available during this season.

Sources	Frequency	Percentage
Available	16	32%
Scarce	34	68%
Well	6	12%
Borehole	6	12%
Stream	38	76%

Source : Field work 2018

Conclusion

From the results it is obvious that the farmers are aware of climate change to a high extent, although most of them had non-formal education, they can easily be tutored by research institutes representatives and other agencies. Their main sources of livelihood are trading of forest products and agriculture. The health risk analysis shows that malaria is the prevalent health challenge experienced by the farmers, also acute water shortage is experienced during dry season .Finally the study showed that deforestation is on the increase in the study area. Sequel to this findings and conclusions, it is hereby recommended that functional /accessible source of water supply be made available to farmers in the area to aid farming practice during dry season. The act of sporadic tree cutting –deforestation should be discouraged and more afforestation policies be adopted to enhance the livelihood of farmers in the area.

Email: chibuzoranyim@shell.com

Abstract
The study investigated the effect of community driven infrastructural projects executed by Abia-CSDP in rural communities of the state. Multi stage sampling procedure was employed to select a sample size of 270 respondents. Data were collected using Focus Group Discussion, case studies, key information with the aid of structured questionnaire. Data generated were analyzed using mean scores. Results on Infrastructural sector analysis revealed that Educational sector had a mean score of ($\bar{x}$ = 3.52), water sector had a mean score of ($\bar{x}$ = 3.05), Transport sector had a mean score of ($\bar{x}$ = 3.67), Health score ($\bar{x}$ = 3.35) and socio-economic activities ($\bar{x}$ = 3.50). from the results, it was concluded that the bottom-top approach adopted by Abia-CSDP for rural development projects was effective in transforming the livelihood activities of the rural households in the state and recommends that efforts should be made in providing more specific agricultural infrastructural facilities as it will enhance agricultural productivity.
Key words: Abia-CSDP, Rural households and Livelihood activities

Introduction
Community development includes all strategies at the community level accrued to bringing about social and economic development (Akpomuvie, 2010). Development planners for several decades adopted approaches which were essential top-down in nature, with donors and central authorities dominating the entire process. This non -participatory model did not yield optimal results (Chebil and Haqu, 2001). According to (Anieten and Abiodun, 2016), for a rural development programme to effectively alleviate poverty. It must have the following qualities, pro poor, sustainable and must be able to empower the poor. In the early 19th century, it was widely believed that all it took to improve the economic situation of developing countries was financial inputs and modern technology, later on however; it became clear that the transfer of technology did not solve the problem. Development workers and research from the universities and research institutes began to understand the complex relationship between environment, economy, culture and politics in rural communities. They therefore began to view and tackle the various aspect of rural life as a part of integrated systems. It was realized that system for example, the complex agricultural system found in most developing countries through adaptive changes rather than by linear progresses, that is dynamic and its parts interacts by influencing each other (Obetta and Okide, 2011). It is not possible to effect a change in one element of the system in isolation without affecting other parts. Consequently, the system as a whole has to be understood in order to identify and help bring about a desired change. The Federal Government of Nigeria and the World Bank are unanimous on the desirability of the Community Driven Development (CDD) approach in the over all strategy for poverty reduction in the country.

The Community Social Development Projects (CSDP) emerged in 2008 as a new intervention strategy that was designed to effectively target social and environmental infrastructure at the community level as well as improve Local Government Areas responsibly to service delivery. The development objective of this project is to sustainably increase access of poor people to improved social and natural resource infrastructural services (CSDP, 2008).

In the light of these developments, the question that readily comes to mind with respect to governance and farming community in Abia State is whether the provision of rural infrastructure had made any effect on the livelihood of rural farmers in the state. The main objective of this study was to ascertain the (CSDP) intervention on the livelihood of rural dwellers in the largely agrarian participating communities in the state. The aim is to assess changes in the wellbeing of individual household or communities attributable to CSDP micro projects. The key performance indicator was increased number of rural dwellers with access to social services and rural infrastructure.

Methodology

The study was carried out in communities participating in Abia-CSDP projects. These communities are spread over the three agricultural zones of the state, namely Abia-South, Central and North with 7, 5 and 5 Local Government Areas respectively. Multi stage sampling procedure was used in the selection of the sample size. In the first stage, 3 Local Government Areas were selected from each zone, followed by the selection of 3 communities from each of the selected nine LGAs and selection of 3 villages each from the 9 communities. In each village, 10 rural households that actively participated and have been benefiting from the projects were selected, bringing the total to 270 respondents. The benefiting communities were identified in conjunction with the state agency. Data for the study were collected using Focus Group Discussion (FDGs), case studies, key information interviews and in-depth interview, with the aid of structured questionnaire sets. Secondary data were obtained form the Monitoring and Evaluation unit of the agency. Data collected were analyzed using mean scores, 4-point Likert type scale of SA (4), AG (3), SD (2) DIS (1).

Results and Discussion

Results in Table 1, shows the effects of infrastructure demand driven projects executed by Abia-CSDP in selected communities in the state. Educational sector had a grand mean of ($\bar{x} = 3.52$) indicating a positive outcome. According to some of the respondents, there is a reduction in the average time taken by students to get to school due to Abia-CSDP intervention in the construction and rehabilitation of schools. Measurable improvements were also recorded in number of students in science classes in schools were science laboratory were provided. Poor quality of rural schools turns out children too ill equipped to transfer technologies to their illiterate parents accurately in rapidly industrializing economy there by affecting their productivity. Oni and Adeyemi (2008) opined that poor access to infrastructural facilities especially educational facilities may led to a low agricultural productivity.

From the table also, the grand mean for water sector was ($\bar{x} = 3.05$) indicating a positive significance. During the Focus Group Discussion (FGDs) the respondents affirmed that; there is a reduction in cases of water borne disease, reduction in cost of buying water and some of the respondents expressing the opinion that there is a change in personal hygiene after the provision of water facilities by Abia-CSDP in their communities. Some of the benefitting communities, were relying on open streams as their sources of water supply for domestic use before CDSP's intervention.

Furthermore, health sector had a grand mean score of ($\bar{x} = 3.35$). The implication of the result is that, there is increase access to Medicare by members of those communities that benefitted from the intervention. There is a direct and positive relationship between the health of these rural dwellers and agricultural productivity, since about 70% of them are involved in agriculture (Odoemelam, 2012). This is also in agreement with Osabuohien and Alufohai (2015) opined that agriculture as carried out today is a dangerous occupation as some agricultural workers sustain injuries and die throughout the world. So, access to medical facilities will be a well come development. Farmers illness and diseases problem are capable of reducing agricultural productivity through the loss of productive adults and their assets with which they cope with these illness (Ulimwengu and Badiande, 2011).

Table 1: Sectorial Analysis of Projects and its Effect on Rural Farmers' Livelihood Activities

Sectorial Projects	Mean Scores
Educational sector	
Increase in school enrollment	3.42
Increase in school attendance	3.32
Short distance to school	4.00
Students are now leaving science subjects	3.34
Grand mean	3.52
Water	
Reduction in water borne disease	3.02
Reduction in average time to fetch water	3.47
Changes in personal hygiene	2.67
Grand mean	3.05
Health sector	
Increase in antenatal attendance	3.57
Distance to health centers reduced	3.0
Children immunization enhanced	3.48
Grand mean	3.35
Transport sector	
Number of vehicles plying the road increased	4.0
Reduction in cost of transportation	3.31
Reduction in average travelling time	3.68
Grand mean	3.67
Rural electrification	
Households connected to electricity	3.62
Small scale business established	3.43
Households using electrical/electronic gadgets increased	2.48
Establishment of tele centers	2.34
Grand mean	3.0
Socio economic activities	
Training skill acquisition center built	3.48
Civic centers constructed	3.40
Construction of market stalls	3.64
Grand mean	**3.50**

Source: Field Survey, 2018.

Transport sector had a grand mean score of ($\bar{x} = 3.67$). The implication of the result shows that provision of feeder roads in the rural communities had a positive effect on the rural households. Porter (2013) in his findings revealed that adequate and reliable rural needs improves productivity, enhance physical access, reduce poor people's vulnerability to shocks and stress and enable them to build their livelihood assets. These findings agree with earlier results that describe transportation as a major constraint to the marketing of agricultural products (Ayuk, 2014). The movements within rural area are made on foot by bicycles along foot path and at best on narrow roads. In order to make rural-rural and rural-urban mobility which is easier and thus facilitate the marketing of produce as well as feed the rural areas with essential commodities, there is a dire need to improve the transportation system in rural Nigeria (Emokaro and Oyoboh, 2016). Rural electrification had a grand mean of ($\bar{x} = 3.0$) implying a positive effect as well. The respondents stated, "that number of households connected to electricity was high". The best outcome, as measured during the visits to those communities recorded increase in number of new business establishment as a result of the provision of electricity through CSDP's intervention. This would go a long way in strengthening the income earning ability of beneficiaries. This intervention could easily expand agricultural value chain in the micro community in the short run and ultimately beyond on a more sustainable basis (Emokaro and Oyoboh, 2016).

Socio economic activities had a grand mean of ($\bar{x} = 3.50$). The result indicated a positive effect. The respondents stated that the skills acquired has helped them in getting extra income instead on relying only on agriculture. This would ultimately result in long term transformation of the rural economy and beyond. It equally agrees with the view of (Eboh, 2013), that such development would ultimately bring about quantitative changes which culminate in improved standard of living of rural population.

Conclusion

This study considered the effect of the CDD approach adopted by the Abia state government CSDP in transforming the lives of rural households in the state. From the result, it was observed that this approach was quite effective in achieving the objective of increasing access of the rural poor to improved infrastructure on a sustainable basis. Effort should be geared towards the provision of more specific agricultural infrastructure in rural communities to increase the productivity of the farmers and enhanced improved standard of living. Specifying rural physical infrastructure and institutional e.g. fertilizer distribution centers, advisory services, micro credits centers among others should also be provided.

Abstract
The study assessed the socio-economic characteristics of cocoyam-based farmers in Ekiti State, Nigeria. A 2-stage random sampling technique was employed in the selection of 118 respondents and a structured questionnaire was used in collecting data from the respondents. Descriptive statistics and regression analysis were employed for data analysis. Findings showed that 50% of the sampled farmers were within their economic active working age. It was also revealed that 90% were men while 10% were women. The regression analysis reveals that the variables in the model were significant (P<0.05) with co-efficient of determination of 85%. About 34.7%, 25.4%, and 13.6% complained that government supports, subsidies and extension services are the major constraints faced by the farmers in the study area respectively. The study recommended that farmer's inputs should be subsidized; infrastructural facilities should be provided and more awareness on the importance of the crop should be created.
Key words: Socio-economic characteristics, Cocoyam-based farming, Ekiti State, Farmers

Introduction
Cocoyam-based production system is a process where cocoyam is been intercropped with other crops, which has been the prevalent arable cropping system since time immemorial in the large guinea savanna vegetation agriculture in Nigeria (Oluwatusin & Shittu, 2014). The predominance of the system has been occasioned by Nigeria's climate which is basically tropical and favourable for cocoyam production. Though cocoyam when cultivated as a sole crop results in high outputs, the greatest disadvantage of sole cropping is that during instances of pest or disease outbreaks, the farmer usually loses a significant part of his crops and sometimes even lose all (Matikiti *et al.*, 2016).

Cocoyam belongs to the monocotyledonous family Araceae known as the Aroids. The name cocoyam is generally applied to a variety of useful and edible species belonging to different genera including Colocasia, Xanthosoma, Alocasia, Crytospema and Amorphophallus. Cocoyam (*Colocasia spp*) is an important staple crop cultivated for food security in Nigeria and ranks third in importance after cassava and yam among the root and tuber crops cultivated and consumed (Amusa, 2012). Cocoyam is a stem tuber that is widely cultivated in the tropical regions of the world and is a well-known food plant which has a long history of cultivation(Achampong *et al.*, 2017). According to (Fadipe *et al.*, 2015), Nigeria is the largest producer of cocoyam in the world, accounting for about 40% of the total world output. Cocoyam is composed of 70-80% water, 20-25% starch and 1.5-3% protein with high minerals and vitamin nutrients (Eze, 2014). According to Talwana *et al.* (2009), cocoyam is relevant in the dietary needs of households and noted that about 280 million people eat cocoyam mainly Colocasia Esculenta and Xanthosoma Saggittifoluim (known as taro and tannia respectively in Nigeria) species worldwide. The importance of cocoyam is not only attributed to its use as source of food for man; industrially, cocoyam is used for production of alcohol, medicines, flour, starch and feed for livestock (Ijioma *et al.*, 2014). However, cocoyam has hitherto suffered stiff competition from yam, which is preferred for consumption and from cassava which yields more heavily and required less care (Awodunmuyila, 2008). According to Amusa (2012), the productivity of the crop per hectare is low which is characterized by small-scale farmers. Expansion in cocoyam production, therefore has the potential of bridging the wide demand and supply gap, and enhancing the income (thereby reducing poverty) of the rural farmers, particularly the vulnerable group.

Despite cocoyam contribution to nutritional status of the diets of Nigerians and its contribution to industrial development and creating income for farmers, production of this crop has not received required attention. Past researchers have limited themselves to the cultural practices like fertilizer application, spacing, weeding, etc., as evidenced in the studies of Baruwa and Oke (2012); Fadipe, Adenuga, and Raji (2015); Ifeanyi-Obi, Togun, Lamboll, Adesope, and Arokoyu (2017) with little emphasis on the socio-economic aspects of the production. Therefore, this study examined principally the socio-economic characteristics of cocoyam-based farming.

Methodology

This study was carried out in Ikole Local Government Area of Ekiti State occupying an area of about 374,940km^2. The primary data used was collected with a structured questionnaire administered by enumerators. A 2-stage sampling technique was used in this study. Five villages were purposely selected. A simple random sampling technique was used to select 25 respondents from each of the selected villages which brings it to a total sample size of 125 respondents but 118 questionnaire were returned and analyzed. Data were analyzed using simple descriptive statistics and multiple regression analysis. The regression model used in its implicit form is specified as follows:

$$Y = f(X1, X2, X3, X4, u)$$

Where Y = Quantity of cocoyam output in Kilogram; X1=Farm size; X2=Labour; X3=Educational level; X4 = Fertilizer and u = Error term.

Results and Discussion

Socio-Economic Characteristics of Farmers

The socioeconomic characteristics of cocoyam-based farmers as shown in Table 1 revealed that majority (50%) were between the productive age of 30-49 years while 15% of the respondents were above 60 years of age. Also, majority (90%) of the respondents were males while 10% were females. The study also revealed that about 68.6% of the respondents were married, 26.3% were single and 5.1% are widowed. The high percentage of those married in this report can be attributed to the fact that women play important role and contribute a lot to farm work (Ifeanyi-Obi *et al*., 2017). The study further revealed that majority of respondents (94%) had basic education. Educated farmers are known to be better informed, have access to information and adopt new and improved technologies. This assertion could be corroborated by works of Abosede *et al.* (2014), Bello (2015) and Mohammed *et al.* (2014). Majority (47.5%) of the respondents got their land through inheritance. Farm size is very important in agriculture because it determines the output of the farmer. Also majority (57.6%) of the farmers operates on a small scale holding of farm size less than 1 hectare. The larger percentage (44.1%) of the respondents have crop combinations of cocoyam/maize/cassava.

Table 1: Socio-Economic Characteristics of the Respondents

Socio-Economics Characteristics of the Respondents (N=118)

Variables	Frequency	Percentage
Age		
< 30	19	16.3

Cocoyam/Yam/Cassava	37	31.4
Cocoyam/Maize/Vegetable	24	20.3
Cocoyam/Cowpea	6	5.2

Source: Field Survey, 2017

Regression Analysis

All specified variables in the model were significant (P<0.05). The regression result clearly shows that there is a relationship between the key inputs; land, labor, education and fertilizer, and the output. This simply implies that if there is an increase in these variables there will be a resultant increase in the output and vice-versa.

Table 2: Regression Analysis

	Constant	Land	Labor	Education	Fertilizer	Adjusted R	F-Value
Cocoyam-based system							
Cocoyam/Maize/Cassava	19.214	89.924	2.589	0.017	0.179	0.642	649.04

Constraints
Table 3 reveals that about 34.7%, 25.4%, and 13.6% complained that government supports, subsidies and extension services are the major constraints faced by the farmers in the study area respectively.

Table 3: Frequency Distribution of the Constraints Faced by Farmers

Constraints	Frequency	Percentage
Lack of information	3	2.5
Irregular extension services	16	13.6
No government subsidies	30	25.4
Lack of access to improved varieties	15	12.7
Absence of government support	41	34.7
Low awareness level on the crop	7	5.9
Poor research on the crop	6	5.1
Total	118	100

Conclusion and Recommendations
The study examined the socio-economic characteristics of cocoyam-based farming in the study area. From the study, it shows that cocoyam-based production has a bright prospect despite numerous constraints faced by farmers. Increase in production could be achieved if both institutional and infrastructural facilities are provided in the study area.
The study recommended that inputs should be subsidized, infrastructural facilities like good road network to aid the transportation of produce to the market in order to reduce production cost should be provided by the government, and more awareness should be created on the importance of the crop.

Assessment Of Awareness and Perceived Benefits of Yellow Root Cassava Value Added Innovation in Umuahia- North LGA Abia State

Chimaroke, C.O., Nwakor, F.N, Asumugha, G.N. and Mbanasor, E.O
National Root Crops Research Institute Umudike, Abia state, Nigeria
Email;obigerichimaroke@yahoo.com

Abstract
The study assessed the awareness and perceived benefits of yellow root cassava value-added innovation on livelihood of rural farmers in Umuahia North Local Government Area of, Abia state, Nigeria. Multi- stage sampling technique was used in the study. Sixty (60) farmers were randomly selected from the host of farmers in Umuahia North Local Government for the purpose of this study. A structured questionnaire was used to obtain data from the farmers. Data collected were analyzed using descriptive statistics such as frequency distribution tables, mean and percentages. The result showed that 60% of the respondents make use of value added cassava as food while 40% used it as a source of income. The women also have their constraints in processing the products due to poor yield of cassava (27%) and lack of processing equipment (24%). The study recommended that improved, high yielding cassava varieties and processing equipments shall be made available to the women for increased production.
Keywords; impact, assessment, yellow root, cassava

Introduction
The large component of vulnerable population - women of childbearing age and children – in cassava producing areas are at risk of Vitamin A deficiency. It was against this background that researchers at National Root Crops Research Institute Umudike (NRCRI) put down efforts to release six yellow varieties of Cassava that are rich in vitamin A. The development of the varieties was a major breakthrough that would change the nutritional status of people living on cassava-based foods. The new varieties contain higher amounts of beta-carotene – the substance that the body converts to vitamin A – and are at least six times more nutritious than the common white-fleshed cassava. Vitamin A deficiency can impair the body's immunity to infectious diseases and cause eye damage that can lead to blindness and even death. Nearly one in three Nigerian children under five and one-quarter of all pregnant women in the country are vitamin A deficient. The newly released vitamin A cassava varieties can provide up to 40 percent of the vitamin A recommended daily allowance for children under five. They are twenty-five percent richer in beta-carotene than the first set of vitamin A cassava varieties released in 2011 and which are now being grown by over 250,000 Nigerian farmers. The newer improved varieties are expected to gradually replace the earlier ones (Egesi & Eke-Okoro, 2013). Value-addition to these yellow cassava varieties through processing them into different products will increase the income of the farmers.
Processing is the conversion of edible food into another more acceptable or more convenient to the consumer. Cassava can be processed into many products which may be put into variety of uses. Various people use cassava for food. In Abia State, majority use cassava for garri while many use it for *fufu* and *abacha*. This shows that the major diet from cassava in rural Abia State were *garri* and *fufu* (Nwakor & Nwakor, 2012). The rising demand for more processed agricultural products

has created new industries to supply better quality products in more readily usable forms. Processed cassava products like odourless *fufu* have high capacity to wedge hunger for a longer period of time (Amamgbo *et al.*, 2002).

Objective of the study

The broad objective of the study is to find out the impact assessment of yellow root cassava value addition among rural women in Umuahia North.

❖ To describe the socioeconomic characteristics of rural farmers, determine the impact of selected cassava value added innovations (cassava fufu, high quality cassava flour, chips, garri and starch)

❖ To ascertain the awareness and perceived benefits of this innovation among the respondents

❖ To identify constraints encountered by rural women in the yellow root cassava value added innovation.

Methodology

The study was conducted in Umuahia North Local Government Area (LGA) of Abia State of Nigeria in 2018. Four communities were randomly selected in Umuahia North LGA. They were Ohia, Ossai, Umuoriehi and Amafor. In each of these communities 15 women were randomly selected and interviewed using structured questionnaire. Data collected were analyzed using descriptive statistics, such as frequency tables, percentages, and means.

Results and Discussion

Socio-Economic Characteristics of the Respondents

Table 1 showed the distribution of respondents according to their socio-economic characteristics. The result indicated that the average age of the respondents was 42.81 years. This implies that majority of the farmers were in their active age and ready to get involved in cassava business. The majority (63.33%) of the farmers were females. This suggests that women are more involved in cassava production. Majority (65%) of the famers were married and majority of the respondents had formal education. The result also indicated that the average income of the farmers was ₦58, 083.

Table1: Socio-economic Characteristics of the Respondents

Variable	Frequency	Percentage	Mean
Age			
20-30	17	28.33	42.81
33- 39	9	15	
41 – 49	18	28.34	
54 – 59	6	10.01	
60 – 68	6	10.01	
70 -75	3	5.01	
	60	100	
Gender			
Male	38	36.67	0.63
Female	22	63.33	
	60	100	
Marital status			
Married	38	63.33	0.63
No married	22	36.67	
	60	100	
Educational level			
Non-formal	5	8.33	
Primary	17	28.33	
Secondary	23	38.33	12
Tertiary	15	25.00	
Farm experience			
10 years	43	71.67	
10 years and above	60	100.00	10.16

1– 2 hectare	13	21.67	
2 – 3 hectare	20	33.33	
3 - above	2	3.33	
In come			
10,000 – 37,000	24	38.29	58083
40,000 – 59,000	20	362.35	
60,000 – 77,000	8	13.35	
80,000 and above	10	16.69	
	60	100	

Table 2 showed the distribution of respondents according to awareness and benefit of yellow root cassava. The result showed that 60% of the respondents used yellow root cassava for food while 40% used it as source of income. All the respondents were aware of yellow root cassava. The result showed that 48.33% of respondents processed the yellow root cassava into garri and 45% of the respondents consumed about 100 – 200kg of their products. The result showed that 58.33% of the farmers sold garri from yellow root cassava.

Table 2: Distribution of respondents according to their awareness and benefits of yellow root

Options	Frequency	Percentage	Mean
Benefit			
Food	36	60.00	
Income	24	40.00

Chips	4	6.67	
Chinchin	2	3.33	
Bread	1	1.67	
	60	**100.00**	

Constraints

Constraint in the production of yellow root cassava is presented in a chart as shown in Figure 1. The major constraints militating against yellow root cassava production were poor yield of yellow root cassava (27%), followed by unavailability of processing equipment (24%), poor education of farmers and lack of interest in yellow root.

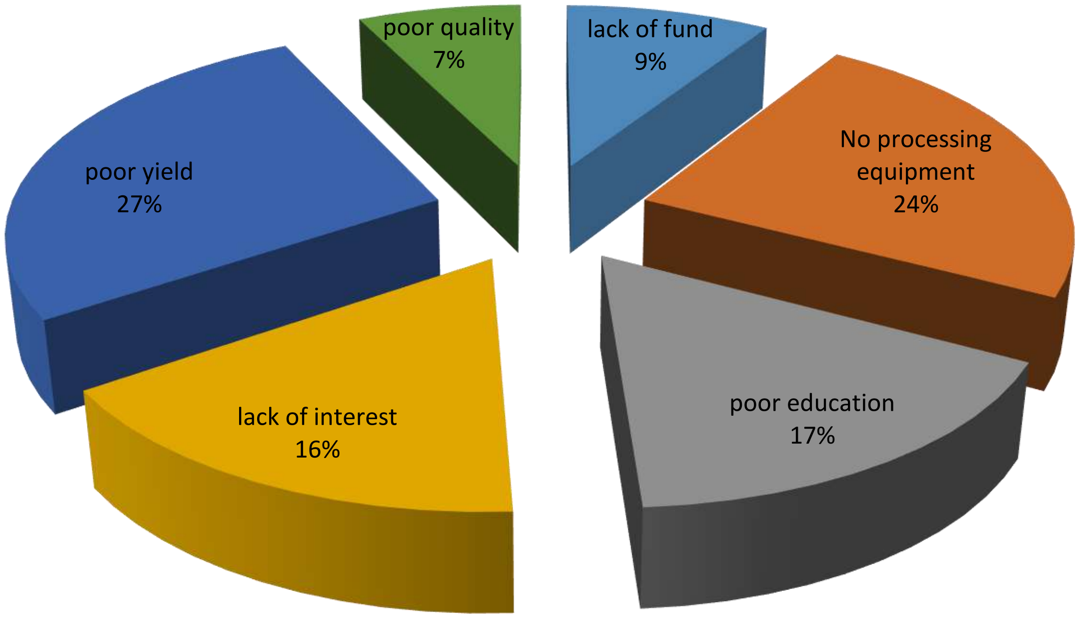

Figure 1: Constraints to production of yellow root cassava

Conclusion

The findings indicate that farmers in Umuahia were using yellow root as source of food and income. The major products from yellow root cassava were garri, flour and fufu, garri. The major constraints in the production of yellow root cassava were poor yield and lack of processing equipment.

Recommendations

- Farmers in Umuahia North LGA need to be provided with fertilizers and organic manure to improve the yield of crops.
- Processing equipment should be made available to rural dwellers in the study areas.
- Farmers need to be trained on how to diversify the use of yellow root cassava through processing it to many other products outside garri, flour, and fufu.

Economic Analysis of Smoked Fish Marketing in Ikorodu LGA, Lagos State

D.P. Ani and O.I. Fawole
Department of Agricultural Economics, University of Agriculture, P.M.B.2373 Makurdi, Benue State, Nigeria
E-mail: doranonye@yahoo.com

Abstract
This study examined the economics of smoked fish marketing in Ikorodu Local Government Area, Lagos State. One hundred and twenty smoked fish marketers were selected using multi-stage sampling procedure. The data collected through the use of structured questionnaire were analysed using descriptive statistics, marketing margin, and inferential statistics such as correlation and t-test. The findings revealed an average marketing margin of 15%. Lack of capital, high taxes, poor feeder roads, high cost of transportation, price fluctuations were the major constraints the marketers faced in the study area. These numerous marketing problems could explain the low profitability among smoked fish marketers. It is recommended that inactive cooperatives should be strengthened so that members could secure better bargaining power. Fish smoking could be achieved using cheaper alternatives to wood like rice, husks, wood wastes and maize cobs. Government could also assist marketers with funds in form of aids, grants and soft loans; smoking keens, cold rooms and warehouses for proper storage and marketing.
Keywords: Marketing, smoked fish, marketing margin, profitability

Introduction
Fish is an important component of total human food consumption, it is one of the main sources of protein and fat, it has some peculiar qualities that make it a valuable source of nutrient. The protein in fish is adequate, important and digestible (Apata, 2002). It has no religious rejection or biases compared to other sources of protein, like pig which is condemned and religiously rejected by Islam. Fish is a good source of sulphur and essential amino acids such as lysine, leucine, valine and arginine and it is therefore suitable for supplementing diets of high carbohydrates contents (Amao *et al*., 2006). It has high content of Polyunsaturated (Omega III) fatty acids, which are important in lowering blood cholesterol level and high blood pressure (Coaster & Otufale, 2010). It has also been implicated to have decreased the risk of bowel cancer and reduces insulin resistance in skeletal muscles (Esiobu *et al.,* 2014). Fish and fish products are known worldwide as a very important diet because of their high nutritive quality and significance in improving human health. Fish plays a vital role in feeding the world's population and contributing significantly to the dietary protein intake of billions of the populace (Adeosun & Adebukola, 2012). On a global scale, almost 16 percent of total average intake of animal protein was attributable to fish in 1988 (FAO, 2012).

Recently demand for fish product has doubled as other sources of animal protein have become expensive due to pressure by the ever increasing population and the high cost of the other animal protein source (Ojo & Fagbenro, 2004). Despite Nigeria's rich moderate tider dynamics in her coast and the existence of high fisheries potentials, notably within the upwelling zones of the continental shelf or the enrichment of the land based sources through the rivers, fish production has for a long time consisted of localized activities aimed at providing protein to her teeming population. Nigeria's fishing sector accounts for about 4% of GDP, and 50% of the animal protein intake (Oluyole, 2010). The Food and Agriculture Organization (2012) recommended that a person takes 35 grams per caput of animal protein per day for sustainable growth and development. Fish which contributes 36.6 grams per day of net protein utilization in Nigerian homes is still below the recommended requirement by the WHO (Ohen & Abang, 2009). Malnutrition is a major health hazard in many developing countries. It impedes health, work-efficiency, productivity and general economic progress. It has been recognized that fish is a veritable source of protein, therefore if readily available and affordable fish can alleviate the problem of malnutrition.

Fish marketing is one of the oldest livelihood income generating activities of man since time immemorial. Fish marketing describes all various activities which concerned from the point of catching/harvesting of fish, to processing and ultimately to the point of final consumption. Agricultural marketing dictates how often the producer will increase and/or produce their output/yield. A good marketing organization directs production along the most suitable needs of the consumers (Esiobu *et al*., 2014). The market mechanisms have to be efficient to be able to play the role of propelling yield. An efficient market system therefore is the one that provides satisfactory and cheap services to consumers or one that maximize the ratio of input and output of marketing. Fish supply and marketing suffer from various set- backs, ranging from shortage of supply, price fluctuation due to drying up of the source and spoilage in transit amongst others.

Agricultural marketing is central to agricultural development and the overall growth and development of the economy. Previous studies have shown that efficient marketing system stimulates agricultural production (Adescope, Ajibefun and Akeremale 2005 as cited in Awoyinka, 2009). In Nigeria, the annual demand for fish far exceeds local production such that according to the Federal Bureau of Statistics, over 800,000 metric tonnes of fish are imported. This high level of fish importation is absurd considering nutritional and other economic importance of fish, and rich coastal heritage and endowment of the country. As important as marketing is, most of the studies on fish have concentrated on production (Inoni, 2007; Kudi, 2008; Dagtekin & Emeksiz, 2009). Besides, the empirical evidences emerging from few studies (Ohen and Abang, 2009; Coaster and Otufale, 2010 etc) yielded mixed results that are inconclusive and conflicting. Particularly, in Lagos State little or no study has rigorously modelled the economic analysis of smoked fish marketing. The specific objectives of the study are to;

i. determine the marketing margin of the smoked fish marketers;
ii. assess the relationship between socio-economic characteristics of respondents and their returns from fish marketing;
iii. identify constraints associated with smoked fish marketing in the study area.

The hypothesis tested in the null form was "smoked fish marketing is not profitable in the study area".

Methodology

The study was carried out in Ikorodu Local Government Area (LGA) of Lagos State. Ikorodu LGA is situated approximately 36 km North of Lagos. It is located along the Lagos Lagoon and shares a boundary with Ogun State. It is bounded to the South by the Lagos Lagoon, to the North by a boundary with Ogun State, and to the East by a boundary with Agbowa-Ikosi, a town in Epe Division of Lagos State. Ikorodu LGA has a coordinate 6°36′N 3°30′E / 6.600°N 3.500°E and a population of 535,619 people (NPC, 2006). Ikorodu LGA consists of nineteen (19) wards. The main industries in the town are trading, farming and fishing. Major water bodies in Ikorodu include Agboyi River, Ajegunle River, Majidun River, Ogudu River, River Ogun, and the Ikorodu Fish Farm Estate. These river bodies serve as a veritable means of livelihood to residents of Ikorodu LGA who are involved in fishing activities. As a result of the abundance of river bodies, fishing and fish marketing is fast becoming a popular trade among youths and young school leavers in Lagos as a whole, and Ikorodu LGA in particular.

The population of the study consisted smoked fish traders in Ikorodu LGA of Lagos State. A multi-stage sampling procedure was employed in the selection of respondents. At the first stage, purposive sampling technique was used to select four (4) wards in Ikorodu LGA namely; Agbala, Ibeshe, Ipakodo, Odogunyan, due to their relative high level of smoked fish marketers and processors. In the second stage a simple random sampling method was used to select 51 smoked fish traders from Agbala market; 22 from Beshe market; 17 from Ipakodo market; 30 from Odogunyan market applying a uniform sampling proportion of 35% to their sampling frame. Thus, a sample size of one hundred and twenty (120) respondents was used. Primary data was collected using a structured questionnaire. Marketing margin analysis, correlation, Likert scale rating (which was used to arrange the data) and one-sample t-test were used to analyse the data. The four Likert scale was specified as follows: Very serious (VS) =4, Serious (S) =3, Not serious (NS) =2, Not a Problem (NP) =1

Model Specification
Marketing margin

$$\text{Marketing Margin} = \frac{Selling\ price - purchase\ price}{selling\ price} \times 100$$

Results and Discussion

Marketing Margin of Smoked Fish marketers
Table 1 presents the result of the marketing margin of respondents in the study area. The average marketing margin was 15%. This implied that 15 percent profit would be realized from every purchase made. Majority of the respondents (63.3%) had a marketing margin of between 10% and 20%, 10.8% had between 20% and 30% while 21.7% had below the average marketing margin. This low marketing margin suggests low returns from fish marketing. This result is in line with the findings of Enete and Agbugba (2008) who obtained 22.3% marketing margin for wholesalers that engaged in charcoal marketing in Abia State. Also, marketing margins of 11.9 and 24.4% were obtained for pineapple marketing in rural and urban areas in Lagos State by Oladapo *et al.,* (2007); which are similar to this study.

Also, as a rule of thumb, Riley (1972) had reported that efficient markets in developing countries must have a retail margin of less than 10 percent of the consumers 'price for non-perishable goods. Thus, marketing margin of 15% found in this study therefore does not suggested inefficiency since fish is perishable.

Table 1: Marketing Margin of Smoked Fish Marketers

Class Interval	Frequency	Percentage	Mean
4.50 - 10.00	26	21.7	14.97%
10.01- 20.00	76	63.3	
20.01- 30.00	13	10.8	
30.01-32.40	5	4.2

Relationship between Socio- Economic Characteristics of Marketers and their Profit Margin
Table 2 showed the Pearson correlation result which was used to predict the relationship between socio-economic characteristics of smoked fish marketer and their profit margin. The result showed that majority of the socio-economic variables-age, level of education, household size and fish experience had no significant relationship with the profit margin of smoked fish marketers. This implies that an increase, or decrease in these variables will have little or no effect on the marketer's profit margin. On the other hand, only annual income had a positive and significant relationship with their profit margin at 10% level of significance. This means that an increase in annual income of smoked fish marketer will increase their profit margin. This result implies that increasing the financial base of the marketers can go a long way in expanding their business profitably.

Table 2: Correlation result showing relationship between Socio-economic characteristics of respondents and their Marketing Margin

Variables	Pearson correlation	Sig
Age	-0.004	0.968
Level of education	0.004	0.963
Household size	0.084	0.360
Annual income	0.430**	0.000
Marketing experience	-0.068	0.458

Dependent variable - Profit. ** significant at 1% **Source**: Field Survey, 2018.

Test of profitability of Smoked-Fish Marketing
Table 3 presents the results of profitability of smoked fish marketers in the study area. The average revenue for smoked fish marketers was ₦46,760 while the average variable cost was ₦40,689. Although the mean difference shows a value of 6070.167 which indicated that the business may be able to pay its bill, there was no significant difference ($t=1.08$; $P \geq 0.10$) between the revenue and cost incurred by smoked fish marketers. This indicates that the smoked fish

marketing is not profitable in the study area. Therefore, the null hypothesis which stated that smoked-fish marketing is not profitable in the study area is accepted.

Table 3: Test for profitability of Smoked Fish Marketing

Groups	Mean	Mean difference	t-value	Df	Sig
Revenue	46760	6070.167	1.082	238	0.280
Cost	40689

Constraints of Smoked Fish Marketing

Table 4 showed the constraints of fish marketers in the study area. Lack of capital, High taxes, Price fluctuation (t=7.78, 16.83, 14.11;P≥0.01) were the challenges that affect smoked fish marketing in the study area. These factors were very critical to the availability, quality and accessibility of fish consumed, and also, on the efficiency and profitability of smoked-fish marketing. As such, these challenges if not addressed could serve as disincentives to fish marketers with its resultant losses in employment, income and socio-economic growth and development of the country. Other constraints which were found to have significant effect on smoked fish marketing include high cost of fishing materials, high transportation cost, inadequate storage facilities, lack of electricity supply, poor feeder roads, consumers' choice on fishes, union activities, insect infestation and processing problems.

Table 4: One sample t-test showing constraints to Smoked Fish Marketing (test value=2.50)

Constraints	Mean	Std. Dev	Mean Diff	**t-value**	Sig. (2-taild)	**Rating**
Lack of capital	2.98	0.419	0.475	17.78	0.000	Ist
High tax	3.14	0.395	0.64	16.83	0.000	2nd
Price fluctuations	2.83	0.436	0.33	14.11	0.000	3rd
Poor feeder roads	3.05	0.427	0.55	12.41	0.000	4th
High cost of transportation	3.04	0.353	0.54	9.32	0.000	5th
Union activities	2.82	0.43	0.32	8.37	0.000	6th
Problem of processing	2.55	0.659	0.05	8.07	0.408	7th
Consumer`s choice on fishes	2.62	0.758	0.117	4.07	0.000	8th
High cost of fishing materials	2.88	0.44	0.375	1.69	0.094	9th
Inadequate storage facilities	2.58	0.694	0.075	1.18	0.239	10th
Insect infestation	2.32	0.85	-0.183	0.83	0.020	11th
Lack of electricity supply	2.73	0.63	0.233	-2.36	0.000	12th

Source: Field Survey (2018).

Conclusion and Recommendations

There was no significant difference in the revenue and the cost of the smoked fish marketers, indicating that the smoked fish marketing is not profitable in the study area. An average marketing margin of 15% was recorded. This suggests low return for marketers which may discourage others from venturing into the business. It was also shown that increase in annual income will increase the smoked-fish marketers' profit margin. Lack of capital, High taxes and price fluctuations were the major constraints of smoked fish marketers in the study area.

Inactive fishermen cooperatives should be strengthened so that members could secure fishing inputs. This could enhance better bargaining power and thus give more access to better market prices that will translate to higher returns. Due to inadequate and high cost of fish preservation/storage in the area, fish smoking can be achieved by using cheaper alternatives of fuel such as rice husks, wood wastes and maize cobs as substitutes for wood. Government should assist marketers with smoking keens, cold rooms and warehouses which enhance proper storage. Funds in forms of aids and soft loans should be provided by the government to the marketers. This will increase the capital base of the individual fish marketers and also attract more people to the business. This will result in a more competitive market where prices of fish will be determined solely by the forces of demand and supply thereby making fish easily available and affordable to majority of Nigerians;

Abstract
The assessment of consumers' preference and consumption pattern of catfish was studied. A total of eighty (80) respondents were selected by the use of multistage random sampling technique. Descriptive statistics such as percentage and frequencies were used to determine the effect of socio-economic characteristics of the respondent and the constraint to consumer preference and consumption pattern in the study area. The result showed that a higher percentage of the respondents consume fresh catfish fish in the study area. The result shows that majority of the respondents preferred fresh catfish, followed by smoked fish and frozen fish. Therefore, for the current level of fish consumption in the study area to be sustained and improved upon, strategies towards boosting the production of fish both in the study area as well as at the national level should focus on creation of income-enhancing jobs and trainings through capacity building in fish production and value addition to the products.
Keywords: Consumers, Preference, Pattern, Catfish

Introduction
Catfish is an important source of protein in Nigeria. In the last three decades, the Federal Department of Fisheries (FDF) statistics show that catfish consumption in Nigeria has been increasing at no less than 5.6% per annum (FAO, 2006). The Nigeria Bureau of Statistics (NBS, 2012) backed this by stating that Nigeria is the largest producer of catfish in Africa. It must be noted that out of the 15,489 tonnes of fish produced in Nigeria in 2011, catfish production accounted for about 4,627 metric tonnes (NBS, 2012). Catfish are a diverse group of ray-finned fish. Catfishes especially members of the family Clariidae are very important in Africa and are very abundant in commercial catches in Nigeria. Members of this family that are very common in the study area include Heterobranchus species (*H. bidorsalis and H. longifilis*) and Clarias species (*C. gariepinus and C. anguillaris*) and their cultured hybrids (Heteroclarias). These species are very important because they not only keep well in both fresh and dried condition, but are highly valued and enjoyed a greater level of popularity among consumers. The economic importance of Heterobranchus and Clarias catfishes and their hybrids is enhanced by their hardiness and adaptability to adverse environmental conditions, tolerance of high density culture, resistance to diseases, fast growth rate, high consumer ranking and their ability to accept or thrive on cheap feed.

Consumer behavior for fish with respect to consumers' taste, preference, food habits, family income and consumption expenditure on fish and related commodity is essentially important from its production, processing and marketing point of view. Preference is considered to be major factor influencing general food consumption behaviour (Myriand *et al*., 2000). Pieniak *et al*. (2008) reported that fish consumption is mostly affected by tradition and habit and the level of consumption is also enhanced by nutritional awareness. Consumer preference for food items is an important variable used in determining the extent on the degree of household purchasing ability. Households make choice out of various food items available at their disposal and this in turn determines the level and extent to which consumption would be based. Therefore, an analysis of consumer preference for forms of fish is important, and this may be useful for fish production, planning, trade, and distribution and marketing.

Many catfish consumers are known to consider various factors such as acceptance of product, preference and pattern in which it is been consumed amongst others before making their demand for the product. The term consumer preference refers to the consumers' general likes and dislikes for products (e.g. consumers general likeness for fried chicken better than hash browned potatoes) while consumer acceptance on the other hand refers to the consumers' reaction to a specific product (i.e. method of preparation, specific serving temperature, specific ingredient and so on) according to Brunso (2009). He went further to state that these two terms are not uniformly agreed upon as consumer preference is measured by the use of questionnaire in which the respondents indicates their degree of preference to a produce while consumer acceptance can only be obtained from the respondents reaction to the actual food item which is obtained typically from a kitchen experiment or from an actual field situation. But for the purpose of this study, the field situation will be adopted to test the consumer acceptance of catfish in Enugu State. In line with the above, Akeson-Samson (2005) reported that consumers usually have a natural preference for a particular fish species while acceptability may be influenced by taste, price and income of consumers. As suggested by Grunert *et al*. (2003), consumers learn about their preferences over time by observing the relationships between their own reactions to alternatives and the attributes of the alternatives. The study analyzed consumers' preference of catfish in Ibeju-Lekki Local Government Area (LGA) of Lagos State Nigeria.

Methodology

This study was carried out in Ibeju Lekki LGA of Lagos State, Nigeria. Ibeju-Lekki is bounded in the east by Epe local government while its southern end joins the Atlantic Ocean. It is about 75 kilometres long and 20 kilometres at its widest point. According to the 2006 national census, the total population of Ibeju-Lekki is 117,793 consisting of 60,729 males and 57,064 females. Ibeju – Lekki is a rural community with eleven rural markets located at various villages and natural resource-based economic activities like fishing, agriculture, timber /saw-milling, mat/ raffia weaving, oil-palm processing and emerging eco-tourism. Towns and villages that make up Ibeju/Lekki LGA include Aiyeteju, Awoyaya, Bogoje, Akodo, Eputu, Badore, Elerangbe, and Iberikodo. Ibeju/ Lekki LGA also hosts the Lekki Local Council Development Area. A random sampling technique was used to select four (4) communities (Aiyeteju, Awoyaya, Badore and Iberikodo) out of the various communities in the study area. Questionnaire was administered on twenty (20) respondents in each of the four (4) selected communities to make total of eighty (80) respondents.

The data collected was using descriptive statistics and chi-square analysis. The computation of chi- square of statistic is given by

$$X^2 = \sum \frac{(Oi - Ei)^2}{Ei}$$

Where; O = Observed frequency, E = Expected or theoretical frequency, $\sum$ = summation sign, X^2 = Chi square

Results and Discussion

Socio-Economic Characteristics of Respondents

The socio-economic characteristics of respondents is presented in Table 1. Education is taste changing and usually affects the consumption pattern and nutrition of a household. This is because as the years of formal education increase, consumers become increasingly aware of the nutritional value of certain food items like fish, meat and eggs and subsequently increase their consumption of them. Household size is another important variable affecting the consumption pattern of households it can be observed that a large proportion of households fall within household size of 4-6 persons per household, accounting for about 52.5 % of the total number of sampled households. This was followed by household with 7 - 9 persons per household representing about 31.5% of sampled households. The lowest household size fell within the range of 10 persons above per household, accounting for approximately 3.7% of the total sampled households. This tendency towards small family size in the study area may be attributable to the high level of education of respondents and their corresponding awareness of family planning measures. There is a tendency for the age of the household head to affect the consumption pattern of a household and may determine to an extent the type, quality and nutrition of a given household. a large number of household heads (38) fell within the age group of 31 – 45 years and represented about 47.5% of the sample size. This was followed by respondents within the age groups of 15 – 30 years, 46 – 60 years and 60 years above representing 32.5%, 15% and 5% of the total sample respectively.

Table 1: Socio-Economic Characteristics of Respondents

Characteristics	Values	Aiyeteju Frequency	Iawoyaya frequency	Badore Frequency	Iberikodo Frequency	Total frequency
Age Of Consumers (Years)	15 – 30	7	8	6	5	26

Total	45	23	12	

Source: Survey Data 2017; ***Significant at 1% level

There is significant difference in the socio economic returns in the forms of the catfish consumed.

Constraints

Table 5 showed that among the constraints affecting the consumption of Clarias fish in the study area the high cost of fish (28.75%) and the low income level of the consumer (26.25%) constitute the highest level in the constraint.

Table 5: Distribution of respondents according to constraints

Constraints	Frequency	Percentage
High cost of fish	23	28.75
Rapid fish Spoilage	18	22.5
Health Reason	12	15.00
Religious Belief	6	7.50
Low income level of consumer	21	26.25
Total	**80**	**100**

Conclusion and Recommendations

The result of analysis in this survey showed that catfish an animal protein sources is highly consumed among the respondents in Ibeju Lekki Local Government Area. The result shows that majority of the respondents preferred fresh catfish, followed by smoked fish and frozen fish. This result shows that a higher percentage of the respondents consume fresh catfish fish in the study area. Therefore, for the current level of fish consumption in the study area to be sustained and improved upon, strategies towards boosting the production of fish both in the study area as well as at the national level should focus on creation of income-enhancing jobs and trainings through capacity building in fish production and value addition to the products. These should be complemented with strategies of equitable income distribution and food and nutritional awareness programmes. As household income increases, the importance of fish as a protein source in the diet should become more pronounced and increased for the much publicized, aggressive and far reaching awareness campaign. These will help reduce malnutrition and food insecurity problems, increase productivity among the populace and eventually lead to national development.

Abstract

The study analyzed the economics of ornamental fish marketers across the nation. The specific objectives were To: profile the socio-economic characteristics of the ornamental fish traders, estimate the gross margin and to describe the constraints affecting ornamental Fish Marketing. A two-stage sampling technique was used to select Ornamental Fish traders. The traders were stratified into fishermen, middlemen and exporters, from where 50% sampling from each stratum was carried out. A total sample size of 196 Ornamental Fish traders located in 14 producing States of Nigeria (Lagos, Ogun, Edo, Delta, Rivers, Bayelsa, Abia, Cross River, Akwa Ibom, Kano, Benue, Ondo, Niger and Nassarawa) was used for the study. This includes 139 fishermen, 40 middlemen and 17 exporters. Data were collected on personal characteristics of respondents, sources of fund, types of fish holding facilities, transportation and labour costs, quantity and types of and cost of Ornamental Fish supplied, and revenue generated on quarterly basis using structured questionnaire. Data were analyzed using descriptive statistics, gross margin and multiple regression models at p=0.05. Male respondents were 91.3%; this includes 72.0%, 19.6% and 8.4% of fishermen, middlemen and exporters respectively. The mean ages of the fishermen, middlemen and exporters were 47.3 ± 1.2, 44.5 ± 1.5, and 42.6 ± 2.3 years respectively. Respondents with no formal education, primary school leaving certificate, secondary school certificate, and tertiary education were 37.3%, 32.3%, 23.5% and 6.1% respectively. The Ornamental Fish marketing channel involved fish sales from fishermen to middlemen who finally sell to consumers. Gross margin of the middlemen were highest in the first (₦9,288,876) and third (₦4,054,679) quarters, while the gross margin of the exporters were highest in the second (₦3,485,961) and fourth (₦4,088,522) quarters of the year. Exporters had the highest average marketing efficiency (85.1%) throughout the four quarters of the year. Factors that significantly influenced the supply of Ornamental Fish were start-up capital (β = 0.98) and membership of association (β = 0.32). Supply of fish by middlemen were significantly influenced by international price (β = -0.61), membership of association (β = -1.33), and educational qualification (β = 1.03). Only capital (β = 0.00) had significant influence on exporters demand for Ornamental Fish. Lack of capital and seasonality of fish species (100.0%) were the major constraints to Ornamental Fish trade.

Introduction

Nigeria is blessed with an abundant variety of fish species some of which have been exported over the years. Large quantities of fishes and fishery products are exported from Nigeria in different forms and this has been a source of foreign exchange earnings for the country. An estimate value of exports in the fishery sub-sector is approximately $31 million for shrimps, sole fish cat fish and crabs. More than US $3million was realized from sales of ornamental live fishes in 2007 (Fisheries Statistics of Nigeria, 2008) In the United States the ornamental fisheries resource is a great source of income opportunity. In 1996 the United States imports and exports in ornamental fisheries were valued at approximately $1000 million. In Florida, cultured fresh water and collected salt water species accounted for $70 million and $4 million respectively in annual dockside revenues (Chapman *et al*, 1997). The United States fish farmers of just two hundred people within Florida province have been able to generate a large amount of revenue from the rearing and marketing of tropical ornamental fishes. This indicates a great success in National income generation to the United States through the effort of the Florida farmers.(Chapman *et al*, 1997). Ornamental Fishes are used in indoor recreation and usually kept in aquarium. An aquarium is an enclosed volume of water containing a mixture of aquatic organisms. It is a water-holding structure made of glass for keeping ornamental fish species for decorative purposes. It is made of glass for transparency and ornamental brightly coloured fishes used for their aesthetic values and recreational potentials are kept there. Recreation is a means of entertaining oneself after work; for the relaxation of ones mind, body and brain (Ayodele, 2002). The ornamental fisheries sector in Nigeria is still young, though young depends on wild collection of indigenous species and breeding of exotic species (Areola, 2001).

In Nigeria, the situation is different. The existing few marketers are scattered within Lagos and their impact is not felt in the economy, despite the abundance of over 300 species (Areola, 2004). The 1985 Western World Pet Supply Association (**WWPSA)** trade show in Long Beach California exposed many countries like Germany, USA, Malaysia, Peru, France and Singapore to the gains in ornamental fish trading who subsequently took advantage of these opportunities. Currently World trade in ornamental fish is estimated at about 1.8 billion US dollar per annum. Singapore, Malaysia, Hong Kong, Taiwan and Japan control about 60% of the world's ornamental fish product and export earnings while North America and Europe have introduced new dimensions of biotechnology, to produce genetically modified organisms They have succeeded in modifying the natural colours of the fish species to produce desired colour combinations as well as stronger and robust species (Areola, 2004). Nigeria ranks high in export of ornamental fishes amongst African nations such as Republic of Congo, Malawi and United Republic of Tanzania but has not fully exploited her stock of colourful, dark and lovely shaped ornamental fish species. About 100 species of ornamental live fishes have been identified to be regularly exported in Nigeria. There is no stock assessment of the different species but records show that ornamental fish export trade has been carried out in Nigeria for over 40 years.(Areola, 2004). Nigeria is particularly blessed with some species that enjoy high demand in the world market. These fish species are not brightly coloured but have characteristically distinctive shapes which make them unique. These include Longnose (Elephant nose), Reed and Butterfly. Long nose is available in large numbers in Nigeria during the dry season.

Butterfly and Reed are rare species found in our waters. Long nose is used as pollution indicator and also in entertainment centers and games resorts as souvenirs/gifts for its high market price. Reports have it that it is used in laboratories for the preparation of vaccines and anti-allergic ointment. The high demand of some of these ornamental fish species is because they are endemic to Nigeria and all known and reported attempts to reproduce them artificially over the years have failed. The opportunity therefore, exists to capitalize on this and dictate the market price. There is paucity of information on available resources. To date, there is no detailed resource survey to determine the species distribution or the production of exportable fish species in Nigeria.

The collection of these fishes from the wild is not sustainable. There are problems of transportation from collection points to point of exports, loss of time, and high fish mortality due to stress. Very few exporters are breeding some common species such as cichlids, catfish etc. Most often orders are cancelled for lack of the specific fish species. During the rainy season, the volume of water discharged and flooding does not allow for easy exploitation of these species of fishes. The roads leading to the remote areas where they are located are often not motorable resulting in little or no export during the rainy season. All export is through the Muritala Mohammed International Airport, Lagos, Nigeria. This curtails sourcing and exploitation of the vast abundant resource in the Northern and Eastern States. Other limiting factors include pricing and poaching of customers, losses or "dead on arrival" reports or antics of dubious customers, airline booking and airfreight charges and sourcing of finance for the export of ornamental fishes.

Nigeria has vast natural resources of tropical aquatic life which are high in demand abroad but here export of ornamental fish is estimated at only 5% of the total 20% potential of African's contribution to ornamental fish trade (Areola, 2004; Mbawuike & Pepple, 2003) took an inventory of the locally available fish species in Nigeria for export and discovered that most of the fishes exported are ornamental fishes apart from shrimps as Nigeria has not been able to meet up with the local demand for fish. Much work has not been done on ornamental fish in Nigeria; that is why this study was carried out. The objectives the study includes the following profiling the socio-economic characteristics of the ornamental fish traders, estimating the gross margin and ascertaining the constraints affecting ornamental fish marketing.

Methodology

The Federal Republic of Nigeria is the largest single geographical unit along the west coast of Africa and occupies a position where the western parts of the African continent meet at the equatorial Africa (Nigerian Year Book, 1970) lying between latitude 4^0 and 14^0 North and longitude 3^0 and 14^0 East. Nigeria's land area of about 92,377 million hectares is entirely within the tropical zone extending Northward from coastline for over one thousand and forty-nine kilometers. The major ornamental fish marketing activities is carried out mainly in Lagos State. Exportation of ornamental fishes are carried out from Lagos State. There are ornamental fish markets at Ikorodu town, and Epe town (Oja Oba), Ibiajengbede and Akio Village.The Nigerian Aviation Handling Company shed of the Muritala Mohammed International Airport is the only outlet for ornamental fish export.

Primary data was collected from One hundred and ninety six ornamental fish marketers with the use of a structured questionnaire. The ornamental fish species are from different states of the country. A two stages sampling approach was used to select one hundred and ninety six marketers from 386 respondents involved in the sale of ornamental fishes located in fourteen states in Nigeria [Lagos Ogun Edo Delta Bayelsa Abia Niger Ondo Nasarawa Rivers Cross River Akwa Ibom Kano and Benue].

Stage one was the stratification of the population into 3 strata; Fishermen, Exporters and Suppliers. Stage two involved the simple random sampling of 50% of marketers from each stratum. Data collected were analysed using descriptive statistics and gross margin analysis.

Results and Discussion

Socioeconomics characteristics

Table 1 shows the distribution of respondents by their socioeconomics characteristics across the three main activities of respondents. Majority of respondents (91.3 percent) were male and 47.4 percent fall between the age group of 41-60 years. Table 1 revealed that majority (79.1 percent) of respondents were married. Also, the results revealed that majority (85.2 percent) of the respondents have stayed long in the business for the range of 6-21years and above while about 33.2 percent of respondents have primary education level, 33.7 percent of respondents had no form of education.

Marketing Margin and Marketing Efficiency of Ornamental Fish

Gross Margin

The gross margin analysis was used to determine the profitability of the marketers in the study area as shown in Table 2. Result shows that the gross margin of suppliers is the highest throughout the four quarters with ₦9,288,876, ₦2,183,506, ₦4,054,671 and ₦2,611,749 for the first, second, third and fourth quarter respectively. The exporter earns the least gross margin (₦2, 186,677) which occurs in the third quarter. This may be due to the introduction of some marketing functions like transport cost, packaging etc. which the suppliers and fishermen can avoid. In the first three quarters, profit of the exporter increases but decreases in the fourth quarter. This could result from the fact that the fishermen supply to some of the consumers directly.

Profit

Table 3 presents the distribution of profit margin among fishermen, exporters and middlemen throughout the four quarters. In the first quarter (Jan-March), the profit margin of middlemen (₦9, 208,066) is the highest followed by that of the fishermen (₦1, 897,486) and exporters (₦2, 881,972). From the first quarter, there is an increase in the supply of fish which led to a higher profit margin for the fishermen which invariably reduces the profit margin of middlemen due to glut in the market but increases the profit of the exporters'. In the third quarter (July-Sept) the middlemen paid the same amount to the fishermen because of their pre-knowledge of the market which now reduces the profit margin of the latter and increases that of the former. And due to the higher supply, the price of fish dropped thereby reduced the profit margin of the exporters. In the fourth (October-December) quarter due to the trend of the production which has been affecting their profit margin, the fishermen reduce their production and this increases price which consequently increases their profit margin (₦1, 897,878). Efficiency of the exporters also increases but that of the suppliers decreases due to the fact that the supply falls and the exporters bought some of the fish from the fishermen directly.

Constraints to Ornamental Fish Marketing

Table 3 above shows the constraint encounter by Ornamental Fish marketers in Nigeria. The result shows that ornamental fishes are not available all the year round (seasonality) especially during the rainy season (between June and September) which is the breeding season for fishes. The fishes usually migrate to the shore where there are grasses. They hide under the grasses to feed and breed and are rarely seen. This accounts for 12.23% given by the respondent. Also the high cost of transportation(17.98%) reveals that transportation cost is high. The fishes are abundant in the villages, but not available in the cities where the shippers reside. The result in table 5 above reveal that the financial Constraints constitutes the highest percentage (30.94%) this suggest that a higher proportion of the respondent fishermen, suppliers and shippers do not have enough funds to have a very good facilities where they can keep the fishes until they can be sold. Banks do not give them loans because they trade in perishable goods.

Table 3: Constraints of Ornamental fish marketing

Variable	Frequency	Percentage
Seasonality	17	12.23
Low Participation of Farmers	13	9.35
High cost of Packaging materials	19	13.67
High Cost of Transportation	25	17.98
Financial Constraints	43	30.94
Naira Depreciation	14	10.07
Airline Problems/Multiple Taxation	8	5.76
Total	139	100

Source: field survey, 2016.

Conclusion

The fishermen, middlemen and exporters profit margins were positive for the period under study. Their marketing efficiencies were greater than one. There is freedom of entry and exit so the market can absorb more traders. A gradual trend towards effective regulation of activities and data collection has been established through the effort of the Federal Department of Fisheries. The sector is a potential developing source of foreign exchange earnings for the country, if strategic management policies are put in place. The sector also poses ultimate self-employment opportunities for the unemployed graduates most especially the fisheries graduates.

Recommendations

Based on the research findings of following recommendations were drawn.

1. The Federal Department of Fisheries do not have a formally established office at the Airport. There is need to establish these service in all airports include the certification of all exports, data collection and to ensure that all exports are covered by export permit which is a source of revenue to the Government from the fish harvested from the wild.
2. There is the need to carry out research in the breeding of these fishes by research institutes and Department of Fisheries in the universities.
3. There is a need to provide basic rural infrastructure to make the fishing communities where the fishes are bred to be accessible throughout the year.
4. There is a need for adequate monitoring so that the fraudulent customers abroad do not cheat Nigerian exporters. The exporters lose a lot of revenue as the banks dictate the exchange rate used in converting the proceeds of live fish export.
5. Loan should be given at a subsidized interest rate to the fishermen, suppliers and shippers in the study area. This will go a long way to alleviate their financial constraint.

Abstract
Rural farming households in Nigeria have a long tradition of producing primarily for home consumption and they only rely on the markets for the foods they cannot produce on their farms. However, due to changing economic trends, particularly in the face of rising poverty among rural households, the pattern of household production was such that most of the rural household productions are sold to the market for income in order to meet the financial obligations of the households. This paper examines the level of household reliance on some market purchased root and tuber crops to sustain the farm family food needs in Nigeria. Primary data collected from 96 households randomly selected from 4 villages were analysed using a simple descriptive statistics. The study revealed that, the mean quantity sold for cassava (≈744kg) was the highest followed by the quantity consumed (≈286kg). However, Cassava and yam (76%) ranked highest in the percentage distribution of farmers, based on the type of root and tuber crop produced in Abia State. Therefore, the study concludes that there is a high level of market orientation of cassava and yam only by the rural households and it varies significantly across poverty levels in the study area.
Key words: Levels, Market orientation, Producers, Nigeria

Introduction
Understanding the changes in the share of food consumed by the rural farming households that is from the market in the face of changing socio-economic environment in which they operate is very important for several reasons (Onubuogu and Onyeneke, 2012). It, for instance enables us to see how the rural farming households, who have hitherto in the previous year's been able to meet substantial parts of their home consumptions of food from own production and how much of own food produced offered to the market have been affected by the changing social, economic and political environments in the country (Hernandex *et al*., 2007). Looking across poverty levels is also desirable so as to see the effect of household poverty on the degree of market orientation of both the poor and non-poor households (Weatherspoon and Reardon, 2003).

This paper is another effort in food demand studies with a view to understanding the level of market orientation of rural households and also to determine the appropriate points of policy intervention in food supply programmes. Furthermore, the role of markets in poverty and food intervention programmes needs to be better understood in the country in the face of changing socio-economic factors such as population, personal income levels, rapid rate of urbanization and tastes. Therefore, there is need for an assessment of the household food demand in the context of the role of the rural markets with a view to providing the empirical evidence required to understand the issues involved in designing an appropriate mix of policies for national and regional food and market planning (McCullough *et. al*., 2008). There are comparatively few published that have addressed the level of market orientation of cassava, yam and cocoyam producers in Nigeria.

Methodology

A purposive sampling technique was used in selecting a state and respondents. Abia state was chosen based on Cassava, Yam and Cocoyam production. Two local government areas was selected, four communities, four villages was also selected, finally, twelve cassava, yam and cocoyam farmers were selected based on the number of registered farmers in that area, making it a total of 96 farmers. However, these respondents comprised of producers, processors and marketers. Information were elicited from the respondents by means of focused group discussion, interview schedule and structured questionnaires. Data were analyzed using descriptive statistics, means and percentages.

*Multiple Response
Source: Field survey data, 2016

The result in table 1.0 pointed out that 85% of the respondents were within the age range of 35-44 years with a mean age of 40 years. This implies that majority of the respondents were young and are ready to accept innovations, this in line with Poison and Spencer (1991). Dominance of female (54%) as against 45% male, suggests that root and tuber crop production is gender sensitive and requires more women than men, this is in agreement with Anyiro *et al* (2013). Also majority (90.6%) of the respondents were married also acquired basic education. This result is in line with the findings of Onubuogu and Onyeneke, (2012) who posited that education and training enhances farmers' productivity and market oriented production objective. Household size between 5-10 persons had 84.3% with the mean household size of 6 persons. The large household size is attributed to the need for cheap and dependable labour derivable for on-farm and off-farm activities. This findings is in agreement with the findings of Onubuogu *et al*. (2014) reported the most farm families have large household size between 5 to 10 persons with mean of 6 persons Furthermore, 60.3% of the respondents fell within the monthly income level of ₦41,000 - ₦60,000, with mean income of ₦45,620. This shows that market orientation of cassava, yam and cocoyam can be found to be very lucrative as the income of the farmers are higher than normal.

Levels of Market Orientation

Sampled respondents mentioned quantity of root and tuber crops sold in kg in the available markets. These were summarized and presented in Table 2.0

Table 2: Mean Value of the Allocation of Household Root and tuber Crop Productions (n=96)

Type of Root and Tuber Crop	Quantity Sold (Kg)	Quantity Consumed (Kg)	Quantity given as gift (Kg)
Cassava	743.5417	285.5208	70.41667
Yam	142.5521	88.33333	30.72917
Cocoyam	19.07292	6.020833	2.927083

Source: Field Survey, 2016

The pattern of household production was such that most of the rural household productions are sold to the market for income in order to meet the financial obligations of the households. Thus in agreement with Ololade and Olagunju (2013) report which earlier posited that income enhances productivity and promotes standard of living by breaking vicious cycle of poverty of small scale farmers. Some of the root and tuber crop produced goes into home consumption while some households gives their farm produce as gifts to friends and relatives. This is firmly rooted in the tradition of Africans that you have to be your brothers' keeper. Apart from gifts some other uses also occur in that category.

According to Eke-Okoro (2011), root and tuber crops play significant roles in the food economy of Nigerians. The root and tuber crops sector provides job opportunities and generate income for Nigeria.

Output Size of Cassava, Yam and Cocoyam Production

Figure 1.0 below shows the percentage distribution of farmers based on the type of root and tuber crop produced. From the result; planting cassava and cocoyam ranked lowest (4%), followed by Cassava only (20%) and the highest of them all is Cassava and yam (76%). Eke-Okoro (2011) also

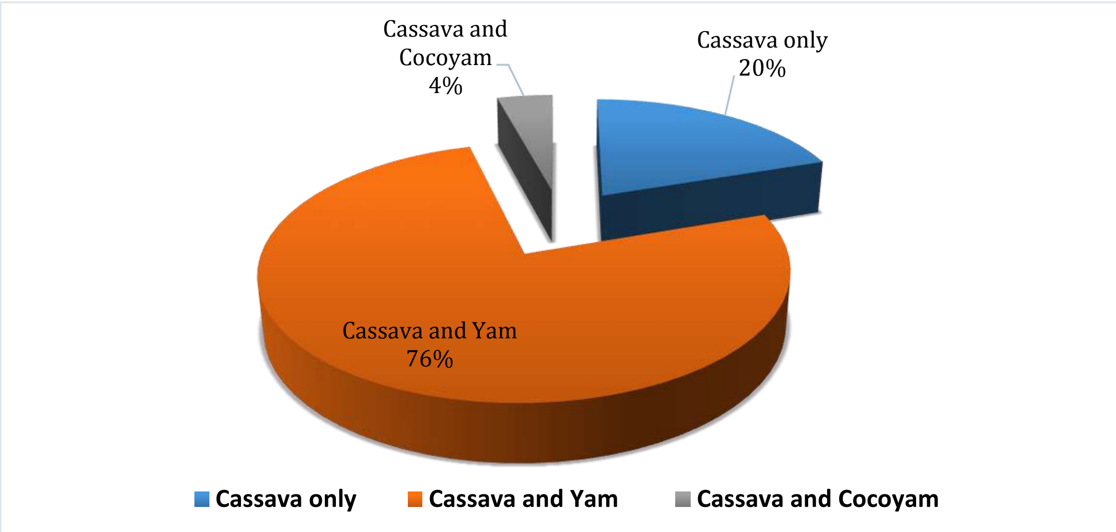

Figure 1: Percentage Distribution of farmers based on the type of root and tuber crop produced

posited that the importance of cassava in the lives of many Nigerians cannot be over-emphasized. As food, it comes first among the root and tuber crops despite the respect yam commands as a ceremonial crop. He also mentioned that the advantages of cassava as a candidate crop for hunger alleviation, poverty eradication and food security include tolerance to drought, low demands on soil nutrients, and capacity for providing good root. While yam (*Dioscorea spp)* are major carbohydrate staple and provides food for over 60 million people in West Africa. The importance of yam in Nigeria and indeed throughout the West African yam belt is not only for its role as a major food staple but also its sociocultural significance in the life of the people. Cocoyam (*Xanthosoma sp: Colocasia sp*) are also important staple in Nigeria ranking third among the root and tuber crops after cassava and yam. Nigeria is the world's largest producer of cocoyam and has an increased production output for more than 12 million tonnes. (NRCRI, 2000).

Conclusion

The study concludes that there is a high level of market orientation of cassava and yam only by the rural households and it varies significantly across poverty levels in the study area. Policies that would enhance the income generating activities of the rural households in the study area is desirable so as to enhance their food purchasing power, reduce food insecurity and reduce poverty relative to food. Furthermore, there should be an appropriate policy that would take care of the anticipated changes in the structure of food demand as poor households tends to become non-poor, when their income increase.

Abstract
The study examined the effect of National Special Programme on Food Security (NSPFS) on farmers' income from cassava production in South-East, Nigeria. Specifically, it described the socio-economic characteristics of beneficiaries of NSPFS and determined whether NSPFS has increased farmers' income from cassava production in the study area. Multi-stage random sampling technique was utilized in selecting three hundred and sixty respondents (comprised 180 NSPFS participants and 180 non-participants) used for the study. Data were obtained with the aid of structured interview schedule and Focus Group Discussion, and analyzed using descriptive and inferential statistics, such as percentages, means and Z-test. The findings showed significant difference between incomes of participants and non-participants. The National Special Programme on Food Security increased farmers' income in South-East, Nigeria. The null hypothesis that there is no significant difference between the income of participants and non-participants in cassava production was therefore, rejected, while the alternative hypothesis was accepted. The study, therefore, recommended that more farmers should be encouraged by government to participate in the next phase of the National Special Programme on Food Security for increased food production, income and enhanced standard of living.
Keywords: Income, cassava production and National Special Programme on Food Security

Introduction
Agriculture is the most assured engine of development and a reliable key to industrialization in Nigeria. Therefore, its development is very important. This is because over 70% of its population live in the rural areas and derive their livelihood from agriculture, which comprises crop production, livestock, fishery and forestry, which accounts for about 35% of the total Gross Domestic Product (GDP) of Nigeria (CBN, 2010).
The major developmental challenges facing developing countries, especially Nigeria today is how to reduce the high level of poverty (Abiola and lofin, 2008). The World Food Summit in a meeting in Rome in 1999 estimated that 790 million people in the developing world do not have enough food to eat (Alamu *et al*., 2005). As a follow up to the summit, Nigeria, one of the 82 Low-Income Food Deficit Countries (LIFDC) requested for assistance under the FAO's National Special Food Security Programme (NSFSP). The pilot phase of National Special Programme on Food Security (NSPFS) in Nigeria started in Kano state, after a tripartite participatory review meeting of FAO, government, and beneficiary communities in March 1998 in Nigeria. The pilot phase focused on household and community level food security and livelihood issues.

In 2002, the programme was scaled up to the 36 states of the federation and Abuja, Federal Capital Territory at a cost of $45.2 million to be financed entirely by Federal Government of Nigeria (Onugha, 2008). The programme had three production/demonstration sites in each of the 36 states, one per senatorial district and one site in the Federal Capital Territory, which gave a total of 109 sites in the Federation. The first phase lasted for five year 2002 – 2006 and it tackled food security at national level by scaling up to all parts of the Federation. On seeing the achievement of NSPFS, and the need to improve small-scale production and sustainable agriculture for food security to reduce hunger rapidly, the government expanded the programme to six additional sites in each of the 36 states and two sites in Abuja, from 2007 to 2014. At this expansion phase the programme was renamed National Special Programme on Food Security (NSPFS) in 2007. It was expected that the programme would improve national food security, reduce pressure on national resources and reliance on food aid, and stimulate wider economic development. National Special Programme on Food Security (NSPFS) is farmer-driven as all activities are based on farmers' demands. The farmers' demand can be summarized as follows: timely provision of agricultural inputs and access to credit to acquire inputs.

The NSPFS mandate is to respond to these farmer-driven demands in a timely and coordinated fashion (Ihekoronye, 2013). Farmers in South-East Nigeria engage predominantly in cassava production. Cassava is one of the major staple crops, and is widely grown and consumed in Nigeria, and is inclusive in food security crops in the country. The implementation of National Special Programme on Food Security in Nigeria was expected to have enhanced farmers' income in South-East Nigeria, among other objectives. However, the programme with all the laudable objectives ended in 2014, but the extent to which it has increased farmers income is apparently unknown. It is in this regard that this study was conceived. Specifically, the study described the socio-economic characteristics of beneficiaries of NSPFS and determined whether NSPFS has increased farmers' income from cassava production in the study area.

Methodology

The study was conducted in South-East, Nigeria. The area lies within latitude 5^o 20' and 7^o 75' North, and longitude 6^o 85' and 8^o 46'East of equator and covers a land area of about 28,987 square kilometers, or 3.19 percent of the total land area of Nigeria. The Zone is made up of five states, namely, Abia, Anambra, Ebonyi, Enugu and Imo States. The states in the zone share similar characteristics (NPC, 2006). The zone covers the bulk of the Igbo-speaking ethnic territory or Igboland. The area lies mainly on plains under 200m above sea level. It is bounded on the south by Akwa Ibom and Rivers States, on the east by Cross River State, on the west by River Niger and Delta State, and on the north by Benue State (Monanu, 2000). The people of South-East Nigeria, especially the rural dwellers, engage mainly in subsistence farming. The major crops grown are cassava, yam, oil palm, cocoyam, rice, cocoa, maize, plantain, melon and okra. The respondents for the study were selected through purposive and multistage random sampling techniques from South-East Nigeria. There were four States that participated in the National Special Programme on Food Security in the zone. Three states namely Ebonyi, Enugu and Imo States were randomly selected from the four States that participated in the programme. Three agricultural zones were purposively selected from each of the selected states. This gave a total of nine agricultural zones. They were Okigwe, Orlu, Owerri in Imo State; Nsukka, Enugu, Awgu in Enugu State; Ebonyi North, Ebonyi Central and Ebonyi South in Ebonyi State. Two blocks were randomly selected from each of the selected agricultural zone; two circles were randomly selected from each of the blocks selected. Five participants of NSPFS were randomly selected from the list of participants in each of the selected circle, while five non-participants were randomly selected from the list of non-participants in the thirty-six selected circles. The lists of farmers were obtained from the respective circle extension agents. A total of Three hundred and sixty respondents were interviewed, comprised 180 NSPFS participants and 180 non-participants. Data were obtained with the aid of structured interview schedule and Focus Group Discussion, and analyzed using descriptive and inferential statistics such as percentages, means and Z-test. The objective on whether NSPFS has increased farmers' income from cassava production was realized by comparing the mean income of participants and non-participants. The null hypothesis that, there is no significant difference between the income of participants and non-participants in cassava production was tested at 5% level using z-test. The participants and non-participants indicated their income from cassava production in the last cropping season. Farmers' mean income from cassava production was computed and used to calculate the z-test by applying this formula:

$$Z = \frac{X_1 - X_2}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}$$

Where Z = calculated value
$\overline{x_1}$ = Mean income of cassava for NSPFS participants
$\overline{x_2}$ = Mean income of cassava for non-participants
n_1 = Sample size of NSPFS participants
n_2 = Sample size of non-participants
σ_1^2 = Standard error for NSPFS participants
σ_2^2 = Standard error for non-participants

Results and Discussion

Socio-Economic Characteristics of Beneficiaries of NSPFS in South-East, Nigeria

The results in Table 1 show that the mean age was 43 years. It revealed that the beneficiaries were within the active and productive working class. This is in agreement with Ifenkwe and Umeh (2014) that active age of farmers is a positive factor to sustainable food production, poverty alleviation among farmers and improved agricultural extension. The mean household size of the beneficiaries of the National Special Programme on Food Security in south-East Nigeria was 7 persons. It is an indication that families in south-east Nigeria have large family members. The mean farming experience of the NSPFS beneficiaries was 13 years. This shows that most of the participants are young/or middle aged. Years of farming experience could give indication of the practical knowledge acquired in farming, especially the importance of participation in agricultural programmes like the NSPFS. On the average, the beneficiaries had secondary school education. This indicates that farmers in South-East Nigeria are literate. Educational attainment is a desirable condition for agricultural development, since it augurs well for adoption of new technologies and participation in agricultural programmes (Mazza *et al*., 2017).

Farmers' income from cassava production

The study determined whether NSPFS has increased farmers' income from cassava production. This was realized by comparing mean income of participants and non-participants. The findings revealed that the National Special Programme on Food Security has increased farmers' income from cassava production. The participants realized mean income of N230,556 per hectare, while non-participants made mean income of N103,444 per hectare (Table 2). Better income gives better purchasing power and hence the improvement in living standard. This implies that the National Special Programme on Food Security has improved the living standard of those who participated in the programme. This is in line with the work of Panwal and Arene (2014) that the National Special Programme on Food Security increased income of participants in Plateau State. Increase in income is as a result of increase in yield which leads to improvement in the living standard of the farmers. Increase in farmers' yield, or income as a result of application of better technologies can be used to measure the success of an agricultural development programme because increase in yield translates to increased income, which further translates into improved standard of living (Agbarevo, 2010).

Table 2: Z-test significance of difference between cassava incomes of participants and non-participants

NSPFS	N	Mean	SD	t- tabulated	t-calculated
Participants	180	230,556	34.23093	1.96	1787.21**
Non-participants	180	103,444	21.74823		

Source: Field Survey, 2016. **Significant at 5% level.

Conclusion

The National Special Programme on Food Security has succeeded in increasing the income of participants which in turn translates to improved standard of living. Hence, it has partly met its mandate of increasing farmers' income in South-East, Nigeria. However, the effect of this increase in farmers' income does not seem to be very visible because of the small proportion of cassava farmers that participated in the programme. If all or majority of the farmers in the Region participated in the programme, the increase in farmers' income would have been achieved relative to cassava production in South-East, Nigeria. The study therefore recommended that more farmers should be encouraged by government to participate in the next phase of the National Special Programme on Food Security for increased income and enhanced standard of living.

Abstract

This research is aimed at evaluating the efficiency of the marketing of snail in two local government areas in Rivers-State, Nigeria (Ikwerre and Obio-Akpor). The sample size was 60 respondents, four markets in the selected local government areas were purposively selected because of the high presence of snail marketers, and primary data were obtained from well structured questionnaires. The data obtained were analyzed with the use of descriptive statistics, multiple regression analysis, marketing efficiency, costs and returns (using enterprise analysis). The result obtained from the socio-economic characteristics of the respondents showed that they contributed to the successful performance of marketing, types of snail marketed, were examined. The regression results showed that the selling price, market frequency, and gender were positive and significant at 5%, 1% and 10% respectively while the buying price was significant at 10% and negatively influencing the quantity of snail sold. Based on the econometric criteria R^2, F –Statistics, number of significant, and signs of significant variables as they conform to the a priori expectations. The efficiency of snail marketing evaluated showed that the snail marketing is efficient which concurs with the a priori expectations. The result of the costs and returns showed that the marketers incurred more costs but the business was profitable. The major constraints which limited the marketers were high transportation cost, financial difficulties, high cost of snail, low credit facilities. Based on the finding, more entrepreneurs should be encouraged to engage in snail rearing (Heliciculture) and marketing to reduce the buying price and make it more profitable.

Introduction

Snail are members of the *phylum mollusca*, they represent a large and varied group of shelled gastropod mollusks in the class *gastropoda* which contains at least 80,000 species and the second largest phylum in animal kingdom. The member of this group are found throughout the world, they are diverse in size and ecologically, bring terrestrial, freshwater or marine. Example of terrestrial species is *Helix pomatia* which is an edible snail (Cobbinah, 2008). The external characteristics of snail include a spiral shell, flattened foot and anterior head with prominent tentacle. When provoked, the snail can withdraw into its shell and in some cases, the shell opening can be closed by a horny or calcareous plate called aneperaulum. In Nigeria at large and in Rivers State most especially there are several types of snails that are good for food (edible) and been marketed for consumption, and this gives room for choice making in which a buyer decides the one to buy and consume, though the choice here, will depend on preference of buyers and his relations.

Snail as a meat is a rare delicacy for many because it provides a substantial source of protein. It is used to prepare a variety of meals including soup (Azeez, 2009). Protein from snail meat is said to be very rich in essential amino acid such as lysine, liucine, arginine and tryptophan, while being low in sodium, facts and cholesterol. Snail meat has a high nutritional and medicinal value. The snail meat can control hypertension and its blue liquid is used in stopping excessive bleeding from open wounds.

Importantly, snail has become a source of income capital, the iron and calcium content of snail contributes to the proper building/development of strong bones especially in babies. The snail meat aids in easy movement of foetus, easy delivery and good source of iron for pregnant and nursing mothers. Generally, its economic returns are high and are earner of foreign exchanged (CBDD, 2000).

Methodology

The sampling frame is the list of every member or units of the population from which a sample is drawn (Vitalis, 2005). With respect to the research work, the sampling frames covered include; Marketers of snail.

The selection of respondents was on multi-stage pattern and involved both purposive and random sampling techniques. The purposive sampling was used to select the six (4) markets under study for Obio Akpor the markets include Oil Mill, Rumuokoro and Mile 3. For Ikwerre the markets are Igwuruta (Ahia Odu). Simple random sampling was used in selecting the various participants (marketers) involved. The distribution of questionnaires to respondents was according to the area of study (Obio Akpor and Ikwerre). Obio Akpor had 45 while Ikwerre, had 15.

The sampling size was 60 respondents.

Method of Data Collection

Primary data was used for this study. The primary data were obtained through well structured questionnaires which were administered to the respondents, oral interview and personal observations. Relevant data collected include socio economic characteristics of the marketers, types of snail sold, cost and return of snail.

Method of data analysis

A number of analytical techniques were used in processing the data include descriptive statistics, multiple regression analysis, marketing efficiency model and cost and return model.

Model Specification

Formula for marketing efficiency= $\frac{\text{Total Revenue (₦)}}{\text{Total cost(₦)}}$

Multiple Regression Analysis

Explicitly, the function is stated thus,

$Y=b_0 +b_1X_1+b_2X_2+b_3X_3+b_4X_4+b_5X_5+b_6X_6+b_7X_7+b_8X_8+b_9X_9+b_{10}X_{10}+b_{11}X_{11}+b_{12}X_{12}+\mu$

Where;

Y= Quantity of Snail Sold (in paints)

X_1=Buying Price (₦)

X_2=Selling Price (₦)

X_3=Types of Snail (*Achantina achantina=1, Achantina maginata=2, Achantina fulica=3)*

X_4= Sources of Snail (wild=0, breeding =1)

X_5= Customers (number)

X_6=Market Frequency

X_7= Gender (female = 0, male =1)

X_8= Age (years)

X_9= Level of Education (years)

X_{10}=Household size (number)

X_{11}=Marital Status (married =1, single =0)

X_{12}= Sources of Fund (equity =1, debt =0)

μ= Error terms

b_0= Intercept

b_1- b_6=Coefficients to be estimate

Results and Discussion

The types and sources of snail traded in the study area

Table 1 shows the result of the types of snail marketed in the study area. This revealed that the major types of snail traded in the study area are *Achantina achantina, Achantina maginata, and Achantina fulica. Achantina maginata* had the highest percentage of 51.7 followed by *Achantina achantina* with 33.3% the least which is *Achantina fulica* has 15.0% with reason been that *Achantina maginata and Achantina achantina* command higher market price than Achantina fulica. And this concurs with Ajayi (1997) as noted that the Achantina fulica is of a low economic value as compared to *Achantina marginata and Achantina achantina* as these two command higher market price.

Table 1: the types of snail traded in the study area

Types	Frequency	Percentage (%)
Achantina achantina	20	33.3
Achantina maginata	31	51.7
Achantina fulica	9	15.0
Total	60	100

Source: Field survey data, 2017

Table 2: Distribution of the source where snails are bought by the respondents in the study area

Towns/Market	Frequency	Percentage
Igwuruta/Ahia Odu	6	10.0
PH Township/Borikiri	5	11.7
Elele/Ekekwu	4	6.7
Egeda/ Ekeoma	7	8.4
Yenegoa/Mbaima	33	55.0
Omuduoga/ Nkworakwor	5	8.4
Total	60	100

Source: Field survey data, 2017

Table 2 shows the various towns/ markets where snails where bought by the respondents. From the table it is obvious that the respondents bought more snails from Mbaima in Yenegoa with 55.0% while Ahia odu, Borikiri, Ekekwu, and Nkworakwor in Omuduoga had 10.0%, 8.4%, 6.7%, 11.7%, and 8.4% respectively. This shows that the major source of snail comes from Mbaima where snails are sold in their large quantity followed by Borikiki (Port-Harcourt Township). Ekekwu in Elele Town had the least percentage of 6.7%, which means that few of the respondents bought from the market.

The Factors influencing the Quality of Snail Traded in the Study Area

This is achieved using multiple regression analysis.

Table 3 Multiple Regression Results of Respondents

Variable	Coefficient	Error	t statistics
Intercept	0.033113	0.422858	0.078308
Buying price	-6.2E-05	2.99E-05	2.08136*
Selling price	7.92E-05	2.5E-05	3.05525**
Types of Snail	0.026449	0.058069	0.455483
Sources of snail	0.105558	0.155946	0.676886
Customers	-0.04036	0.097893	-0.41232
Market Frequency	0.49756	0.12138	4.098906***
Gender	34.0678	12.90867	2.639141*
Age	-0.06034	0.056765	-1.06299
Education	0.080412	0.066608	1.207246
Household Size	-0.00294	0.025158	-0.11673
Marital Status	0.042661	0.100597	0.424078
Sources of Fund	-0.05662	0.161305	-0.35103
R^{-2} 0.872			
R^2 0.913			
F-statistics 45.756			

Source: Field survey data, 2017 note: *** Significant at 1%,** Significant at 5%*Significant at 10%

From the result of the findings in Table 4.9 above, based on the adjusted R^2 (0.87%) and R^2 value (0.91%). This revealed that approximately 91% of the independent variables was accounted for by the dependent variable (quantity of snail sold).

Buying Price(X_1) was negative and significant at 10%. This indicates that there is a negative relationship between the buying price of snail and the quantity sold that is to say that an increase in the buying price of snail will lead to a decrease in the quantity of snail bought by the snail marketers. This conforms to a priori expectation as buying price generally affects the quantity of any commodity or goods sold. Due to the fact that marketers would not want to buy at a high price, thereby reducing the quantity sold. In other word, as the buying price increases the quantity sold decreases, as customers would not want to buy much when the price is high, with their income level remaining constant.

Selling Price (X_2) - Based on the estimated coefficient of the selling price which is positively related to the quantity of snail sold and significant at 5%. This indicates that as selling price increases the quantity of snail sold also increases. This is because price which generates income serves as motivation for marketers to buy and sell more of snails in the study area.
Market Frequency(X_3) – From the finding of this study, which also revealed that market frequency, is positively related to the quantity of snails sold and highly significant at 1%. This shows that an increase in the market frequency of respondents in the study area leads to increase in the quantity of snail sold. In other word, the more frequent marketers are in ensuring its availability, the more quantity they have for sale, thereby increasing their level of profit.
Gender (X_4) –From the result of the estimated coefficient of gender, which is positively related to the quantity of value added snail traded in the study area and significant at 10%. Means that as the gender increases the quantity of value added snail sold increases alongside, that is when more gender (male/female) marketers are involved in the business the quantity of snail sold is likely to increase.

Constraint limiting the efficiency of snail marketing
The Table as shown below presents the constraints limiting the efficiency of snail marketing in the study area.

Table 4 Constraints limiting the efficiency of snail marketing in the study area

Constraints	Mean	Standard deviation
High cost of snail	2.6667	1.72873
High cost of transportation	4.1333	89955
Financial difficulties	5.3667	3.55725
Low demand	1.5667	50401
Lack of credit facilities	1.7333	1.01483
Inadequate measurement	1.3000	46609
Theft	1.1667	37905

Source: Field survey data, 2017

From the result of the findings in Table 10 financial difficulty, high cost of snail, high cost of transportation and lack of credit facilities are major constraints to snail marketing efficiency. Having high limitation capacity followed by high transportation cost which is another constraint to snail marketing which concurs with Anebunwa, (2008) work in which he concluded that transportation is a major constraint in marketing, which he said accounted for nearly 80% of the total marketing cost.
Generally, lack of credit is one of the major constraints which the marketers faced as this is in agreement with Gyanendras (2013) as he stated that lack of credit, marketing intelligence, transportation are major constraints to marketing.

Table 5 Determination of efficiencies of snail marketing and the cost and returns in the study area

Items/Operations	Values (₦)	Percentage (%)
Average Purchase Price	2286000	
Average Selling Price	2675000	
Average Return from sale	2480500	
Variable cost		
Transportation	185000	
Loading / offloading	25900	
Feeding	72000	
Union dues	31000	
Total Variable Cost	313900	75.47
Gross Margin=TR- TVC	2166600	
Fixed Cost		
Depreciation on Equipment	102000	
Total Fixed Costs	102000	24.53
Total Cost	415900	100.00
Total Revenue	2064000	
Net Return from sales= Total Revenue(TR)-Total Cost(TC)		

Source: Computation from field survey data, 2017

From Table 5 above, the fixed cost of ₦ 102000 gave 24.53% of the total cost of ₦ 415900 and the variable cost of ₦ 313900 gave 75.47% of the total cost. The result shows that the marketers incurred higher variable cost than the fixed cost. That is to say in snail marketing, marketers incurred more cost in the day to day running of the business than in cost that do not change over time.
The Gross Margin which is gotten when total revenue is deducted from total variable cost showed to be ₦2166600 while the Net return, after all cost has been deducted was ₦2064000. This indicates that the business is profitable.

Table 6 Marketing efficiency of snail marketing
This is analyzed using marketing efficiency of snail respondents.
The result of the efficiency of snail marketing was computed, result presented thus,

Marketing Efficiency	Frequency	Percentage (%)
1.2 - 5.3	33	55.0
6.2 - 10.4	22	36.7
11.0 - 20.0	3	5.0
21.0 - 30.4	2	3.3
Total	60	100

Source: Field survey data, 2017

The computation of the marketing efficiency to determine the efficiency of snail marketing in the study area.
The result in Table 6 shows the marketing efficiency of marketers who fall within the efficiency ratio of 1.2-5.3 to be 55%, while those within 6.2-10.4 (36.7%), 11.0-20.0 (5.0%), and 21.0-30.4 (3.3%). This generally implies that there is efficiency in snail marketing in the study areas. Owning to the result gained from the analysis of data collected on the basis of snail marketing efficiency showed to be efficient and this concurs with the work of Odii and Obih (2000). Which states; the technical and economic efficiencies are efficient, if the operation /activity in which the ratios are computed is greater than one and inefficient when they are less than one.

Conclusion

The study in "Evaluating the Efficiency of Snail Marketing in Rivers- State, Nigeria" shows that snail marketing in the study area is profitable and efficient.

Also most of the constraints affecting the efficiency of the market were high cost of snail, lack of credit facilities, financial difficulty as well as transportation cost. The study is of the opinion that, if these constraints are taken care of the business of snail marketing will thrive the more in the study area.
Marketing of Snail is profitable with respect to the level of inputs used, to output obtained and it is a business which people should be encouraged to engage in mostly, for people who have no job. Snail marketing creates job opportunity for jobless individuals and serves as a means to earn a living. It does not necessarily owe to the fact that, it is a business for the uneducated; both the educated and non educated can venture into it. The marketing efficiency can be improved when those with formal education get involved thereby promoting the ability to evaluate new techniques and high tendency to adopt improved methods of technology.

RECOMMENDATION

The following recommendation are suggested to address the setbacks,
From the study it was obvious that women dominated the marketing of snail. It is pertinent to encourage males to get engaged in the marketing of snail so as to attain absolute efficiency and perfection in snail marketing. Owning to the fact that two out of the three types of snail traded in the study area command value and one out of the three showed to be of low economic value in order to improve upon this shortfall, agricultural scientist (breeders) are encouraged to venture into the business of raising snails in order to ensure that the one with lower economic value be cross bred so as to enhance its economic value. The choice of the source of snail can only be widened if agriculturalist incorporates snail production in the numerous agricultural activities.
From the findings, it was gathered that inadequate finance, credit facilities as well as high cost of transportation, and high cost of purchasing snail constitute major constraints in the course of marketing snail. I recommend that marketers of snail should form a cooperative society so as to ensure credit facilities and the government should come in to assist these marketers so as to improve upon the scale of operation by providing means by which they could gain access to credit facilities as these could help the marketers of snail to enhance and stabilize snail supply thereby achieving perfection in the business.

Abstract
The effect of agricultural information usage on the sustainability of food production strategies is the focus of this study. Multi-stage and purposive sampling techniques were employed to select the study population from Egba and Yewa zones (Ogun Central and Ogun West). The random selection of 4 local governments was done from the zones followed by purposive selection of communities noted for intensive arable crop production in the study area. The findings revealed that majority of the arable crop farmers surveyed were above 30 years old and possessed elementary education. Agricultural information relevant to their farm operations were sourced from neighbors, fellow farmers, agricultural extension agent among others. The highest level of benefit was recorded among the farmers that had access to the full complements of available sources. ANOVA, Duncan Multiple Range test was used for analysis. The Mean score was significantly higher comparatively with those who did not access all the sources. The information utilized very frequently include Pest/Disease control, Weed Control crop processing, storage and marketing procedure. Changes perceived due to utilization include change in income and production level, adoption of new agricultural practice, and produce marketing strategies. Conclusively, strategic sustenance of food security and livelihoods could be enhanced through regular transfer or cross exchange of various crop production strategies particularly with the current global climate change challenges.
Key words: Agricultural information, Agripreneur, hunger, communication, poverty, security.

Introduction
The role of information sharing as an indispensable tool in all areas of human endeavor put to task the need to broaden agricultural production base through efficient innovation adoption system. Agricultural communication requires that key underlying factors must be considered to ensure effective information delivery, agricultural productivity and live transformation. Technology transfer in agriculture remains the pivot for development and this can be achieved through incorporation of appropriate information communication tools to disseminate and encourage eventual adoption of innovations. Yahaya (2003) noted that extension institutions and technology transfer programmes exist in almost every developing country yet the coverage of farm family is still limited. The quality of developing country extension programs is seriously questioned and the transfer of potentially beneficial new and underutilized technologies continues to lag. The involvement of various communication channels and strategies into extension programs with adequate funding will positively improve the impact of extension with its multiply effect on food security enhancement.

Agricultural Communication

Food and Agriculture Organization (FAO 2012b) identified communication among the key elements for global promotion of the use of food insecurity experience. The emphasis on communication as a potent tool for development is very important to achieve sustainable food security. Two-third of the population in Africa are employed in agriculture with the vast majority being smallholder farmers. Agriculture could provide one of the best pathways out of poverty but many farmers lack the knowledge and means to improve their farming practices, However digital technologies are beginning to change the trend (Pye-Smith 2018).

It is noteworthy that the peculiarity of information need of a farmer must be taken into consideration as a primary factor for its effective utilization Information transfer is very germane, reliable and efficient for technology transfer. Insufficient technology transfer initiatives have caused many producers to stick to sub-optimal practices and approaches. Small scale farmers need to be informed about the need to transit towards more nutrition-sensitive farming systems that will provide benefits in both economic and health related issues (Sania 2017) (Aliza and Daramola 2017).

The necessity of developing farmers and consumers capacity as major stakeholders in agribusiness through information sharing on agricultural innovation is very important for sustainability of food security and livelihoods.

Adedoyin *et al.* (2002) viewed agricultural extension as comprehensive program of services deliberately put in place for expanding and strengthening of prospective farmers, farm families and other rural economic operators. The goal of agricultural extension cannot be achieved without effective agricultural information utilization.

The objective of agricultural extension as proposed by Bokor (2005) include among others the dissemination of information relating to advanced technology in agricultural production which includes usage of improved seeds, methods of chemical and fertilizer application. The issues of farming systems, production and processing techniques are also involved among others. Communication process in agricultural extension is a functional organ for effective management of the various processes such as innovation decision process, teaching and learning processes among others. (Torimiro and Alfred 2003)

Agricultural Information Transfer

Agricultural information transfer is the heart of agricultural extension activities. Madukwe (2008) noted that the problems of lack of staff, poor staff mobility, quality of staff, weak linkages with agricultural research and weak financial support bugged agricultural extension work. The information transfer in agriculture is for empowerment using various communication strategies and tools with the ultimate goal of increasing food supply and breaks the poverty chain. The agricultural information system deals with issues relating to agricultural information generation, dissemination and utilization for agricultural development. It enables stakeholders in extension service to meet the agricultural needs of farmers from various backgrounds.

Demryurek *et al* (2008) noted that agricultural information interacts with agricultural productivity in variety of ways. It helps to improve productivity by supplying relevant reliable and useful knowledge. The judicious application of agricultural innovation knowledge is crucial to food security and livelihood sustainability because knowledge is power.

Kizilaslan (2006) opined that information system with effective feedback in the research--publishing—farmers' triangle is very crucial. The distribution of agricultural information to users and reciprocal user feedback is vital because it is the essential mechanism by which a consistently reliable and effective distribution of information can be maintained.

Challenges of Poverty and Sustainable Food Security

Food security is a situation in which people at all times have enough physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life (CFS 2016). The issue of poverty is also a major challenge particularly with the upsurge of insurgence, internal and cross border conflicts and climate change effects that led to displacement of several rural settlers and farm families.

Globally 870 million people (one-eighth) suffered from chronic undernourishment in 2010-2012 (IFAD/FAO/WFP 2012). The figure of the poor rose from about 280 million in 1990 to 390 million in 2013 and since the accompanying leveraging measures are not in place hence the unbalance of population growth and poverty.

In Nigeria poverty declined by the first quarter of 2018 even though the International Monetary Fund (IMF) projected a growth of 2.1% by the end of 2018 (Kale 2018).

The rate of progress in poverty alleviation is uncertain and unstable because several factors and conditions are associated, while on the other hand it is essential to assess the level of hunger and food insecurity to be able to develop and monitor policies aimed at tackling the issue since no single indicator can measure or quantify the many dimensions of food and nutrition security.

The strategic objective 1 of Food and Agriculture Organization is contribution to the eradication of hunger, food insecurity and malnutrition (FAO 2012b). The establishment of Voice of Hungry Project in 2013 and its evaluation in 2017 was initiated by the FAO as part of efforts to fast track sustainability of food security. (FAO 2012(b)

Dimensions of Food Security

The physiological and socio -economic dimensions of hunger pose a conceptual challenge for measurement. According to Ballard (2013) FAO prevalence of undernourishment is one of the indicators selected to monitor progress toward achievement of Millennium Development Goals to reduce the proportion of people who suffer hunger to half by 2015.

It estimated the number of people who are likely not ingesting food to meet dietary energy needs based on national estimates using various parameters.

The strategic formulation and effective implementation of agricultural policy among other factors is crucial to provide solutions to food security issues at different levels thus providing access to cheap and varieties of nutritious food supply to all.

Methodology

Arable crop farmers were selected for the study using multistage sampling technique. Fifty percent of the four geopolitical divisions of Ogun State were selected while forty percent of the local government in each of these divisions were randomly selected leading to the choice of (Abeokuta North and Obafemi Owode Local governments) Two local governments in each division (Yewa North and Ipokia local governments.

Five communities were purposively selected from each local governments on the basis of high intensity of arable crop production. Finally, 25% of the arable crop farmers were covered by the survey using Snow-ball approach and eventually, were sampled for the study.

Results and Discussion

Socio Economic Characteristics and the Sustainability of Food Security Measures

Majority of the farmers were in the age range of 41-60 years. 30.68% and 27.5% constituted the age range of 41-50 and 51-60 respectively. This implies that the current drive for youth involvement in agriculture should be sustained. The Nigerian Youth In Agriculture, Youth Agripreneur programme, Children in Agriculture Programme (CIAP) and Youth Farmers' Club should be further encouraged to dramatically spur the interest of youths in agriculture.

The farm size of 1-3 hectares possessed by majority (35%) of the farmers was an indication that farmers need to be granted access to information on acquisition of large land area for farming either through outright purchase, leasehold etc. Sustaining food security and livelihood cannot be done without increase in land area under cultivation and increase in yield per hectare.

Sources of Agro Information

The sources of agro information as covered in the survey are: Fellow farmers, Electronic media, Extension Agents and Print media. The information sources sought by the farmers were done such that more than one information sources was utilized at a time by some of the farmers. All the sources of information identified in the study were utilized by the farmers to seek agro information based on their need as per time, resources and peculiar situations. About 36.8% of the farmers surveyed sourced information from three sources together Extension Agents, Fellow farmers and Electronic media. The educational level must have facilitated their choice and use of sources like Electronic Media, Print Media and Extension Agents.

Table 1: Sources of Agricultural Information

Fellow Farmers	14	8.7
Fellow Farmers Extension agents	11	6.9
Fellow Farmers, Ext Agent, Electronic Media	20	12.5
Fellow farmers, Ext Agent Electronic Media and Print Media	38	23.8
Fellow Farmers, Ext. Agent, Electronic Media Print Media And Commercial Agent	77	48.1
Total	160	100.1

Field Survey 2017

Table 2: Analysis of Variance (ANOVA) of Agricultural Information Utilization from different sources

Source of variation	Df	Sum of squares	Mean square	Fcal	Ttab	Remarks
Between groups	4	3050.997	762.749	78.445	2.43	Sig
Within groups	155	6409.747	41.353			
Total	159	9460.744				

In Table 2, the calculated F value in the Analysis of Variance Test was greater than the critical value (2.43) at P> 0.05. This shows that significant difference exist between some of the means. Field Survey 2017

Frequency of Agricultural Information Utilization

The result revealed that technical information on Crop disease /pest control was utilized more frequently with agro information on crop processing weed control and seeds sourcing. The information marketing and labour were also utilized than other information. The high level of utilization of information on Disease/pest control signals the farmers' response to the rise in waves of crop pests and diseases due to climate change impact. The agricultural information on marketing and labor were utilized more frequently by the farmers at 50.6% and 25.6% levels. This implies that agricultural information on marketing and labor were the needs of the farmer and must have affected the level of utilization. The pest/disease control and weed control information used frequent west analyzed using ANOVA test. The calculated Value in the ANOVA test (18.45) was greater than the critical value (2.43) at P>0.05 and this indicated significant difference between some of the Means. The Duncan Multiple Range test showed that 3 distinct homogenous subset exist in the sample.

Perception of Changes due to Accessibility and Utilization of Agricultural Information

The changes perceived through utilization of various agro information on production, processing and other services reflected on Awareness of innovations in agricultural practices, marketing of farm produce and increase in income. At another level access to labour usage, adoption of new farming techniques and access to labour and labour usage were the changes perceived due to the effect of information utilization.

Table 3: Perception of Changes due to Utilization of Agricultural Information

Change Perception	X_1 Strongly Agreed	X_2 Agreed	X_3 Undecided	X_4 Disagree	X_5 Strongly Disagree
Awareness of new agricultural practices	60 (37.5)	49 (30.6)	14 (8.8)	32 (20.0)	5 (3.1)
Income	42 (26.3)	82 (51.3)	22 (13.8)	14 (8.8)	-
Access to Land	9 (5.6)	74 (46.3)	12 (7.5)	45 (28.1)	20 (12.5)
Access to Labour	10 (6.3)	109 (68.1)	10 (6.3)	27 (16.9)	4 (2.5)
Usage Adoption New Farm Activities	10 (6.3)	78 (48.8)	18 (11.3)	36 (22.5)	18 (11.3)
Access to Loan and Effective Loan Use	8(5.6)	56 (3.5)	6 (3.8)	18 (11.3)	72 (40.5)
Change in Production level		28 (17.50	12 (7.5)	81 (50.6)	39 (24.4)
Marketing of Produce	49 (27.5)	61 (38.1)	11 (6.9)	19 (11.9)	25 (15.6)

Conclusion

Information were sourced mainly from Extension Agents, Fellow Farmers and Electronic media and Print media. The changes perceived eventually reflected on income generation, adoption of new production techniques, labour access and usage, access to land and better marketing of farm produce.

Abstract
The study investigated the Influence of factors of production among yam farmers in Enugu State, Nigeria. A multistage random sampling was use to select 120 farmers. Structured interview schedule was used for data collection. Descriptive statistics and regression model were used for data analysis. The results showed majority (62.5%) of the farmers were male while that of the female counterparts were 37.5%. About 51.7% of the farmers were married while 23.3% of farmers were single. The average mean age of the farmers was 44 years while the average mean years of farming experience were 11 years. The average mean household size of the farmers was 8 and 54.2% of the farmers were full time farmers. Similarly, majority (37.5%) of the farmers used hired labour while the average farm size cultivated by the farmers was 1.08ha. Out of the fourteen variables investigated, only eight variables were found to be statistical significant as regards to the influence of personal and socio-economic characteristics of farmers on yam production in Enugu State. They were sex (P=0.000), farm size (P=001), farming experience (P=003), soil fertility (0.000), income (0.002), access to extension service (0.004), cost of seed yam (0.001) and constraint perceived (0.007). The major constraints militating farmers against yam production were: high cost of seed yam (2.86), high cost of labour (2.95), low soil fertility (2.89), poor use of improved varieties (2.65), poor road network (2.58), pest/disease infestation (2.06), inadequate extension service (2.28), and drought factors (2.45). This study recommended that agro input such as yam seedlings should be made available to farmers thereby subsidizing them in a way that can be affordable to farmers. More extension workers should be recruited, remunerated and posted to rural areas as to get more farmers acquainted with innovations as well as the farming practices available at their usage.

Key words: Yam farmers, influence, and factors of production

Introduction
Yam is in the class of roots and tubers that is a staple of the Nigerian and West African diet. Babaleye (2003) observed that yam contributes more than 200 dietary calories per capita daily for more than 150 million people in West Africa while serving as an important source of income to the people. Interestingly, yam is categorized as chief among the major staple food of Nigerians on account of its indispensability (Oluwatusin and Shitu, 2014). Its highly produced in all parts of the country. Also, national food security is strengthened due to variability in production in different part of the country. This was so due to differences in season as a result of different vegetation which characterized farming system of the nation.
In Enugu State Nigeria, yam cultivation still depends largely on labour intensive, traditional hoe-cutlass techniques of production. Many aspects of production like clearing, planting, weeding, staking and harvesting require considerable inputs of labour. However, as rural labour becomes more scarce and expensive, and the price of inputs increases, the cost of yam in the market increases making it a luxury food rather than a staple (Hahn, Osiru, Akoroda & Atoo, 1993).
Nigeria is the world's largest producer of yams, accounting for over 70–76 percent of the world production (Wikipedia, 2011). FAO (2008) reported that Nigeria produced 18.3 million tonnes of yam from 1.5 million hectares, representing 73.8 percent of total yam production in Africa. According to 2008 figures, yam production in Nigeria has nearly doubled since 1985, with Nigeria

producing 35.017 million metric tonnes with value equivalent of US$5.654 billion (FAO, 2008). Also in West Africa, average statistics has shown that 95% of the world's output of 34 million metric tonnes (mmt) of yam in 2001was produced and Nigeria alone produced 75% of this total Output.

Awoniyi *et al.* (2006) in Oluwatusin and Shitu (2014) reported that in many yam producing areas of Nigeria, it is said that yam is food and food is yam. This shows that, the importance of yam to the existence of the people cannot be overemphasized. It is therefore worthy of note that yam to an average Nigerian man is indivisible. Moreover, researchers over the years have been able to look into values of yam health wisely. Ekp, Idiong and Chinemerem (2000), Oluwatusin and Shitu (2014) reported that Yam tuber contain pharmacologically active substances such as dioscorine, saponin and sapogenin. Dioscorine which is the major alkaloid in yam is medicinally a heart stimulant while saponin has a bioactivities and therapeutic uses. Saponin has been used as adjuvant in vaccines as well as together with immunotoxins as cure for leukaema, lymphoma and other cancers. It is also used in preparation of traditional medicine (Oluwatusin and Shitu, 2014). Also, yam tuber is a good source of energy mainly from their carbohydrate contents since it is low in fat and protein. However, yams tend to be higher in protein and minerals like phosphorus and potassium when compared with sweetpotatoes though the latter are richer in vitamins A and C (Consultative Group on International Agricultural Research, CGIAR, 1997). Also, it has been reported that yam is a good source of industrial starch whose quality varies with species.

In spite of significance of yam production in the economic and socio-cultural aspect of Nigeria as a nation, it has not been accorded the needed attention (Orkwor and Aseidu, 1999). This was reflected in the fall in output percentage growth rate of yam from 42% in 1990 to 16.3% in 2001, despite the increase in land devoted for the production of crop from 120 million hectares in the same period (Federal Ministry of Agriculture, 2001). In spite of the tremendous importance of the yams in the West African sub region, Babaleye (2003) affirms that the crop has hitherto been neglected in policy decisions related to research, crop production and marketing. Most of the efforts of the policy makers and researchers have been concentrated on cash crops and the more familiar crops (Oluwatusi and Shitu, 2014).

According to Akoroda and Hahn (1995) in Oluwatusi and Shitu (2014), the production of yam in Nigeria is grossly inadequate and cannot meet the ever-increasing demand for it under present level of input use. One of the major factors that contribute immensely to this fallout in productivity of yam over the years is the problem of production inefficiency. This is so as production efficiency is directly related to increase in production. In view of these, it is therefore imperative to assess the socio-economic factors that influence the performance of yam farmers in Enugu state, Nigeria. The specific objectives are to examine the influence of personal and socio-economic characteristics of farmers on yam production in the study area.

Materials and Methods

The study area is Enugu State, which is one of the five States in South eastern Nigeria. The State lies between latitude 5^0 56'N and 7^0 06' N and longitude 6^0 53' E and 7^0 55'E. The State occupying a land area of about 802,295km^2 (Ike and Inoni, 2006**)**. The State shares boundaries with Abia, Imo, Ebonyi, Benue, Kogi and Anambra. The estimated population of the state in the last population census is 3,267,837 (NPC, 2006). It is characterized by small farm holdings with yam and cassava as the dominant crop. Enugu State comprises 17 Local Government Areas (LGAs) with three agricultural zones, namely Awgu, Enugu and Nsukka. Two agricultural zones (Enugu and Nsukka) were selected out of the three zones in the state .Two LGAs were selected from each of the zones making it a total of four local governments that were used for the research. The selected local government areas are Nkanu East, Nkanu West, Udenu and Uzo-Uwani. From each of the LGA, three communities were randomly selected giving a total of 12 communities. From the list of yam farmers prepared for each of these communities, 10 farmers were randomly selected giving a total of 120 farmers used for the study. Structured interview schedule was used for data collection. Frequency, percentage, mean scores and regression model were used for data analysis.

Measurement of Variables

To ascertain the influence of personal and socio-economic characteristics of farmers on yam production in the study area, regression model was used.

Y = a+b1x1+b2+x2+b3x3+b4x4…….b14x14 + u

Y = yield of yam (measured in kg/ton)
a = constants term
b1 –b14 = regression co-efficients
x1 = Age (measured in years)
x2 = Sex (dummy variable, male = 1, female = 2)
x3 = Education level (measured by years spent in school)
x4 = Household size (measured by the number of people living under one roof)
x5 = Member of social organization (member = 1, non-member = 2)
x6 = Farm size (measured in hectare)
x7 = Farming experience (measured in years)
x8 = Trading received (Received training = 1, non-training = 2)
x9 = Soil fertility (dummy variable for good soil = 1, poor = 0)
x10 = income of the farmers (measured in Naira)
x11 = Extension contact (access to extension service = 1, No access = 0)
x12 = Access to credit (access = 1, No access = 0)
x13 = Farming practice (shifting cultivation = 1, No shifting cultivation = 0)
x14 = perceived constraints (very serious = 3, serious = 2, no serious = 1)
u = error term

Results and Discussion

Entries in Table 1 show that majority (62.5%) of the farmers were male while that of the female counterparts were 37.5%. These imply that male participated more actively than their female partners in the activities of yam production in Enugu state. However, the participation could be attributed to be gender specific in the sense that culture restricts female from participating fully in the activities of yam production in some communities. Based on these, Oguntate, Thompson and Ige (2010) said that yam production was dominated by men in Oyo state. About 51.7% of the farmers were married while 23.3% of farmers were single. The very high percentage of the married yam producers could be attributed to the fact that respondents require helping hands to carryout tedious process of yam production. This is also an indication that most farmers depends on family members as cheap source of labour. The average mean age of the farmers was 44 years. This implies that young people of active productive age dominated the farming activities of yam production in the study area. This could also help to increase their productivities. The average mean household size of the farmers was 8 while 54.2% of the farmers were full time farmers. This implies that farmers have large family size and this is expected to influence yam production positively. It has been shown that decisions are made by the farm family, since the various farming operations are carried out by the members of the family. Also the family size constitutes a major source of labour available in yam production.

Similarly, majority (37.5%) of the farmers used hired labour while the average mean years of farming experience were 10 years. This implies that farmers had long period of farming experience which could increase their experience as regards to yam production. Greater proportion (52.5%) of the farmers acquired land by rent while about 47.5% of the farmers cultivated less than 5 hectares. The average farm size cultivated by the farmers was 1.08ha. This implies that farmers in the study area are still small-scale farmers. This finding agreed with Udemezue and Onwuneme (2017) who said that farmers in Anambra state were small scale farmers. Moreso, majority (52.5%) of the farmers completed secondary school while about 33.3% of the farmers completed primary school. Since the greater proportions of the farmers were literate, this could make them integrate educational knowledge in their values and farming system to increase production. The farmer's educational level is expected to have a positive influence on the adoption of improved technologies such as farm mechanization, fertilizer usage, agro-chemical, high yielding seeds variety which should have high potentials to increase farm productivity. Hence, education is seen as one of the key factors to adoption of agricultural technologies. About 64.2% of the farmers belonged in social organization. Majority (58.3%) of the farmers had access to credit while 67.5% of the farmers did not have access to extension service therein. In the same vein, greater proportions (37.5%) of the farmers earned between N300,000 – 350,000 as income while about

1.7% of the farmers realized less than N50,000 from yam production. The average mean income of the farmers was N270,000.

Source: Field Survey, 2018.

The results of regression model in Table 2 of the independent variable (sex, age, household size, educational level, social participation, farm size, training received, farming experience, soil fertility, income, access to extension service, access to credit, cost of seed yam and constraints received) on determinants of yam production by farmers shows that a strong correlation (R = 0.875) exists between dependent variable and independent variables. These variables were able to explain 77% of the variation in the influence of personal and socio-economic characteristics of farmers on yam production (R^2 = 0.769). Adjusted R^2 also supported the claim with a value of 0.672 or 67%. This implies that the independent variables explain the behavior of the dependent variable at 67% level of confidence.

Out of the fourteen variables investigated, only eight (8) variables were found to be statistical significant as regards to the influence of personal and socio-economic characteristics of farmers on yam production in the state. They are sex, farm size, farming experience, soil fertility, income, access to extension service, cost of seed yam and constraint perceived.

Sex: Sex is one of the factors influencing yam production in the study area. This could be the fact that yam production is labour intensive and requires a substantial energy and time of which majority of women could not cope with. This finding is in line with the results of Okwor (1998); Udemezue and Onwuneme (2017) which described yam production as a token of masculinity.

Farm Size: This is another factor that influences yam production in the findings. Farmers with large farm size are more likely to produce more yams than those with small area of land if all things being equal. Therefore, the positive influence of farm size implies that the larger the farm size, the more productivity from the farmers. This finding agreed with the findings of Oguntate et al (2010) which saw farm size and farming experience as the determinants of yam production in their study.

Farming Experience: Years of farming experience were positive and significantly influenced yam production in the study area. This implies that the contribution of explanatory variable is inversely proportional to dependent variables. Therefore, the more farming experience farmer had, the higher the productivity of yam.

Soil Fertility: Level of soil fertility has a negative influence of the determinants of yam production in the study area. This indicates that the more fertility land is, the higher the productivity of yam provided that all things being equal. On the other hand, it also shows that the lesser the soil fertility, the lower the productivity of the crop. This finding is in consonance with Udemezue and Onwuneme (2017) who saw soil fertility as the determinants of yam production in Anambra state.

Access to Extension Service: Extension contact has a negative influence on the yam production. The positive sign implies that frequent contact with extension agent by the farmers gives them the opportunity to know about the use of new farming techniques to increase their production while negative contact with extension agent will affect their production due to the fact that farmers may have missed information or the basic inputs needed to increase production. Therefore, regular contact with extension agent makes farmers being aware of new technologies and how they can be applied to improve their livelihood. This finding is in line with Mutain, Agunda, Muluvi, Kibert and Maina (2013) who said in their study that access to extension played a positive role in the activities of sweetpotato production in Vihiga Country, Kenya.

Income: This is another factor that influenced yam production in the study area. Income generated from yam helps to improve farmers' living standard. Increase in income by 1% can as well cause the probability of farmers engaging in yam production as far as there is cash flow in the business. The increase in cash resources will make the farmer invest more on yam production. Therefore high income from yam production is important for an increase in the overall amount of involvement and adoption of improved technologies. Based on this, Mutai *et al* (2013) saw income as a variable that influenced socio-economic characteristics of farmers in Vihiga Country, Kenya.

Cost of Seed Yam: Source of seed yam is positively influenced the intensity of adoption of yam production practices in the study area. Access to farm inputs such as seed yam makes farmers engaged significantly into yam production technologies. Farmers who have access to agro-inputs tend to adopt technologies more readily than those who have not. This implies that those with access to farm inputs are likely to involve more in yam production than those who have not. Hence, high cost of seed yam has been limited some farmers from yam production.

Perceived Constraints: Constraint is one of the factors influencing socio-economic characteristics of the farmers on yam production. It has a negative influence which implies that is inversely related to the dependent variables. Therefore, the higher the perceived constraint by the farmers, the lower the rate of yam production in the study area. Therefore, for production rate to be maintained with respect to yam production, constraints have to be less effective.

Table 2: Regression model for the influence of personal and socio-economic characteristics of farmers on yam production in Enugu State

Table 3 shows the constraints faced by the farmers in the study area. The major constraints militating farmers against yam production were: high cost of seed yam (2.86), high cost of labour (2.95), low soil fertility (2.89), poor use of improved variables (2.65), poor road network (2.58), pest/disease infestation (2.06), inadequate extension service (2.28), and drought factors (2.45). Other constraints were lack of finance, inadequate farm inputs, high perishables of the product, age of the farmers, poor health status of the farmers, poor income from the crop and large farm size. Their finding agreed with Oluwatusin and Shitu (2014) who saw high cost of labour as the constraint working against yam production in Nigeria.

Table 3: Distribution of respondents according to constraints faced in yam production

Variable	Mean	SD
Lack of finance	1.33	0.454
High cost of seed yam	**2.86**	0.623
Inadequate farm inputs	1.58	0.711
High cost of labour	**2.95**	0.758
Low soil fertility	**2.89**	0.734
Poor use of improved yam varieties	**2.65**	0.63
Poor road network	**2.58**	0.53
High perishability of the product	1.30	0.52
Pest/disease attack	**2.06**	0.75
Inadequate extension service	**2.28**	0.84
Age of farmers	1.18	0.45
Poor health status of the farmers	1.50	0.71
Poor income from the crop	1.35	0.82
Large farm size	1.28	0.51
Drought factors such as rainfall, temperature and solar radiation.	**2.45**	0.76

Source: Field Survey, 2018. Cut-off-point = 2 and above. SD = standard deviation

Conclusion and Recommendations

Out of the fourteen variables investigated, only eight variables were found to be statistically significant as regards to the influence of socio-economic characteristics of yam farmers in the study area, they were: sex, farm size, farming experience, soil fertility, income, access to extension service, cost of seed yam and constraints perceived. High cost of labour, low soil fertility, poor use of improved yam varieties, poor road network, pest/disease infestation, inadequate extension services and drought factors were perceived by the farmers as serious constraints working against yam production in the study area. Sequel to the above, this study therefore recommends that:

High cost of inputs such as seed yam has been identified as one of the major constraints to yam production. Therefore, effort should be made to make agro inputs available to farmers thereby subsidizing them in a way that can be affordable to farmers.

There should be more investment on yam production since it serves as self-employment especially for men and this will help to fight agricultural imbalance and shortage of employment in Nigeria. Training among farmers should be encouraged, regularized and implemented by the stakeholders in order to update the minds of the farmers on agricultural innovations. Extension agents should educate farmers on the alternative use of organic agriculture and soil management practices as to retain soil fertility. Stakeholders including nongovernmental organization at all levels should intensify effort to rehabilitate all the existing roads leading to farming field in order to be accessible by the farmers. More extension workers should be recruited, remunerated and posted to rural areas as to get more farmers acquainted with innovations as well as the farming practices available at their usage.

Analysis of Cassava Marketing In Ivo Local Government Area of Ebonyi State, Nigeria

C. Kadurumba; I. Igbojionu and E.Mbanaso
National Root Crops Research Institute Umudike
kaduphil@gmail.com

.

Abstract
The study was on the analysis of cassava marketing in Ivo LG of Ebonyi State, Nigeria. Data were collected from randomly sample of 80 cassava marketers in the area, using a structured questionnaire. The study revealed that most of the cassava marketers had a secondary education (67.9%). The investigation also revealed that marketing of cassava is mostly undertaken by females (82%). The result showed that married people (71.2%) were primarily involved in the marketing of cassava. The study revealed that cassava marketing is operated in a competitive market environment and the marketing margin obtained by an average cassava marketer is 31%. Cassava marketing is a profitable venture in the study area. It was also revealed that a higher percentage of cassava traded in the study area was primarily obtained from the farmers. Majority of the respondents (72.5%) do not belong to the cassava marketing association. Transaction cost ((-4.727) and Marketing Experience (4.010) of cassava marketer in the Ivo L G A were statistically significant at varied probability levels. More specifically gender and Transaction cost were negative and highly significant at the 1% level of probability. This implies more female in the trade will lead to a corresponding decrease in transaction cost. This conforms with a prior expectation that household activities make the women to have less attention to the trade and the bulky nature of the trade will lead to a decrease in market efficiency. Transaction cost was negative and significant at 10% level of probability. This implies that any increase in transaction cost will decrease marketing efficiency. The study calls for policies that will assist marketers in reducing transaction costs through the provision of infrastructures.
Keywords: Cassava and Marketing

Introduction
Cassava (Manihotesculenta) is an important food crop in the tropics.It is a significant carbohydrate staple. According to FAO, the tropical root crop cassava is the third most important source of calories in the tropics, after rice and corn (FAO 2002). The use of cassava as a source of ethanol for fuel, energy in animal feed, and starch for the industry is increasing (Kolawole and Agbetoye (2007); Kehinde (2006). As a food crop, cassava is grown in all the agro-ecological zones of Nigeria (Graffham *et al.* 1998). Fresh cassava does not store well because of its high moisture content. Therefore cassava is usually processed traditionally to obtain different relatively shelf stable intermediate and final products for various food applications. These products include "*gari*", a roasted, fermented cassava meal, "*agbelima*" which is a fermented cassava mash, and the dried cassava chips known as "*kokonte*" which is further processed into cassava flour. *Tapioca* is a minor product or by-product from cassava processing. For industrial use, cassava is processed to obtain *starch*. Cassava can be used as a feed ingredient for animals such as cattle, pigs, poultry, sheep, goats, and fish. While the majority of cattle and small ruminants still rely extensively on grazing, the poultry and pig industry have been identified as significant potential markets for dried cassava as a raw material for feeds. In particular, it is estimated that layer hens absorb about 80 – 90% of animal feed specific, rations in Nigeria. The broiler sub-sector is relatively small mainly due to overseas imports of poultry meat. The bulk of the poultry feed is mixed on-farm by medium to large-scale farmers, with commercial feed millers often supplying feed concentrates. Cassava is an extremely

vital crop, not only in the domestic market but also to the export market. Domestically, it is not just a primary source of income, but it is a stable crop vital to food security. (Bolarinwa and. Oladeji, 2009) The Objectives of the study are to Analyze the Cassava Marketing in Ivo Local Government Area of Ebonyi State, Nigeria and Identify determinants of transaction costs

Methodology

The study was carried out in Ebonyi State. The study covered one out of the three agricultural zones in Ebonyi state. Multistage random sampling technique was used in the selection of Agricultural zones and respondents. One local government area was randomly selected from the agricultural chosen zones. Two markets were randomly selected from each L G A. The markets chosen were: Nkwogbo market in Umuogbo and Orie Akaeze Ukwu in Akaeze Ukwu. Forty cassava marketers were chosen randomly from each chosen market. This gave a total number of 80 cassava marketers. The primary data were collected with structured questionnaire. The data collected were analysed using descriptive statistics such as frequency, and multiple regression model

Results and Discussion

Table.1 shows that more females (82.0%) participated in cassava marketing than males (18.0%) in the study area. Also, the result indicates that the majority of cassava marketers are relatively young individuals (45%) who are in their youthful age (34-43 years). The result indicates that transaction and participation in cassava marketing were dominated by married people (71.0%). This implies that the trade is a source of income to many families from which they meet their basic needs. The result reveals that majority of the respondents (46.0%) had household sizes of 5-8 persons and 93 .34% of the cassava marketers had one form of education or another while 6.66% had no formal education. This shows that literacy level was high amongst them and could enhance marketing technology. The level of education was identified to increase the marketing efficiency and the marketing techniques and this was in line with the findings of Obasi, (1991).

Factors Influencing Transaction Costs of cassava Marketers:

In analysing the factors that influenced the transaction costs incurred by cassava marketers in the study area regression model was used. The result of the analysis for the cassava marketers is presented in Table 2; the double log function was selected as the lead equation based on the R^2 value which is high at 73% and the number of explanatory variables that was significant. The coefficients of Gender (-4.315), Age (1.635), Transaction cost ((-4.727) and Marketing Experience (4.010) of cassava marketer in the Ivo L G A were statistically significant at varied probability levels. More specifically gender and Transaction cost were negative and highly significant at the 1% level of probability. This implies more female in the trade will lead to a corresponding decrease in transaction cost. This conforms with a prior expectation that household activities attached to them and the bulky nature of the trade will lead to a decrease in market efficiency. Transaction cost was negative and significant at 10% level of probability. This implies that any increase in transaction cost will decrease marketing efficiency. This is in agreement with aprior expectation cassava is bulky in enormous nature cost is involved in moving the product from one point to other The coefficient for Age, and marketing experience was positive and significant at 1% and 10% levels of probability respectively. This implies that with an increase in age, the marketing efficiency will increase because the aged ones have been in trade; they know the market techniques and market strategies and perform better than their younger canter parts. Also the more experience the marketer, the better.

Table 1: Social Economic Characteristics of the cassava Marketers

Dependent variable = Marketing Efficiency in Naira

Conclusion

This study revealed that the trade is gender sensitive and needs serious strength. The transaction costs and marketing of cassava could be improved by reliable information and government provision of basic infrastructures as this will facilitate faster delivery of cassava and ensure marketing efficiency.

Abstract
Food insecurity is lack of enough and timely access to enough quantity of qualitative food at all times through an acceptable means. This study investigated the factors that influence choices of coping strategies in militating against food inadequacy among irrigation farming households under the Sokoto Rima River Basin Authority. Using a two-stage sampling procedure, 240 households were selected from who information were collected using a well designed questionnaire. The data collected was analyzed using descriptive statistics and OLS. Reducing the quantity of food consumed is the most used coping strategy and 21% and 42% of the households were moderately food insecure and severely food insecure respectively. Farm size and education were found to influence the choice of coping strategies at 5% and 10% level of significance respectively. The study recommends that the households increase their hectrage of irrigation farming cultivation and continue to encourage higher levels of education as these give them a better chance to withstand the effect of food insecurity
Keywords: Socioeconomic, food, Insecurity, Coping and Strategies

Introduction
The term food insecurity refers to lack of access to enough food. According to Lemma and Wondimagegn (2014), food insecurity is the absence of food to everyone at all times which is nutritionally adequate food (in terms of quality, quantity and variety) through a means that is acceptable within the given culture. The majorities of the world's poor and food insecure people live in rural area and they are directly or indirectly dependent on agriculture for their livelihoods. The likelihood of food insecurity is influenced by household level conditions such as education, harvests, health, assets and expenses as well as by regional level conditions such as infrastructure, markets, enabling institutions and conflict or disasters (International Fund for Africa Development, IFAD, 2011). Coping strategies are means by which households survive in the face of food insecurity. Coping strategies according to Snel and Staring (2001) involves a conscious assessment of alternative plans of action. When the quantity of food available to households dwindle, they device means to survive. Previous studies like Olagunju, Oke, Babatunde, and Ajiboye (2012), Abimbola and Kayode, (2013); Ibrahim, H.Y., Adeola, S.S. and Ibrahim, H.I. (2016) have looked at the factors influencing the food insecurity of different household groups however, this study looked into the factors that influences the choice of the food insecurity coping strategies of the households.

Methodology
The North-Western Nigeria is a region comprising of seven states namely: Kano, Jigawa, Katsina, Kaduna, Zamfara, Kabi and Sokoto. There are various irrigation projects across the region. One if the irrigation projects is under the Sokoto Rima River Basin Development Authority. For this study, a Two-stage sampling procedure was used in selecting the households used. In the first stage, four states of the states where the Sokoto Rima River Basins are located were purposively selected (Sokoto, Katsina, Zamfara and Kano). In the second stage, using a random selection based on a

proportionality factor according to Ibrahim (2011), 240 households engaging in irrigation farming were selected for the study. A structured questionnaire was used to collect useful information that was analyzed using descriptive statistics and ordinary least square (OLS) regression. The regression equation is given as: $Y = B_0 + B_1X_1 + B_2X_2 + B_3X_3 + B_4X_4 + \cdots + B_{10}X_{10} + \varepsilon$ where B_1-B_{10} are the coefficients of the socio-economic variables in the model; X_1=farm size (ha), X_2=household size (number of dependants), X_3=Years of irrigation farming experience, X_4=distance of farm from home(Km), X_5=distance of home from markets (Km), X_6=dependency ratio, X_7=volume of credit accessed for irrigation farming (₦), X_8=Years of formal education, X_9=Age of household head (Years), X_{10}=number of extension contacts per season of irrigation farming and $\varepsilon = error\ term$. Y=the coping strategy Index Score (whole numbers) generated by the summation of the frequencies of use of each strategy multiply by its severity.

Results and Discussion

Coping strategies adopted by irrigation farming households

In order to survive the challenges of household food insecurity, households adopt various kinds of coping strategies. The irrigation farming households studies in the North-Western Nigeria are not left out. Table 1 below shows the various strategies adopted by the households. The most commonly adopted of the strategies are reducing the quantity of food consumed, eating less preferred meals and consuming seed stocks held for next season as being practiced by 74%, 70% and 67% of the households respectively. Furthermore, the least adopted of the coping strategies include restricting adult consumption, gathering of wild fruits and sending members to eat elsewhere as adopted by 23%, 35% and 35% respectively. It should be noted that because household members adopt more than one strategy at a time, the percentage summation is more than 100% due to multiple responses. A study in Katsina by Ibrahim, Adeola and Ibrahim (2016) revealed that gathering of wild fruits is the most used. The strategy adopted depends on a number of factors chief among is if it is acceptable culturally and not derogatory.

Table 1:Coping strategies adopted by irrigation farming households

Strategies	*Frequencies	*Percentage
Skipping of meals	90	37
Eating less preferred meals	169	70
Begging for food	49	20
Food rationing or reducing number of meals	147	61
Borrowing of food	99	41
Purchase food on credit	133	55
Reducing the quantity of food consumed	178	74
Restrict consumption by adults to enable children eat	56	23
Consume seed stock held for next season	162	67
Send household members to eat elsewhere	84	35
Gather wild food (Fruits)	84	35

*Multiple responses were allowed.

Distribution of households based on their Coping Strategies Index (CSI) Scores

The Table 2 below presents the distributions of the households studied based on their CSI score. The scores of a household also categorized it into a food security status (as shown on the table also). Those with CSI score of between 0 and 2 are considered to be food secured because they use very minimal or none of the coping strategies. The implication of this is that they were food secured and therefore has nothing to cope with. About 22% of the households are in this category. This also means that a good majority of 78% are in various levels of food insecure categories. Majority (42%) of the households are within the Severely Food Insecure categories. They are the households that have CSI score of more than 30. They are the categories that use a higher percentage of the Coping strategies and more frequently per week. The other categories are those with CSI scores of between 3-15 and 16-30. They are the Less food Insecure (15%) and the Moderately Food Secure (21%) categories respectively. These are higher than the findings of Ibrahim, Adeola and Ibrahim (2016). The volume of those within the Food Insecure categories emphasized the relevance of the coping strategies studies and the factors that influence it.

Table 2: Distribution of households based on their Coping Strategies Index (CSI) Scores

CSI scores	Food Security Status	Frequency	Percentage
0	Food Secured	53	22
1-15	Less Food Insecure	36	15
16-30	Moderately Food Insecure	50	21
>30	Severely Food Insecure	101	42
Total		**240**	**100**

Socio-Economic Factors Influencing Food Insecurity Coping Strategies

Table 3 presents the OLS result of the factors influencing the Food Insecurity Coping Strategies among the households studied. The R^2 is 19% implying that the independent variables captured explained 19% of the variation that occurred in the dependent variable. This is possible because there will be many other factors that could not be captured that affects the coping strategies adopted by the households. The F statistics however is significant at 1% level ($p<0.01$) implying that the independent variables captured improved the model. Out of the ten (10) variables captured in the model, about six (6) were significant at various level of significance. The size of farm cultivated by the household was significant at 10% and has a positive sign. This means that it is an important factor in determining how the households cope with food insecurity and that as the size of farm increases, the households have a better ground to cope with food insecurity. Gama, Folorunso and Adeola (2015) established that farm size positively influenced output. This is in line with the *apriori* expectation because; all things being equal, larger size of cultivated farms should translate to more output and better food security level for the households. The distance from home to the farm is significant at 5% level but positive. However, the distance from the market to the homes is negative and significant at 1% level. The negative sign implies that as the distance between the residences of the farmers reduces, they have better ability to cope with food insecurity. This probably might be due to the fact that households buy food on credit (as a coping strategy) and therefore the closer to the source of buying the cheaper(in terms of transportation cost) and more accessible the food becomes (on credit). Furthermore, the result reveals that the level of education of the household heads had a significant impact on the coping strategies adopted. It is significant at 10% and is positively related implying that higher level of education affords better chances of food security coping strategies among the households studied. Similarly, the number of extension contacts the farmers had is significant at 5% and positively related. This is what will be expected as extension trainings will aT ford the farmers of making better choices to handle food insecurity challenges. Although the variable of the amount of credit received per season is significant at 5% it is negatively related with the coping strategies implying that as the volume of credit received increases, the households are likely to have weaker chances to survive. This is contrary to *apriori*expectations. However, this might be possible if the numbers of the farmers that have access to credit are not much.

Conclusion and Recommendation

From the findings of this study, it is concluded that the irrigation farming households under the Sokoto Rima River Basin Authority are food insecure but uses various coping strategies to survive. The study recommends that the households increase their hectrage of irrigation farming cultivation and continue to encourage higher levels of education as these give them a better chance to withstand the effect of food insecurity

Abstract
This study analyzed the utilization of orange fleshed sweet potato (OFSP) among rural households in Abia State, Nigeria .Orange fleshed sweet potato is rich in Vitamin A and serves as a staple food in Nigeria. The study identified the rural household reason for utilization of OFSP in the study area, the factors influencing rural household's level of utilization of OFSP in the study area and identified the rural household constraints in utilization of OFSP in the study area. Data for the study was collected from 72 rural households through a multi-stage sampling techniques using well structured and validated questionnaire. Results on the level of utilization revealed that the rural households frequently utilized orange fleshed sweet potatoes as; food; source of Vitamin A for deficient patients and as fortification of Vitamin A for children. The results of the socio-economic characteristic of rural household influencing the level of utilization of OFSP in the study area showed that the coefficient of age and sex were significant at 5% while the coefficient of household size and level of education were significant at 1%.. Analysis of factors constraining the rural households in utilizing OFSP showed that unavailability of OFSP (37.5%), inadequate income (36.11%) and inadequate information about the nutritive benefits of OFSP (36.11%) were identified by the respondents as constraints faced in their utilization of orange fleshed sweet potatoes in the area. The study recommended that policy makers, extension agents, research institutes and Non-governmental Organizations should create adequate awareness about Orange fleshed sweet potato in rural areas through community- level education programs that will emphasize the needs of vitamin A especially for children and women.
***Keywords**: Utilization, Orange fleshed sweetpotato, rural households.*

Introduction
Orange Fleshed Sweetpotato (OFSP) is a special type of biofortified sweet potato that contains high levels of Beta-Carotene. Beta-Carotene is an organic pigment abundant in plants and fruits and it is converted to Vitamin A in the body after consumption to provide nutritional benefits. OFSP is a staple food in Nigeria and can serve as a cheap and sustainable source of Vitamin A for the vulnerable population (especially children and pregnant women in rural areas) (Maru, 2017). The OFSP was primarily introduced in Nigeria as part of an integrated approach to mitigate Vitamin A deficiency, which affects about 70% of children under age 5, and 11% of women living in rural areas (International Institute of Tropical Agriculture, 2016) and was recently introduced in Abia State in 2016 by National Root Crop Research Institute Umudike. According to Ezeano (2006), the low usage of sweet potato technologies by rural household were attributable to the newness of the crop, its technologies, poor knowledge of the use of the technologies, lack of finance to purchase the inputs and low extension agent-farmer/consumer ratio predominant in the study area. The sweet potato has been utilized in so many ways such as a substitute for wheat in making of flour for bread, cake and other confectionary products (Henok, 2015). It also serves as livestock feed and can be dried to produce chips (Ojeniyi, 2001). Sweet potato can be boiled, fried or roasted and canned. The flour can be used as a substitute for wheat flour in bread making or maize flour in balanced feeds (Rabiu, 2015). Mostly in the rural areas, apart from the roots, the young leaves of

sweet potato serve as green vegetable for man, while the leaves and vines are cherished as fodder and hay by livestock (Olayinka, 2016). In spite of all these benefits of OFSP, rural household socio-economic characteristic that may influence their utilization of OFSP in the study area was relatively unknown. Moreover, the rural household level of awareness on the OFSP is not even known in the area.
While the benefits of OFSP are too many, there exists an on-going debate regarding whether or not households would perceive these benefit and utilize it.The specific objectives were to; identified the socio-economic characteristic of rural households in the study areas; described the rural household reason for utilization of OFSP in the study area; determine the factors influencing rural household's level of utilization of OFSP in the study area and identified the rural household constraints in utilization of OFSP in the study area.

Methodology

The study was carried-out in Abia State, Nigeria. Abia State is in the southeast zone of Nigeria. The study used multi-stage sampling technique in the selection of the respondents for the study. Three agricultural zones of the state were covered in the study. Two local government Areas (LGAs) were randomly selected from each of the zones of the state. Two rural autonomous communities were purposively selected from each of the selected LGAs. This made up to twelve communities. Finally, the list of households in the communities which formed the sample frame was obtained from the community leaders and from the list; six households were randomly selected from each of the communities making it a total sample frame of 72 respondents.

Results and Discussion

Analysis of the utilization of orange fleshed sweet potato (OFSP) among rural households in Abia State, Nigeria. The study revealed that about 44.44% of the respondents identified their reasons for utilization of OFSP as the richness of the Vitamin A content. Results on the level of utilization revealed that the rural households frequently utilized orange fleshed sweet potatoes as; food; source of Vitamin A for deficient patients and as fortification of Vitamin A for children. The results of the socio-economic characteristic of rural household influencing the level of utilization of OFSP in the study area showed that the coefficient of age and sex were significant at 5% while the coefficient of household size and level of education were significant at 1%.. Analysis of factors constraining the rural households in utilizing OFSP showed that unavailability of OFSP (37.5%), inadequate income (36.11%) and inadequate information about the nutritive benefits of OFSP (36.11%) were identified by the respondents as constraints faced in their utilization of orange fleshed sweet potatoes in the area. Table 1 show the results of analysis of the perceived factors influencing rural household's level of utilization of orange fleshed sweet potatoes in the study area.

Table 1: Distribution of respondents on reason for utilizing OFSP

Conclusion and Recommendations

The utilization of Orange Fleshed Sweet Potato (OFSP) among rural households in Abia State, Nigeria, Reviled that rural households were aware of Orange fleshed sweet potatoes and utilized it for various reasons, especially as a source of Vitamin A fortification in food. The National Root Crop Research Institute at Umudike (NRCRI) bulletin was a good source of information about Orange fleshed sweet potato. The study recommends that Extension agents should educate rural households on the nutritive benefits of Orange fleshed sweet potatoes and the various ways it can be utilized and also encourage farmers to utilize the orange fleshed sweet potato technology and increase their production to ensure all year round availability

Socioeconomic Factors Influencing Production of Cocoyam among Farmers in Ikwuano Local Government, Abia State, Nigeria

Igbojionu , I. C. Kadurumba, & F.N. Nwakor
National Root Crops Research Institute Umudike, Abia State, Nigeria.
Email;*innocentigbojionu@gmail.com*

Abstract
This study focused on the socio economic determinants of cocoyam production among farmers in ikwuano local government area Abia state. Data for the study were collected from 90 cocoyam farmers with the means of well structured questionnaire from the six communities in Ikwuano LGA. Data were analyzed by means of descriptive statistics such as frequency distribution tables, percentages and means. Ordinary least square regression analysis was used to analysis the determinants of cocoyam production. The results showed that Cocoyam farmers in the area had mean age of 54 years of which majority (70%) were males, with an average of 30 years of farming experience. The result of the regression analysis showed that five out of the eight explainable variables were significance these include gender, household size, farming experience and land ownership status of the farmers. Sex of the household head significantly and negatively affected output of cocoyam at 5%. Based on the result it is recommended that policies aimed at encouraging the women to go into cocoyam production becomes .
Keywords; Socio economic, Factors, Influencing, Cocoyam, Production, Farmers

Introduction
In Nigeria, the importance of cocoyam cannot be over emphasized, based on the vital role it plays in human nutrition, income generation and source of employment especially among the rural dwellers One of the major constraints is the low fertility status of most of the soil causing the crop to winter due to organic matter and nutrient status of the soil. According to Asumade and Tetteh (2013), cocoyam like any other root and tuber crops is a heavy feeder exploiting greater volume of soil for nutrients and water. There is a need to encourage rural farmers in the cultivation of cocoyam in order to meet the demand for cocoyam and for increase food production. The cultivation of cocoyam is declining. there is need to increase its production because cocoyam is going extinct in most farm lands and markets and can only be seen in few cultivated lands (Okorji and Eze, 2003).Farmers need to be encouraged to continue/promote cocoyam production and making them available in Nigeria market. Most farmers hold on to traditional farming methods of depending on household manure instead of using fertilizer due to unavailable credit facilities and these effects grossly the output of cocoyam. The following constraints have been reported by researchers on Cocoyam production among farmers. Lack of government support, Ineffective extension service, Low demand for the crop, Lack of ready market. , Diseases and pest in the field, Low soil facilities. Labour shortage, Scarcity of organic manure, Rot and decay during storage. Cocoyam is almost going extinct in our farms and markets and there is need for its sustainable production, it becomes pertinent to investigate the socio-economic factors affecting cocoyam farmers in Ikwuano Local Government. This study will serve as a basis for information to the farmers on cocoyam profitability which is expected to drive increased cultivation of the crop

Objectives of the study
i. describe the socio economic characteristics of the respondents;
ii. determine the factors influencing cocoyam production output

Methodology

Multistage random sampling technique was used in selecting the respondents. Two communities were randomly selected from each of the six communities in Ikwuano Local Government Area. With the assistance of key informants, the list and location of cocoyam farmers in each of communities were compiled from which the sample for the study was drawn. Fifteen (15) farmers were sampled from each of the six communities across the State totaling 90 cocoyam farmers in all. Structured questioner was used for data collection. This focus mainly on socio-economic characteristics of the farmers, output of cocoyam in tons, cropping system and constraints militating against cocoyam farmers in the study area. The data for the study were collected in June 2015. The data collected were analyzed using descriptive statistics, Ordinary Least Squares regression analysis

The following is the implicit of the model:

$Y = (x_1, x_2, x_3, x_4 \ldots\ldots\ldots x_n)$ where y = output of cocoyam (in tons).

X_1 = Age of the farmers (in years).

X_2 = sex (gender) of the household head (male = 1, female = 0).

X_3 = household size (in number).

X_4 = years of education of the household head (in years).

X_5 = farm size (in hectares).

X_6 = farming experience of the household head (in years).

X_7 = land ownership status (owned = 1, otherwise = 0).

X_8 = membership of cooperative (1 = yes, 0 = No).

e = Random error term.

Result and Discussion

Majority (62%) of the respondents were aged between 41 -60 years, about 11% fell within 20-40 years; while 27% of the respondents were above 60 years of age , majority (69%) of the farmers were female while 31% were males. This is not an indication that men were less involved in cocoyam production. About 30% of the respondents had no formal education while majority (41%) had Primary education. Majority of the respondents (60%) had household sizes ranging from 6-10 persons; about 32% of the had between 1-5 persons while 8% fell within the size of 11-15 persons. 30% of the respondents had between 10-20 years, while 29% had between 21-30 years of farming experience. 24% of the farmers have 31-4 years farming experience,

Table 2 presents the results of the regression analysis and its shows that the linear functional form had the best fit, based on the values of R2 (0.93), level of significance of explanatory variables and their signs. The f-value of (131.646) indicated that the overall equation was significant at ($p<0.01$) while Durbin-Watson (DW) of 1.996, showed the absence of autocorrelation. Out of the eight explanatory variables specified, five were statistically significant; these were sex, household size, farm size, years of farming experience, and land ownership status of the farmers. Sex of the household head significantly and negatively affected output of cocoyam at ($p<0.01$).

Conclusion and Recommendation

In Nigeria, the importance of cocoyam is indispensible, based on the vital role it plays in human nutrition, income generation and as source of employment especially among the rural farmers. Sex of the household head significantly and negatively affected output of cocoyam at ($p<0.05$)

Recommendations

1.The result therefore calls for policies aimed at provision of free education especially to the girl child and encourage those who are experience to study the production and increase adoption of cocoyam technologies.

2. There is therefore need for government policies towards encouraging the female farmers who are younger more active and agile to increase Production. .

Assessment of Certified Cassava Seed Flow among Farmers In North Central Nigeria

M.H. Tokula, C.N.Egesi, A.O. Olojede and G.N. Asumugha
National Root Crops Research Institute Umudike

Abstract

Nigeria was initiated to bring about commercialization of cassava cuttings and link buyers to producers of certified cassava seeds in the area. The study was conducted using interview schedule, focused group discussion, Phone interviews The development of cassava seed certification and flow through cluster formation among farmers in North central and interaction among cassava seed entrepreneurs and other farmer groups and individuals identified as cassava seed out growers. Two Hundred Respondents were identified and selected through their participation in farmer groups; attendance and participation in Training organized for commercial cassava stem producers and recruited Village seed entrepreneurs (VSEs). Results showed that thirty demonstration plots were established to popularize seed certification among sixteen communities in Benue State. 12000 bundles of certified seeds were sold to five different locations two hundred farmers were trained in ten locations. The results revealed that the Major constraints farmers encountered were uncertainty of market as indicated by 80% of the respondents., improved varieties were sourced largely from fellow farmers while foundation seed was sourced principally from National Root Crops Research Institute (NRCRI) and International Institute for Tropical agriculture (IITA) and development partners such as Catholic Relieve Services (CRS), and also members of cooperatives or ADP contact farmers.

Keywords: Assessment, and Certified Cassava Seed

Introduction

Cassava seed Certification is a recent development in cassava production in the evolving cassava seed system which is hitherto largely informal in Nigeria. Cassava farmers are known to source their planting materials by recycling from their previous fields and also depend on informal cassava cuttings exchange with their neighbors for cassava production with little or no commercial value attached. Consideration was never given to genetic purity and maintenance of standard to prevent mixture of varieties. According to Erker and Brick(2018) Seed certification maintains a pedigree on seed of a specific variety, once a superior variety of seed is developed, painstaking effort must be taken to keep it pure and produce it in large quantities for use. Seeds are basic and critical input for enhancing agricultural production and productivity. The seeds which seeds companies sell in the market and our farmers grow are commonly "certified seeds". The certification of seeds is a legally sanctioned system for quality control of seeds that are used to cultivate crops. The certified seeds are grown under stringent production requirements and they have improved traits such as better yield, pest resistance, drought tolerance, and herbicide tolerance. Agrinfo (2015).The benefits of using quality foundation seeds includes: Genetic purity (true to type). The good quality seed has high return per unit area as the genetic potentiality of the crop can be fully exploited. Seeds are basic and critical input for enhancing agricultural production and productivity. The certified seeds are outcome of few years of research and development to get these improved traits. This R&D is done on their parent plants. On this basis, there are five different categories viz. Nucleus Seeds, Breeder Seeds, Foundation Seeds, Registered Seeds and finally certified seeds. The foundation seed shall be the progeny of the breeder seed, or it can be produced from foundation seed clearly traceable to the breeder seed. Foundation seed is seed so designated by an agriculture experiment station. Its production must be carefully supervised or approved by representatives of an agricultural experiment station. It is the source of all other certified seed classes, either directly or through registered seeds. Breeder seed is used for the production of foundation seed. Foundation seed can be multiplied to meet demands, but should be clearly traced from the breeder seed. Field observations should be made during the entire growing season to monitor the crop under field conditions. Rouging operation should be done carefully from vegetative to maturity stages to remove all possible mixtures. Foundation seed must be certified by a Seed Certification Agency (NSC).

Recent innovation in the seed system has brought about the development of the large scale commercial seed sharing arrangement leading to farmer cluster formation and the emergence of cassava out growers.

The seeds from off springs with best and desired quality are selected and certified as Breeder seeds. Such seeds are protected by legal rights called as Breeder's rights. The Breeder seed is further multiplied into the foundation and certified seeds.

Methodology

The study was conducted using interview schedule, focused group discussion, Phone interviews and interaction among cassava seed entrepreneurs and other farmer groups and individuals identified as cassava seed out growers. Two Hundred Respondents were identified and selected through their participation in farmer groups, registration as large scale cassava producers, attendance and participation in Training organized forcommercial cassava stem producers and recruited Village seed entrepreneurs (VSEs).

Results and Discussion

Results in Table 1 showed that thirty demonstration plots were established to popularize seed certification among sixteen communities in Benue State. 12000 bundles of certified seeds was sold to five different locations two hundred farmers were trained in ten locations. Fig.1 showed certified seed distribution from Benue to various states with the peak of 15000 Bundles circulating in Benue State.

Fig 2 revealed that the Major constraints farmers encountered was uncertainty of market as indicated by 80% of the respondents. This is followed by low knowledge of certification guidelines and scarcity of foundation seeds indicated by 75 and 70% the respondents respectively. Fig. 3 showed that improved varieties are sourced largely from fellow farmers while foundation seed was sourced principally from NRCRI and IITA.

Profitability Status of Cassava Entrepreneurs in Abia State

C.A .Kalu
National Root Crops Research Institute Umudike
Corresponding author Email: c.kalu@nrcri.gov.ng, confidence.kalu@gmail.com

Abstract

The study examined the profitability status of cassava farmers in Abia state. A multistage sampling technique was used to elicit information from 120 respondents with the help of well-structured questionnaire on socioeconomic characteristics and other relevant variables for the study. Both descriptive and net income analysis were used to analyse the data. Results showed that majority of the respondents were between the 41-50 years and greater percent were females(64%), most of the respondents(81%) have formal education, with 7 years and above farming experience . having a family size of 4-9 (80%) people and operating on a farm holding of less than 3 ha. Gross margin result indicated that farmers obtained a net return of 145,604.07 per ha with a benefit cost ratio of 1.35kobo. It was therefore recommended that male farmers most especially the younger ones be encouraged by creating more enabling environment in other to embrace farming as business
***Key words**: socio economic, profitability and cassava*

Introduction

Cassava (*ManihotEsculentuz*Crantz) is an important root crop in Nigeria. Nigeria is the largest producer of cassava in the world. Currently, production of cassava is put at about 34 metric tons. Cassava serves as food for man as well as in feeding livestock animals. Man consumes over two thirds of the total production of cassava roots in various forms and the remainder is used as animal feed. The starchy, thickened storage roots are valuable source of inexpensive calories (Awoyinka, 2009). Cassava roots are consumed raw, boiled or processed into cassava flour which is used in many industries. Leaves are used as vegetable and can be harvested periodically throughout the growing season (Nwaiwu et al, 2010). As a result of its use as an industrial crop, cassava has been categorized as a cash crop. Cassava as an important crop with huge potential and has gained the attention through the launching of "Presidential Initiative on Cassava Production in Nigeria" which was inaugurated with the aim of achieving on annual basis five billion dollars from export of cassava. In spite of the various uses cassava is known for, as an agent of self-sufficiency in food production, the gain derived from its production by rural farmers is still not sufficient to keep the resource poor farmers above poverty line. The socio economic characteristics and resources of individual households have been identified as basic factors influencing the food security status of households (Sanusi et al).When the returns from agricultural production is not be equated to the investment, agricultural production will be left in the hands of the elderly or the non-educated ones who cannot make decision. Efforts aimed at increasing cassava output to meet the demand for the output to meet the demand for output cannot be properly directed unless the costs and returns of cassava production are determined. For cassava production to attain its potential in area of ensuring food security, is important that the socio economic conditions of cassava producers must be known and their profitability be examined. It is to this end that this paper aims at examining the socio economic characteristics and their profitability status of cassava farmers in Abia state, Nigeria. The specific objectives of the study were to; examine the socio economic characteristics of cassava farmers in the study area; determine their profitability status of farmers in the study area.

Methodology

Study area

The study was carried out in Abia state, Nigeria. Abia State is located in the South East geopolitical zone of Nigeria. It has three senatorial zones namely: Abia North, Abia South and Abia Central with seventeen local Government Areas. The climate of the state is tropical one, having rainy and dry seasons. Farming and trading are major occupations of the people.

Sampling technique

The Study adopted multi-stage sampling technique in selecting respondent. The first stage involved the purposive selection of six (6) local government areas from seventeen local government areas of the state. Secondly, four (4) communities will be randomly selected from each of the selected local Government area, five (5) cassava farmers will be randomly selected from each the selected communities, given us a total of 120 respondents.

Analytical techniques Objective (i) which is to examine the socio-economic characteristics of the respondents in the study areas was analyzed with descriptive statistic such as frequencies, means and percentages; objective (ii) which is to estimate the cost-return ratio of cassava farmers in the study area was analysed using Net income analysis.

Specifications of model

For objective (ii) which is estimate the cost-return ratio of cassava farmers in the study area was be analysed with Net income analysis. This is stated as;

NI = TR – TC

Where;

NI = Net income

TR = Total returns

TC = Total cost

Results and Discussion

The socio economic characteristics of the respondents in table 1 showed that majority of the respondent (25.83) were between the ages of 41-50 years. About 20.83% of the respondents were between 31-40 years. This shows that majority of farmers were still active. Age is said to be a primary latent characteristic of adoption decisions.(Bonabona-Walhi, 2002; Nwaru, 2004; Nwawusi et al., 2007 and Agwu and Anyaeche 2007) found out that the ability of a farmer to bear risk, be innovative decreases with age.

Table 1: Socio-Economic Characteristics of cassava farmers.

Age	Frequency	Percentage
<21	3	2.50
21-30	8	6.67
31-40	25	20.83
41-50	25	20.83
51-60	31	25.83
>60	28	23.33

2.0-2.9	57	47.50

Source: field survey 2016

The results show that 53.33% and 46.67% of the farmers were females and males respectively. This implies that women constitute a greater percentage of those involved in cassava cultivation in the state. This indicates that cassava production is not gender exclusive but is mostly carried out by the female folk.Findings from the study also showed that 22.50% of the respondent did not attain any form of formal schooling while most (34.17%) attained primary and secondary levels each. Educated farmers are expected to be more receptive to improved farming techniques. While farmers with low level of education or without education would be less receptive to improved farming techniques (Okoye et al., 2004 and Ajibefun and Aderinla, 2004).The results further showed that majority of the farmers were into full time farming while 40.00% were part time farmers. Full time farmers are expected to treat farming as business by applying improved farming practices and informed management decisions on their farms. The results show that majority (76.67%) of the farmers do not belong to any cooperative societies while 23.33% were members. Farmers who belong to cooperative societies are expected to access more fertilizer because of the present fertilizer policy where farmers are encouraged to form cooperative to enhance easy access to fertilizer. The result from table 1 showed that 38.33% and 30.83% had household size range of 4-6 and 7-9 persons. This shows that the study area is dominated by respondents with large households, Effiong (2005) and Idiong (2005) reported that a relatively large household size enhance the availability of labour. About 52.50% of the farmers had farming experience between 11-20 years while 9.17% had more than 30 years of farming experience. This implies that the farmers have long years of farming experience.About 35.83 % of the respondent had farm size of 1-1.9ha while majority (47.50%) of the farmers operate on farm holdings of about 2-3ha. This shows that they are smallholder farmers. Farm size affects adoption costs, risk perceptions, human capital, credit constraints, labour requirements, tenure arrangements and more. With small farms, it has been argued that large fixed costs become a constraint to technology adoption (Abara and Sing, 1993) especially if the technology is costly.

Cost and Returns Analysis of Cassava Production per hectare in the Study Area

The results in Table 2 showed the profitability analysis of cassava production in the study area. The results showed a total revenue of N567635.07 (N420,635.07 from cassava roots and147,000.00 from sale of stems).

The total variable costs generated was N419,451.00 and total fixed cost of N2, 490.00 A gross margin and profit estimates of N148,184.00 and N145,604.07 respectively were generated.

Table 2: Cost and returns analyses of cassava production in Abia State per hectare

Item	Qty	Price	Total
A-Revenue			
Roots	17,295.95	24.32	420,635.07

Total costs (B+C)			422,031.00
Gross margin (A-B)			148,184.00
Profit (A-B-C)			145,604.07
BCR = Revenue/TC			1.35:1.00

Source: Field survey, 2016

Conclusion and Recommendation

From the findings of the study, it was observed that majority of the farmers are active and young, that greater percent where female .It was therefore recommended that male farmers most especially the younger ones be encouraged by creating more enabling environment in other to embrace farming as business.The profitability analysis proofed that cassava farming is a profitable venture in the study area. It recorded a gross margin of 148,184.00 per ha. The benefit cost ratio shows that for every one naira invested in the enterprise, a profit of 1.35kobo will be realised.

Abstract
The study analyzed trends in farmers' accessed and repayment of Agricultural Guarantee Scheme Loan (ACGS) in Cross River State, Nigeria from 1977 to 2017. Time series data obtained from the Central Bank of Nigeria were analyzed using descriptive and regression techniques. The empirical results showed that accessed and repayments of ACGS loans were influenced both in short and long runs. Exponential growth rates of 2.60% and 14.96% were obtained for loan accessed and repaid respectively. The quadratic trend analysis showed that accessed of ACGS loans were increasing at a decelerating rate over a long period of time; while repayment became stagnated over a long period of time. The policy implication is that financial institutions became reluctant to participate in ACGS Fund in the State. This affected the level of adoption of agricultural innovation that drove modern farming practices. With the creation of the Commercial Agricultural Credit Scheme in the State in 2010, farmers moved to the State's loan window (whose financial was small,) to acquire credits for their productions thus abandoning defaulted loans to increase in value. It is recommended that efforts be geared toward narrowing the big gap between accessed loans and repayment which will encourage more banks to participate in the Scheme.
Keywords: Accessed, Repayment and Agricultural guarantee scheme loan

Introduction
The demand for food is increasing due to growing world population. It is a known fact that a strong and efficient agriculture sector has the potential not only to feed its population, create employment, and generate foreign exchange but also provide primary raw materials for industries. These have multiplier effects on all sectors of the economy. Globally, there has been increase demand to expand farm production in the last two decades than ever before 1980s. The main cause seemed to be associated with increased growth rate in population with alarming unemployment rates. In realization of the above situations, many polices, programmes, schemes/ projects and institutions have been established in many of the developing economies for the purpose of extending loans to farmers. In Nigeria for instance, the Government has established specialized schemes/funds and banks to channel loans to the agricultural sector of the economy. It is the realization of the core role which agricultural credit plays in agricultural economy and agribusinesses that large amount of funds have been committed to farmers and agro-entrepreneurs in the country through formal public credit schemes/institutions. These schemes are usually promoted by Government but financed and driven by the private sector. In facilitating increased availability of credits for agricultural production and encourage the banking system in extending loans and advances for agricultural purposes, the Federal Government of Nigeria widely adopted various strategies to remedy the challenges of financing agriculture through the establishment of specialized public credit institutions such as Nigerian Agricultural Cooperative and Rural Development Bank which later became Bank of Agriculture and the Agricultural Credit Guarantee Scheme Fund later (CBN, 2010). The Federal Government of Nigeria legally established the Agricultural Credit Guarantee Scheme Fund (ACGSF) in March 1977 with the Central Bank of Nigeria (CBN) as its Managing agent. According to the provisions of the ACGSF Act, the Fund commenced operation with an authorized capital of one hundred million naira, shared between

the Federal Government and CBN in the ratio of 60 to 40 percent. The authorized share capital subscription continued to increase over the years from an initial contribution of N85.50 million as at December, 1977 to N357.70 million as at 1998 and N4 billion as at 2006 (Umoren, 2008). The purpose of the Scheme/Fund is to encourage deposit money banks to lend to farmers for agricultural production by providing guarantee for loans granted by such banks for the purpose as enunciated in the ACGSF Act of 1977. Umoren, (2008) maintained that the cardinal purpose of ACGSF was to guarantee loans/advances to the banking sub-sector and minimize credit/lending risk. In recent time, not much effort has been focused on the analysis of trends in Accessed loans and repayment under Agricultural Credit Guarantee Scheme at the State level. Cross River State for instance is an agrarian State that has benefitted from the scheme for a long period of time. The study sought to provide answer to such question as 'what are the trends in ACGS loans/advances and repayments from 1978 to 2017 in Cross River State? Premised on above issue, the specifically analyzed the trend in accessed ACGS loans and repayments in Cross River State over a certain period of time space. The results from the study would provide a spring board for policy formulation by the regulator, participating financial institutions, farmers and other stakeholders in the agrarian economy.

Materials and Methods

Study Area, Data Source and Analytical Technique

The study was conducted in Cross River State, located in the southern region ofNigeria. It occupies land area of 20,150km (National Population Commission, 2006). Secondary data used in the study were collected from the statistical bulletins of the Central Bank of Nigeria (CBN). The study employed trend analysisand simple regression model to analyze data collected. The study period spanned from 1978 to 2017.

The trend Analysis of ACGS Loans Accessed and Repayment's Performance in Cross River State, Nigeria (1978 – 2017)

The study investigated the nature of exponential growth rate in accessed ACGS loans over time in Cross River State, Nigeria. An exponential trend equation was specified as thus:

$$log_e ACSLAD_t = b_0 + b_1 T + U_t \ldots\ldots\ldots\ldots (1)$$

Where:

'T' is the time e[illegible]d in year; $ACSLAD_t$ is the value of ACGS Loans accessed in Cross River State. $ACSRE_t$ represents ACGS loan repayments over time

$$log_e ACSRE_t = b_0 + b_1 T + U_t \ldots\ldots\ldots\ldots (2)$$

The exponential growth rate in ACGS loans ($ACSLAD_t$) is given as: (r) =$(e^{b1} - 1) * 100 \ldots\ldots\ldots (3)$

The trend equation and the exponential growth rate were estimated for Accessed ACGS loans and Repayment in Cross River State ($ACGRE_t$).T = Time expressed in year (i.e. 1, 2… 40) b_0 =intercept and U_t = error term.

The Quadratic trend equation

$$log_e ACSLAD_t = b_0 + b_1 T + b_2 T^2 + U_t \ldots\ldots\ldots\ldots (\mathbf{4})$$

This was inserted to test the impact of increase time on ACSRE and ACSLAD

ifb_2>0; then variable under investigation indicates accelerated growth rate whereas $b_2 < 0$ it indicates that variable under investigation has decelerated growth rate over time while b_2= 0 shows stagnation (Edet, Akpan and Patrick, 2014)

Results and Discussion

Table 1 shows the descriptive summary statistics for ACGS accessed loans and repayments during the study period. The mean values for accessed loan/advances guaranteed and repaid in Cross River State are N2418230 and N29428570 respectively. Furthermore, the maximum and minimum accessed and repaid N2,9579,000.00 and N246,000.00 respectively whereas maximum and minimum repaid loans were N137,190,000.00 and N288,800.00 respectively.

Table 1:Descriptive Summary of ACGS Accessed and Repaid Loan in Cross River State (1976-2017)

Descriptive statistics	ACSLAD	ACGLRE
Mean	24184.23	29428.37
Median	1560.900	4592.100
Maximum	295795.0	137190.0
Minimum	246.0000	288.8000
Std. Dev.	64611.17	38294.11
Skewness	3.358180	1.154666
Kurtosis	13.47577	3.155176
Observations	40	40

Source: Authors' computations 2018.

These statistics showed wide disparity between Accessed loans and repayment under ACGS in the study area. These might suggest poor behavioural capacity of beneficiaries in favour ofaccessed ACGS loan and repayment. It could also suggest poor farmers – banks relationship issues

Exponential linear trend equations for ACSLAD and ACGLRE

Tables 2 presents the results of estimated linear trend equations for ACGSaccessed and repaid loans in Cross River State during the study period. The result revealed that, both loan accessed and repaid varied directly with time. In other words, these variables increase as time increases. The exponential growth rates stood at 2.6% and 14.9% for loan accessed and repaid respectively. This means that, loan disbursement rate was far lower than the repayment rate. This could likely be attributed to the high rate of default among beneficiaries in the State. The structure and the working mechanism of the ACGS could also be responsible for this conspicuous difference in the growth rates of the ACGS accessed loan and repayment during the study period.

Quadratic trend equations for ACSLAD and ACGLRE

The result for the quadratic trend equation for ACGS loan accessed and repayment is shown in Table 3. The coefficient of time squared for loan access is significant and is negatively signed. This implies that, accessed ACGS loans in Cross River State were increasing at a decelerating growth rate over a long period of time. In other words, the volume of loan disbursed by ACGS in the State did not sufficiently or efficiently match the demand within the period of study. On the other hand, the coefficient of time Squared in ACGS repayment equation was positive and insignificant. This implied that, loan repayment over a long period of time was stagnated in the State and perhaps it impedes accessibility.

Therefore, dynamic Agricultural loan scheme/ programs as well as institutions must change over time to facilitate increased participation by the lending institutions and beneficiaries in Cross River State.

Figure 1 showed the pictorial trends in Agricultural Credit Guarantee Scheme accessed loans and repayment in Cross River State during the period of the study. The graph depicted a wide disparity between Accessed loans and repayment. This trend might have discouraged the participating financial institutions from granting more loans to farmers which would have greatly accelerated agricultural production in Cross River State from 2000-2006. The peak periods for ACGS loans accessed and repayments occurred around 2009 to 2010. This might have been associated with impact of interest drawback, a rebate package aimed at reducing effects high market driven interest rate on ACGS loan beneficiaries in the country. This might suggests that incentive-linked credit facility could improve loan repayments. This pushed more beneficiaries and operators to increase accessing loans and lending to the farmers respectively

Conclusion and Recommendations

The major findings from the study showed that accessed and repayments of ACGS loans exhibited accelerated trends within the year while over a long period of time the trend in accessed loan decelerated whereas repayments remains stagnated. There is a wide gap between value of accessed loan and loan repayment over time in Cross River State which might have suggested bylow participation among lending institutions and the beneficiaries over the years. Thus the awareness, strategies and guidelines of ACGSF might be too slow in catching up with the current development in financial market approaches in reaching out to farmers in Cross River State. These could be ascribed to high cost of lending and poor business environment coupled with poor incentives and awareness of the Scheme in Cross River Stare. It is suggested that incentive-linked credit facility could improve loan repayments. This could push more beneficiaries and operators to increase access loans and lending to the farmers and institutions respectively. Furthermore, it is also recommended that feasible incentives that would encourage inclusive –sustainable growth and participation be institutionalized by the Managing Agent of the Scheme.

A Review of Economic Importance and Efficiency of Cocoyam Production in Nigeria

Q.C. Uwandu. B.C, Okoye,. E. Amajor and M.E. Ejechi
National Root Crops Research Institute Umudike, Abia State, Nigeria
Corresponding Author: queenuwandu@gmil.com

Abstract
Cocoyam ranks third in importance and extent of production after yam and cassava in Nigeria. This can be expanded by emphasizing the need to market the crops in such a way as to maximize returns. Nigeria is the world's leading producers of cocoyam, accounting for up to 3.7 million metric tonnes annually. Given that cocoyam is an important staple food in Nigeria, any attempt to increase its productivity would be a right step towards the resolution of food crisis. The implication of the review is that efficiency in cocoyam production among the farmers could be increased through better use of available resources given the current state of technology.

Keywords: Cocoyam, Economics, Importance, Production and Nigeria.

Introduction
Agriculture has been an important sector in the Nigerian economy in the past decades and is still a major sector despite the oil boom. Basically, it provides employment opportunities for the teeming population, eradicates poverty and contributes to the growth of the economy. Despite these however, the sector is still characterized by low yields, low level of inputs and limited areas under cultivation (Izuchukwu, 2011). Root and tuber crops which are among the most important groups of staple foods in many tropical African countries constitutesthe largest source of calories for the Nigeria population . Cassava (*Manihotesculenta*) is the most important of these crops in terms of total production, followed by yam (*Dioscoreaspp*), cocoyam (*Colocasiaspp and Xanthosomaspp*) and sweet potato (*Ipomoea batatas*). Cocoyam (*Colocasiaesculenta*and *Xanthosomamafafa*) are important carbohydrate staple foods particularly in the southern and middle belt areas of Nigeria (Asumugha and Mbanaso, 2002). Nutritionally, cocoyam is superior to cassava and yam in the possession of higher protein, mineral and vitamin contents in addition to having more digestible starch. Cocoyam which ranks third in importance and extent of production after yam and cassava is of major economic value in Nigeria. Edible cocoyam cultivated in the country is essentially species of *Colocasiaspp* and *Xanthosomaspp*. The average production figure for Nigeria was 5,068,000mt which accounts for about 37% of total world output of cocoyam (Food and Agricultural Organization, 2011). Small scale farmers, especially women who operate within the subsistence economy grow most of the cocoyam in Nigeria. The surplus of the product is supplied to the market in the rapidly growing urban centres. The bulk of the production of cocoyam is in Southern Nigeria. According to them a large number of households grow cocoyam as a cash crop, selling at least half of their yearly production. As a food crop cocoyam tubers are eaten in homes in various forms. They can be boiled or roasted like yam. They can also be pounded or mixed with cassava and eaten with soup. Research on cocoyam has trailed behind that of other staples in Nigeria and other countries. Ezedinma (1987), Had earlier noted that the totality of published scientific work on cocoyam is insignificant when compared with those of rice, maize, yam and cassava. That was only in the last decade that policy makers and national agricultural research systems began to show systematic interest as a result of a number of technical, socio-economic and institutional constraints, which need to be addressed. This review is expected to provide valuable information on profitability and production efficiency of growing cocoyam to enable farmers consider its production as a viable option.

Cocoyam Production in Nigeria

Cocoyam production is available all the year round, making it preferable to yam, cassava, etc. It is more resistant to drought, pests and diseases and tolerance to a variety of climatic and soil conditions on the farm. It is one of the recognized crops in Nigeria. Apart from the tuber, other parts of the cocoyam plant are of domestic significance. For instance, the leaves and petioles may be cooked and eaten as a vegetable, taro *spp*is a valuable staple carbohydrate food, relatively easy and inexpensive to produce. It has become a staple food for most Nigerians, not only among rural people but also among the urban dwellers. Furthermore, its roots are storable in the ground for months after they mature. Where cocoyam production system aim to produce human food, animal feed or industrial raw materials, yield is not the only objective. A further qualification of the earlier simple objective is that money is often the ultimate product which is required from the system through the sale of the crop materials. Profit from the system and an adequate return on investment are important consideration. Efficiency in the use of financial resources in growing crops is an important factor. This can be expanded by emphasizing the need to market the crops in such a way as to maximize returns. As noted by Zubair and Hunter (2000), the cultivation of cocoyam is not encouraging as the yield per hectare is still low. One of the reasons for the low yield may not be unconnected to dismal and little attention farmers give to cocoyam when compared with cassava and yam that are close substitute root/tuber crops. For profit efficiency of cocoyam farmers to be increased, there is need for the qualitative extension services among farmers. Their performance and interest in this respect have to be rose. Cocoyam farmers can be helped to obtain high yield through introduction of modern and effective farm technologies and improved varieties by the extension services, which bring about expected result to the farmer.

Cocoyam Producing Countries

Cocoyam ranks third in importance after cassava and yam among the root and tuber crops cultivated and consumed in Nigeria (Udealor *et al*., 1996). Currently, Nigeria is the world's leading producer of cocoyam, accounting for up to 3.7 million metric tonnes annually (NRCRI, 2003). This accounted for about 40 percent of total world output of cocoyam (Eze and Okorji, 2003).

Table 1: Top ten cocoyam producing countries in the world

Rank	**Countries**	**Production(mt)**
1	Nigeria	32,657,440
2	China	1,702,367
3	Cameroun	1,490,000
4	Ghana	1,299,650
5	Madagascar	224,888
6	Papua New Guinea	222,916
7	Japan	171,928
8	Rwanda	168,521
9	Central Africa	122,719
10	Republic Philippine	110,718

Source: FAO (2011)

Conclusion

This review shows that cocoyam production in Nigeria is profitable .Given that cocoyam is an important staple food in Nigeria; any attempt to increase its productivity would be a right step towards the resolution of food crisis. This can be achieved through improved farmer-specific factors. These review call for policies aimed at encouraging new entrants especially the youths who are agile and stronger to grow cocoyam and the experienced ones to remain in farming.

Abstract
The study analyzed the cost and returns of dry season tomato production by small scale farmers in Onitsha Agricultural Zone of Anambra State, Nigeria. Eighty farmers were randomly selected for the study and data were analyzed, using descriptive analysis and profitability analysis. The results showed that the mean age of the farmers was 41 years, implying that they were in their active ages. The respondents were fairly educated as about 40 percent of them had secondary school education. The result of the profitability analysis revealed average gross margin and net income per hectare of N105,414.05 and N86,710.57 respectively. This indicated that dry season tomato production was a profitable venture in the study area. The analysis further identified inadequate farm credit, poor storage and processing facilities and inadequate extension services as the main problems faced by the farmers. The study therefore recommends that farmers should be encouraged to form cooperative societies so as to enable them obtain loans from commercial banks and agricultural banks at regulated interest rates. Government should provide efficient extension services in the study area by organizing workshop, training and make provisions to facilitate their work and provide adequate storage facilities.
Keywords : Cost, Dr season Tomato

Introduction
Tomato (Lycopersiconesculentum Mill.) is one of the most cultivated vegetable in most regions of the world, ranking second in importance in many countries (Ojo*et al.,* 2009). In Nigeria, an annual total area of one million hectares is reportedly used for its cultivation and it makes up about 18 percent of the average daily consumption of vegetables in Nigerian homes (Chidi, 2012). Nigeria is also ranked second largest producer of tomato in Africa and thirtieth largest in the world, producing 1.701 million tonnes of tomato annually at an average of 25-30 tonnes per hectare (FAO, 2010).Nwalieji *et al.* (2015) opined that both wet and dry season tomato cropping systems, contributes immensely to the national requirement; though bulk production is from the dry season cropping. The broad objective of the study therefore, was to analyze the cost and returns of dry season tomato production by small-scale farmers in Onitsha Agricultural Zone of Anambra State, Nigeria. In Nigeria, there are two distinct seasons, the rainy and dry seasons. The rainy season is the normal cropping season and starts from April and stops in October, while the dry season starts from November and ends in March. During the rainy season, the production of tomato is high; resulting in saturation of the market, but during the dry season, there is usually the scarcity of this important farm product, thereby leading to a high price due to short supply. This seasonality has resulted in food insecurity, which is a challenge to sustainable food production. There is therefore need to encourage dry season tomato cropping system so as to bridge the demand and supply gap. Dry season tomato production in Anambra State is done mainly in swampy (Fadama) areas along river banks. This activity is both an income earner as well as a source of employment to a large proportion of the populace or otherwise, underemployed labour force (Nwalieji *et al.,* 2015)
Tomato is perhaps the most important popular vegetable crop grown all over the country. Tomatoes are important in the daily meal preparation since it can be eaten raw or cooked. Larger quantities are used to produce soups, juice and sauces, ketchups, purees and paste. It can be used

in canning industries; green tomatoes are used for prickles and preserve. The seeds which are extracted from the pulp and its residues contain 24% oil, which is used for salad dressing and in the manufacturing of margarine and soap. The residual press cake is used as stock feed as well as fertilizer. In addition, vegetable such as tomato, apart from being consumed at home, also earns foreign exchange to the producer countries, due to exportation. Quite a number of studies have investigated the cost and returns of small-scale dry season vegetable production (Usman and Bakari, 2013; Ehirim *et al.,* 2014; Onoh *et al.,* 2016; Samshunnahar *et al.,* 2016; Tsoho and Salau, 2012; Ajayi and Nwalieji, 2010; Nwalieji *et al.,* 2015; Sanusi and Ayinde, 2013). The results from most of these studies highlighted the need to extend the farming season beyond the rainy season through irrigated agriculture, since self-sufficiency in food production based on rain-fed agriculture is difficult to achieve (Ajayi and Nwalieji, 2010).

Methodology

Study area

The study area was Anambra State and it has 4 agricultural zones namely Anambra, Awka, Onitsha and Aguata. Onitsha zone was purposively selected for the study because of the high intensity of tomato production in the area and also the proximity to swampy (fadama) areas which support tomato production. A total of 80 farmers were selected, using a multi-stage random sampling technique across the zone.

Methods of analysis

Descriptive statistics were used to analyze the socio-economic characteristics of the respondents as well as problems faced by the respondents, while profitability of tomato farmers was determined by Gross Margin and Net Income Analysis. Afolami and Ayinde (2002) defined gross margin as the difference between the gross farm income (GFI) and the total variable production cost (TVC); while net farm income (NFI) was defined as the difference between gross margin and total fixed production cost. It is expressed as follows:

$$GM = TR - TVC \quad (1)$$

Where:

GM = Gross margin (N/Ha)

TR = Total revenue (N/Ha)

TVC = Total variable costs (N/Ha)

And

$$NFI = GM - TFC \quad (2)$$

The variable costs mentioned include seed, family labour, hired labour, tractor hiring, transportation, fuel, empty basket, fertilizer, and agrochemicals; while fixed costs include: depreciation on fixed assets and rent on land.

Results and discussion

A summary of the socio-economic characteristics of the sampled respondents in the study area reveals that actual mean estimates obtained for variables did not show much variation (Table 1). Most of the farmers were still within the productive age. Majority of the farmers in the area were young and energetic male farmers with reasonable literacy level. The table further revealed that most of the respondents were married and it is likely that they produce tomato, to cater for their family. About 45 percent of the respondents had less than five years of experience in tomato production. This may affect their efficiency, because the more experienced a farmer is, the more efficient he may be on the farm and vice versa. The table further indicated that majority (84 percent) of the respondents were small scaled and command farm holdings of 0.1 – 2.0 hectares. This implied that mechanized farm production among the respondents could not be feasible.

Table 1: Descriptive Statistic of some of the socioeconomic variables

Variable	Mean value	Standard deviation
Proportion		
Age	41	10.13
Education	0.40	0.32
Farm size	0.72	1.42
Extension	1.76	1.91
Farming experience	1.89	3.42

Average Cost and Returns per Hectare

Table 2 showed the cost and returns analysis of tomato production among the respondents. The average gross revenue per hectare generated by tomato farmers in the study area was N298,240.20 while the total average cost of production incurred during the production was N211,529.63. The average gross margin and net farm income per hectare therefore, were N105,414.05 and N86,710.57 respectively. Hired and family labour, empty basket, loading and transportation, as well as fertilizer accounted for 65.25% of the total variable costs. The farm gross ratio was 0.58; the ratio showed that the total farm cost was about 6% of the gross revenue, which is in line with Olukosi and Erhabor (2008), which states that a gross ratio of less than one is desirable for any farm business. Therefore, based on the information in Table 2, it is obvious that dry season tomato production was a profitable venture in the study area.

Table 2: Average Costs and Returns per hectare

Variables	Value (N)	(%)
Variable cost		
Fertilizer	20,865.12	9.12
Agrochemicals	21,844.54	10.15
Seed	5,545.20	3.56
Family labour	38,724.74	17.02
Hired labour	50,494.52	20.14
Loading & transportation	21.950.60	12.54
Fuel	10,500.93	7.53
Empty baskets	22,900.50	12.16
Total Variable Cost (TVC)	192,826.15	92.22
Fixed cost		
Rent on land	6.453.48	2.58
Depreciation on fixed assets	12,250.60	5.20
Total Fixed Cost (TFC)	18,703.48	7.78
Total cost of production (TVC + TFC)	211,529.63	100
Returns		
Gross revenue (GR)	298,240.20	
Gross margin (GR – TVC)	105,414.05	
Net Farm Income (GM – TFC)	86,710.57	
Farm Gross Ratio (GM/TR)	0.58

Table 3: Constraints Associated with Tomato Production

Constraints	Frequency	%	Rank
Inadequate farm credit	70	23.75	1
Poor storage and processing facilities	48	21.25	2
Inadequate extension services	45	17.23	3
Attack by pests and diseases	42	13.95	4
Storage/high cost of inputs	38	9.67	5
High cost of fuel	28	07.35	6
Land shortage	25	06.80	7
Total	**300**	**100**	

Source: Field survey, 2013
Multiple responses

The result in Table 3 showed the constraints faced by the respondents. The table revealed that, the major problem faced by dry season tomato producers is inadequate credit facilities, which accounted for 23.75%. This is in line with the study by Usman and Bakari (2013), who reported that, inadequate capital hinders tomato farmers from expanding their business. This was followed by poor storage and processing facilities (21.25%). This problem causes the price of tomatoes to fluctuate with season. Farmers are forced to sell their produce at harvest at a very low price. Inadequate extension services among producers were also a major challenge to most producers (17.23%). Due to this problem, dissemination of new production technologies among the respondents was bound to be limited. Similarly, 13.95% of the respondents pointed out high incidence of pests and diseases as a constraining factor. Another problem mentioned by the farmers was shortage/high costs of inputs which necessitated farmers to use organic manure. This is in line with the report of Afolami (2002), who noted high input cost among tomato farmers in Ogun State. In addition, about 7.35% of the respondents mentioned high cost of fuel while 6.80% mentioned shortage of land, as other problems facing tomato farmers in the study area. All these problems can limit output and profit; they can also explain the prevalent poverty cycle among the respondents.

Conclusion and Recommendations

The results indicated that majority of the tomato farmers in the study area were married and also males in their active ages. The study also showed that most of the respondents were small-scale farmers, with little experience in tomato production. However, the respondents make good farm profit, with average gross margin and net farm income per hectare of N105,414.05 and N86,710.57 respectively. While inadequacy of farm credit was identified as the most significant problem among the respondents, land shortage was the least significant constraint. The study therefore, recommended that farmers should be encouraged to form cooperative societies so as to enable them obtain loans from commercial banks and agricultural and rural cooperative bank, at regulated interest rates. Government should ensure efficient extension services in the study area by organizing workshops, training and make provisions to facilitate their work and also provide adequate storage facilities.

Abstract
Consumption of the pro vitamin A cassava could be an antidote to fight hidden hunger and food security issues in Nigeria. Bio-fortified [illegible] out of the to eradicate hidden hunger in rural and urban households in Nigeria. The review assessed the emerging potentials of pro-vitamin A cassava consumption in Nigeria and its contribution to the state offood security. Specifically, it explained the concept of pro-Vitamin A Cassava, assessed the nutritional and health benefits of pro vitamin A cassava and identified the constraints to the consumption of pro vitamin A cassava in Nigeria. The awareness and consumption of pro vitamin A cassava in Nigeria is ongoing growth funding support from Harvest Plus, Nigeria and the collaborative efforts of Federal College of Agriculture, Akure, Ondo State.The paper found that pro vitamin A cassava could help to address the adverse health effects of vitamin A deficiency among urban and rural consumers of cassava products because of its high Vitamin A content. Harvest Plus has established the proof of concept that consuming Pro-vitamin A cassava could eradicate hidden hunger and solve some health related issues. Constraints in Pro-vitamin A cassava consumption including accessibility of Pro-vitamin A cassava products in the market, ignorance of the nutritional benefits of Pro-vitamin A products and low level of utilization of Pro-vitamin A cassava products. The study concluded that access to Pro-vitamin A cassava products will eradicate hidden hunger and its complexities among rural and urban households in Nigeria. The study recommended that Harvest plus and all collaborators should create more awareness of the various nutritional and health benefits of Pro-vitamin A cassava among rural and urban households in Nigeria and also make available the stems of Pro Vitamin A cassava to interested farmers
Keywords: Bio-fortified, Vitamin A Deficiency, Cassava

Introduction
Food security "exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life". From the statement above, four components of food security are identifiable: availability, accessibility, utilization and stability of food. Food insecurity remains prevalent, particularly in the global southern nations of Asia and Africa, and in Nigeria, malnutrition has resulted in death of many of its citizens. African Food Security Briefs (AFSB) estimated that approximately one out of every three persons in the sub-Saharan Africa is undernourished.(Matemilola and Elegbede,.2017).Cassava also known as *Manihotesculenta*or *Manihotutilissima* is a widely-consumed staple food in Nigeria, it was considered a promising vehicle for bio-fortification to increase vitamin A content and, therefore, dietary intake. Cassava production occurs predominantly in the southern rainforest savannah ecological zones. Relatively small quantities are produced in northern Nigeria, although drought tolerant cassava varieties are being introduced into those areas as well. The initiative to expand the range of cassava production

to drier zones is supported by drought tolerance breeding initiatives at IITA and CIAT.Cassava roots are primarily white in colour and contain no pro-vitamin A. Vitamin A deficiency continues to be a significant public health problem in Nigeria, despite improving diets due to rising incomes and administration of vitamin A capsule and fortification programs over the past decade. The first variety of pro-vitamin A cassava was approved for release in Nigeria in late 2011, eight years after crop development activities were initiated in 2003 at the International Centre for Tropical Agriculture (CIAT) and the International Institute of Tropical Agriculture (IITA) under funding from the Harvest Plus program. Five years after release and thirteen years after initial research activities, it is estimated that one million Nigerian farm households are growing "yellow" cassava varieties, which contain significant amounts of pro-vitamin A even after processing. Yellow cassava now represents an additional source of vitamin A in Nigerian diets which is essential for eyesight. Products derived from pro-vitamin A cassava include garri, starch, tapioca, fufu, pellets, flour and chips. It is produced mostly by smallholder farmers on marginal or sub-marginal lands of the humid and sub-humid tropics (Ani, 2010). Such smallholders systems as well as other aspects of its production often creates problems, including; the unreliability of supply, uneven quality of products, low producer prices and often costly marketing structure.

Pro- Vitamin A Cassava is an extremely adaptable crop, it is drought tolerant, high yielding resistant to major pests and diseases ,requires limited land preparation, and grows well in poor soils.

Objectives of the Study

The objectives of the study are to;

i. explain the concept of pro-vitamin A cassava;
ii. discuss the nutritional and health benefits of pro vitamin A cassava; and
iii. identify the constraints encountered in the cultivation and consumption of pro-vitamin A cassava in Nigeria.

Methodology

The study was carried out to review present trend on the emerging issues of Pro-Vitamin A Cassava in Nigeria Food Security Situation.

Concept of Pro-Vitamin A Cassava

Vitamin A is a fat soluble vitamin playing an important role in vision, bone growth, reproduction and in the maintenance of healthy skin, hair and mucous membrane (FAO/WHO, 2010).The World Health Organization has established the Estimated Average Requirement (EAR) for vitamin A by age group. For children 4-6 years, this is 275 μgretinol; and for women, 500. Adequate vitamin A is important for healthy immune function; vitamin A deficiency leads to severe visual impairment and increased risk of illness and death from common infections. Cassava had been chosen for bio-fortification in Nigeria because of its importance as a staple crop. It is a staple food and animal feed in tropical and sub-tropical Africa, Asia and Latin America. It's a preferred candidate for use as vehicle to convey vitamin A to target beneficiaries- women and children less than 5 years. Other factors such as food preferences, the number of people consuming cassava and cassava-based products, and the population size of those in need of Vitamin A were also considered in the selection of cassava and Nigeria as a pioneer country. There has been remarkable progress since its inception. (Dixon,*et al*.,2010). Bio-fortified vitamin A "yellow" cassava can help address the adverse health effects of vitamin A deficiency because of its high Vitamin A content. HarvestPlus has established the proof of concept that vitamin A cassava varieties can be developed without compromising yield levels and that these varieties are widely accepted. Bio-fortified cassava could alleviate some aspects of food insecurity in developing countries if widely adopted (Montagnac, 2009).

Potentials of Pro-Vitamin A Cassava in Human Diet

Two forms of vitamin A are available in the human diet: preformed vitamin A (retinol) and pro-vitamin A carotenoids. Preformed vitamin A is found in animal-source foods; pro-vitamin A is found in some plant-source foods, and is metabolized by the body into retinol when consumed. Vitamin A cassava has numerous functions; while vitamin A is best known for its vital role in vision, the retinoid forms of this vitamin also participate in physiological activities related to the immune system, inflammatory system, and maintenance of epithelial and muscular tissues, growth, and reproduction among others. (Ilona, *et al*.,2017). Biofortified vitamin A "yellow" cassava can help address the adverse health effects of vitamin A deficiency. In 2016, Harvest Plus and its partners among whom are the Federal College of Agriculture, Akure and International Institute of Tropical Agriculture; Ibadan (IITA) had successfully developed and delivered vitamin A cassava varieties to more than one million farming households in Nigeria. The Federal College of Agriculture has embarked on the awareness and multiplication of Pro-Vitamin A cassava with efforts of the provost, Dr. Adeola Samson Odedina through various programmes in the institution, Ondo State and in Nigeria. In terms of availability ,the country director, Dr. Paul Ilonanoted that pro-vitamin A cassava varieties are being multiplied and at least 50% of households have already received information on the importance of bio-fortification through farmer to farmer, field days (FCA, Akure), and radio jingles (Ilona, *et al*. 2017).These have helped to increase awareness of Pro-Vitamin A products in urban and rural households .The country Director of Harvest Plus further stated that farmers and consumers have also become increasingly nutrition conscious, leading to the rapid integration of bio-fortification in to food and dietary systems. Yellow fufu has become a preference for fufu consumers while yellow garri (biofortified) is a growing preference for consumers in regions that traditionally consume white garri.

Challenges Encountered in Promoting the Consumption of Pro-Vitamin A Cassava in Nigeria
Constraints in pro-vitamin Cassava consumption in Nigeria includes but not limited to;

i. Inadequate information on the health and nutritional benefits of pro-vitamin A cassava products among rural and urban households;
ii. Poor market opportunities for pro-vitamin A cassava products; and
iii. Low level of utilization of pro-vitamin A cassava products among rural and urban households.

Conclusion

The review concludes that access to Pro-vitamin A cassava products will eradicate hidden hunger and its complexities among rural and urban households in Nigeria.

Acknowledgement

The authors acknowledged the funding support from HarvestPlus Nigeria to the Federal College of Agriculture, Akure in the massive awareness and multiplication of Pro-Vitamin A cassava in Ondo State and in Nigeria at large.

Abstract
This study was conducted specifically to ascertain the socio-economic and enterprise characteristics as well as determine the profitability of on-farm income generation among small holder snail farmers in the study area. Primary sources of data were obtained from questionnaire administered to fifty (50) snail farmers in the study area. The result indicated that the farmers were old adults with a mean age of 50 years; a mean household size of thirteen (13), literacy level was high, income level was low and snail production in the study area was profitable. It is recommended that the farmers should diversify production as well as form co-operative society. It is also recommended that extension agents should be encouraged to have contact with the farmers.
Keywords: On- farm, production, small-holder, snail and income

Introduction
A major concern of the Federal Government of Nigeria is how to increase food production and ensure security. Dixon *et al* (2011) reported that hunger and malnutrition are consequences of food insecurity. The only economic sector that can address this perennial problem of food insecurity is agriculture (Kaine 2018). Ume and Kaine (2017) and CBN (2013) reported that the contribution of agriculture to the national gross domestic product (GDP) is about 48%.This is why Adaigbo and Nwadioha (2010) reported that agriculture an important pivot for economic development of most developing countries of the world. Agenor *et al* (2004) reported that agriculture is a vehicular means of reducing poverty. Kaine (2017) reported that the agricultural sector provides the protein requirements for the healthy growth and development of man. However, Adeniyi *et al* (2012) reported that animal protein is regarded as first class or high quality protein due to the presence of high amount of amino acid.Snail farming in recent times is becoming popular such that it is now complementing snails from the wild life (Nwadukwe, 2000). Snail meat is good source of protein; it provides the much needed protein for growth and healthy development of both the rural and urban dwellers. The protein content of snail is about 12 – 16%. It is low in fat (0105 – 0.80%), high in iron content (45.50mg / kg) and contains the essential amino acid required by man (Ugwumba *et al,* (2016). Snail meat is useful in the treatment of ulcers, asthma and anemia due to the high iron content (Efamspro, 2008). Several studies have been conducted in different areas of snail production, however, little or no study have been conducted with respect to on-farm income generation of snail production among small holder snail farmers in IkpobaOkha Local Government Areas of Edo State, Nigeria. This research therefore was carried out to determine the socio-economic variables enterprise characteristics and profitability of snail production in the study area.

Methodology
On farm income generation of snail production among smaller holder snail farmers was conducted in IkpobaOkha Local Government Area, Edo State, Nigeria.. A total of fifty identified snail farmer were randomly selected and used for the study. First stage involved the selection of communities. Five communities were randomly selected. The second stage involved selection of snail farmers.

Ten snail farmers were randomly selected from each of the five communities using well-structured questionnaire giving a total sample size of fifty that was used in the study. Data for the study was generated using primary data. Data generated were coded and analyzed using both quantitative and qualitative techniques.

Model specification

Profitability Analysis

Profitability analysis of snail production among small-holder snail farmers was determined using the gross margin analysis. Gross margin analysis (GM) is expressed as the difference between total revenue (TR) and total variable cost (TVC). Net profit margin (NPM) shows the difference between gross margin and depreciation. Gross Margin and Net Profit is expressed as

Gross Margin and net profit is expressed as:

GM = TR – TVC

TC = VC – TFC

NPM = GM – Depreciation

Where

GM = Gross Margin

TR = Total Revenue (#)

VC = Variable Cost (#)

NPM = Net Profit Margin

Return on Investment (ROI)

This was obtained by dividing the net profit by total cost of production multiplied by 100 and expressed as a ratio (Kaine, 2018). The equation is expressed as:

$$\mathrm{ROI} = \frac{NetProfit\ (Revenue)\ perannum}{TotalCostincurredperannum}\, x\, \frac{100}{1}$$

Result and Discussion

The socio-economic variables of dry snail farmers were presented in Table 1. The result showed a mean age of fifty (50) years. This indicated that the farmers were old youths involved snail production. The result also showed that snail gender specific both sex were involved in the production. Further analysis showed that thirty nine (78%) of the respondents were married. The result further revealed that literacy level among the farmers was high as only three (6%) of the farmers had no former education. A mean household size of thirteen (13) was observed in this study.

Farmer's enterprise statistics as represented in Table 2 showed that the farmers were well experienced with a mean experience of ten (10) years. The study also showed that small holder snail farmer majorly (64%) financed their enterprise through personal savings. A detailed analysis of the status of the farmers showed that thirty nine (78%) of the respondents were part time snail farmers. Farm size analysis showed that the farmer small holder farmers a mean production capacity of one thousand, eight hundred and eighty one (1,881) snails. The study also showed that the farmers were low income earners with a mean income of #206,360.00. Forty eight (96%) of the farmers had no contact with extension agents. The result also showed that forty three (86%) were not members of cooperative society and were all involved in other on-farm activities.

The profitability of snail production among small holder farmers in the study area was determined and presented in Table 3. The result indicated that the total variable cost was one hundred and sixty four thousand, five hundred and seventy naira thirty four kobo (#164,574.34) while the total fixed cost was one hundred and sixty three thousand and twenty naira, thirty two kobo (#163020.32). The result showed that snail production was profitable in the study area with a return on investment of 0.23. This implies that for every one naira invested there is a return of 0.23 naira.

Source: Field Survey, 2018

Conclusion

The result of the study revealed that on-farm snail farmers were old youths with high literacy level and house-hold size. The result also revealed that on-farm snail production was profitable. Further analysis established that farmers were low income earners and majority had no access to extension agents. The result also showed that majority were not in any form of cooperative. Since the study established that the farmers were low income earners, it is recommended that they should diversify into off-farm enterprise. It is also recommended that the farmers should form co-operative society so as to achieve the benefit of economies of scale. Since majority of the farmers had no contact with extension agents, it recommended that extension should be encouraged to have contact with the farmers.

Village Seed Entrepreneur Model: Prospects and challenges for a Sustainable Cassava Seed System in Southeast Nigeria

J.E Ewuziem, and G.N. Asumugha
National Root Crops Research Institute Umudike, Nigeria
Email: j.ewuziem@nrcri.gov.ng

Abstract

Building a Sustainable and Integrated Cassava Seed System is a project that seeks to develop a formal cassava seed system in Nigeria. One key strategy to achieving this is the village seed entrepreneur model as drivers of change in the rural farming communities. The village cassava seed entrepreneurs are already existing cassava farmers in selected communities who, having adopted the use of improved cassava varieties, have the capacity and are willing to take up cassava seed production and marketing as a business. High yielding and disease free (clean) planting materials (Certified cassava seed) from the foundation seed are multiplied and sold to cassava farmers who are expected to increase the yield of cassava in Nigeria. In this business model, the village seed entrepreneurs are expected to produce at least 400 bundles of cassava seed per hectare with the root as extra source of income. With the potential of multiplying specific improved varieties of cassava to plant 8 times the initial farm size means a huge yield increase and better income to farmers. However, aside bulkiness of cassava seed and difficulty in moving it from one location to another, the complexity of seed sourcing behavior of cassava farmers in southeast Nigeria are some of the numerous challenges faced by the village seed entrepreneurs. Also, slow diffusion of the adopted improved cassava varieties is likely to slow down market opportunities for certified seed selling in the rural communities. Cassava farmers tend to hold on to the already existing varieties in their area due to perceived desirable traits for different food forms. It is therefore suggested that a more aggressive sensitization programmes such as the use of radio jingles and market day promos be intensified to popularize the village seed entrepreneurs in the communities and possibly enlarge the number of existing participants.

Key words: Cassava, seed, certified, production, market, improved, varieties, sustainable, integrated, entrepreneurs, system

Introduction

Since its emergence in Africa in the 16th and 17th centuries, cassava has replaced several traditional staples and has been successfully incorporated into many farming and food systems on the continent. This crop, initially adopted as a popular famine reserve crop because it provided a more reliable source of food during drought and hunger periods, has in recent times emerged to be both a staple food and profitable cash crop of industrial significance in the world economy (Aerni, 2006).The production of cassava is dominated by over 6 million families, typically smallholders with an average farm size of 0.5 Hectares. Over 90% of these farmers use the informal seed system by recycling stems from the previous harvest. Less than 5% buy new stem cuttings, leading to poor yields. Cassava production is plagued with issues of inefficient production and distribution of quality planting materials and an unreliable quality assurance system. These issues hinder the production of quality cassava roots that are of interest to end users particularly industrial processors (Sahel Capital 2016).Nigeria is currently the largest cassava producer in the world with estimated annual production of over 50 million metric tons.Despite being the largest cassava producer in the world, Nigeria only averages a yield of 14 t/ha–less than half of what is attainable, due largely to the use of low yielding varieties that are most time not clean. It is acknowledged in some quarters that the seed industry in Nigeria is still developing especially for crops like cassava whose botanical seeds are not consumed or popularly used for planting. However, seeds are the

foundation of agriculture and the most important input (Onunka*et al* 2016) in the production process of most crops especially root and tuber crops. Although cassava planting materials can be produced from true seeds, or rapid multiplication method, the crop is propagated by stem cuttings and the main sources of the planting materials are the farmers' fields, farmers' neighbours and sometimes rural markets. High-quality cassava cuttings for planting are often in short supply.Thus the introduction of improved varieties and agronomic practices into cassava production system consequently can increase yields per unit area by 40% (Nweke *et al.* 2001). A survey conducted in Nigeria in 2003 indicated that a lack of clean planting material (clean stakes) was by far the most important problem in cassava production systems, followed by low yields of fresh roots (Dickson, 2003).
Building an economically sustainable, integrated cassava seed system (BASICS) is a project that seek to help Nigerian cassava producers reach the potentials of 45MT/ha by involving the development of a commercially sustainable cassava seed value chain based on the purchase of quality seed by farmers. To further ensure the sustainability of the project, vibrant and profitable village seed entrepreneurs are encouraged to venture into the seed business. These seed businesses will provide healthy seed of more productive varieties leading to adoption of new varieties to improve productivity and food security, increase incomes of cassava growers and seed entrepreneurs, and enhance gender equity. The village seed entrepreneur model is a distinctive pathway of seed delivery in thepilot States of Benue, Abia, Imo, Cross Rivers and Akwa Ibom states, to help develop a network of 130 community based seed enterprises. These VSEs will source certified stems of improved varieties of cassava from NRCRI and IITA to multiply and sell to farmers in their vicinity. This way, farmers will not have to go far to source quality stems for planting. It is expected that the VSE model will increase incomes to the farmers, ensure that women are given opportunity to express their potentials in cassava seed business and facilitate sales of quality seed of new, farmer, and market preferred varieties. The strategy is to carefully select grass root entrepreneurial seed producers in the project target areas as VSEs using laid down criteria to ensure compliance requirements for certification by the National Agricultural Seed Council of Nigeria. Some of the criteria for selection of the VSEs include:

- Ability and willingness to take up seed production as a business
- Must have adopted the use of improved cassava varieties
- Should possess the financial ability to cultivate at least 1ha of cassava field
- Must belong to a registered cooperative society
- Must be ready to be trained
- Must abide by seed certification regulations by NASC

The VSEs are trained on improved agronomic and business management practices of cassava production, so that they can establish and manage their own small seed business. These VSEs are linked to National Agricultural Seed Council (NASC) so all their seed production plots are duly certified so the buying farmers are assured of the quality.Apart from building their capacities, Catholic Relief Services (CRS) and National Root Crops Research Institute (NRCRI) Umudike, in partnership with other institutions support the VSEs by facilitating the availability of certified foundation seed to meet their planting material needs and by creating demand for their produce through strategic communication and marketing campaigns. A number of strategically located demonstration plots are set up to showcase the benefit for using certified seeds for planting. (http://www.rtb.cgiar.org/basics/activities/village-seed-entrepreneurs/).

The National Agricultural Seed Council (NASC) will pay certification visits to the VSEs at least three times before the stems are harvested for sale. These visits are to ensure that the guidelines for seed certification are followed to produce clean certified cassava seed. Also, the VSE is expected to obtain foundation seed every two years from NRCRI seeds, GoSeed and Reniscence (Agro alliedSeed Company) who are foundation seed producers. Breeder seeds are produced by research institutes such as NRCRI and IITA.The success of cassava seed multiplication and marketing depends on the quality of planting material. Quality should actually separate the local and improved varieties. The criteria used in determining quality of planting materials of cassava are generally based on the threshold levels of infestation of diseases and pests. Certified cassava seed implies that the stems are clean and has been authorized for distribution and use in the cassava based farming systems of Nigeria by the Nigeria Agricultural Seed Council (NASC). This paper therefore discusses the prospects and challenges of the VSE model as a pivot where the production and marketing of clean cassava seed will rotatein Southeast of Nigeria.

Prospects for the VSEs in Southeast Nigeria

To ensure availability of foundation seed for the VSEs at all times, National Root Crops Research Institute (Umudike Seeds) and Renascent Agro Inputs and seed company ltdare producing enough to ensure that the backup of new and clean seed are available. Training and retraining is an integral part of the programme designed to equip the VSEs with the required skills that they need to be efficient in the cassava seed multiplicationbusiness. Some key aspects of these trainings include Best Agronomic practices, Development of business models and networking using the cassava seed tracker technology. The seed tracker will enable the VSEs to become visible by prospective buyers in Nigeria and beyond using the internet communication technology to create market.In Africa, about 600 million people are dependent on cassava for food (IFAD 2012). Cassava stem production as a profitable venture requires compromising the root yields by reducing the planting distance to as low as 1m x 0.5m inter and intra row spacing instead of the normal 1m x 1m spacing. By this arrangement, the plant population of about 20,000/ha is expected. This will translate to about 400-500 bundles of cassava stem at first ratoon depending on variety. In the south east of Nigeria, the price of improved cassava stem went a record time high in 2017. A bundle of cassava stem was sold as high as ₦1,000 for TME 419 and ₦1,500 for the pro vitamin A varieties. This means that a VSE can realize up to ₦500,000 from stem on a 1ha farm of improved cassava variety within the first 6-9 months after planting. However, in 2018, the price of stems generally dropped to between ₦500 to ₦800 per bundle, also indicating a positive trend for cassava seed business in the area.Because of the clean cassava stems planted by the VSEs, their farms are usually outstanding in the community, attracting the attention of other farmers who, in turn would want to have such variety of cassava in his/her farm. Community based farmers are likely to cluster around the VSEs for information concerning cassava. Markets are created within the cluster of farmers around a VSE. The multiplier effect of this will mean that within two planting seasons in a locality, the VSE will form a kind of nucleus for certified cassava seed. In some locations in the Southeast of Nigeria, cassava is now planted almost all year round. This will imply increased demand for certified seeds. Huge transaction cost incurred during the movement of cassava stems due largely to its bulky nature is eliminated because of the presence of the VSEs within the farmer's environment. Cassava farmers may no longer travel beyond their community to obtain certified seed for planting.This strategy will positively impact on the incomes of the farmers.

Challenges to the VSEs

High cost of transportation of foundation seed to the location of the VSEs poses a serious challenge to operators in the scheme. Also, the packaging and method used to convey these stems, predisposes the stems to varietal mix up in transit. When this happens, the VSE is not likely to be able to sort out the different varieties and plant them separately in different certification fields as specified by NASC. This could further lead to supply of wrong cassava varieties other than the one requested by their clients. Also, slow diffusion of the adopted improved cassava varieties is likely to slow down market opportunities for certified seed selling in the rural communities. This is because cassava farmers in some communities are yet to see reasons why they should discard the already existing varieties that they have been using over the years, for which they appear, satisfied with their performance in terms of quality.

In Nigeria, the seed industry is still developing especially for crops like cassava whose botanical seeds are not consumed or popularly used for planting. Although production of cassava is dominated by over 6 million families, typically smallholders with an average farm size of 0.5ha, over 90% of these farmers use the informal seed system by recycling stems from the previous harvest (Sahel Capital 2016). The common characteristics of the existing informal seed system include:

- Cassava seed gets to farmers from fellow farmers
- Bought from local markets
- Sourced from friends and well wishers.

- Collect cassava stems from farms where harvesting has been carried out and the stems abandoned in the field.
- Cassava farmers see stems as not useful except as planting material.
- Cassava varieties are distributed in such a manner that the farmer may not trace the source of his planting materials

Typical of Nigerian farmers, a vast majority of the rural farming population especially cassava farmers still hold on to the above practices. In some localities, sharing of cassava seed among friends and relatives is a common practice. This has made it somehow difficult for VSEs to sell the certified seeds as planned. In extreme cases, these certified seeds are harvested from the VSEs farm without the consent of the owner. The sharing of cassava seed ideology that is prevalent in most rural communities of southeast Nigeria is most likely to frustrate some of the VSEs out of business. It is reported that in AkwaIbom State for instance, people go about harvesting TME 419 variety of cassava stem without the consent of the owner, due to the popularization of the variety by a programme that is supported in the state by the wife of the governor (personal communication with a VSE). Again, the business model aspect of the project has not been fully embraced by the VSEs. Some are still dragging their foot to invest their money to purchase foundation seed from NRCRI or Reniscence. They are yet fully comply with NASC regulations for seed certification. Apart from the above, theft of certified cassava seed from the VSEs field in locations where sharing is not a norm is a source of worry to VSEs. At the moment, the traditional institution has not been able to address this properly so as to make the people understand that cassava seed multiplication is now a business especially among the rural farming populace.

Conclusion

Building a Sustainable and Integrated Cassava Seed System is a project that seeks to develop a formal cassava seed system in Nigeria. One key strategy to achieving this is the village seed entrepreneur model as drivers of change in the rural farming communities. These carefully selected champions of cassava seed multiplication and marketers are expected to bring about the desired change from the already existing informal seed system for cassava to the much desired formal seed system. A formal seed system for cassava has great potentials as a business model. Apart from increasing incomes to VSEs, the gap between actual yields from the farmers' fields and potential yields will narrow down significantly in Nigeria. To achieve this in a developing seed system environment will certainly be faced with some inherent challenges, but with synergy among the operators in the system, a lot will be achieved. It is therefore suggested that a more aggressive sensitization programmes such as the use of radio jingles and market day promos be intensified to popularize the village seed entrepreneurs in the communities and possibly enlarge the number of existing participants.

Abstract
This study analyzed the level of access and utilization of Agricultural insurance scheme among farmers in Orlu LGA of Imo state. Data were collected with the aid of a structured questionnaire using a multistage random sampling procedure to select 60 respondents from the study area. Descriptive statistical tools, likert scale, Z test and simple regression were used to analyze the data obtained. Results from the study showed some levels of participation in the insurance scheme by the farmers. The results of the simple regression analysis showed that access to credit increases by ₦0.84 with each additional increase in insurance. Insufficient income, lack of agricultural disbursement, lack of security and high interest rates were the major factors affecting farmers' access to credit. Therefore, there is need for policies aimed at the establishment of insurance companies and agricultural and micro finance banks in the study area which will facilitate the farmer's access to credit to help boost their capital base.
Keywords: Agricultural Insurance, farmers, Credit, and Orlu LGA

Introduction
Agriculture remains an important economic sector in many developing countries. It is a source of growth and a potential source of investment opportunities for the private sector. Approximately three-quarters of the world's agricultural value added is estimated to be created in developing countries with agriculture contributing as much as 30 percent to gross domestic product (GDP) (FAO, 2012). Agriculture is a risky enterprise due to its cyclical nature, risk of loss from fires and natural disasters. More so, agriculture is particularly exposed to adverse natural events; such as droughts, floods, pest and diseases and the economic cost of major disasters may even increase in the future because of climate change; this unexpected event or loss can lead farmers to poverty if not checked. Agricultural insurance is a variable tool that agricultural producers can use to adapt and even mitigate the risk associated with their business. According to Ajieh, (2010), agricultural insurance is an economic component of farm management designed to reduce the adverse effect of natural disaster on farmers' income through the payment of indemnity. The Federal Government of Nigeria introduced agricultural insurance scheme in order to broaden farmer's access to farm resources and change their attitude to risk in the choice of resource use positively. Specifically NAIC was established for farmers to have more access to essential farm resources that would motivate them to embrace the use of modern farm practices with the assumption that such practice will lead to increase the quantity and quality of farm production and food supplies to the market (Olubiyo et. al., 2009). This is possible because the policy holders are assured of a certain income in a case of crop and livestock failure. Several studies have shown that agricultural insurance not only protects farmers against financial disaster (and closing of the business) after suffering any of the insured risks but also empowers the farmers to obtain farm credit (Olubiyo and Hill, 2003; Arene, 2005; Epetimehin, 2010). However, the Nigerian farmers are not really excited about taking an insurance policy which may be due to the unsatisfactory image of the insurance industry regarding loss compensations. In addition, the low income, small sizes of enterprises, large scale ignorance, poverty and the adverse view of other people's experiences with activities of insurance companies in other sectors have made farmers reluctant to patronize the

scheme, let alone agree to pay the small premiums in exchange for their farm risks (Olubiyo et. al 2009; Akintunde, 2015). Nevertheless, crop insurance is important for the adequate supply of credit to farmers, it gives assurance that farmer will be able to repay their operating loans in the event of weather or price related calamities as stated by Jeff Gerhert (2012). This has necessitated the study on the level of access and utilization of agricultural insurance in Orlu local government area of Imo State, Nigeria. The specific objectives are to ascertain the farmer's level of participation in the agricultural insurance schemes, compare the amount of credit received by insured and non-insured farmers, determine the effect of insurance on access to credit and also identify the constraints militating against access to credit.

Methodology

The study was carried out in Orlu local government area of Imo state. Farming is the predominant occupation of the people in the state. The farmers practice mixed farming as well as mixed cropping. A multistage random sampling technique was used to select sample respondents to analyze the level of access and utilization of agricultural insurance in Orlu local government area of Imo State. Three communities were randomly selected from the study area. Secondly, two villages were randomly selected from each of the communities giving a total of six villages. The third stage involved the random selection of seven insured and seven uninsured farmers from each of the six villages giving a total of 84 respondents. However, only 24 insured farmers' and 32 insured farmers' questionnaires were retrieved giving a total of sixty respondents for the study. Data were collected from primary sources with the use of structured questionnaire designed in line with the objective of the study. The farmers' level of participation in agricultural insurance scheme was analyzed using likert scale. The 4-point likert scale had legends ranging from Very high = 4; High = 3; Low = 2; Very low = 1. This was used to determine the mean score on responses of the level of participation

$$\text{Mean score} = \frac{4+3+2+1}{4} = 2.5$$

Ƶ-test was used to compare the amount of credit received by insured and uninsured farmers and is given thus:

$$Ƶ = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{S_1^2/N_1 + S_2^2/N_2}} \qquad (1)$$

Where
Ƶ = Ƶ-test
X1 = mean level of access to credit by insured farmers.
X2 = mean level of access to credit by uninsured farmers.
$S^2{}_1$ = Standard deviation of credit level of insured farmers.
$S^2{}_2$ = Standard deviation of the credit level of uninsured farmers.
N_1 = Number of insured farmers
N_2 = Number of uninsured farmers
Simple regression model was used to analyze the effect of insurance on access to credit and is specified thus:

$$y_1 = b_0 + b_1 x_1 + e_1 \qquad (2)$$

Where;
y_1 = Access to credit
x_1 = Insurance (1=access, 0=otherwise)
b_o = Constant
b_1 = Slope coefficient
e_1 = error term

The 4-point likert scale had legends ranging from Strongly Agree = 4, Agree = 3, Disagree = 2 and Stongly Disagree = 1. This was used to determine the mean score on responses of constraints militating against farmers' access to credit.

$$\text{Mean score} = \frac{4+3+2+1}{4} = 2.5$$

Results and Discussion

Level of Participation in Agricultural Insurance Scheme

The likert scale was used to determine the mean score on responses of the level of participation in agricultural insurance scheme. The result of the analysis is presented in Table 1.

Table 1: level of participation in insurance scheme

Insurance scheme	VH	H	L	VL	Score	Mean	Decision
Whole farm insurance	32	8	3	12	201	2.92	VH
Fixed insurance	30	15	5	10	204	2.97	VH
Revenue insurance	2	10	30	12	175	2.32	H
Income insurance	5	5	15	35	85	1.42	VL
Yield insurance	5	10	20	25	115	1.92	L
Combined insurance	0	0	20	40		1.47	VL

Source: Field Survey

VH, H, L, VL represents very high, high, low and very low respectively.

The perception of the respondents on the level of participation in agricultural insurance scheme in the study area is presented in Table 1. The result shows that the respondents' participation in whole farm insurance (2.92) and fixed insurance (2.97) were very high followed revenue insurance (2.32). The income insurance and combined insurance with mean of 1.42 and 1.47 respectively had very low level of participation in the study area. This implies that the respondents are not fully aware of the other insurance schemes available.

Comparison of the amount of Credit received by Insured and Uninsured Farmers

$\underline{X}_1$ = mean level of access to credit by insured farmers = 26.87

$\underline{X}_2$= mean level of access to credit by uninsured farmers = 24.274

$S^2{}_1$= standard deviation of credit level of insured farmers = 17.193

$S^2{}_2$= standard deviation of the credit level of uninsured farmers = 14.778

N_1= number of insured farmers = 24

N_2= number of uninsured farmers = 32

Z = 0.877.

The Z test carried out above indicated a Z value of 2.877 which was significant at 5% level indicating significant difference in the credit level of insured farmers and the credit level of uninsured farmers. This implies that, participation in agricultural insurance scheme in the study area gives the farmers more access to credit than non-participation. This will result to high resource use efficiency, reduced cost of production and increased production capital on the side of the insured farmers and high cost of production, lack of capital on the side of the uninsured farmers in the study area.

Effect of Insurance on Access to Credit in the Study Area

In fitting the functional form, regression analysis was employed and the estimated result is shown in Table 2.

Table 2: Effect of Insurance on Access to Credit

Variable	Coefficient	Standard error
Constant	5.00	11.3***
Insurance	0.75	13.8***
R2	0.84	
F- ratio	12.94***	

***, ** represents 1%, 5% and levels of probability respectively

From the simple regression result on the effect of insurance on access to credit in the study area, the R-squared value of 0.84 means that the independent variable (insurance) contributed to access to credit variability by 84%. The remaining 16% is influenced by other factors. This is in conformity with Olubiyo et al., (2009) who opined that availability of insurance scheme grants farmers access to credit but did not necessarily translate to increased output due to some other factors. On the hand, the equation of the access to credit is, $Y = 5.00 + 0.84 X_1$. This suggests that access to credit increases with ₦0.84 with each additional increase in insurance.

Constraints to Access to Credit in the Study Area

The problem encountered by farmers in obtaining credit from sources is shown in Table 3.

Table 3: Constraints to Access to Credit

	Constraints	SA(4)	A(3)	D(2)	SD(1)	Score	Mean	Decision
1	Lack of Agric credit disbursement	5	10	10	35	160	2. 58	A
2	Much documentation	5	10	20	25	115	1.85	D
3	Insufficient income	25	10	10	15	165	2.75	A
4	Lack of security	15	18	12	15	153	2.55	A
5	High interest rate	22	15	0	23	1	2. 50	A

Source: Field Survey

From the result on the constraints militating against access to credit, constraints such as insufficient income, lack of agricultural credit disbursement, lack of security and high interest rate with mean of 2.75, 2.58, 2.55 and 2.50 respectively are the major factors affecting farmer's access to credit in the study area, while much documentation with mean of 1.85 is the least affecting challenge of farmers access to credit in the study area.

Conclusion

Insurance and other risk transfer solutions can be part of a systemic adaptation approach and can enable vulnerable countries to better manage the risks associated with agricultural business. Insurance can provide financial security against the economic impacts of extreme climate events and many for be more cost effective that certain prevention measures. This study indicated a higher level of participation of the farmers in whole farm and fixed insurance scheme which significantly affected their access to credit in the study area. Also, the findings showed that insufficient income, lack of agricultural credit disbursement, lack of security and high interest rate as the differentials in farmers' level of access to credit. Therefore, the establishment of insurance companies, agricultural and micro finance bank in the study area which will facilitate the farmer's access to credit to help boost their capital base is highly recommended.

Analyses of Cassava Processing and Profitability among Small-Holder Cassava Farmers in Abia State, Nigeria

C.I. Daniel-Ogbonna, and A.C. Okoye
National Root Crops Research Institute, Umudike, P.M.B 7006, Umuahia, Abia State, Nigeria
Email :dan.charity1980@gmail.com

Abstract
This study analysed cassava processing and its profitability among smallholder cassava farmers in Abia State, Nigeria. Data used for the study were obtained from 120 respondents using a multistage sampling technique. The data was analysed by the use of descriptive statistics and cost and returns analysis which showed that the estimated cost was N250,465 while the estimated total revenue was N544,490. For the gari enterprise, result of the analysis showed a gross margin of ₦326,814.53/tonne and an estimated Net income (NI) of N294 ,025.19. Furthermore, the estimated profitability index (PI) of 0.5400 implies that for every N 1.00 earned as revenue N1.54 were returned as net income . Hence, the cassava processing enterprise was profitable. The rate of return on investment (ROI) was calculated as a percentage ratio of the net income to the total cost (TC). The estimated ROI for the gari enterprise was 117.39%. Thus implies that the gari enterprise made more than double the amount on every N1.00 Invested. However cassava processing have some constraints prominent among which include; inadequate capital, high cost of transportation, high input price, high interest rate, high cost of labour, provision of credit support to investors in cassava processing not only as an agricultural loan but small and medium scale enterprise (SMEs). Access to grant to expand their capacities, adopt new technologies / innovation, improve scale of operations and income are recommended for increased processing.
Keywords: Cassava, Processing, Profitability, and Small-Holders Farmers

Introduction
Cassava (*manihot esculata*) has been acknowledged as one of the most popular staple crops in the Africa diet (Nweke *et al,* 2003). It production is characterised by small scale producers who use old varieties and traditional production technologies which largely accounts for how yield. Abia State accounts for 634 metric tonnes of cassava Annually (NBS, 2007). The crop is produced mainly in fresh and processed forms starting from the producers through myriads of processors to the end users. Acceptance of cassavas low cost food in urban centres and as a source of steady income for rural households, depend on how it can be processed into a safe form (Bokanga, 2005). It stands to gain in domestic demand as well as a potential export, if it can be processed in more efficient manner depend on how it can be presented to urban consumers in an attractive form at prices which are competitive with those of wheat cereal and yam. In addition if producers could harvest cassava and process then into staple commodities (such as gari), that could be stored for several months, they could earn higher profits during the period of scarcity. The acquisition of simple processing equipment is an investment which the majority of the small scale cassava processors cannot afford; consequently, poor credit facilities and high interest rate make such investment risky and financially unattractive and hinder the development of the economic potentials of the crop. More so, the inability to analyse effectively the cost benefit returns from the activity, with poor access to productive inputs according to Oyewole and Philip (2006) stagnate expansion and expansion and investment opportunities. Therefore this study analysed the cost and returns for cassava processing into gari and identified the constraints militating against the enterprise in the study area.

Methodology

The study was carried out in Abia State, Nigeria. The zone lies between latitude 4^0 45^1 and 06^0 and 06^0 and 17^0 N longitude 07^0 00 and 08^0 00 East of equator (Abia ADP, 2005). It has seventeen (17) Local Government Areas. Cassava production is a common business in the zone, usually processed into different forms like gari, fufu, abacha, flour, chips and starch. A multi-stage sampling technique was used to randomly select 120 processors from four LGAs in the state. Data were collected from primary source and a structured questionnaire was designed in line with the objectives of the study. Data collected were analyzed using budgetary technique and descriptive statistics. Budgetary technique was used to estimate the gross margin, profitability index, rate of return on investment, operating expenses, net income and benefit cost ratio. The gross margin technique was given thus;

$$GM = GR - TVC \qquad (1)$$

Where;
GM = gross margin in naira per kg
GR = gross revenue in naira
TVC = total variable cost in naira
The result of the budgetary analysis was used to obtain the following ratios:

$$PI = \text{profitability index} = NI/TR \qquad (2)$$

$$RRR = \text{rate of return on investment} = \frac{NI}{TC} \times \frac{100}{1} \qquad (3)$$

$$OR = \text{operating expenses ration} = \frac{TVC}{TR} \qquad (4)$$

Where;
NI = net income
TR = total revenue,
TC = total cost,
TFC = total fixed cost
TVC = total variable cost

Results and Discussion

Profitability analyses of cassava processing

The budgetary technique was used to analyze the profitability of cassava processing into gari while BC ratio, profit index and rate of return on investment were calculated. The result of the analysis presented in Table 1 showed that the cost incurred in cassava processing includes cost of raw materials, labour and cost of depreciated assets. An average of 2730.63kg of cassava was processed into gari and accounted for 29.17% of TVC, and 25.35% of TC of labour. The estimated total cost was N250,465 and total revenue of N544,490.94 for the gari enterprise. Result of the analysis showed a gross margin of N326, 814.53/tonne and estimated net income of N294,02.519. Furthermore, the estimated profitability index (PI) of 0.5400, implies that 54% of total revenue generated constituted net income for the gari enterprise and for every N1.00 earned as revenue, 54 kobo were returned as net income. Hence, the cassava processing enterprise was profitable. The rate of return on investment (ROI) was calculated as a % ratio of the net income to the total cost (TC) return on investment as 117.39%, implying that the gari enterprise made more than double the amount on every N1.00 invested. This could also be seen in the estimated benefit cost ratio for the enterprise. For every N100 spent there was a return of N1.17 in the enterprise. This confirms the findings of Elunmove *et al.* (2015) that the processing of cassava is profitable, return of benefit cost ratio between 1.75 and 2.24 in Abia State Nigeria. Operating Ratio (OR) profitability indicators which measure the percentage of variable cost per N1.00 sale/revenue to the percentage of variable cost was 40%. This could be attributed to the prices and qualities of the inputs of variable cost items used in the production process.

Constraints to Gari Production

Gari production in the study area is faced with numerous challenges affecting it productivity which can also result to various levels of inefficiencies. The problem associated with gari production is the study area include; inadequate capital, high cost of labour, high cost of transportation lack of processing and storage equipment among others. Findings from Table 2 showed that inadequate capital, high cost of transportation, high cost of input, high interest rate and high cost of labour were major constraints militating against cassava processing in the study area. Capital serves as a major backbone in any business enterprise. High cost of capital ranked the highest followed by high cost of transportation

Conclusion

Based on the findings, the enterprise was profitable at varying levels with gari and abacha enterprise returning more than double the amount invested in them. While problems such as inadequate capital, high transportation costs, high input prices, high interest rates and high cost of labour were most of the important constraints militating against cassava processing in the State. The study therefore calls for policies aimed at provision of credit support at little or no interest rates to invest in cassava processing and expand their capacities. Need for provision of social amenities especially rural access roads to reduce the transactions cost in cassava production and processing.

Table 1: Cost and retune analysis for cassava processing into garri in a study area

Item		Garri value
A	Revenue	544490.94

SUB-THEME 2

ASN 52nd Annual Conference Proceedings

Response of Lettuce (*Lactuca sativa* L.) to Poultry Manure Rates and Sources of Green Manure at Samaru

A. D. Hinjari, M. O. Onubaye and A. S. Isah
Department of Agronomy, A.B.U, Zaria
hakumir@gmail.com

Abstract
A pot experiment was conducted at the Orchard of the Department of Agronomy, Faculty of Agriculture, Ahmadu Bello University, Zaria during the 2016 rainy season to study the response of lettuce to rates of poultry manure and three types of green manure. The treatments consisted of three rates of poultry manure (0, 2, and 4 t ha^{-1}) and three types of green manure plants (Soyabean, Mucuna, and Lablab). The treatments were factorially combined and arranged in a Randomised Complete Block Design (RCBD) and replicated three times. An increase in the level of poultry manure application application gave a corresponding increase in the plant height, number of leaves and fresh weight at harvest. There were significant differences in the plant height, number of leaves and fresh weight at harvest of lettuce due to the type of green manure with lablab having the highest values for growth and yield parameters. Regression analysis of poultry manure with the yield of lettuce indicated a linear response which means that the optimum poultry manure rate was not attained. Therefore it can be concluded that 4 t ha^{-1} of poultry manure and in combination with lablab as green manure is sufficient for lettuce production at Samaru.

Introduction
Lettuce *(Lactuca sativa L.*) is one of the most important salad crop that is grown worldwide and a native of Europe, Asia and North Africa (Ananda and Ahundeniya 2012). The plant grows well on a wide variety of soils, ranging from light sand to heavy clay. However the best results are obtained on fertile loams that are rich in organic matter. A pH of between 5.5 and 7.0 is optimum (Valenzua *et al.,* 2012). Lettuce is used mainly in salads however, the leaves may be boiled like spinach and is frequently used in sandwiches. Regular inclusions of lettuce in the diet is known to prevent osteoporosis, anaemia and believed to protect from cardiovascular diseases, alzheimers disease and cardiovascular diseases and cancer (USDA, 2016). The productivity and quality of lettuce depends on the growing conditions and soil amendments such as poultry manure, green manure and farmyard manure. Organic vegetable growing has its attendant benefits among which includes, tastier and healthier vegetables that are better than chemically grown ones. The soil nutrient status is also maintained and improved. The quality and quantity of fertilizers applied are key factors affecting the growth, yield and quality of plants however excessive amounts are applied to vegetables in order to achieve maximum yield (Stewart *et al*., 2005). Thus, organic manure can serve as alternative practice to inorganic fertilizers for improving soil structure, reducing the amount of toxic substances such as nitrates produced by conventional fertilizers in vegetables hence improving the quality of leafy vegetables inclusive of lettuce as well as human health. Organically grown fruits and vegetables contain more minerals and vitamins than conventionally grown ones (Worthington, 2001). Therefore the productivity and quality of vegetables especially lettuce depends on the growing conditions and fertilizer applications.

Materials and Methods
A pot experiment was carried out at the orchard of the Department of Agronomy, Ahmadu Bello University, Zaria. (11^{0}11'N 7^0 38^{0}E) and 686m above sea level in the northern guinea savanna ecological zone of Nigeria, The treatments consisted of three rates of poultry manure (0, 2 and 4 tons^{-1}) and three (3) green manure sources (soyabean, mucuna and lablab) factorially combined

and arranged in Randomised Complete Block Design (RCBD) replicated three(3) times. The lettuce variety used was Eden. It is tolerant to heat and bolting, tolerant to necrosis, makes a large compact forming head. The soil was collected from the research farm of the Institute of Agricultural Research (IAR) Samaru Zaria and analysed before placement in pots as per treatment and allowed to decompose in the soil for two (2) weeks. The three legumes were sown as per treatment and at 8 weeks after sowing (WAS) they were harvested and analysed for their chemical components before incorporation in to the pots as green manure as per treatment. Seeds of lettuce were sown manually by broadcasting on 8th July 2016. Weeds were frequently hand pulled carefully from each pot to avoid damage to crops. There was no incidence of pests and diseases observed during the period of the experiment. Harvesting was done at 56 WAS and yield parameters were taken by uprooting the entire crop. Two crops were tagged in each pot and measurements of plant height, number of leaves and fresh plant weight were taken. The height of the crop was taken from the ground level of the plant to the apex using a metre rule, the number of leaves were counted and the average was obtained and recorded. All plants in the pots were harvested and the fresh weight was taken using a Mettler Toledo SB16001 electronic weighing balance.

Results and Discussion

Table 1 shows the chemical composition of the soil amendment applied. Nitrogen content was found to be higher in poultry manure followed by that from Lablab then Mucuna and the least was from Soybean. Table 2 shows the growth and yield of lettuce as influenced by poultry manure and green manure at Samaru. Poultry manure significantly influenced the parameters. Application of 2 t ha^{-1} of poultry manure significantly increased the plant height and number of leaves of lettuce similar trend was observed with 4 t ha^{-1}. There was a corresponding increase in the fresh weight at harvest with increasing poultry manure from 0 to 4 t ha^{-1}. The use of different sources of green manure significantly influenced the plant height and fresh weight at harvest of lettuce. Where Lablab and Soybean produced comparably taller plants than Mucuna while the use of lablab as green manure produced significantly the heaviest plant fresh weight followed by that from the use of soybean and the least was when Mucuna was used. The significant interactions between poultry manure and green manure on the number of leaves and plant fresh weight of lettuce is presented in Table 3. When Mucuna and lablab were used application of 2 t ha^{-1} poultry manure gave a significant increase in number of leaves of lettuce. However beyond this rate no significant improvement in this parameter was observed but when soybean green manure was used varying the rate of poultry manure did not significantly influence leaf production. At fixed manure rate of 0 t ha^{-1}, use of soybean green manure resulted in more leaf production only than for mucuna or lablab but when 2 t ha^{-1} of poultry manure was applied, leaf production where either mucuna or lablab green manure was incorporated were similar and more than for the soybean. When the highest poultry manure rate of 4 t ha^{-1} was considered varying the source of green manure had no significant effect on leaf production. The interaction between poultry manure and green manure on plant fresh weight. (Table 3). At fixed poultry manure rate 0 t ha^{-1}, the use of Lablab as green manure resulted in similar plant fresh weight with that of Soybean though heavier than Mucuna. When 2 and 4 t ha^{-1} poultry manure were considered, Lablab still had heavier fresh plant weight than for other sources of green manure. Application of 2 t ha^{-1} poultry manure and further increase to 4 t ha^{-1} significantly enhanced plant fresh weight of lettuce regardless of the source of green manure. A combination of 4 t ha^{-1} of poultry manure and lablab significantly produced the heaviest plant fresh weight while the interaction of 0 t ha^{-1} and Mucuna produced the least plant fresh weight. The positive influence of poultry manure on virtually all the parameters of the crop might be due to the release and use of the nutrients contained in the poultry manure. This result confirms the Masarirambi *et al*., (2012) from the results of an experiment conducted showed that the chicken manure levels significantly affected the growth, yield and nutritional quality of lettuce. The low fertility status of the soil on which the experiment might have been the reason for the positive response response of the crop to the applied poultry manure rates. The significant differences in plant height and fresh weight of lettuce as result of using different sources of green manure could be attributed to the high N content of the Lablab. Another positive effect of green manure on lettuce could be partly associated with the amounts of plant nutrients in general and nitrogen in particular, returned to soil biomass (Shah *et al.*, 2011). The higher values for number of leaves as well as plant fresh weight observed by the combination of the poultry manure and lablab could be as a result of the fact that both poultry manure and lablab green manure were very rich in nitrogen which is a key element for higher vegetable yield and quality and it is involved in all parts of the plants metabolic processes and its rate of uptake and partition being largely determined by supply and demand during the stages of plant growth (Delogua *et al*., 1998).

Conclusion

Based on the results obtained it can be concluded that application of 4 t ha^{-1} poultry manure and the use of lablab as green manure resulted in a good crop of lettuce.

Abstract
The experiment was conducted at National Root Crops Research Institute Umudike Southeastern Nigeria to determine the effect of sett-size and spacing on elite landrace of white yam. The variety was Yandu. Parameters assessed were: tuber number, tuber weight (g) and tuber yield (t/ha). Data obtained was subjected to statistical analysis of variance (ANOVA) using Genstat Discovery Edition 3 Statistical package and treatment means was separated by using (LSD) Least Significant Difference at 5% probability level. The result obtained indicated that sett-size of 55g at spacing 1m x 1m gave the highest yield of 4.0 number of tuber per 1000 plants/ha fresh weight of tuber per plot. Also, spacing of 1 x 0.5m and sett-size of 55g gave the highest tuber yield of 27.03 t/ha. These indicate that sett-size of 55g and spacing of 1 x 0.5m could be used in the production of Yandu white yam cultivar.

Key words: Sett-size, spacing, landrace and tuber yield

Introduction
Yam (*Dioscorea species*) is a tuber crop belonging to the family Dioscoreaceae. The species of economic importance include (*Dioscorea rotundata*), (*Dioscorea alata*), (*Dioscorea cayenensis*), (*Dioscorea dumentorum*), (*Dioscorea bulbifera*), (*Dioscorea esculentus*) are most widely cultivated (Akinbo, *et al,* 2016.). It is the most important food and income sources for millions of producers, processors and consumers in West Africa. Yam is also integral to the socio cultural life in the sub-region of the Sahara. Also, yam is a monocotyledonous and annual herbaceous plant and according to Nwankwo, *et al* (2017), yam has a long climbing stems which wind themselves around support. He further reported that a single plant can produce up to five tubers of various shapes which can weigh up to 5kg. Yam is very rich in starch and protein and is a popular tropical food. It grows well where there are light, well drained soils and the most fertile land is used for yam cultivation. Yams are staple food crops in the West Africa except for cereals. Yam can be multiply through the use of mini-sett. A mini-sett is defined as a set of about 25g or less which is one quarter the normal planting set for seed yam production. It will develop to address the problem of high cost of scarcity of seed yam. In traditional, yam growing area, the setts of seed yam are planted in mounds especially made at the end of the rainy season before the soils becomes too hard to work on. The yams are planted during dry season and begin to sprout at the onset of the next rainy season. Stalks are usually provided for the yam vine to climb on by cutting the sticks or dried maize and guinea corn stems (Nwankwo, *et al,* 2017). Harvesting of the tubers starts in the middle or later period prior to rainy season. In the Northern parts of Nigeria where yam growing is new, planting is usually done on ridge and staking is extremely rare. (Akintola, 2008). National Root Crops Research Institute, (Umudike) and IITA, Ibadan developed the mini-sett technique to overcome the critical problems of the unavailability of good quality seed yam by improving the rate of multiplication of white yam (IITA, 1985). The mini-sett technique is by cutting mother seed tubers to smaller sizes with a reasonable amount of peel (periderm) from which sprouting occurs. The mini-sett will be treated with chemical to prevent termite attack and rot. Nevertheless, mini-sett could be used in all yam multiplication. There will be varietal differences in the performance of the mini-sett. Therefore, the objectives of this study were to

determine the effect of sett-size and the effect of spacing on the yield of Yandu white yam cultivar.

Materials and Methods

The trial was conducted at the Eestern farm of National Root Crops Institute, Umudike, (NRCRI) in 2016 and 2017. One white yam cultivar (Yandu) was used. The setts weights were 35g, 45g, 55g and 65g. The land was prepared with tractor, the ridges were spaced 1.0m apart and the tuber setts were planted on the crest of the ridge. The plot size was 4x2m = ($8m^2$) and the number of the treatments were 16. The treatments consist of four levels of sett-size and four levels of spacing which were: 1mx0.25m, 1mx0.5m, 1mx0.75m and 1mx1m. Pre-emergence herbicide (Premextra) was applied complemented with manual weeding to ensure weed free plots. The Experimental Design was Randomized Complete Block Design. Each plot contained 16 plots and replicated 3 times. Each plot was separated from each other with a space of 1m. Fertilizer NPK (15:15:15) was applied by the use of side application method.

Data collection: Data collected include the Number of ware yam, weight of ware yam, number of seed yam, and weight of seed yam, number of tuber per plot and weight of tuber per plot.

Data analysis: The number of tubers per plot were counted and recorded at harvest. All tubers per plot were weighed after harvest and analysis of variance was used (ANOVA). For the tuber yield analysis, treatment means was separated using the LSD (least significant difference) at 5% probability level. The tuber yield was measured in tones per hectare.

Results and Discussion

The effect of sett-size and spacing on the number of tuber of the white yam cultivar in 2016 and 2017 are represented in Table 1(a) and 1(b). In 2016, Table 1(a), there was no significant ($p>0.05$) differences on sett weight of the white yam (Yandu) variety. However, the 1.0m x 0.25m spacing and sett-size of 45g gave the highest number of tuber of 2.21 number of tuber per 1000 plants/ ha. This was followed by 1.0m x 1.0m spacing and of 35g sett-size which gave 2.16 number of tuber per 1000 plants/ ha. There was no significant differences ($p>0.05$) on the interaction of sett weight and spacing. In 2017, Table 1(b), there was significant difference ($p<0.05$) of sett weight of Yandu white yam variety. The 1.0 x 1.0 m spacing and sett-size of 55g gave the highest yield of 4.0 number of tuber per 1000 plants/ ha followed by 1.0 x 0.75m spacing and 45g sett-size which gave 2.09 number of tuber per 1000 plants/ ha. For the spacing, there were no significant differences ($p>0.05$). However, there was significant differences ($p<0.05$) in the interaction on the number of tuber per 1000 plants / ha. Sett-size at 55g and spacing of 1 x1 m gave the highest yield of 4.0 number of tuber per 1000 plants/ ha. Effect of sett-size and spacing on the tuber weight yield (t/ha) of Yandu white yam cultivar are represented in Table 2(a) and (b). There was no significant ($p>0.05$) differences in the set weight in 2016 (Table 2a). For spacing, there were significant ($p<0.05$) differences. The spacing of 1 x 0.25 m and sett-size of 65g gave the highest tuber weight yield of 23.69t/ha followed by spacing of 1x0.25m and set-size of 35g of the tuber weight yield of 23.23t/ha. For the interaction, there was also no significant ($p>0.05$) differences. In 2017, (Table 2b), there was significant difference in both sett weight, spacing and the interaction. The 55g sett size and spacing of 1x0.5m gave the highest fresh tuber weight yield of 38.70t/ha, followed by sett-size 35g and spacing of 1 x 0.25m with the tuber weight yield of 23.80t/ha. For the interaction, sett weight of 55g and spacing of 1 x 0.5m gave the highest fresh tuber weight yield of 38.70t/ha. There was high significant ($P<0.01$) differences in the spacing for the planting of Yandu variety. The spacing of 1x 0.25m gave the mean yield of 15.46t/ha, followed by the spacing of 1x0.50m which also gave the yield of 15.93t/ha. When the spacing was increased to 1x0.75m and 1 x 1.0m, the tuber yield dropped to 5.54 and 6.14t/ha respectively. This indicated that the wider the spacing, the lower the yield. So, for Yandu variety, smaller spacing gave the higher yield of tubers (Table 3). To obtained the maximum yield of tuber, planting at the space of 1x0.5m gave the highest yield of 27.03t/ha and this is hereby recommended for Yandu variety production. The high significant ($p<0.01$) differences obtained from the sett-size indicated that the sett-size of 35.0g gave the mean yield of 12.94t/ha while the sett-size of 45.0g gave tuber yield of 8.69t/ha. Also, sett-size of 55.0g gave the tuber yield of 13.09t/ha while the sett-size of 65.0g gave the tuber yield of 8.35t/ha. This showed that environmental factor might have had effect on the tuber sizes which affected the tuber yield. However, the tuber size of 55.0g at the spacing of 1x0.5m gave the highest tuber yield of 27.03t/ha. The tuber size and planting space is hereby recommended for the cultivation of the white yam, Yandu.

Evaluation of Five Pre-Emergence Herbicides for Effective Weed Control in Cocoyam (*Colocasia Esculenta (L.*) Schott) Farm, Umudike, Abia State

U.E.C. Cyprian, D.C. Korieocha and F. Duru
National Root Crops Research Institute, Umudike Nigeria
E-mail: chikaodiadaeze@gmail.com.

Abstract
The field experiment was conducted at the Research farm of National Root Crops Research Institute, (NRCRI) Umudike (05°, 29N, 07°, 31E and 122M above sea level) in 2015 and 2016 cropping season to identify effective herbicides and rate for weed control in cocoyam production. There were 12 treatments consisted of five preemergence herbicides with rates, namely: Dunon at 3L/ha, Diuron at 4L/ha, Goal Tender 4F at 0.5L/ha, Goal tender at 0.75L/ha, Liberator forte at 1L/ha, Liberator forte at 3L/ha, codal Gold at 3L/ha, Codal Gold at 4.5 L/ha, primextra Gold at 3L/ha, Gold at 4.5L/ha, Hoe weeding at 4,8 and 12 WAP and weedy check. The treatments were laid out in a randomized complete block design (RCB) and replicated 3 times with cocoyam variety (Nce 012) as test crop. Application of Goal Tender 4F of 0.5L/ha and goal tender 4F at 0.75L/ha had minimal percentage in jury in both years when compared with other treatments. Goal tender 4F at 0.75 had the lowest weed density, while the unweeded check had the highest weed density. Goal tender 4f at rate 0.75L/ha gave the highest mean yield weight (3.95t/ha) in both years where unneeded check had the lowest mean yield cormel weight (0.38t/ha).

Introduction
There are two main edible types of cocoyam crops of economic importance (Green and Oguzor 2009). They belong to the Araceae family. Cocoyam is probably one of the oldest crop on earth and its domestication is likely to have occurred more than 10,000 years ago. Although some authors (Yen and Wheeler, 19968; Mathews, 1990) considered that cocoyam originated in Indo-Malayan region, between Maynmar and Bangladesh, there is insufficient evidence to confirm this supposition. Nigeria remains the largest producer of cocoyam in the world, with estimated production of 5.49 million metric tons (FAO, 1990), followed by Ghana and China. It is a starchy widely cultivated crop and consumed in south eastern agricultural zone of Nigeria for decades (Ndon *et al.,* 2003). Currently, weeds, pest ad diseases are the most limiting factors in cocoyam production; resulting in significant yield losses in the field and after harvest. Weeds are plants growing where man does not want it to be (Onwueme and Singh, 1998). According to Jackson *et al.,* (2003), weeds account for an estimated 14% loss of yield on worldwide basis. In cocoyam production, weeds have been observed to drastically reduced farmer's yield and constitute a major constraint to cocoyam production in the humid tropics. Hence there is need to identify effective herbicides for weed control in cocoyam production.

Materials and Methods
A field study were conducted at the experimental farm of the National Root Crops Research Institute (NRCRI) Umudike. The cormels were sown on ridges at plant spacing of 100cm by 50cm within and between rows respectively.
Two days after planting, the pre-emergence herbicides were applied using knapsack sprayer for various treatment listed below.

1. Diuron at 3L ai/ha
2. Diuron at 4L ai/ha
3. Goal Tender 4F at 0.5L ai/ha
4. Goal Tender 4F at 0.75L ai/ha
5. Liberator forte at 1L ai/ha

6. Liberator forte at 3L ai/ha
7. Codal Gold at 3L ai/ha
8. Codal Gold at 4.5L ai/ha
9. Primextra Gold at 3 Lai/ha
10. Primextra Gold at 4.5 Lai/ha
11. Hoe weeding at 4,8 and 12 WAP
12. No weeding.

Date collected include; weed density assessment, visual rating of crop injury and cormel weight. The data was subjected to analysis of variance (ANOVA) using the genstate Discovery Edition 12 (Genstat, 2009) and he mean separation was done using least significant difference (LSD).

Results and Discussion

Weeds reduced crop yield and quality. They also decrease the value and productivity of land; reduce harvesting and processing efficiency, increase, cost and labour for control measures. Result showed that all the herbicides applied significantly reduced yield loss in cocoyam when compared to the no weed control treatment. However Goal Tender 4F at both rates proved to be superior among others by significantly lowering the crop injury and also lowering the weed density. In both years, goal tender 4F at 0.75L/ha had comparable weed density with hoe weeding at 8WAP. At 10WAP also, it was observed that Gold Tender 4F at 0.75L/ha gave the least mean value of weed density of apart from hoe weeding. The same trend was observed at 12 and 14WAP. But a significant difference was observed among the treatments.

Conclusion

Application of Goal Tender 4F at 0.5L ai/h and 0.75L ai/ha gave the highest weed control efficacy when compare with the other treatment. Infact, with good weed control, lower crop injury, lower weed density and higher cormel number and weight, Goal Tender 4F at 0.75L/ha can be recommended for weed control in cocoyam especially on mimosa invisa in south eastern Nigeria.

Effect of Some Plant Extracts and Pesticides in the Control of Bacterial Leaf Blight Disease of Cocoyam (*Colocassia esculenta*) in Umudike, South Eastern Nigeria

U.E.C. Cyprian and F. Duru
Cocoyam Research Programme, National Root Crops Research Institute, Umudike
Chikaodiadaeze@gmail.com

Abstract
A pot experiment was carried out in 2010 and 2011 cropping seasons at the screen house of Michael Okpara University of Agriculture, Umudike to determine the Effect of some plant extracts and Pesticides in the control of Bacterial leaf Blight of cocoyam (Colocasia esulenta L) Scholt. The material used include orange peel (citrus sinesis), Bitter cola (Garcinia Kola), Ginger (Zingiber Offlilcinale) streptomycin sulphate (antibiotic), Floraplus (fungicide) and sterile water (control). The experiment was carried out in complete randomized design (CRD) and replicated six times. The plant materials used were first made into aqueous extracts using cold water extraction and diluted to 10% concentration. Application on leaves was by use of hand sprayer for two weekly intervals. Data were collected on disease severity and incidence including growth parameters and on yield of corms. The result obtained showed that all the extracts were able to reduce disease and increase yield better than the control.

Introduction
Cocoyam colocasia esculenta (L.) Scholt constitutes one of the basic food crops of major economic importance in the south eastern Nigeria. It ranks the third after cassava and yam, in terms of total production, land area under crop and consumption (Chukwu and Nwosu, 2008). There are two main edible types of cocoyam in Nigeria Viz: Colocasia esculenta (L) Scholt, otherwise known as “taro” and xanthosoma saggittifoleium also known as tannia (Arene and Ene, 1987). The former is by far more popular than the later. Taro requires heavy fertile upland soil and plentiful rainfall for good yield. It does well also in a fertile low land environment (Agboola, 1987; Anikwe *et al.,* 2007) and commonly grown in South Eastern Zone of Nigeria. Tannia is well cultivated in the South Western zone of Nigeria (Ikwella, 1999).
Colocasia esulenta (taro) is currently threatened to extinction in south eastern Nigeria as a result of its high susceptibility to bacterial leaf blight disease. Therefore this study was undertaken to isolate and identify the cause organism and determines the effect of some selected local plant extracts in the control of bacterial leaf blight of colocasia esculenta.

Materials and Methods
The study was carried out for two years during 2010 and 2011 cropping seasons under pot trials. Top soil was collected from the Eastern farm site of the Michael Okpara University of Agricuture, Umudike. Soil analysis and characterization was conducted to determine the macro ad micro elements and other constituents of the soil.The soil was sterilized and soil, fine sand and poultry droppings respectively (the poultry dropping was allowed to decompose for two weeks before use) and later the sterilized soil mixture dispensed into plastic pots of 15cm in diameter (three, quarter filled). The experiment was arranged in a completely randomized design (CRD) consisting of six treatments and six replications. The plant materials used as extracts were bitter cola ginger, orange peel and two synthetic pesticides, cocoyam corms were planted into experimental pot at the rate of one seedling per pot.

Results and Discussion

This study shows the bactericidal potential and effect of three plant extracts used namely *Garcinia kola*, *Zingiber officinale* and *Citrus sinensis* in comparison with standard pesticides as far as reducing both disease severity and incidence are concerned and at the same time enhancing growth and yield of cocoyam which is an important staple food crop in South Eastern Nigeria. It was noted that the plant extract proved to be as effective as standard synthetic pesticides such as antibiotics (streptomycin sulphate) and fungicide floro plus and were even in some cases at par with these conventional chemicals usually used in disease reduction, indicating that some natural anti-microbial active ingredients are indeed contained in these plant extracts (Stoll, 2000, John and James, 2004). Oparah and Obani (2010) made similar observation in bacterial blight of eggplant. Amadioha (2004) reported that the greater effectiveness of the extracts may be due to inherent chemical constituents or bioactive ingredient of the plant extracts be concluded contain anti-bacterial polyphenolic compounds.

Effect of Poultry Manure, Time of Introduction of Cowpea Varieties and Clipping on Popcorn (*Zea mays everta* L.) and Cowpea (*Vigna unguiculata* (L.) Walp.) Intercrop at Maigana, Northern Guinea Savannah of Nigeria

***[1]G. L. Luka, [1]E. C. Odion and [2] U.L. Arunah**

Abstract
The experiment was carried out at Maigana (11º11'N, 07º37'E and 707.6mm above sea level) during the 2013 rainy season. The treatments consisted of four poultry manure rates (0, 2, 4 and 6 tha^{-1}), two cowpea varieties (SAMPEA 6 and Kananado), time of introduction of cowpea (mid June and Mid July) and clipping (clipped and unclipped) laid out in a split plot design and replicated three times. The clipped foliage was incorporated into the soil as green manure. Results obtained showed no significant differences on popcorn parameters in the intercrop but 2tha^{-1} and 6tha^{-1} poultry manure significantly increased cowpea shoot dry weight and canopy width respectively. SAMPEA 6 had higher yield (843.97kgha^{-1}) than Kananado (658.09kgha^{-1}). Wider canopies were also recorded when the cowpea was sown early into the popcorn and unclipped. Significant interactions were recorded between cowpea varieties and their time of introduction on canopy width and shoot dry weight, and also on canopy width between cowpea varieties and clipping, poultry manure, cowpea varieties and clipping. Based on this research, better performance of the intercrop can be obtained by applying 4tha^{-1} of poultry manure with SAMPEA 6 relayed into the popcorn without clipping or applying 6tha^{-1} of poultry manure, sowing SAMPEA 6 early into the popcorn and later clipping it.

Introduction
The sustainability of crop production in the tropics is at a great risk because of the inherent low fertility of the soil and a further decline in the fertility due to intensive cultivation, climate change, high temperature and rates of decomposition of organic matter, leaching, total removal of crop residues and erosion by wind and water (Anon., 2011). These have resulted in degradation of the soil which has also led to low productivity and dwindling food supplies as such creating yield gaps (Pablo and Ken 2013). In an attempt to boost crop production, farmers employ the use of chemical fertilizers but this often result in soil degradation expressed as acidity, nutrient imbalance and loss of soil structure (Cassman, 1999). These problems can however be alleviated by adopting appropriate environmentally friendly and affordable cultural practices that will improve and maintain the soils productive capacity and this can be achieved through intercropping, use of animal manure, compost and green manuring (Heinrich, 2013). Manures have been proven to help amend the soil by improving soil physical, chemical and biological conditions, soil microbial activities as well as soil moisture movement and retention thus ameliorating the soil. The use of manures on the soil also help to feed the soil and allow the soil feed the crops instead of fertilizing the crop alone thus resulting in crops producing at optimum levels and bridging yield gaps (Pablo and Ken 2013). A Popcorn (*Zea mays everta* L.) /cowpea (*Vigna unguiculata* (L.) Walp.) mixture was used to demonstrate the effect of organic manures (poultry manure and green manure) on productivity of the crops in the mixture.

Materials and Methods
The experiment was carried out at Maigana (11º11'N, 07º37'E and 707.6mm above sea level) during the 2013 rainy season. The treatments consisted of four poultry manure rates (0, 2, 4 and 6 tha^{-1}), two cowpea varieties (SAMPEA 6 and Kananado), time of introduction of cowpea (mid

June and Mid July) and clipping (clipped and unclipped) laid out in a split plot design replicated three times. Clipped foliage was incorporated into the soil as green manure. Parameters taken on popcorn were; crop growth rate (CGR), cob weight and yield and on cowpea canopy width, shoot dry weight and yield. Canopy width and shoot dry weight of the cowpea were taken at 12 weeks after sowing. The data collected were summarized and subjected to analysis of variance as described by Snedecor and Cochran (1967) and the treatment means were separated using Duncan Multiple Range Test (DMRT) (Duncan, 1955).

Results and Discussion

The treatments imposed had no significant effect on the crop growth rate (CGR), cob weight and yield of popcorn in the intercrop (Table 1). Also, no significant interactions were recorded between the treatments on the popcorn parameters taken. The cowpea in the mixture however showed significant differences due to some of the treatments imposed. Canopy width significantly increased with increase in poultry manure rates up to 6tha^{-1}. When the cowpea was sown early and unclipped, the canopy width was significantly increased. The shoot dry weight was significantly affected only when poultry manure was applied, where 2tha^{-1} gave the heaviest dry shoots and a significant difference in yield was recorded between the varieties where SAMPEA 6 out yielded Kananando. Significant interactions were observed between cowpea varieties and their time of introduction (V*T) on canopy width and shoot dry weight while cowpea varieties and clipping (V*C) and poultry manure, cowpea varieties and clipping (P*V*C) were observed on shoot dry weight. Table 2 shows that wider canopies were recorded on the two varieties when sown early. Also SAMPEA 6 had the heaviest dry weight when sown early though similar to late sown Kananado. In table 3, wider canopies were recorded on the unclipped plots with SAMPEA 6 having the widest canopies. Table 4 shows that canopy width increased as poultry manure rates increased in both varieties whether clipped or not with unclipped SAMPEA giving the highest at 6tha$^{-1.}$ Increases in canopy width and shoot dry weight of the cowpea in the intercrop with the application of poultry manure can be attributed to its ability to effectively amend the soil by improving the organic carbon content as well as nitrogen, phosphorous and potassium levels of the soil. More so, the increases recorded could be attributed to the shade tolerant ability of cowpea which enables it adapt itself under tall cereals in an intercrop (Kurt 1982). SAMPEA 6 could have out yielded Kananado because it is an improved variety and has better adaptability to the environment than the local cultivar, as local cultivars have been found to be poor in resource capture and utilization. Singh *et al*. (2002) reported that local cultivars recorded significantly lower yield and yield components than improved cultivars which could produce up to 4 tonnes per hectare. Wider canopies and increased shoot dry weight as a result to early planting and non-clipping recorded early in the season could be attributed to higher solar radiation, adequate moisture (rainfall) as well as lower pest pressure in early season Akande *et al*. (2012).

Abstract
Leaf and stem-bark aqueous extracts of neem-Azadirachta indica (A), pawpaw-Carica papaya and bitter leaf-Vernonia amygdalina (V) at 2.5, 5.0, 7.5 and 10% of the active ingredient were used in investigating their effectiveness in the control of web blight of cowpea, incited by Rhizoctonia solani. In vitro, all plant extracts except those of pawpaw stem bark and its leaf at 2.5% concentration, significantly reduced mycelial growth of the fungus compared with the control. In vivo, both leaf and stem-bark extracts of A and only the leaf extract of V reduced the incidence of the pathogen by 35-73%. Combinations of AC and CV (1: v/v) significantly enhanced the anti-fungal properties of pawpaw extracts than when its extracts alone were used on the pathogen.
Keywords: Vignia unguiculata, web blight and plant extracts

Introduction
Cowpea, *Vigna unguiculata* (L.) Walp., is an important food for both human beings and livestock in Nigeria. The dry seeds may be eaten in its form or milled into flour, which is then used in several ways. Similarly, the fresh seeds and immature pods are eaten as vegetables. The young shoots and leaves are eaten as spinach and they are widely used as potherbs in Tropical Africa (Onwueme and Singh, 1999). However, many diseases threaten its production. One of the most destructive fungal diseases of cowpea is web blight caused by *Rhizoctonia solani* Kuhn. Synthetic fungicides have been used to control this disease (Oyekan, 1979), but being a soil-borne disease, its elimination in the soil after establishment by chemicals is costly and sometimes hazardous. Besides, the fungicides are gradually becoming ineffective due to the development of new physiological races of pathogens (Wellman, 1977). Thus, the search for more acceptable alternative means of control has been stimulated in the use of plant products with fungicidal properties, which are less phytotoxic and biodegradable (Singh and Singh, 1980; Tewari and Nayak, 1991; Gerard et al., 1994). More higher plants and their constituents which have shown success in controlling certain other diseases but which have not been tested on *R. solani* elsewhere because of their non-availability in those areas need to be investigated (Adebitan, 1997; Obagwu et al., 1997; Olufolaji, 1999; Owolade and Osinkalu, 1999). This study was undertaken, therefore, to screen extracts from the leaves and bark of neem-*Azadirachta indica* Juss, pawpaw-*Carica papaya* and bitter leaf-*Vernonia amygdalina* to control web blight of cowpea.

Materials and Methods
Preparation of plant extracts
For the preparation of plant extracts, fresh leaves and stem bark of *A. indica*, *C. papaya* and *V. amygdalina* were collected, and washed thoroughly under running tap water and sterile distilled water. Hot water extraction method of Kurucheve and Padmavathi (1997) was used. The plant materials (leaves and stem-bark) were separately chopped into the required amount of water (1:1 w/v) using a grinder. The contents were emptied into conical flasks placed inside water bath, which was heated at 80°C for 10minutes. Each suspension was vigorously agitated for 24 hours using the orbit shaker to effect dissolution.

Laboratory study
To prepare plant extracts; potato dextrose agar-lactic acid amended media (PDAL), all of each aqueous plant extract (prepared as described above) of 1.25, 2.5. 3.75 and 5.0 mL was separately mixed with 48.75, 47.50, 46.25 and 45.0 mL of molten PDAL which had earlier been autoclaved at 1.1 kg.cm^3 at 121°C for 15 minutes and cooled to about 50°C to get the final concentration of 2.5, 5.0 7.5 and 10% of the extracts in the media. Three drops of 10% lactic acid were added to prevent bacterial contamination. Each of the media was then poured into four petri dishes at the rate of about 20 mL per dish and allowed to cool. Benlate, a standard fungicide with formulated concentration of 3.3 g/200 mL of water was used to compare the efficiency of the test materials. Un-amended (i.e. normal PDAL) plates served as the check treatment. With the aid of sterile needle, each petri dish was inoculated in the centre with 5 mm disc mycelia of the fungus cu from the edge of a 7-day old fungal colony. The plates were incubated at 28±2°C for 9 days after which records of colony diameter was taken. Colony diameter was determined by taking the difference between the diameter of the initial mycelial inoculum and that of the cumulative radial growth measured using a pair of compass along two lines drawn perpendicularly to each other on the bottom of each plate. The mean of the two lines was recorded for each colony. The experiment was repeated twice and all treatments in each case were laid out in a completely randomised design.

Screen house studies
One hundred and four perforated plastic pots (1.2 dm2) were sown on each pot filled with sterilised sandy clayey soil. Four seeds of cowpea (cv ART 91-2) susceptible to web blight) were kept on the screenhouse bench and watered daily with tap water. Seedlings were thinned to three at 7 days. At 21 days after emergence, all seedlings were directly inoculated with sclerotia produced from the pure culture of *R. solani* by injecting the stems of the disease-free potted plants at the area between the cotyledons and first leaves with a hypodermic syringe. The inoculated plants were removed from the top of the bench. The aqueous suspension of each plant extract was sprayed at the various rates to run-off after h of inoculation against the disease. Benlate was also sprayed and a control was set up with only pathogen inoculation. All treatments and the control were replicated four times and the experiment was repeated twice. Observation on disease incidence and disease severity were recorded on the 12th day after spraying the extracts. Disease incidence was calculated from the number of infected plants in the plant population. The severity of web blight on the seedlings was scored on a 0-5 scale in which 0= no visible *Rhizoctonia* web blight infection, 1= greater than 0% but less than 12.9% of the plant foliage affected, 2= 13.0- 24.9%, 3= 25.0-49.9%, 4= 50.0-74.9% and 5= 75-100% of plant foliage affected.

Effect of plant extracts combination
The complementary effect of the fungi-toxicity of the combination of the extract of the three plants on *R. solani* at 2.5 and 10% concentrations were also tested in separate experiments. The extracts were combined together in pairs on 1:1 v/v basis both in the laboratory and in screenhouse. Experimental set-up was as earlier described for each case.

Statistical analysis
Data collected from the experiments were analysed by analysis of variance (ANOVA) and means were separated using Duncan's New Multiple Range Test.

Results and Discussion

Compared to the check treatment, *in vitro*, all the plant extracts significantly (P <0.05) reduced the mycelial growth of *R. solani* at the various concentrations tested except that of *C. papaya* at 2.5% (Table 1). Reduction in growth obtained from the use of the extracts over control ranges from 46.5 to 79.1%. Extracts of *V. amygdalina* were most effective. The least mean mycelial growth was recorded in limiting the growth of the fungus than the leaf extracts. However, there was no significant difference between these extracts obtained from the two different plant parts. This observation probably indicates that extracts from both plant parts possess the same amount of toxic principles for their fungicidal effects. Generally, there was decrease in mycelial growth with increase in the concentrations of the extracts demonstrating the fact that the fungitoxic effect of the extracts was more fully expressed at higher concentrations. This is in conformity with earlier reports (Basak and Chacraborty, 1988). Similarly, in the screen house, evaluation of the plant extracts showed the same pattern of results as those earlier obtained in the laboratory. Disease incidence and severity of web blight of cowpea was significantly affected by type of plant extracts and concentrations used. A percent reduction ranging between 35 to 73% for disease incidence and 29-60% for disease severity was recorded, as a result of using extracts of *V. amygdalina* and *A. indica* at various concentrations. With increased concentration of plant extracts, there was corresponding significant (P <0.05) decrease in the incidence and severity of the disease, although none of the extracts at the various concentrations favourably compared with Benlate in reducing web blight (Tables 2 and 3). These findings reveal the anti-fungal properties of extract of the plant parts used in the control of web blight disease of cowpea in this study. This corroborates the findings of other workers who worked on *R. solani* using other plant species (Singh and Singh, 1980; Tewari and Nayak, 1991; Gerard et al., 1994). As a result of pairing the extracts of the three plants, there were more reductions in mycelial growth than when each of the extracts was used alone at the two concentrations tested (Table 4). For instance, it was previously observed in the present study that there was no significant difference in mycelial growth due to the use of *C. papaya* extracts at 2.5% concentration. However, because of the combination, with the extracts of either of the plants, there was significant reduction in mycelial growth. This observation was further supported by the additive effect of AV (when used at a higher concentration of 10%) which resulted in a similar reduction comparable to Benlate. Screenhouse studies also revealed similar results as shown in Table 5. This may thus suggest that there was synergism, which might have enhanced the anti-fungal activities of the individual plant extracts.

Conclusion

The plant products used in this study are locally available everywhere in Nigeria. Their potential as biocidal substances for the control of *R. solani* infecting cowpea has been demonstrated. With further field studies confirming their efficacy, especially at higher concentrations than used presently, their extracts could offer a practicable and environmentally friendly alternative to the use of synthetic fungicides, which are fraught with many limitations.

Abstract
A field experiment was conducted during the 2010 rainy season at the Faculty of Agriculture, *Teaching and Research Farm, Bayero University, Kano, Nigeria (11⁰ 58'N, 8⁰25'E and 475 m above sea level), to determine the influence of Foliar fertilizer on the productivity of grain amaranth (Amaranthus cruentus L.). The treatments consisted of four levels of foliar fertilizer (0.0, 2.5, 5.0 and 7.5 kg BONUS NPKha^{-1}) which were replicated five times and laid out in a Randomized Complete Block Design (RCBD). Data was collected on; Plant height, Number of leaves, Leaf area, Leaf area index, Days to 50% anthesis, Panicle length, Number of lodged plants and Grain yield. The result showed that only number of leaves per plant of grain amaranth at 8 weeks after transplanting was significantly (P≥ 0.05) affected by the foliar fertilizer. The lack of response on other characters could be attributed to the high fertility of the soil at the experimental site. Application of 2.5 kg BONUS NPKha^{-1}foliar fertilizer gave the highest grain yield, even though it was statistically similar to other levels. The experiment could be conducted under different soil conditions to ascertain if there is significant contribution of the foliar fertilizer on the productivity of grain amaranth.*
Keywords; Grain amaranth, Foliar fertilizer and Grain Yield

Introduction
Grain amaranth also called *Amaranthus cruentus* L. is a nutritious crop and contains relatively high amounts of minerals and vitamins, which are needed for healthy body growth, sustenance and alleviation of problems of hunger and malnutrition mostly experienced amongst children in developing countries (Aphane *et. al.,* 2003). *Amaranthus cruentus* L. is a member of the family amaranthaceae and is widely cultivated in Nigeria (Omidiji, 1976). It was introduced several centuries ago in to tropical Africa from Central America by European explorers, in Africa it passed quickly from tribe to tribe probably as weed in millet, maize or sorghum seed. *Amaranthus cruentus* is an erect annual herb which grows to a height of 1-2 m and often with a branching habit (Grubben and Vansloten, 1981). It has a growing period of 5 to 6 weeks thus making it to have an advantage to the rural and peri-urban farmers in Nigeria to keep cultivating it two or more times on the same piece of land in a year (Adewole and Igberaese, 2011). According to National Research Council (NRC, 1984), *A. cruentus* is probably the most adaptable of all the amaranth species. For seeds to germinate and establish roots amaranth require well drained soil and for optimum yield, it requires fertile well drained soils with a loose structure and high level of moisture throughout the growing season (Tindall, 1983). Foliar fertilizer is any fertilizing substance applied in a liquid form on the plants shoot. Certain of the fertilizing nutrients soluble in water may be applied directly on the aerial portion of the plants. When problems of soil fixation exist, foliar application constitutes the most effective means of fertilizer placement (Tisdale *et al*., 1966). So far, the most important use of foliar sprays has been in the application of micronutrients. The greatest difficulty in supplying N, P and K, in foliar spray is in the application of adequate amounts without severely burning the leaves and without unduly large volume of solution or number of spraying operations. However, foliar sprays are an excellent supplement to soil application of the major nutrients (Tisdale *et al*., 1966). Currently, there is a dearth of information on the growth performance, yield and nutritional quality of *A. cruentus* after repeated application of foliar fertilizer. While it is true that the major elements N, P

and K are more economically supplied in solid form, some experts believed that it was only the quantity of these that counted (Anon, 2010). Foliar spraying produces more rapid absorption of Nitrogen than soil application. Much more needs to be learnt about foliar application and its value in supplementing standard soil fertility programmes (Tisdale *et al*., 1966). Therefore, this research is aimed at determining the productivity and yield of grain amaranth (*Amarantus cruentus* L.), as influenced by foliar fertilizer in the Sudan savannah ecological zone of Nigeria.

Materials and Methods

A field experiment was conducted during the 2010 rainy season at the Faculty of Agriculture, Teaching and Research Farm, Bayero University, Kano, Nigeria (11^0 58'N, $8^0$25'E and 475 m above sea level) in the Northern Sudan Savannah ecological zone of Nigeria. The site has mean annual rainfall and temperature of about 800 mm and 31^0C, respectively (KNARDA, 2001). The treatments consisted of four levels of foliar fertilizer (0.0, 2.5, 5.0 and 7.5 kgha^{-1}) of BONUS NPK 20:20:20. They were laid out in a Randomized Complete Block Design (RCBD) and replicated five times. The field was cleared, ploughed, harrowed and ridged 75 cm apart using tractor and marked into plots and replicates. Alley ways of 1.0 m between plots and two ridges between replications were used. The field was marked into five rows of three meters length with two middle rows as the net plot and the third middle row for sampling. The gross plot size was 11.25 m^2. Seeds of grain amaranth (NHAR 493-1) were obtained from National Horticultural Research Institute (NIHORT) Progeny substation, Bagauda, Kano, Nigeria and sown in a well prepared nursery bed of 1.5 m x 5 m in drills of 10 cm apart. They were mixed with fine sand before planting. Watering was done regularly before the establishment of rainfall. Seedlings of 7-10 cm length with 4-6 leaves were removed from the nursery and transplanted three weeks after sowing (WAS) early in the morning at a spacing of 25 cm on ridges spaced 75 cm apart. Appropriate measures were used to control pests and diseases. Inorganic fertilizer was applied at the rate of 50 kg N ha^{-1}, 30 kg P_2O_5 ha^{-1} and 30 kg K_2O ha^{-1} (NPK 15:15:15) by side dressing at two weeks after transplanting (WAT). Urea was later used to balance the remaining Nitrogen at 5 WAT together with the foliar fertilizer (see product analysis in Table 4) as per treatment level by spraying the foliar fertilizer on the leaves using a mini sprayer (Hand held) following manufacturers guide. Harvesting was done by cutting the heads when the grain appear to be physiologically matured (>110 days after sowing) and dried before threshing. The dried heads were placed in a bag (Woven sack) and beaten (Plailing) with a stick which loosens the grain and separated them from the panicle and later winnowed gently to obtain clean grains according to the plots, weighed and bagged separately. Data were collected from five randomly sampled plants at 8 and 10 WAT weeks after the foliar fertilizer was applied on the following parameters; Plant height (cm), measured from the ground level to the terminal bud using a measuring tape; Number of leaves per plant, recorded by counting the number of fully opened/expanded leaves on the sampled Plants; Leaf area (cm^2), determined by measuring the length and width of the sampled plants and their product fixed into the equation: $LA = -0.854 + (LW) * 8.744$, where, L= length and W= width (Kintomo and Ojo, 1997); leaf area index (LAI) was determined from the total leaf are obtained per ground cover per plant as described by Watson (1952), thus;

$$\mathrm{LA} = \frac{\text{Total leaf area per plant}}{Areaofgroundcoverperplant}$$

Panicle length (cm), obtained by measuring the length of the panicle from the base to its peak/apex using a measuring tape at the time of harvest; Days to 50% flowering/anthesis recorded when 50% of the plants in each plot commenced flowering; grain yield per hectare (kg ha^{-1}), determined after harvesting, drying, threshing and winnowing the amaranth. The grains obtained were weighed using a scale and the value obtained fixed into the equation:

$$\text{Total grain yield} = \frac{10{,}000\ \mathrm{m}^2}{Planta\ rea} * Yield\ per\ plant.$$

Data collected were subjected to analysis of variance (ANOVA) to test for significant differences of the treatment means using SAS software (SAS Institute, 1993) Significantly different means were separated Using Duncan's Multiple Range Test (Duncan, 1955).

Results and Discussion

The effect of foliar fertilizer on plant height (cm), number of leaves, leaf area and leaf area index of grain amaranth at 8 and 10 WAT is presented in Table 2. The different levels of the foliar fertilizer had no significant effect on the plant height. This could be attributed to the fact that the soil of the experimental site is fertile enough and had satisfied the crops requirement, also the soil is rich in nitrogen as it has been cultivated the previous year with cowpea and the haulms were not removed, as such they serve as green manure (Table 1). Brandy, (1999) observed that foliar fertilizer assist plants in absorbing other nutrients and corrects nutritional imbalances when there is deficiency. Significant differences were observed on number of leaves of grain amaranth at 8 and 10 WAT, were 0.0 and 2.5 kg ha^{-1} recorded more number of leaves (49.7 and 49.0, respectively). The decrease in number of leaves at higher doses could be attributed to toxicity of the fertilizer. The different levels of the foliar fertilizer also had no significant effect on leaf area and leaf area index per plant of grain amaranth; this may also be as a result of the soil being fertile enough to supply the needed nutrients to the crop. The effect of foliar fertilizer on days to 50% anthesis, panicle length (cm) at harvest, number of lodged plants and grain yield per hectare (kg ha^{-1}) at harvest is presented in Table 3. Application of foliar fertilizer had no significant effect on the above mentioned parameters. It was observed that, the number of lodged plants was more at the control. This may be attributed to the fact that the plants produced longer panicles and as such more prone to lodging. Application of foliar fertilizer had no significant effect on grain yield of grain amaranth in this experiment. It may be as result of the soil having enough nutrients in addition to the NPK applied initially to supply the needed nutrients for the crop. Manga, (2001) reported that application of NPK in the ratio 50:30:30 respectively, were observed to be optimum for growth and yield of grain amaranth in the savannah ecological zone of Nigeria. In this experiment, application of 2.5 kg $ha^{-1}$of the foliar fertilizer was observed to produce the highest yield even though it was statistically similar to all other levels.

Conclusion

From the results obtained, application of foliar fertilizer had increased the number of leaves to a certain limit beyond which further application had no significant effect. Application of 2.5 kg ha^{-1} of the foliar fertilizer was observed to give the best yield even though it was statistically similar to all other levels. The experiment could be conducted under different soil conditions with poor soils to ascertain whether there is any contribution of the foliar fertilizer on the productivity of grain amaranth.

Abstract
The use of physical mutagens such as gamma ray and x-rays is one of the ways through which genetic makeup of a plant can be altered. The seed of T. africana, P. macrophylla and P. biglobosa were exposed to ionizing radiation (x-rays) before sowing at different doses. The doses used for the study were taken from dosimetry test carried out. The effect of x-rays was observed on the germination and growth parameters of the seedlings. In T. africana 86.7% germination emerged from 8 MGy, 4 MGy produced 76.7% germination in P. biglobosa and 8 MGy in P. mecrophylla gave 86.6% germination. Some of growth parameters were influenced positively by the ionizing radiation among the tree species. Some characters were influenced negatively by some dose. It was concluded that x-rays can be used to generate high germination percent in forest fruit trees.Further exploration in using physical mutagen should be taken for the improvement of indigenous forest fruit trees.

Key words: Ionizing radiation, Treculia africana, Parkia biglobosa, Pentaclethra mecrophylla, germination and growth parameter

Introduction
The harvesting, utilization and marketing of fruit and nuts from indigenous trees have been central to the livelihoods of majority of rural communities throughout Africa (Akinnifesi *et al.,* 2004; Leakey *et al.,* 2005) and can make a difference during period of famine and food scarcity (Mithofer and Waibel, 2003). Wild harvesting of fruits from forests and semi-domesticated trees growing on-farm and homesteads can substantially boost rural income and employment opportunities in Africa (Leakey *et al.,* 2005; Ruiz-Perez *et al.,* 2004). Indigenous fruits form a staple food during the hunger periods in the agricultural cycle. A study in Malawi, Mozambique and Zambia reveal that 26 – 50 % of rural households relied on indigenous fruits as a coping strategy during critical seasonal hunger period which usually last for three to four months per year (Akinnifesi *et al.,* 2004). *Treculia africana, Parkia biglobosa,* and *Pentaclethra macrophylla;* are indigenous fruit trees that are cheap source of food, medicine, fodder and cash (Maghembe *et al.,* 1994). There has been limited interest in their conservation, propagation and genetic improvement. Their domestication is hampered by a number of factors: they are perceived as growing slower and taking longer to produce fruits as compared to agricultural and horticultural crops, they have a low ratio of edible to non-edible parts with seasonal availability and limited number of their species. The impact of ionizing radiation on plant growth is largely deleterious and at high doses, is lethal. Although at low doses growth stimulation may occur, the sensitivity of various plant species to different doses of ionizing radiation varies greatly (Sax, 1955). The behavior of numerous plant species under exposure to Gamma radiation have been extensively studied (Irfaq and Nawab, 2011). In comparison, studies on effect of x-rays are relatively limited. Nonetheless, x-rays irradiation was shown to induce biological modifications that affected plant growth, cellular mechanisms and metabolism functions (Younis *et al.,* 1962). Heavy doses of x-rays were shown to reduce seed viability, germination and growth in wheat and barley (*Hordeum vulgare*) (Froier and Gustafsson, 1941). Moreover, x-radiation can cause cytological changes and induce mutations (El Araqi *et al.,* 1997). In a recent study, Al-Enezi and Al-khayri (2012) have shown that x-irradiation induced changes in the content of DNA, photosynthetic pigments and ions in date palm seedling. Narah and Jameel (2012) have suggested that irradiation is a powerful tool for genetic improvement of agricultural plant. Keeping in view of some positive effect of

irradiation, it is in order to evaluate impacts of x-ray on *T. africana, P. biglobosa,* and *P. macrophylla* seeds. Further, it is also assumed that the understanding of x-ray responses on seed of forest trees could provide insight for strategic genetic modification in general and more specifically in economically valuable seedlings under breeding programs.

Materials and Methods

Study Area

The experiment was conducted in an experimental nursery at Forestry Research Institute of Nigeria, Eastern Research Station, Okwuta Isieke Umuahia North in Abia State. This FRIN outstation is located on the low land rainforest of Nigeria. It lies on the latitude 05 ^{0}29`N, and longitude 07 $^0$33`E with average rainfall of 2238 mm per annum, which is distributed over eight months rainy season period (March – October) with bimodal peak in June /July and long dry season occurring between Novembers to February. The minimum and maximum temperature is 23 ^{0}C and 32 ^{0}C respectively and the relative humidity is 60-80 % (Source: Metrological Section of National Root Crops Research Institute (NRCRI) Umudike Nigeria, 2005).

Fruit collection and seed extraction

Mature fruits of *Treculia africana* were procured from mother tree at Okwuta Village in Umuahia North, Abia State. The seeds were extracted from the fruits following the method of Ugwu and Oranye (2006). Fruits of *Pentaclethra macrophylla* were procured at Forest Estate of Forestry Research Institute of Nigeria, ERS Umuahia. The fruits were broke longitudinally for seeds extraction. Mature fruits of *Parkia biglobosa* were also procured from mother tree at Asunara village, Ibarapa area in Oyo State, Nigeria. The fruits were depulped for the seed extraction. The seeds collected were air dried for three days. In order to determine suitable dose for the selected tree species, dosimetry test was carried out for the seeds of *T. africana, P. biglobosa* and *P. macrophylla* at Radiology Department, FMC Umuahia.

Seed treatment/seed bombardment

Irradiation of *T. africana, P. biglobosa* and *P. macrophylla* seeds was performed using X-ray source in ambient condition at Radiology Department Federal Medical Centre Umuahia. The dose used was from the result of dosimetry test carried out. Thirty- five (35) seeds of *T. africana* were exposed to 6 MGy. Another Thirty- five (35) seeds were exposed to 8 MGy exposure. Thirty- five (35) seeds of *T. africana* were used for control. For *P. biglobosa,* thirty- six (36) seeds were exposed to 2 MGy. Another thirty- six (36) were exposed to 4 MGy. Thirty- six (36) seeds were also used for control. For the species *P. macrophylla,* twenty- five (25) seeds were exposed to 4 MGy. Another twenty- five (25) seeds were exposed to 8 MGy. Twenty- five (25) seeds of *P. macrophylla* were also used for control (un-irradiated seeds).

Sowing of irradiated seeds

Immediately after the irradiation of the samples, the seeds were sowed into germination boxes containing sharp river sand. After two weeks of germination in each selected plant species, the seedlings were pricked into prepared poly pots containing loamy soil from the same source.

Recording of germinating seeds

Data recording on germination started when shoot tip was noticed in each selected three species. This was carried out every day for the period of two weeks.

Germination percentage was calculated after two weeks of germination in each plant species using this equation;

$$\text{Percentage germination} = \frac{\text{number of germinated seeds after n}^{\text{th}}\text{ day}}{\text{total number of seeds kept for germination}} \times 100$$

Germination rate was also calculated using the method of Djavnshir and Pourbeik (1976)

Design of the experiment

The design of the experiment is a complete randomized design (CRD) with two treatments. Treatments were replicated 11 times for *T. africana,* and 9 times for *P. biglobosa* and 8 times for *P. macrophylla.* CRD is used because the only source of variability apart from experimental error is the treatment applied. The analysis is based on the linear model

Y_{ij} = μ+ Ti + Eij (Wahua, 1999)

Where

Y_{ij} = value of any observation

μ = population mean common to all treatment

T_i = treatment effect

E_{ij} = random error

Recording of growth parameters
Growth parameters recorded were plant height, number of leaves, leaf area and stem diameter. Plant height was measured from the soil level to the terminal leaf using a meter rule. Stem diameter was obtained by using the venire caliper. Leaf area was determined by tracing the number of squares covered by the leaf on graph sheet. Each square equals 1 cm^2. Number of leaves was by visual counting of the leaves as the plants grew. The recording of these growth parameters were taken every fortnight.

Results and Discussion

Germination percentage of irradiated seeds of selected tree species
T. africana seed germinated 14 days after sowing in control and irradiated sample with 8 MGy. The irradiated seed with 8 MGy and control gave 86.7 % germination, while 6 MGy dose gave 76.6 % germination. Germination occurred in *P. biglobosa* 7 days after sowing. The irradiated seeds with 4 MGy gave 76.7 % germination. The seeds exposed to 2 MGy gave 66.7 % germination while the least germination percentage 56.7 % was emanated from un-irradiated seeds. In *P. macrophylla,* radical tip emerged 19 days after sowing in irradiated seeds with 8 MGy, produced highest germination percentage of 86.6 %. This followed by irradiated seed with 4 MGy which gave 73.3 %. The least germination percentage was recorded in control, un-irradiated seeds of *P. macrophylla* with 66.6%.

Results of growth parameters of *T. africana*
Height growth (cm)
The shoot height of *T. africana* treated with 6 MGy was 14.1cm, treatment 8 MGy gave shoot height of 12 cm and control height was 13.1cm (Table1). Treatment significance calculated showed significant difference ($p < 0.05$) in the shoot height of the seedlings due to differences in dose applied to the seeds.
Stem diameter growth (cm)
The mean stem diameter ranged from 0.181 cm to 0.198 cm (Table 1). The highest mean diameter (0.198 cm) was recorded for seeds treated with 8 MGy. This was followed by the seeds bombarded with 6 MGy (0.185 cm) while the control had the least mean stem diameter growth of 0.181 cm. Analysis of variance showed significant difference ($p < 0.05$) in the diameter growth of the seedlings.
Leaf area (cm^2)
The largest mean leaf area was recorded in seedling was recorded in seedling of control (14.5 cm^2). This was followed by the leaf area seedlings growing from the seeds bombarded with 6 MGy (13.5 cm^2) while the smallest leaf area (13.4 cm^2) was recorded for the seedlings produced from seeds treated with 8 MGy (Table.1). Analysis of variance shows that doses were not significantly ($p < 0.05$) influenced leaf expansion of the seedlings.
Leaf production
Effect of x-ray doses used (6 and 8 MGy) for seeds bombardment were influenced leaf production of the seedlings, that is, there were significant ($p < 0.05$) effects of the rays on leaf production of *T. africana.* The number of leaves produced varied between 3.30 and 3.61, with the highest mean leaf production (3.61) recorded from the control. This was followed by seeds treated with 6 MGy, (3.44) while the least leaf production (3.30) was recorded for 8 MGy dose (Table .1).

Table 1: Treatment means and standard error for *T. africana* growth parameters

Parameters	6 MGy	8 MGy	Control
Seedling height mean ± std. error	14.1 ± 0.5700	12.0 ± 0.4400	13.1 ± 0.54300
Seedling diameter mean ± std. error	0.185 ± 0.0731	0.198 ± 0.0400	0.181 ± 0.0766
Seedling leaf area mean ± std. error	13.5 ± 1.0400	13.4 ±1.1800	14.5 ± 1.2600
Seedling number of leaf mean ± std. error	3.44 ± 0.1920	3.30 ±0.1820	3.61 ± 0.2160

Results of growth parameters of *P. biglobosa*
Height growth (cm)
Result in (Table 2) shows that the shoot mean height of *P. biglobosa* seedlings produced from seeds exposed to x-ray range between 20.3 and 22.3 cm. The highest mean height was observed in 8 MGy with mean value of 22.3 cm. The mean height value for the seedling raised form seeds

exposed to 2 gray was 20.3 cm. While control seedlings gave 20.7 cm. Analysis of variance showed significant ($p < 0.01$) effect on the shoot growth.

Stem diameter growth (cm)

The mean stem diameter growth ranged from 0.161 cm to 0.167 cm (Table 2). The highest mean diameter (0.167 cm) was recorded for seedlings germinated from seed treated with 4 MGy exposures. The same value was also recorded in control. While 2 MGy exposure produced seedlings with mean diameter of 0.161 cm. Analysis of variance showed that x-ray treatment had no significant ($p < 0.05$) effect on mean diameter growth of the seedlings.

Leaf area (cm^2)

Effect of x-ray dose significantly influenced leaf expansion of the seedlings. There was significant effect ($p < 0.05$) of x-ray on leaf area increment. The treatment, 4 MGy gave mean leaf area of 16.6 cm^2. and 2 MGy gave mean area of 12.0 cm^2 while the control produced leaf area mean of 12.8 cm^2 (Table2).

Leaf production

The number of leaf production in both 2 MGy and 4 MGy seedlings ranged from 3.37 to 3.59. In control the mean leaf production was 3.63 (Table 4.1.9). X-ray treatment on leaf production of *P. biglobosa* was significant ($p < 0.05$) from the analysis of variance calculated.

Table2 Treatment means and standard error for *P. biglobosa* growth parameters

	2 MGy	4 MGy	Control
Seedling height mean ± std. error	20.3 ± 0.992	22.3 ± 944	20.7 ± 0.864
Seedling diameter mean ± std. error	0.161 ± 0.0043	0.167 ± 0.0490	0.167 ± 0.0049
Seedling leaf area mean ± std. error	12.0 ± 0.996	16.6 ± 1.38	12.8 ± 0.832
Seedling Number of leaf mean ± std. error	3.37 ± 0.195	3.59 ± 0.170	3.63 ± 0.168

Results of growth parameters of *P. macrophylla*

Height growth (cm)

From Table 3, the mean height for the rays applied were between 34.8 cm and 36.6 cm with highest mean obtained from seedlings produced by control (36.6 cm). While 4 MGy and 8 MGy gave mean height of 34.8 and 35.8 cm respectively. The height of *P. macrophylla* were not significantly ($P < 0.05$) influenced by 4 MGy and 8 MGy.

Diameter (cm)

The mean stem diameter growth ranged from 0.279 cm to 0.3 cm (Table 3). The highest mean diameter was recorded for seedlings germinated from treated seeds with 8 MGy. This was followed by the treated seeds with 4 MGy with 0.293 cm. While control gave mean diameter of 0.279 cm. Analysis of variance showed that the seeds exposed to x-rays at 4 and 8 MGy had significant influence ($P < 0.05$) on mean diameter growth.

Leaf area (cm^2)

Effect of x-rays influenced leaf expansion of the seedling raised from seeds treated with 4MGy and 8 MGy exposures. The highest mean (160 cm^2) leaf area was recorded in the seedlings produced by seeds of *P. macrophylla* treated with 4 MGy. The seeds treated with 8 MGy produced seedlings with the least leaf area (106 cm^2). While control seedlings produced leaf area of 140 cm^2 (Table 3). Effect of exposure to 4 and 8 MGy is significant ($p < 0.05$) from the analysis of variance calculated.

Leaf production

The number of leaves produced (Table3) varied between 3.12 and 3.67, with highest mean leaf production (3.67) recorded from the seedlings emerged from seeds exposed to 8 MGy. The seeds treated with 4 MGy exposure produced seedlings with leaf production of 3.12 while control entity produced mean leaf production of 3.45. There were significant differences ($p < 0.05$) in the leaf production of the seedlings raised from the seeds exposed to x- ray of 4 and 8 MGy.

Table 3: Treatment means and standard error for *P. macrophylla* growth parameters

	4 MGy	8 MGy	Control
Seedling height mean ± std. error	34.8 ± 1.59	35.8 ± 1.8	36.6 ± 1.13
Seedling diameter mean ± std. error	0.293 ± 0.00654	0.300 ± 0.00801	0.279 ± 0.00705
Seedling leaf area mean ± std. error	160 ± 7.8	106 ± 7.32	140 ± 55
Seedling number of leaf mean ± std. error	3.12 ± 0.157	3.67 ± 0.223	3.45 ± 0.184

The favorable germination which occurred *in T. africana*, *P. biglobosa*, and *P. macrophylla* was as a result of stimulation effect of x-rays. The effect of doses lead to acceleration in cell division rate as well as activation of auxins (Gunkel and sparrow, 1991). Variation (reduction and stimulation) in percentage germilation among the treated seeds might have due to the effect of mutagen on meristemic tissues of the seeds (Dhillon *el al.).*The results obtained among the treatments is line with the observation of Mozumder *et al.* 2004, Palashov and Gil 1997,that “the effect of ionizing radiation on any living organism depend on the amount and the rate of ionizing radiation which was absorbed, the type of ionizing radiation which was absorbed and the type and number of cells affected”. The results obtained in term of seed germination is also in accordance with the earlier reports of on *Acacia leucophloea, Albizia lebbeck,* and *Zizyphus mauritiana (*Akshatta *et al.2013).*The x-ray showed both positive and negative effects on the three tree species selected. That is, some doses influenced the plant characters positively while some did otherwise. The stunted effect on height growth experienced from some doses on the selected tree species may due to the negative effect of x-ray on the cells respossible for the shoot growth. Reduced shoot growth of the seedlings may be attributed to the increase in destruction on growth inhibitors, drop in the auxin level, or inhibition of auxin synthesis as reported by Roychodhury and Tah (2011) and Mostafa *et al*. (2014). The stunted growth may also due to physiological damage resulted in the alteration from normal to dwarf (El.Maksoud and El.Mahrouk, 1993). Joshi *et al*..(2011) explained the dwarfed growth to auxin destruction, changes in biochemical disturbance. The impact of x-ray investigated was varied within and among the species. Some dose produced stimulatory effect on stem diameter of the seedlings whereas some have retardation effect on diameter. The favourable effect produced by some doses on the selected species is in line with previous findings of Akashatta *et al*. (.2013) who observed stimulatory effect of ionizing radiation on the stem diameter of *Terminalia arjuna* using gamma rays. The reduction on diameter growth rendered by some of the dose might be attributed to the physiological damage to radial cell which responsible for the growth of diameter. On the leaf area, those doses which have better leaf area than control showed that they influenced the radial cells and other cells responsible for leaf elongation positively. The unfavourable effect on leaf production by some x-ray dose attributed to auxin synthesis as reported by Roychodhury and Tah (2011) and Mostafa *et al*. (2014).

Conclusion

Although small number of different doses was used for this study, some useful results were obtained most especially on the germination seeds of the selected tree species. It was concluded that x-rays can be used to generate high germination percent in forest fruit trees. The result of this study indicates that exposing forest tree seeds to x-rays before sowing would affect some morphorlogical characters of seedlings positively. It is therefore recommended that other source of physical mutagens should be tried on the selected species and other forest tree species for further exploration of this technology to be beneficial for growth strategies of indigenous fruit tree species.

Abstract
Field experiments were conducted at eastern farm of National Root Crops Research Institute, (NRCRI), Umudike in 2016 and 2017. In both years, the experiment was laid out in a factorial trial and in a randomized complete block design (RCBD) with three replicates. Treatments comprised four levels of stake height (0, 1, 2 and 3m) and five levels of NPK (15:15:15) fertilizer (0, 200, 400, 600 and 800kg/ha). Result showed that fertilizer rate of 200kg/ha and stake height of 0m gave the highest number of tubers per plant (3.51) in 2017 while for tuber weight (kg), fertilizer rate of 0kg/ha and stake height of 2m gave the highest yield (0.680 kg) in 2016. For the tuber yield in (t/ha) in 2017, fertilizer rate of 200kg/ha by stake height of 0m gave the highest yield of (20.80t/ha). From this trial, we observe that farmers tend to go for 0kg/ha fertilizer by 2m stake height.

Keywords: Sett-size, fertilizer level, landrace and tuber yield

Introduction
Yam is one of the major stable foods for the people of Nigeria and to a large extent for people in West Africa (Nwankwo *et al,* 2005). There are six types of yam Species that are majorly cultivated in West Africa. They are the following: (*Dioscorea rotundata*), (*Dioscorea alata*), (*Dioscorea cayenensis*), (*Dioscorea dumentorum*), (*Dioscorea bulbifera*), (*Dioscorea esculentus*) (Okoli, 1986). The major aim of yam cultivation by farmers is not only for consumption but also, to generate income by selling it in the market. Not all yam tubers are acceptable in the market by the consumers (Nwankwo *et al,* 2005). Staking appears to perform functions such as increase in light interception of the leaf canopy and increase in ventilation around the leaves. Ventilation is particularly important in humid environments where high humidity in the canopy can increase the incidence of fungal leaf diseases, especially anthracnose. Staking also facilitates weeding, especially with thorny varieties (King and Risimeri, 1992).Scarce in much production area as land use intensifies. Obiazi (1995) reported that the average Nigerian farmer spends 60 person-days per ha in procuring and installing stakes. The dependence of yam genotypes on staking may relate to their strength of apical dominance and their tendency to branch. Those that are slow to initiate branches may develop best on tall stakes, where the vital early growth of the vine is uninterrupted. Those with less apical dominance and greater branchiness may be less assisted by staking. The system of staking depend on local conditions and available materials. A typical method is to provide one vertical stake per stand. Frequently, where stakes are less available, one stake may be provided for 2–6 stands. However, the staking height may depend on the species or cultivars, the planting materials and the environment. Fertilizer has necessitated fertilization which needs to be used rationally in order to avoid negative ecological impact and undesirable effects on the sustainability of agricultural production systems. In order to calculate the amount of fertilizer to be applied to crops, it is necessary to develop recommendation programmes. Irizarry *et al (*2015*)* reported that yams respond to high nutrient levels and fertilizer application under varying agronomic conditions. Consequently, they extract large quantities of nutrients from the soil. For example, a yam yield of 29 t/ha removed 133kg N, 10kg P and 85 kg K from the soil (Sobulo, 1972). Where there is need for fertilizer application, the recommendation is NPK (15:15:15) at 400-500 kg/ha applied at 8-12 WAP in bands on both sides of the ridges for single

row planting (Eke-Okoro *et al*. 2006), and double rows on each side of the ridge. However, Okpara *et aI, (*2014) have shown that fertilizer needs of yam may depend on the technology used to generate planting materials and plant population density, among other factors.

Materials and Methods

The trial was conducted at the eastern farm of (NRCRI) National Root Crops Research Institute, Umudike Nigeria in 2016 and 2017 cropping seasons. Only Yandu white yam cultivar was used. The stake height were 0,1,2 and 3m and the fertilizer levels were 0, 200, 400, 600 and 800kg/ha. The planting material was obtained from Yam Programme, NRCRI, Umudike, Abia State. The treatments were laid out in a Randomized Complete Block Design (RCBD) with three replications after land preparation. The ridge were spaced 1.0m apart and the cut tuber setts were planted on the crest of the ridge. The plot size was 4m x2m. Sett-size of 50g was planted at a spacing of 1m x0.3m in June 2016 and 2017 of each year. Pre-emergence herbicide (premextra) was applied immediately after ridging and this was complemented with manual weeding to ensure weed-free plots. Fertilizer NPK 15:15:15 was applied at different rate using side application method.

Data Collection: The following data were collected: Below the ground (harvest) trials: number of ware yam, number of seed yam, weight of ware yam, weight of seed yam, number of tuber per plot, weight of tuber per plot and tuber yield.

Data Analysis: Analysis of variance was performed on the data using (ANOVA).For the tuber yield analysis, treatment means was separated using (LSD) least significant difference at 5% probability level. The tuber yield was measured in tons per hectare.

Results and Discussion

The effect of NPK fertilizer and staking height on the number of tubers/plant of Yandu white yam cultivar in 2016 and 2017 are represented in Table 1(a) and (b). In 2016, Table 1(a), there was no significant (P>0.05) differences on fertilizer level of the white yam (Yandu) variety. However, fertilizer level of 600kg/ha and staking height of 1m gave the highest number of tubers per plant of 2.05 per 1000plants /ha. This was followed by 800kg/ha fertilizer level and staking height of 1m which gave 1.90 number of tubers per 1000per plant. There was no significant differences (P>0.05) on the interaction of NPK fertilizer 15:15:15 and staking height. Staking of 1m and fertilizer level at 600kg/ha gave the highest yield of 2.05 followed by 1m by 800kg?ha gave the highest number of tubers per plant of 1.90. There was no significant (P>0.05) on the interaction of NPK fertilizer level and staking height. In 2017, Table (1b), there was significant differences (P<0.05) of NPK fertilizer level on Yandu white yam cultivar. The NPK fertilizer of 200kg/ha and staking height of 0m gave the highest number of tubers per 1000 plants of 3.51 followed by fertilizer level of 400kg/ha and staking height of 1m which gave 1.56 number of tubers per plant. For staking, there was significant (p<0.05) difference. The stake height of 0m gave the highest number of tubers per 1000plants of 3.51 followed by 1m and 400kg/ha gave number of tubers of 156. However, there was significant (P<0.05) in the interaction on the fertilizer level and staking height. NPK fertilizer of 200kg/ha and staking height of 0m gave the highest number of tubers per 1000 tubers per plant which is 3.51. Effect of NPK fertilizer and staking height on the tuber weight (kg) of Yandu white yam cultivar is represented in Table 2(a) and (b). There was no significant (P>0.05) differences in the NPK fertilizer level in 2016 (Table 2a). For staking, there were significant (P<0.05) differences. The stake height of 2m and NPK level of 0kg/ha gave the highest tuber weight of 0.680kg followed by stake height of 3m and NPK level of 200kg/ha gave the tuber weight of 0.670g. For the interaction, there was no significant (P>0.05) differences. In 2017, table (2b), there was no significant differences in the NPK fertilizer level. Fertilizer level at the rate of 200kg/ha and 2m staking height gave the highest tuber weight of 0.526kg, followed by fertilizer level of 600kg/ha b and 0m staking height which gave 0.491kg.However, for staking, there were also, no significant (P>0.05) differences on the tuber weight. Stake height of 2m and fertilizer level at 200kg/ha gave the highest tuber weight of 0.526kg followed by staking height of 0m and fertilizer level of 600kg/ha gave the tuber weight of 0.491kg. For the interaction, there were significant (P<0.05) difference in both fertilizer level and staking height. The NPK fertilizer of 200kg/ha and 2m staking height gave the highest tuber weight of 0.526kg. Effect of NPK fertilizer and staking height on tuber yield in 2016 and 2017 are represented in Table 3(a) and (b). In 2016, Table 3(a), there was no significant (P>0.05) differences on NPK 15:15:15 level on tuber yield of Yandu white yam cultivar. However, the NPK fertilizer level at 400kg/ha and 0m staking height gave the highest tuber yield of 31.70t/ha. This was followed by NPK fertilizer level of 0kg/ha and 2m staking height which gave 29.60t/ha of the tuber yield. For the interaction, there was no significant (P>0.05) differences on the NPK fertilizer level and staking height. The NPK fertilizer rate at 400kg/ha and 0m staking gave the highest yield of 31.70t/ha. In 2017, table 3(b), there were no significant (P>0.05) differences in the NPK fertilizer level. The highest tuber yield in gotten from fertilizer level of 200kg/ha and 0m staking height which gave the yield of 20.80t/ha. This was followed by fertilizer level of 200kg/ha and staking height of 2m which gave the tuber yield of 18.33t/ha. For staking, there are significant (P<0.05) differences. The staking height of 0m gave the highest yield of 20.80t/ha followed by staking height of 2m which gave the yield of 18.33t/ha. For the interaction, there was no significant (P>0.05) differences on both the fertilizer level and staking height.

Conclusion

Based on this result obtained, fertilizer application at 200kg/ha and staking height of 0m gave the highest number of tubers per plant of (3.51). Also, for tuber weight, NPK 15:15:15 fertilizer of 0kg/ha and 2m staking gave the highest yield of (0.680kg) in 2016 and NPK 15:15:15 fertilizer of 200kg/ha and 2m staking gave the highest yield of (05260kg) in 2017. Also, for the tuber yield, NPK 15:15:15 fertilizer of 200kg/ha and staking height of 0m gave the highest yield of (20.80 t/ha). Therefore, staking height of 0m and NPK 15:15:15 fertilizer level of 200kg/ha could be recommended for the production of Yandu white yam cultivar.

Abstract

An experiment was carried out in 2012 and 2014 cropping seasons at the National Root Crops Research Institute (NRCRI), farm Umudike (05^{o}, 29N, 07^{o}'31E and 122M above sea level) to determine the effect of the combinations of primextra with paraquat and fusilade forte for weed control in large scale cassava production. There were 10 treatments consisting of 3 herbicides with different rates applied at different weeks after planting. All the herbicides treated plots received a pre-emergence (PE) application of primextra gold 660sc at the rate of 3.0 kga.i/ha, one day after planting. These were followed by directed post emergence application of gramoxone super (paraquat) at 0.5 kga.i/ha and 0.8 kga.i/ha, fusilate forte at 0.3 kgai/ha, 0.45 kaa.i/ha respectively at 6, 10 and 14 weeks after pre-emergence herbicide application, manual weeding at 3 + 8 + 12 weeks after planting (WAP) and a weedy check. The treatments were laid out in a randomized complete block design (RCBD) and replicated 3 times. Application of primextraat 3.0 kga.i/ha, followed by paraquat 0.8 and 0.5 kga.i/ha applied post-emergence at 10 and 14 WAP and 6 and 10 WAP gave an excellent weed control at 12 WAP. Only primextra at 3.0 kg a.i/ha followed by paraquat at 0.8 kga.i/ha applied post-emergence at 10 and 14 WAP controlled weeds excellently up to 16 WAP. Unweeded control treatment gave the least control. Application of primextra gold 660 sc at 3.0kg a.i/ha, followed by paraquat 0.8 kg a.i/ha applied post-emergence at 10 and 14 WAP gave the best cassava mean root yield (22.65 t/ha) in 2012 and 2014. This was followed by manual weeding at 3 + 8 + 12 WAP (19.75 t/ha). The crop phytotoxicity rating was minimal (≤10%), it has no serious injury to the crop. The economic analysis reveals the treatment primextra + paraquat at rate of 3.0 + 0.8 kg ai./ha sprayed at 10 and 14 weeks after planting (WAP) had comparative advantage than the rest of the herbicide used in cassava production. The herbicide yielded N1.07 kobo for every naira invested in the cassava business. The treatment gave an income of N17,200.00.

Keywords: Cassava, herbicides and weed control.

Introduction

The importance of cassava to the agricultural transformation agenda of the Federal Republic of Nigeria has been emphasized (Adesina, 2012). This is evidenced by the fact that cassava produces starch, alcohol, sucrose and quality flour which are of industrial purposes to revive the country's economy. In addition, the crop is important in addressing the hunger alleviation, food security and livelihood challenges of tropical Africa. One way to realize the aim of the agricultural transformation is to increase cassava production through embarking on large-scale production. Weed control is usually a big problem in a situation like this. Manual weeding has been reported to be very ineffective and tedious in any large-scale crop production (Akobundu, 1987).Herbicides have been shown to be a cheaper, more effective and labour saving alternative than manual weed control and is very appropriate to large-scale cassava production.The objective of the study is to determine the effective of combinations of primetra with paraquat and fusillade forte for weed control in large scale cassava production.

Materials and Methods

This study was carried out at the National Root Crops Research Institute (NRCRI), Umudike in June, 2012 and 2014. The land was cleared, ploughed, harrowed and ridged 1m apart. Plot size was 6m x 5m. The test crop was cassava TME 419. The experimental design was randomized complete block design with 3 replications. All the herbicide treated plots received a pre-emergence (PE) application of primextra gold 660 SC at the rate of 3.0 kg a.i/ha, one day after planting. These were followed by directed post emergence applications of gramoxone super (paraquat) at 0.5 kg a.i./ha and 0.8 kg a.i/ha fusillade forte at 0.3kg a.i/ha, 0.45 kg a.i/ha respectively at 6, 10 and 14 weeks after pre-emergence herbicide application. The herbicide was applied with a CP 15 knapsack sprayer, at a spray volume of 220 l/ha. These were compared with hoe-weeded and un-weeded checks. Application of 400kg/ha (15:15:15) fertilizer was made at 8 weeks after planting (WAP). Observations were taken on phytotoxicity evaluations, weed control ratings at 6, 12 and 16 WAP, plant height, plant girth, leaf area, and number of leaves per plant and weight of weeds. Analysis of Variance (ANOVA) procedure was used for statistical analysis of all data and mean comparison was done using Duncan's Multiple Range Test (DMRT). Economic data were collected using cost route approach and analyzed using profitability model (Ezedinma *et al*., 2006).

Results and Discussion

The effect of weed control treatments on weed control at 12 and 16 WAP in 2012 and 2014 are presented in Table 1. The results showed that pre-emergence applications of primextra at 3.0kg a.i./ha, followed by paraquat at 0.80 and 0.50 kg a.i./ha applied post-emergence at 10 and 14 WAP and 6 and 10 WAP gave an excellent weed control at 12 WAP. Weed Control was satisfactory at 12 WAP with treatments containing primextra at 3.0 kg a.i./ha followed by fusilade at 0.45 and 0.30 kg a.i./ha applied post emergence at 10 + 14 WAP and 6 + 14 WAP. Only primextra at 3.0 kg a.i./ha followed by paraquat at 0.8 kg a.i./ha applied post-emergence at 10 and 14 WAP controlled weeds excellently up to 16 WAP. The unweeded control treatment gave the least control.

Cassava Root Yield

Application of primextra gold 660 sc at 3.0 kg a.i./ha, followed by paraquat 0.8 kg.a.i./ha applied post –emergence at 10 and 14 WAP gave the best cassava mean root yield (22.65 t/ha) in 2012 and 2014 (Table 2). This was followed by manual weeding at 3+8+12 WAP (19.73 t/ha), and plots treated with paraquat 0.8 kg a.i./ha applied post emergence at 6 and 10 WAP (10.73 t/ha) .Manual weeding at 3+8+12 WAP recorded the highest number of roots/ha(40167/ha), followed by plots treated with fusillade 0.3 kgai/ha applied post emergence at 10 and 14 WAP. The economic analysis of the weed control treatment presented Table3, showed that primextra + paraquat at the rate of 3.0+0.8 kg a.i/ha sprayed at 10 and 14 weeks after planting (WAP) had comparative advantage than the rest of the herbicides used in cassava production. The manual weeding method could not produce any tangible increase in investment as it loses 78 kobo for every naira invested in the business. However, it could be said that the chemicals (herbicides) were able to yield N1.07 Kobo for every naira invested in the business. Hence, the herbicide could be recommended to relevant actors in the cassava value chain as the income was N17.200.00.

Conclusion

It is concluded that primextra + paraquat at the rate of 3.0 + 0.8 kg ai/ha, sprayed at 10 and 14 weeks after planting (WAP) had comparative advantage than the rest of the herbicides used in cassava production. The chemical yielded N1.07 kobo for every naira invested in the cassava business. The treatment gave an income of N17,200.00. The herbicide primextra + paraquat applied at 3.0 + 0.8 kg ia/ha, could be recommended to relevant actors in the cassava value chain.

Evaluation of Seed Hardening Treatments towards Enhancing Seedling Establishment and Mitigation of Moisture Stress in Some Selected Vegetables

S. U. Yahaya and Y. M. Mika'il
Department of Agronomy, Bayero University, Kano, Nigeria
suyahaya.agr@buk.edu.ng

Abstract
Experiment was conducted at the screen house of the Centre for Dryland Agriculture, Faculty of Agriculture, Bayero University Kano, to assess the efficacy of seed hardening treatment on germination and seedling establishment in some selected vegetables. Treatments consist of factorial combinations of three vegetables (cucumber, water melon and pumpkin) and three seed hardening chemicals ($CaCl_2$, KCl and H_2O). These were laid in Completely Randomized Design (CRD) with four replicates. Results of the study revealed significant increase in germination count with 2% KCl treatment. The findings further revealed that soaking pumpkin and water melon resulted in higher canopy temperature irrespective of hardening treatment employed. Hardening vegetable seeds with KCl is thus suggested for enhanced germination, early seedling establishment and performance in the field.
Keywords: Drought, moisture stress, seed hardening and vegetables

Introduction
Drought can be described as a climatic hazard which implies the absence or very low level of rainfall for a period of time, long enough to cause moisture depletion in soil with a decline of water potential in plant tissues. Drought is often accompanied by relatively high temperatures, which promote evapotranspiration and affects photosynthetic kinetics, thus intensifying the effects of drought and further reducing crop yields (Mir *et al*., 2012). Drought tolerance on the other hand is the interactive result of diverse morphological, physiological and biochemical traits and thus, these components could be used as strong selection criteria to screen out appropriate plant ideotype. Implications of developing an effective screening procedure for drought tolerance have been realized utilizing different procedures. The low productivity under rain fed condition is due to use of poor quality seeds, soil moisture deficit, low and erratic rainfall and improper crop management which translates to poor seedling establishment and loss of vigor. The most common impediment faced by most vegetable farmers is the moisture stress effect. Safe guarding seeds during initial stage of germination will give a special impetus for the seed to overcome the moisture stress condition and develop into a vigorous plant. Pre-sowing hardening is one of the best methods that results in modifying the physiological and biochemical nature of seed so as to get the characters that are favorable for drought resistance. Pre-sowing hardening is the result of extensive physiological re-organization induced by dehydration process. It can be done with water, dilute chemical solutions, growth regulating compounds or using commonly available natural tonics like coconut water or milk. Hardening induces early germination, better root and seedling growth, reduces seedling mortality, increases crop population and enhances the yield potential of the crop varieties. Based on aforementioned, there is a need to identify suitable ameliorative measures to overcome the moisture stress effect. This investigation was conceived with a view to study the efficacy of pre-sowing seed hardening with chemicals on germination and seedling establishment in cucumber, water melon, and pumpkin.

Materials and Methods

The experiment was conducted in the screen house of the Centre for Dryland Agriculture, Faculty of Agriculture, Bayero University Kano (Latitute 11° 58' N and Longitude 8°26' E). Treatments consists of factorial combination of three vegetable types (cucumber, water melon and pumpkin) and three seed hardening chemicals (KCl, $CaCl_2$ and H_2O). These were laid in a completely randomized design with four replicates. A total of 36 plastic pots (17.5 x 18cm size) were filled with top soil in the ratio 3:1 (soil and manure). These were kept wet through frequent irrigation for a period of one week so as to ensure complete decomposition of the manure. The seeds were soaked with KCl, CaCl2 and water for 6 hours (Subburamu and Solamalai, 2004), and dried under shade to its original moisture (TNAU, 2016). Three seeds each of the treated cucumber, water melon and pumpkin were sown in each of the 36 pots at 1 cm depth as according to treatment outline. These were irrigated at three days intervals using watering can. Frequent weeding (by hand pulling) was carried out to check for weed infestation. Data were collected on duration of germination (days), germination count (%), and canopy temperature (°c). The survived seedlings were extrapolated using the relation:

$$\text{Seedling Survival} = \frac{\text{Survived seedlings at the end of the experiment}}{\text{Number of seedlings at germination}} \times 100$$

Data on germination duration and count were transformed into arc sine before analysis. These were subjected to analysis of variance using GenStat 17th edition. Significant treatment means were separated using Student Newman Keuls (SNK).

Results and Discussion

The effects of seed hardening treatments and vegetable type on duration of germination, germination count and seedling survival in some selected vegetables are presented in table 1. Results of the study indicated significant ($p< 0.05$) effects of seed hardening treatment on germination count only. This showed that plants treated with KCl recorded significantly higher germination. This was also at par with plants soaked in water. Seed hardening treatment did not how ever recorded any significant effect on duration of germination and seedling survival in the study. This result corroborates with what Basra *et. al.* (2005) reported, that beneficial effects of seed hardening includes accelerated rapid germination and growth rate of seedling, greater germination uniformity and increased germination percent. Similar result was also reported by Bray *et al*. (1995) that seed hardening increased germination rate and uniformity as a result of the metabolic repair processes occurring during imbibition. The results of the study further revealed significant effect of vegetable type on duration of germination only. This showed that it took more days for pumpkin to germinate, which was also at par with water melon but different from cucumber that germinated much earlier. This could be accounted to genotype differences. The germination count and seedling survival were not significantly influenced by vegetable type with all the vegetables exhibiting similar response. Interaction of seed hardening treatment and vegetable type was not significant on all the measured variables in the study. Seed hardening treatment had no significant effect on canopy temperature in this study (table 2). However, results of the study showed significant variation among the vegetables on canopy temperature. This showed that pumpkin recording the highest canopy temperature at 6 WAS only. Cucumber also recorded the lowest canopy temperature in this study. The results further revealed significant interaction of seed hardening and vegetable on canopy temperature at 6 WAS (Table 3). This showed that pumpkin soaked in CaCl, KCl, and H_2O had the highest canopy temperature. This was also at par with water melon treated with CaCl, KCl and H_2O. The lowest canopy temperature was also recorded from cucumber soaked in H_2O. This outcome contradicts with what Mir *et. al.* (2012) reported on the positive role of seed hardening in the mitigation of drought through decreased temperature and evapotranspiration.

Conclusion

The findings of the study showed that hardening with KCl increases germination count. This also revealed that soaking pumpkin seeds with chemicals resulted in higher canopy temperature. It is thus suggested these vegetables be soaked with KCl for effective germination and potentials for early seedling establishment and performance in the field.

Abstract
A field experiment was carried out in the Institute for Agricultural Research (IAR) Farm at Kadawa (11°39'N, 08°02'E) in the Sudan Savannah agro ecological zone of Nigeria, in the 2015-2016 dry season to study the response of irrigated rice as influenced by urea supergranule, rate and time of application of biostimulant. The experiment consisted of factorial combination of three rates of urea supergranule (USG) (0,1.8, 2.7g/granule), three rates of bio-stimulant (0, 50 and 100 ml/100L of water) and four times of application of bio-stimulant [3 (tillering stage) and 5 (panicle initiation stage) weeks after transplanting (WAT) (A), 3 and 10 (milky stage) WAT (B), 5 and 10 WAT (C) and 3, 5 and 10 WAT (D)]. These were laid out in a randomized complete block design and replicated three times. The results showed that 2.7g size of USG in combination with 50ml/100L of water at 3 and 10WAT increased number of effective tillers, relative growth rate (RGR), weight of paddy per panicle and paddy yield of irrigated rice.
Keywords: Irrigated rice, Urea supergranule, Rate and Time of Biostimulant

Introduction
Rice (*Oryza sativa* L.) belongs to the family Poaceae. It is one of the major food crops in the tropics, particularly in Asia. It is the extensively cultivated crop for half of the world's population (FAO, 2010). The production and consumption of rice is growing faster in trend than for other staple foods (Selbut, 2003). World rice production trend increased from 437.1 million tonnes in 2008/2009 to 480.4 million tonnes in 2017/2018 (Anonymous, 2018). However, FAO's first forecast of world paddy production in 2018 sees global output staging a 10.3 million tonnes annual expansion to a new high of 769.9 million tonnes (510.6 million tonnes, milled basis) (FAO Rice Market Monitor (RMM), 2018). According to NAERLS and FDAE (2014), rice production estimate for 2014 wet season in Nigeria is about 6.734 million tonnes with Kwara state producing 548.7 million tonnes and 1.9million tonnes in Akwa Ibom state. Several factors pose as constraints in rice production which contributes to the low level of paddy production; resulting to insufficiency in meeting the demands of the consumers. However, the availability of suitable high yielding varieties and quality seeds are also a problem. Also, low soil fertility due to soil erosion resulting in loss of plant nutrients and moisture, low and imbalanced use of fertilizers, heavy infestation of weeds and insects/pests such as blast and brown spot and poor attention for their timely control (upland and rainfed lowland). Poor crop plant population in case of broadcast sowing method resulting in uneven germination (upland and direct seeded lowlands). The area under rice cultivation has almost been exhausted; the way to sustain production is to increase the productivity per unit of area. Rice provides 21% of energy and 15% of protein for human, its quantity and quality requires major attention (Zibaee, 2013 and Gnanamanickam, 2009). Nitrogen fertilizer is one of the major nutrient elements for crop production that can contribute a lot for higher rice yield. It is a fact that rice plant requires more nutrients to produce more yields. Slow release nitrogenous fertilizer increases the yield and nitrogen uptake by rice due to less loss of nitrogen from the soil (IFDC, 2014). Urea Supergranule (USG) fertilizer is a simple physical modification of ordinary urea fertilizer. Urea Deep Placement (UDP) is one innovative response (technique of placing Urea Supergranule) we need to increase farmer

productivity (particularly for cereals) in sustainable ways. This technique involves the use of briquetted urea buried several inches deep between 4 rice stands (Tarfa and Kiger, 2013). They make it possible to place the nitrogen in the anaerobic soil layer which is where plant root development takes place (Freney and people 1995). Balanced use of plant nutrients and method of applying required nutrients in standing water using the deep placement of urea supergranules by the applicator. Research has also shown that application of recommended rate of nitrogen fertilizer to lowland rice by broadcasting practiced by farmers is inefficient, wasteful and expensive in terms of fertilizer cost (Johnson *et al*., 2013). Application of urea-N plays a vital role in vegetative growth, development and yield of rice. Positive responses has been reported on growth and yield of rice using urea supergranule by 7-10 days after transplanting (Tarfa and Kiger, 2013), thus the choice of nitrogen rates (1.8 and 2.7g/granule) to determine the optimum became imperative. This also is necessary to minimise losses and avoid wastage of nitrogen fertilizer which is not readily available and affordable which in turn increases rice productivity. In order to increase rice productivity, it is necessary to find agent that can improve and promote rice growth.

The use of Bio-stimulants for this research will foster plant growth and development throughout the crop life cycle from seed germination to plant maturity by improving the efficiency of the plant's metabolism to induce yield increases, improve crop vigour and enhanced crop quality. Despite the positive potentials of USG and bio-stimulant, improper use of the rates and time of application can also limit productivity. The knowledge about this research was conducted to improve the production of irrigated rice by maximizing the use of urea supergranule, rate and time of application of bio-stimulant.

Materials and Methods

An experiment was conducted at the Institute for Agricultural Research Irrigation Farm, Kadawa (11°39'N, 08°02'E) located in the Sudan Savannah agro ecological zones of Nigeria, during 2015-2016 dry season. Prior to planting, random soil samples were collected from experimental site at 0-15 and 15-30 cm depth using soil auger and bulked for physical and chemical analysis. Meteorological data during period of the experiment were obtained from Institute for Agricultural Research Kadawa Meteorological Station. Treatments consisted of three rates of USG (0, 1.8, 2.7g/granule), three rates of bio-stimulant (0, 50 and 100 ml/100L of water) and four times of application of bio-stimulant [3 (tillering stage) and 5 (panicle initiation stage) weeks after transplanting (WAT) 3 and 10 (milky stage) WAT, 5 and 10 WAT and 3, 5 and 10 WAT]. These were laid out in a Randomized Complete Block Design in a split plot arrangement replicated three times. The gross and net plot sizes were 3.0m X 5.0m (15m^2) and 2.2m X 4.2m (9.24m^2) respectively. Glyphosate was applied at the rate of 2 kg a.i ha^{-1} on the land in order to control weeds which after 14 days of application, the site was harrowed to obtain a fine tilth. Ridging was done at 75cm apart and the field subdivided into plots according to the experimental layout. Seeds were sown manually at the nursery and transplanted to the field three weeks after sowing using an intra-row spacing of 20cm by 20cm. FARO 44 (SIPI-692033) with a maturity period of 110 – 120 days was sourced from National Cereal and Research Institute, Badeggi (NCRI), Niger State. Seeds were transplanted according to treatment on the 17th March, 2016. Crops were irrigated every five days up to 30 days after sowing and later at seven days interval up to hard dough stage when irrigation was stopped. Maxicrop an organic bio-stimulant, was applied as foliar spray at the rate of 0, 50 and 100ml/100L of water using a knapsack sprayer of 16L at 3 and 5 WAT, 3 and 10 WAT, 5 and 10 WAT and 3, 5 and 10 WAT. It contains NPK from organic sources and has active ingredients from natural growth compounds, carbohydrates, protein precursors and nutrients. Nitrogen was applied at the rate of 120 kg N, 40 kg P_2O_5 and 40 kg K_20 per hectare. The nitrogen fertilizer was applied as split, half of the nitrogen fertilizer together with 60kg P_20_5 and 60 kg K_2O was applied once at land preparation using NPK (15:15:15) while the second half of nitrogen fertilizer was applied using USG ten days after transplanting. USG was placed 5cm deep into the soil, between four rice stands and applied to every other row and to every other plant. Each plot was hand pulled and hoe weeded at 4 and 8 WAT. The crops were harvested at full physiological maturity and threshed. Ten rice plants from each plot were randomly tagged and data were collected on numbers of effective tillers, relative growth rate (RGR) (g. g. wk^{-1}), weight of paddy per panicle (g) and paddy yield (kg ha^{-1}). These were subjected to Analysis of Variance as described by Gomez and Gomez (1984) using SAS (2007) software. Duncan's Multiple Range Test (DMRT) at 5 % probably level (Duncan, 1955) was adopted for treatment mean separation.

Results and Discussion

The results of soil physical and chemical properties are shown in Table 1. The soil was loamy with neutral to slightly alkaline pH ranging from 6.99 - 7.64. The soil nutrient status ranged from 7.7 - 8.8 g kg^{-1} organic Carbon, 0.28 - 0.36g kg^{-1} total Nitrogen, 3.60 - 9.50 mg kg^{-1} of available Phosphorus while exchangeable bases values were Calcium (2.80 – 3.00 cmol kg^{-1}), Magnesium (0.71 – 0.81cmol kg^{-1}), Potassium (0.13 cmol kg^{-1}) Sodium (0.54 cmol kg^{-1}) as well as Cation Exchange Capacity (CEC) 4.37 - 4.61 cmol kg^{-1} of soil. Table 2 shows the growth and yield of irrigated rice as influenced by urea supergranule, rate and time of application of biostimulant. The application of urea supergranule differed significantly on all the parameters tested except number of effective tillers. The application of 1.8g size of USG recorded the highest RGR while 2.7g size of USG significantly recorded the highest paddy weight and grain yield. There was no significant difference in number of effective tillers with the application of biostimulant rate. However, 0ml recorded the highest RGR which was at par with 100ml. The application of 50ml biostimulant rate recorded the highest paddy weight and grain yield which was statistically similar with 100ml in paddy weight. The effect of time of application of biostimulant was significant on all the parameters studied except RGR. Application at 3 and 10WAT resulted in the significantly highest grain yield followed by 5 and 10WAT and 3, 5 and 10WAT. Interaction among factors studied was significant for the weight of paddy per panicle and grain yield. Weight of paddy per panicle and grain yield followed the same trend in the interaction between USG and biostimulant rate. Where increase in USG from 1.8 to 2.7g size of USG significantly increased weight of paddy per panicle and grain yield. However, 2.7g size of USG at 50ml/100L of water of biostimulant application rate recorded the highest values while 1.8g size of USG at 0ml/100L of water of biostimulant application rate obtained the lowest values. The application of USG from 1.8 to 2.7g size increased weight of paddy per panicle in the interaction between USG and time of application of biostimulant. However, at 3 and 10WAT time of biostimulant application, the highest weight of paddy per panicle was obtained by the application of 2.7g size of USG compared to all other treatments. The lowest weight of paddy per panicle was obtained by the application of 1.8g size of USG at 3 and 5WAT time of biostimulant application. The following trend was obtained in grain yield. The application of biostimulant rate at 50ml/100L of water at 3 and 10WAT resulted in the heaviest weight of paddy per panicle and grain yield compared with 0ml/100L of water at 3 and 5WAT, which obtained the lightest weight of paddy per panicle and grain yield. Further increase in the rate of biostimulant applied from 50 to 100ml/100L of water resulted in no significant increase in marketable yield. Nitrogen is the most important element for cereal as it plays a crucial role on the growth and development due to its major role in cell division, elongation and enlargement. Rice with a high yield component variation might be due to differences in environmental and soil conditions. The significant variation According to Fofana (2012) the main constraint to achieving high rice productivity in Africa is the increased deficiency of major nutrients and particularly nitrogen (N). The application of 2.7g size of USG performed best among the treatments in respect to yield and yield components of rice. This could be attributed to the presence of adequate ammonium in the soil by the deep placement of USG that met the requirement of the plant at the early stage of growth. This was in accordance with Jing Xiang *et al*., (2013) who studied the effect of deep placement of nitrogen fertilizer on growth, yield, and nitrogen uptake of aerobic rice and reported that the field micro-plot experiment showed that urea and urea super granules (USG) deep placement increased grain yield of aerobic rice by 1.66 t ha^{-1} in continuous aerobic rice cultivation. Jayanta *et al.,* (2017) reported that time of application at vegetative, tillering and panicle initiation stages had significant effect on rice with higher grain yield, number of tillers, straw yield using seaweed extract (a constituent of biostimulant). Several researchers observed the influence of urea supergranule (Hasanuzzaman *et al*., 2013, Qurashi *et al*., 2013); biostimulant rate (Srivastava *et al.,* 2010) and time of application of biostimulant (Sunapri *et al.,* 2010) on growth and yield component of rice. According to Ganapathy and Sivakumar (2014) increased growth parameters at lower concentration may be due to the presence of higher levels of N, P, K in the seaweed extract of *C.scalpelliformis*. The increase in panicle weight and grain yield could be attributed to more assimilate partitioning and dry matter production for grain filling.

Conclusion

Based on the results obtained and findings of this study, it can be concluded that the application of 2.7g size of USG in combination with 50ml/100L of water at 3 and 10WAT performed better and resulted in the highest growth and yield of irrigated rice.

ASN 52nd Annual Conference Proceedings

Response of Sorghum (*Sorghum bicolor*) to Different Planting Arrangements and Cow Dung Amended with Urea in Kabba, Kogi State, Nigeria

Ogundare, S.K. and Etukudo, O.O
College of Agriculture, Division of Agricultural Colleges, Ahmadu Bello University,Zaria, Nigeria

Abstract
The experiment was carried out for two consecutive growing seasons (2016 and 2017) at the research site of the Lower Niger River Basin Development Authority, Ejiba, Kogi State of Nigeria The design of the experiment was a Randomized Complete Block Design (RCBD) using factorial arrangement. The treatments consisted of two factors which are planting arrangement (G1=20 cm by 1 plant and G2= 40 cm by 2 plants) and amendment (T2=7.5t/ha plus 62.5 kg urea, T3=5.0t/ha plus 125 kg urea, T4=2.5t/ha plus 187.5 kg urea, T1=250 kg urea, 10t/ha cow dung and no urea, no cow dung (control). Data were taken on growth and yield characters of sorghum. Data on all parameters and response variables were subjected to analysis of variance (ANOVA), means were separated using the Least Significant Difference (LSD) method at 5 % level of probability. From the findings of this work, it was observed that plots with 20 cm by I plant were significantly better in growth and seed yields than plots with 40 cm by 2 plants. Sorghum with either urea or cow dung alone produce growth and yield characters significantly better than sorghum in the control plot. Plots with combine application of cow dung manure and urea compete favourably with sorghum treated with urea at optimum rate. Plot with5.0 t/ha cow dung + 125kg urea had yield that similar to urea at optimum rate, since the cause of the inputs will be reduced. It is therefore recommended to sorghum farmers in the study area. For optimum production of sorghum farmer should plant at 20 cm by 1 plant.
Keywords: Sorghum, planting arrangement, cow dung and urea

Introduction
Sorghum is one of staple food that is indigenous to Africa (IFPRI, 1983). In Nigeria, sorghum occupies 45-50% of land area under cereal and of the total national hectare, close to 99% is found in the savanna zone (Agbede, 2006). It is drought-resistant crop (Rooney *et al*., 1987 and this accounted for many species grown in zones characterized by low and erratic precipitation (Nicou *et al.,* 1990). Many factors are responsible for the low grain yield in sorghum (Abimiku *et al*., 2002). Chief among the factors are soil nutrient depletion, improper planting arrangement which often lead to competition for water, sunlight and soil nutrients among crops. Inorganic fertilizer is scarce and is rarely used by sorghum farmers since the crop is known to be hardy and adapted to adverse soil conditions. The use of inorganic fertilizers alone such as urea is not sustainable, although urea is major source of nitrogen. Nitrogen is a vitally important plant nutrient, the supply of which can be controlled by man (Adediran and Banjoko, 1995; Shanti et al., 1997). In plant nutrition, nitrogen is involved in the composition of all amino acids, proteins and many enzymes. Nitrogen is also part of the puric and pyrimidic bases, and therefore is a constituent of nucleic acids (Mills and Jones, 1996). Continuous use of inorganic fertilizer alone apart from contributing to soil acidity, it also leads to soil physical and chemical degradation. Sustainable agricultural production incorporates the idea that natural resources should be used to generate increase output without depleting the natural resources base. In this context, integrated nutrients management maintains soils as store houses of plant nutrients that are essential for crop growth. The basic principle behind this concept is to use both the chemical fertilizers and organic manures in most efficient manner because of their limited availability and higher prices. The complementary use of chemical fertilizers and organic manures will augment the efficiency of chemical fertilizers as well as that of organic manures. Nambiar and Abnol,

(1989) reported that integrated use of organic and inorganic fertilizers has been found to be promising in obtaining sustainable crop productivity on a long term basis under modern intensive cropping, besides meeting the nutrients turn over in soil plants system. Therefore, the use of organic manure to supplement inorganic fertilizer use, as an integrated management strategy, is of paramount importance to reducing the cost of soil mineral input, maximizing yields and sustaining sorghum as well as other food crops production in Nigeria. In the rural communities, cheaper sources of organic inputs especially cow dung manure is in abundance. A number of studies carried out on organic and inorganic fertilizer combination in cereals production, have attested to a positive interaction between them when simultaneously applied. Due to abundance of major cattle herds in guinea savanna zone, there is need to study the response of sorghum to cow dung manure amended with urea. Therefore the objective of this project is to determine the response of sorghum (*sorghum bicolor*) to different planting arrangement and cow dung amend with urea in Kabba, Kogi State, Nigeria.

Materials and Methods

Description of Experimental Site

The experiment was carried out for two consecutive growing seasons (2016 and 2017) at the research site of the Lower Niger River Basin Development Authority, Ejiba, Kogi State of Nigeria (Lat. 8˚18'N and Long. 5˚39'E). The site is 246 m above sea level, in the southern Guinea savanna agro-ecological zone of Nigeria, having hot dry seasons and also cool wet seasons. The rainy season spans from April to November and attains peaks in June while the dry season extends from December to March. The mean annual rainfall is 1570 mm per annum with annual temperature range of 18 ˚C – 32 ˚C and mean relative humidity of 60% (Meteorological Data, 2011). The major soil order within the experimental site is ultisol (Ajiboye and Ogunwale, 2010). The experiment was sited within a 14 ha agricultural field that has been continuously mechanically tilled for arable crops (maize, cowpea, sorghum, garden egg, okra, tomato and cassava) production for over twenty years.

Field Layout and Treatments

The experiment was carried out in a Randomized Complete Block Design (RCBD) using factorial arrangement and replicated three times, with a plot size of (5m×4m). The treatments consisted of two factors. These factors are planting geometry (G1=20 cm by 1 plant and G2= 40 cm by 2 plants) and application of cow dung and urea either singly or in combination and a control (T2=7.5t/ha plus 62.5 kg urea, T3=5.0t/ha plus 125 kg urea, T4=2.5t/ha plus 187.5 kg urea, T1=250 kg urea, 10t/ha cow dung and no urea, no cow dung (control). Cow dung manure was collected a month prior to application, and was manually incorporated to the upper 10-15 cm of the soil a week before sorghum planting while urea was applied at two weeks after sorghum planting. The sorghum seeds were obtained from National Cereal Research Institute, Badeji, Niger state. Plots were weeded twice at 30 and 45 days after emergence. Insect pests were controlled using Dimethoate 40-D w/v.

Soil sampling and chemical analysis

Before the commencement of the experiment in 2016, surface soil samples (0 – 15cm depth) were taken randomly from the experimental site. The samples were bulked, air dried and sieved using a 2mm sieve and analyzed for particle size, soil organic matter total N, P, K, Ca, Mg and pH. Soil samples (0 – 15cm depth) were also collected at crop maturity on plot basis and were subjected to routine physical and chemical analyses. The samples were taken, bulked and sub sampled as described by Cartel (1993). Particle size analysis was done using hydrometer method (Bouyoucos, 1962) while organic matter was determined by the procedure of Walkley and Black using the di -chromate wet oxidation method (Nelson and Sommers, 1982). Total N was determined by micro – Kjeldahl digestion method (Bremner, 1965) and available P was by Bray – 1 extraction followed by molybdenum blue colorimetry (Bray and Kurtz, 1945). Exchangeable K, Ca and Mg were extracted by EDTA titration method (Jackson, 1962). Soil pH was determined in 1:2 soils – water ratio using digital electronic pH meter.

Determination of growth and yield parameters

Fifteen plants were randomly selected at the center of each plot for data collection. Plant height and leaf area per plant were determined at 120 days after planting when the sorghum plant reaches its peak growth. Plant height was measured with a measuring tape from tagged plants from the ground level to the tip of the panicle. Ten leaves were taken randomly the length (L) and weights (w) were measured and the leaf area was taken in cm and calculated as follows: **Leaf**

area =L.wX0.74 (Yagoub and Abdelsalam, 2010). A vernier caliper was used to measure stem diameter in (cm). Numbers of leaves were also determined by counting.

Statistical analysis

Data on all parameters and response variables were subjected to analysis of variance (ANOVA) using the GenStat statistical package (GenStat, 2007). Means were separated using the Least Significant Difference (LSD) method at 5 % level of probability.

Results and Discussion

The properties of the soil of the site of the experiment are shown in Table 1. The soils are sandy clay loam. Soil of Kabba is slightly acidic (6.21) and high in bulk density (1.62 glcm^3). Organic matter, total N, available phosphorus (P) and exchangeable potassium (K) were 1.93%, 0.13%, 6.14 mg/kg and 0.27 (cmol/kg) respectively. Pre-planting soil analysis indicated that the soil of the experimental site was low in soil nutrients status. The low nutrient status may be due to leaching of basic cations due to intensive rainfall or perhaps due to the parent material of quarts and sesquioxides which are poor in plant nutrients. This agreed with the findings of Nnaji, et al. (2005) and Aberger (2006) who reported large losses of basic cations due to leaching and high intensive and duration of rainfall. Application of organic manure especially cow dung will be of great benefit to the crop. The chemical compositions of the cow dung used are presented in Table 2. The results show that. The material was rich in nutrients. Application of this material, will improve the fertility content of the soil, and improve the performance of sorghum. Effects of planting arrangement and cow dung manure amend with urea are presented in Table 3. Plant height, stem girth and leaf area show significance response to planting arrangement. Sorghum planted at 20 cm by 1 plant were taller, thicker and produce higher leaf area compared to sorghum planted at 40 cm by 2 plants. Table 3 also indicated that all the crops with either urea or cow dung manure alone and their combinations were significantly taller, thicker and produced leaf area higher than the control. All the integrated applications compete favourably with the urea fertilizer apply at optimum rate. Among the integrated application plots with 2.5t/ha cow dung + 187.5kg urea had highest valves of plant height (5.48 m), stem girth (3.59 cm) and leaf area (1.84m^2). Days to 50% flowering was not significantly affected and this could be attributed to the response of sorghum to change in day length which is common among sorghum cultivars. Table 4 presents the effect of planting arrangement and amendment on yield characters of sorghum. Panicle length, seeds per panicle, 1000 seeds weight and grains yield were better in the sorghum planted at 40 cm by 1 plant than sorghum with 2 plants at 40 cm intervals. All plots with amendment were better than the control. Although, plots with urea application recorded the highest yield, the yield was not significantly difference from plots with combined application of urea and cow dung at reduce rate. Among the plots with amendment cow dung alone recorded the least value of grain yield (1.15). Plots with 20 cm at 1 plant were better growth and yield compare to plants at 40 cm by 2 plants. The observed reduction in the height, thickness and leaf area in crop with two plants at 40 cm intervals could be due to competition for soil and air resources that nutrients that could occur among the plants. Sorghum plants planted singly enjoy ample soil volume and consequently had greater soil nutrient interception. This report supports the work of Caliskan, 2007. Sorghum with amendment produce better growth and yield compare to the control. This result is expected because many researchers had reported that sorghum response to both organic and inorganic sources of nutrient and their combinations. Urea fertilizer releases it nutrients quickly to the crop while organic sources such as animal manure can be an effective source of major nutrients (N, P, & K) when applied at optimum rates and can influence the temporal dynamics of nutrient availability (Paul & Beauchamp, 1993), increase water use efficiency of crops (Carter *et al*., 1992) decrease soil P fixation and enhances P availability in the soils (Iyamuremye & Dick, 1996) through its effect on physical and chemical properties of the soil. Plots with combine application of cow dung manure and urea compete favourably with urea application at optimum rate. This indicates that cow dung manure may have other beneficial effects on the soil in addition to the contribution from the urea. This observation agrees with Jama et al., (2000) when they asserted that, organic materials, apart from being rich in nutrients including calcium, nitrogen and phosphorus, can increase the soils moisture retaining capacity, which helps to improve and maintain the biological and physiochemical qualities of the soil thereby improving the growth performance of sorghum.

Conclusion

From the findings of this work, it can be concluded that plots with 20 cm by I plant were significantly better in growth and seed yields than plots with 40 cm by 2 plants. Plots with combine application of cow dung manure and urea compete favourably with urea application at optimum rate. Plot with5.0t/ha cow dung + 125kg urea had yield that similar to urea at optimum rate, is therefore recommended to sorghum farmers in the study area. Yield can also be improved by planting sorghum at 20 cm by 1 plant.

Abstract
Tripartite symbiosis involves association of legume, Rhizobia and Mycorrhiza. This association is reported to be more effective than either rhizobial or mycorrhizal inoculation alone in respect to yields of plants. A greenhouse pot experiment was conducted to evaluate the response of soybean to co-application of rhizobia and Mycorrhiza on yield components of soybean in the northern Guinea savanna of Nigeria. The treatments consisted of 3 levels of N (+N, Rhizobia and –N), 3 levels P (+P, Mycorrhiza and –P) and 3 levels of N and P combinations (+N +P, Rhizobia + Mycorrhiza and –N –P) giving 9 treatments replicated 3 times. The result indicated that significantly higher ($p<0.05$) root dry weight was recorded by inoculation with Mycorrhiza with magnitude of 72% over control. There was also significant ($p<0.001$) difference in dry matter yield of soybean between the levels of P where inoculation with Mycorrhiza and application of P recorded a 69% and 67% dry matter yield over minus P. Also, co-inoculation with Rhizobia and Mycorrhiza gave a statistically similar dry matter yield to where mineral N and P were applied. It is concluded that co-inoculation with Rhizobia and Mycorrhiza can be employed as possible alternative to the much more expensive inorganic fertilizers.
Key words: Co-inoculation, Dry matter yields, Mycorrhiza, Rhizobia and Yield components

Introduction
Grain legumes have the ability to fix N from the atmosphere through a symbiosis with soil bacteria known as rhizobia. Symbiotic relationship between rhizobia and legumes is responsible for contributing the largest amounts of fixed nitrogen to agriculture. Estimates indicate that legumes can fix up to 200 kg N ha^{-1} $year^{-1}$ under optimal field conditions (Giller, 2001). Hence, Symbiotic N_2 fixation is considered as economically viable means of supplying N to crops. On the other hand, Mycorrhizas are common in most terrestrial ecosystems and form relationships with the majority of plant families (Smith and Read, 2008). The beneficial effects of Mycorrhizal symbiotic association on the growth of plants are well known (Okon *et al*., 2010). They help in water regulation of plants by extending their hyphae towards the available moisture zone for continuous water and nutrient absorption and translocating them to plants (Arumugam *et al*., 2010).

Soybean, a grain legume, hosts rhizobia and mycorrhiza at the same time thus benefiting one another. This association involving legumes, rhizobia and mycorrhiza is known as tripartite symbiosis. The association with rhizobia is involved in the fixation of atmospheric N while the association with mycorrhiza modifies the ability of the plant to take up P (Lodwig *et al*., 2003). The dual inoculation with rhizobia and mycorrhizas causes synergistic beneficial effects and they act as biofertilizers for crops (Xavier and Germida, 2002). They play a key role in natural ecosystems and influence plant productivity, plant nutrition and plant community structure. In many experiments dual inoculation with both symbionts resulted in higher plant biomass (Xavier and Germida, 2012). The tripartite symbiotic associations were reported to be more effective than rhizobial or mycorrhizal inoculation alone in respect to yields of plants (Saxena *et al.,* 1997). This experiment was therefore carried out to examine the effect of dual inoculation with rhizobia and mycorrhiza on yield components of soybean in northern guinea savanna of Nigeria.

Materials and Methods

The experiment was conducted in a Screenhouse at the Department of Soil Science, Institute for Agricultural Research (IAR) station Samaru (N11°10´31.3´´, E007°36´38.9´ and 704 m above sea level). A bulk soil was collected from IAR experimental field, air-dried, crushed and sieved through 2mm sieve mesh. The soil was then put into 3 L pot and nutrient solutions were applied. The set up was left for 24 hours to equilibrate. The physical and chemical analyses were determined using standard methods as reported in Okalebo *et al*., (2002). Inoculation with rhizobia was done before planting. Here, seeds were surface sterilized, mixed with the rhizobial inoculant and then planted. The Mycorrhizal inoculation was done in layers in the pot. Here, pots with mycorrhizal treatment were inoculated with mycorrhiza in layers. The experiment was laid out in completely randomized design (CRD). There were 9 treatments replicated 3 times. The treatments consisted of 3 levels of N (+N, Rhizobia and –N), 3 levels P (+P, Mycorrhiza and –P) and 3 levels of N and P combinations (+N +P, Rhizobia + Mycorrhiza and –N –P). Routine management such as irrigation and weeding were done when necessary. Harvesting was done at 8 weeks after planting when the plants had attained flowering stage. The shoot was cut off from the base and the root was carefully removed from soil by passing them through running tap water. The root length was determined using meter rule. Both the shoots and roots were put in separate clean paper bag and then oven dried at 60ºC until constant weight. The root and shoot dry weights were taken and dry matter yield determined. Data collected were subjected to ANOVA using GLM procedure. Where significant F values between the means were recorded, the Tukey honesty significant difference (HSD) was used to separate the means.

Results and Discussion

The physical and chemical properties of the experimental soil showed that the soil is loamy in nature having textural classes fairly distributed (sand = 50%, silt = 26% and clay =20%). The soil is acidic in nature (pH = 4.65), which depicts the nature of the soils in the tropics. Also, the organic carbon content of the soil is low (6.30 gkg^{-1}) while the available P (16.24 gkg^{-1}) of the soil falls within moderate class level. The total nitrogen is also low (1.1 gkg^{-1}). In general it can be said the soil is a medium in fertility.

Effect of Co-application with Rhizobia and Mycorrhiza on yield components of soybean

Analysis of the root dry weight yield showed that there was significant difference between the treatments (Table 1). Highest root dry weight was recorded by inoculation with Mycorrhiza. This was statistically higher than the controls (Minus P and Minus N). The percentage difference between the inoculated soybean with mycorrhiza and controls is 72%. Analysis of shoot dry weight also revealed significant difference (p<0.05) between the treatments (Table 1). Here, highest shoot dry weight was recorded by plus P followed Mycorrhiza and then N + P treatment. These were statistically higher than plus N, Minus N, Rhizobia, minus P and minus N minus P treatments. Similar trend was also observed in the analysis of root length where the highest root length was recorded by plus P treatment. This was statistically higher than minus N and minus N minus P treatments with magnitude of 45% and 46% respectively (Table 1).

Table 1: Mean values of yield components as affected by co-inoculation of Rhizobia and Mycorrhiza

Treatment	Root Dry Weight (mg)	Shoot Dry Weight (mg)	Root length (mm)
Plus N	410ab	1980bc	195b
Rhizobia	350ab	1600c	182ab
Minus N	430a	1830bc	164b
Plus P	390ab	2870a	239.2a
Mycorrhiza	430a	2810a	219.3ab
Minus P	250b	1650bc	187.2ab
N + P	330ab	2800a	202.3ab
Rhizobia + Mycorrhiza	300ab	2230ab	215.7ab
Minus N Minus P	320ab	1970bc	163.7b
SE	80	310	32.8

Means with the same letters in column are not statistically different by Tukey (HSD)

Effect of Co-application with Rhizobia and Mycorrhiza on dry matter yield of soybean

Analysis of the effect dual inoculation and N and P fertilization showed that there was significant variation in dry matter yield between the different treatments (Fig 1). It showed that highest dry matter yield was recorded by the treatment Plus P followed by the treatment Mycorrhiza and these recorded a statistically higher than the treatment Rhizobia and Minus P. The difference between the treatment Plus P and treatment Minus P in terms of dry matter yield was 67%. The plus P treatment was 68% higher than treatment rhizobia. The treatment Mycorrhiza was also 69% higher than Minus P and 66% higher than Rhizobia in dry matter yield.

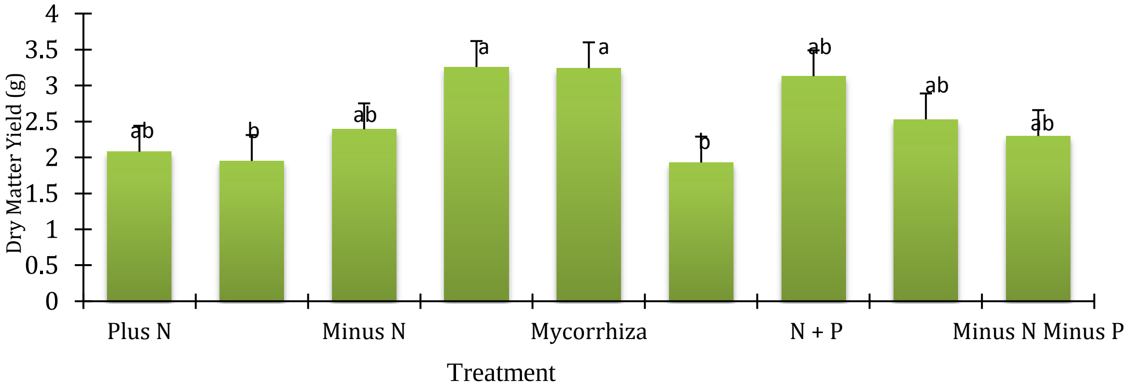

Fig 1: Effect of Co-application with Rhizobia and Mycorrhiza on dry matter yield

The current study shows that co-inoculation with rhizobia and Mycorrhiza significantly increased yield components of soybean under low P and/or low N conditions as indicated by increased root and shoot dry weights as well as the total dry mater yield. In particular, inoculation with Mycorrhiza gave the highest increment in the yield components of the soybean under the same condition. This could be attributed to the increased nutrient absorption capacity by the Mycorrhiza via their hyphal network. This is possible because the hyphal networks, which serve as extension of the plant roots, explore soil volume where plant roots cannot reach and translocate it to the plants. It is reported that inoculation with Mycorrhiza improves nutrient absorption and translocating from soil to plants (Arumugam *et al*., 2010). The resultant increase in the plant growth with application of mineral nutrient may be attributed to response to increased soil nutrient such as P. Phosphorus supply in soil has been noted for several legumes including soybean as reported by Sanginga *et al*., (1994). High dry matter yield observed in the treatment where P was applied was because of the availability of soil P to the plants in question. Phosphorus availability has been widely reported to have a significant positive effect on dry biomass production (Marschner *et al*., 1995). The statistically similar dry matter yield of soybean between N+ P treatments and Rhizobia + Mycorrhiza indicated an impact of the co-inoculation on soybean. Study by Ames *et al.* (1991) has indicated that interaction between Rhizobium and Mycorrhiza significantly affected legumes' growth. The treatment with single inoculation with rhizobia however recorded a significantly lower dry matter than other treatment such as the Mycorrhiza and P application. It is possible that most of the rhizobial cells died during storage before they were put to use. This could result due to high temperature normally experienced in the tropics. The success of rhizobial inoculants is dependent on the number of viable bacteria available to participate in the infection process at the point of use (Catroux *et al*., 2001).

Conclusion

The study showed that the Co-inoculation with Rhizobia and Mycorrhiza increased the yield components of soybean and can give similar yield to where the inorganic N and P fertilizers were applied. This is an indication that the co-inoculation can be employed as possible alternative to the much more expensive and potentially deleterious inorganic fertilizers. Hence research efforts should be focused on quality assessment of inoculants production to identify elite strains of both rhizobia and mycorrhiza that would compete with the inorganic fertilizer.

Acknowledgement

The authors wish to thank soil microbiology lab of the Department of Soil Science Ahmadu Bello University Zaria who provided the inoculants used for this experiment.

Abstract
Field studies were conducted at Cocoa Research Institute of Nigeria (CRIN) Headquarters, Idi – Ayunre, Ibadan Latitude 7⁰25'N and Longitude 3⁰25'E Oyo State and CRIN Substation at Uhonmora, Latitude 6⁰50′ N and Longitude 5⁰50′ E Edo State, to determine the nutrient uptake of coffee plants intercropped with oil palm. The trial had three treatments comprising coffee sole (control), coffee with oil palm (Hollow square) arrangement and coffee with oil palm (Avenue) planting. Equal area of land was used for coffee in all the treatments. Coffee and oil palm were planted at a spacing of 3.0m x 3.0m and 9.0m x 9.0m triangular respectively. The experiment was a Randomized Complete Block Design (RCBD) replicated three times. The least nutrient uptake by coffee in the two locations was in the control (Coffee sole) while the highest was in coffee with oil palm (Hollow Square). This could be due to a better arrangement with better shade regime of oil palm reduced root competition and nutrient build up in Hollow Square arrangement. There were significant differences ($P < 0.05$) among the treatments with hollow square arrangement > Avenue > control
Keywords: Nutrient uptake, Coffee, Oil palm and Intercrop

Introduction
One of the management problems associated with coffee production in Nigeria is how to maintain the level of soil nutrients status during field establishment as virgin soil is no more readily available. A review of available literature on mix-cropping in the tropics has been carried out (Adeyemi, 1997; Onwubuya, *et al.*, 1981; Ofoli and Lucas, 1988; Okpala-Jose and Lucas, 1988; Sparnaaji, 1987; Famaye, 2000). Traditionally, farming system in the tropics is generally a mixed cropping as mono cropping is rare. The benefits from intercropping or mixed cropping include insurance against complete crop failure through diversification; keeping the farmer busy all the time and allowing better use of his time; improving land use efficiency and the income accruing to the farmer as well as increase in profit per unit area of land. The advantage of mix-cropping coffee with oil palm is that it enhances the efficient utilization of the arable land by increasing the total output from both crops and ultimately the income accruing to the farmer. However, the report on nutrient uptake by coffee intercropping is scanty. The objective of this study therefore was to evaluate the nutrient uptake of coffee intercropping with oil palm in avenue and Hollow Square arrangements.

Materials and Methods
The experiment was carried out in two locations in Cocoa Research Institute of Nigeria (CRIN). The locations are Idi – Ayunre, Ibadan Latitude 7⁰25'N; Longitude 3⁰25'E and Uhonmora, Latitude 6⁰ 50'N; Longitude 5⁰ 50'E. The soil of Idi – ayunre and Uhonmora are alfisol and ultisol respectively. These locations are rain forest and derived savanna respectively. The coffee (*Coffea canephora*) seed was obtained from CRIN nursery in both locations. Oil palm seedlings (Tenera variety) were obtained from National Institute of Oil palm Research (NIFOR) Benin City, Edo State. Plantain suckers were obtained from CRIN as shade for coffee seedlings at establishment. The experiment had three treatments, (a) Coffee Sole (control), (b) coffee/oil palm (Avenue arrangement) and (c) coffee/oil palm (Hollow Square arrangement). The experimental design was Randomized Complete Block Design (RCBD) replicated three times. Parameters considered

were physical and chemical properties of the soil at the beginning of the experiment as well as plant height, stem girth and leaf area. Coffee seedlings were also uprooted on treatment basis, washed and weighed. They were then oven dried to constant weight at $70^{0}C$. The dried plants were milled, analyzed for N, P, K and Ca. The uptake was calculated using NC= Yield x nutrient content of plant (Obatolu, 1991). The results obtained were subjected to statistical analysis of variance and LSD was used to separate the significant means.

Results and Discussion

Table 1 shows the result of the soil physical and chemical properties of the study locations. The soil pH of 6.2 and 5.2 for Idi – Ayunre and Uhonmora respectively were appropriate for coffee production as earlier reported by Famaye (2005). The result on plant height, stem diameter and leaf area are shown in Table 2, 3 and 4 respectively. In the first 3 months of transplanting the coffee morphological parameters of all the treatments in both locations were not significantly different; 6 months thereafter, there were little difference but not significant at $P \leq 0.05$. As from 9 months there were significant difference $P \leq 0.05$ in the intercrops. The same trend was followed through to 24 months after transplanting to the field. Coffee in Hollow Square arrangement gave the highest values closely followed by the avenue arrangement. These results showed that shading from oil palm under which coffee were planted in the Hollow Square provided optimal light intensity adequate for better growth than the control in full sunshine and avenue arrangement. The better performance of Hollow Square treatment over Avenue might be due to the shading effects of oil palm trees on coffee as more coffee trees were more shaded by the oil palm in the Avenue treatment thus creating more competition between them for light. This corroborates the earlier work done (Famaye, 2000). The beneficial effect on good growth of coffee was earlier reported for other tree crops like cocoa when plantain was used as shade (Opeke, 1982). The better performance of Hollow Square over control treatment indicates the efficiency of land use on mix-cropping over sole cropping as earlier reported by Onwubuya, *et al.* (1981); Sparriaaji (1987); Aya and Lucas (1988); Coste (1992); Adeyemi (1997). Nutrient uptake of coffee in the first and second years, are shown in Table 5. The highest N uptake was recorded in coffee (Hollow Square) and closely followed by Avenue in the two locations. The amount of nutrient uptake generally increased with the age of coffee. The N uptake is higher in Idi-Ayunre than Uhonmora. This might be as a result of differences in soil classes (alfisol in Ibadan; ultisol in Uhonmora). There was no significant difference ($P<0.05$) between the P uptake in the two locations within the first year while there was significant difference in the second year with the coffee (Hollow Square) giving the highest value. K uptake was significantly higher in the Hollow than in the Avenue with the lowest in the control in the first year while the control was highest in Idi-Ayunre in the second year. Ca uptake showed the same trend recorded for N uptake for Idi-Ayunre and Uhonmora with control being the least and Hollow Square the highest. The sole coffee was not able to satisfy its nutrient needs due to leaching of important nutrient elements. Nigeria farmers hardly use fertilizers mostly due to its scarcity, high cost of the few available ones and generally the poor economic conditions of the farmers. The nutrient uptake in coffee in Hollow Square arrangement that was significantly higher than the control as well as Avenue might was due to nutrient build up as a result of better shading from the oil palm trees which reduced evapotranspiration and enhanced microbial activities (Famaye and Adejobi, 2015; Famaye *et al*., 2014; Famaye *et al*., 2013). Besides, the fibrous root system of oil palm could have enhanced nutrient retention within coffee rooting zone thereby making nutrients available unlike in sole.

Table 1: Soil physical and chemical properties of the experimental sites at the beginning of the experiment

Soil properties	Idi – Ayunre	Uhonmora

Conclusion

The Hollow Square treatment of growing coffee with oil palm was found superior in nutrient uptake to the other treatments of Avenue and control. This could be recommended to the farmers instead of sole planting or Avenue arrangement.

Abstract

The study evaluated the effect of interaction between susceptible rice accessions and mycorrhiza (Glomus hoi) on the resistance of rice accessions and some growth parameters of rice. Ten susceptible rice accessions were planted at the screenhouse in randomised complete block design. Each accession was planted in a bucket inoculated with 60 g of mycorrhizal inoculum and replicated three times and also another 3 replications without mycorrhizal inoculum. The replications were spaced by 0.5 m. The data collected included plant height, number of tillers and leaf blast scores. The data were subjected to Analysis of Variance (ANOVA) and means were separated using LSD at 5% level of probability. The result revealed that there were significant differences between rice accessions inoculated with Glomus hoi and those that were not inoculated. The rice accessions with relatively high value of RFMD index (>25) had leaf blast severity scores ranging from 0 (highly resistant) to 3 (moderately resistant). The study concluded that the association between Glomus hoi and rice roots significantly improves the resistance of rice to blast disease.

Introduction

Rice *(Oryza* spp) is the most important staple food in the world today (FAO, 2014). It has become part of everyday diet of many homes. Currently the world population eating rice is about three billion people which is about half of the world population (IRRI 2009). Rice production is however faced by some challenges which include inadequate input, insufficient number of extension agents, poor acceptance of new innovation on the part of the farmers, climatic changes, pests and poor irrigation system (Singh *et al*., 2008). Sonia and Gopalakrishna (2005) reported that rice blast disease is one of the main pathological threats to rice crop globally. It is a fungal disease caused by *Magnaporthe grisea*. The pathogen attacks the leaves, causing leaf blast during the vegetative stage of growth, or neck, nodes and panicle branches during the reproductive stage (Bonman *et al*., 2012). Blast disease was first reported in Asia, centuries ago and is now present in over 85 countries. Blast propagules can survive on seeds and can easily be moved across borders if safety checks are not in place. Although successful chemical control measures have evolved, these are too expensive and cumbersome to apply, hence, host resistance is given priority in disease control strategy. It is considered as a no-cost technology, especially for the poor farmers and also an important component of the eco-friendly technique of integrated disease management program. However, neither chemical nor breeding for resistance provides absolute control, due to the pathogen's ability to rapidly adapt. Hence, crops remain vulnerable (Sere *et al*., 2011). Breeders have spent years looking for resistant varieties of rice, they have not only collected many traditional rice varieties that are resistant to blast, but have also identified a number of rice genes that they believe are responsible for the resistance. The use of resistant varieties has been proven to be the most effective and economical way of controlling rice blast disease (Xueyan *et al*., 2014). However, failures of resistances are observed under different field conditions, as the susceptibility of rice varieties to blast pathogen differs depending on the locality, diversity of the pathogen and the resistant gene carried by the different species of rice plant (Xueyan *et al*., 2014). Early studies on mycorrhiza, which is an ubiquitous soil inhabitant forming symbiosis with most naturally growing terrestrial (Gai *et al.,* 2006) and aquatic (Javaid *et al*., 2007) plants, showed an improved growth and/or yield of mycorrhizal plants, first attributed exclusively to the improved nutritional status of the plant (Linderman, 2006). Later, several authors reported a higher tolerance of mycorrhizal plants to abiotic stresses, such as drought, nutrient deficiency or presence of heavy metals (Miransari, 2010; Smith *et al*., 2010) and also higher resistance to diseases (Salami, 1999). There is little information on the influence of mycorrhiza on the resistance of rice to blast disease. The objective of this study was to evaluate the effect of interaction between susceptible rice accessions and mycorrhiza(*Glomus hoi*) on the resistance of rice accessions to blast disease

Methodology

Thirty rice accessions were obtained from National Cereals Research Institute, Badeggi, Nigeria screened for resistance against blast pathogen out of which ten susceptible accessions were selected and used for this study (Table 1). This study was carried out in the screenhouse of Faculty of Agriculture, Obafemi Awolowo University, Ile-Ife in 2016. The experiment was laid out in a Randomized complete block design (RCBD) with each accession planted in a bucket inoculated with 60 g of mycorrhizal inoculum and replicated three times and another 3 replications without mycorrhizal inoculum. Two replications were spaced by 0.5 m. Infected leaves were collected from infected rice field, blended into particles and spread along the ten rice accessions in the screenhouse, two weeks after emergence.

Each plant was scored for leaf and neck blast using Standard Evaluation System (Tables 2 and 3). Number of leaves, plant height, number of tillers, stem girth, disease incidence, disease severity and the relative field mycorrhizal dependency (RFMD) index (Plenchette *et al*., 1983) was also recorded.

$$\%RFMD = \underline{\text{Dry weight of mycorrhizal plant – Dry weight of non-mycorrhizal plant}} \times 100$$

Data collected were subjected to statistical analysis SAS version 9.13. Analysis of variance (ANOVA) was carried out and significant means were separated using LSD at 0.05 level of probability. Correlation analysis was carried out between leaf blast severity, leaf blast incidence, neck blast severity, number of leaves, number of tillers, plant height, stem girth and relative field mycorrhizal dependency (RFMD) index. Regression analysis was also carried out on RFMD index and Leaf blast severity.

Results and Discussion

There were significant differences between the mean values of the leaf blast severity for the rice accessions with mycorrhizal inoculum (*Glomus hoi*) and those without mycorrhizal inoculum as from 49 DAP (Table 2). The lowest leaf blast severity for both inoculated and uninoculated rice accessions was at 42 days after planting and this increased gradually from 42 days after planting, having the highest leave blast severity score at 84 DAP (Table 2). The level of disease severity was consistently higher for rice accessions without *G. hoi* in comparison with those inoculated with *G. hoi* (Table 2).

Table 2: Effect of mycorrhizal inoculation on leaf blast severity of ten rice accessions evaluated in the Screenhouse

Parameter	42	49	56	63	70	77	84
No_myco	0.20	0.87	1.40	2.30	3.00	3.80	4.53

$LSD_{(0.05)}$	0.90	0.21	0.21	0.25	0.28	0.44	0.37

(Mean values at 0.05 level of probability), 42, 49, 56, 63, 70, 77 and 84 --- Days after planting

Significant differences in the mean values of the leaf blast incidence for the rice accessions with mycorrhizal inoculation and those without mycorrhizal inoculation were obtained as from 49 days after planting (Table 3). The lowest leaf blast severity for both inoculated and uninoculated rice accessions was at 42 days after planting, however this increased gradually and attained the highest leave blast severity at 84 days after planting. The level of disease severity was consistently higher for rice accessions without *G. hoi* in comparison with those inoculated with *G. hoi* (Table 3).

Table 3: The effect of mycorrhizal inoculation on leaf blast incidence of the ten rice accessions evaluated in the Screenhouse

Parameter	42	49	56	63	70	77	84
No myco	2.23	11.21	21.65	29.31	36.19	44.81	53.04

$LSD_{(0.05)}$	0.99	1.24	2.55	1.72	2.46	1.81	2.93

(Mean values at 0.05 level of probability), 42, 49, 56, 63, 70, 77 and 84 --- Days after planting

The mean values of RFMD index for accessions with marginal RFMD index (< 25%) were significantly different from the other accessions that had moderate RFMD index (25-50%), with accession 10 having the highest value of RFMD index (43.36) while accession 3 had the lowest value of RFMD index (14.72) (Table 4).

Table 4: Relative field mycorrhizal dependency index of the ten rice accessions evaluated in the Screenhouse

Accessions	RFMD_I (%)	LBS

10	43.36	1
$LSD_{(0.05)}$	7.34	

RFMD_I = Relative field mycorrhizal dependency index. LBS = Leaf blast severity

There was high significant positive correlation between leaf blast severity and leaf blast incidence (Table 5). There was also a significant positive correlation between leaf blast incidence and neck blast severity (Table 5). There was a significant negative correlation between leaf blast severity and RFMD index (Table 5). Also, there was highly significant negative correlation between leaf blast incidence and RFMD index. There was no linear relationship among the other parameters correlated (Table 5).

Higher resistance of mycorrhizal plant to a wide range of below-ground attackers such as soil-borne nematodes, fungal, root chewing insects, fungal and bacterial pathogens was reported by Sabine *et al*. (2012). But in the last decade, induced resistance by mycorrhizal association against shoot pathogens was reported by koricheva *et al*. (2009). The accessions used at the screenhouse had leaf blast severity score ranging from 0 (highly resistant) to 7 (susceptible), whereas the same set of accessions had leaf blast severity scores 9 (highly susceptible) on the field. This implies that the mycorrhizal association between *Glomus hoi* and the roots of the rice accessions was able to enhance the innate resistance of the plant thus reducing the magnitude of leaf blast severity in most of these susceptible accessions to an appreciable level. This supported the findings of Effmert *et al*. (2012) who reported that protective effect observed in mycorrhizal plant association does not only confer growth benefits to plants, but also influence interactions with other organisms including pathogens and beneficial microbes. The rice accessions responded in diverse ways to the presence of *G. hoi* which was indicated by the differences in leaf blast scores and relative field mycorrhizal dependency (RFMD) index. The rice accessions with relatively high value of RFMD index (>25) had leaf blast severity scores ranging from 0 (highly resistant) to 3 (moderately resistant). This might be as a result of the dependency of the plant on the nutrient uptake from the soil which was enhanced by the mycorrhizal association between the plant root and the *G. hoi* thereby improving the resistance of the accessions. The correlation analysis between RFMD index and Leaf blast severity/ incidence showed that there was an inverse relationship between the parameters as revealed by the negative correlation coefficient value. This implied that the higher the RFMD index, the lower the level of severity and incidence of leaf blast disease. This is an indication that *Glomus hoi* conferred protective properties on the rice accessions inoculated with *G. hoi*. This conforms to the observation of Liu *et al*. (2007) who reported that the use of mycorrhizal inoculum in crop production increased the plant resistance against biotic and abiotic stresses.

Conclusion

This study has clearly shown us that the association between *Glomus hoi* and rice roots significantly improves the resistance of rice to blast disease.

Acknowledgements

I want to acknowledge the management and staff of National Cereals Research Institute for the support given to me to carry out this research. Also my gratitude goes to the entire staff of Crop Production and Protection department of Obafemi Awolowo University, Ile-Ife.

Abstract
A two-year pot-field experiment was carried out to evaluate the yield performance of three ware-yam cultivars (Alumaco, Nwopoko, Hebamkwase) at National Root Crops Research Institute, Umudike, Abia State, Nigeria (05° 29´ N, 07° 32´ E,122 metres a. s. l.) in 2014 and 2015 cropping seasons. The pot experiment was laid out in a completely randomized design with three replications. The results indicated that all the tested variables were significant in both years except number of seed yams/plot in 2014 cropping season. Alumaco ware-yam cultivar gave the highest fresh tuber yield compared with the other cultivars studied and exhibited the least percentage of nematode incidence in both years. The mean sequence of tuber yield of the ware-yam cultivars in the order: Alumaco > Nwopoko > Hebamkwase in 2014 and 2015 cropping seasons. Fresh tuber yield (t ha^{-1}) indicated highly significant ($P \leq 0.01$) and positive correlation with all the yield attributes, especially weight of tubers/plot and bulking rate in both years with correlation coefficients (r) ranging from 0.55 to 1.00 (2014) and 0.61 to 1.00 (2015). Also, the regression analysis showed a poly-linear and positive relationship between nematode incidence and fresh tuber yield of ware-yam in both years. Alumaco ware-yam cultivar was the highest yielder, hence adjudged to be better endowed genetically to be recommended to farmers within the agro-ecological zone of the study area.

Keywords: Dioscorea rotundata, ware-yam, nematode and tuber yield

Introduction
The field crop Yam (*Dioscorea* spp), which produces an edible subterranean or aerial tubers that are greatly of food and economic value is an annual or perennial crop. It is a veritable source of carbohydrate with about 50 to 80 per cent starch or dry matter yield (Shanthakumari *et al*., 2008; IITA, 2009) and about 1 to 2 per cent dietary protein, which is high compared with other tropical root crops (Udensi *et al*., 2008; Arinathan *et al*., 2009). Yam is a strong food security tuber crop in most Sub-Sahara African countries (Ikeorgu, 2003; Behera *et al*., 2009; Ugwu, 2009; IITA 2009) because it is a source of good dietary energy for human consumption.One of the most cultivated and accepted species of yam in Nigeria is *Discorea rotundata* (white yam) and its production is constrained by many challenges such as high cost of production and poor yield. The edible tubers are normally used in its propagation, hence, production cost is usually high, which therefore constitutes a strong discouraging factor in production Orkwor and Asiedu (1998). More so, the crop is plagued by nematode amongst other pests' attack singly or in combination. Though studies have shown that yam tubers naturally have a periderm, such that micro-organisms cannot penetrate, it is easily scared by nematodes, rodents and man during weeding and harvesting leading to microbial attack on the tuber crop (Marfo *et al*., 1998; Kambaska *et al*., 2009). These constrains, lead to recorded poor tuber yields from cultivated yams across the agro-ecosystem. More so, there is little information on the yield performance of some improved yam cultivars in the low land tropics of Umudike, southeast Nigeria. The aim of the study therefore was to evaluate the yield performance of three improved ware-yam cultivars under rain-fed Umudike agro-ecological conditions.

Materials and Methods

A rain-fed pot experiment was conducted at the yam programme, National Root Crops Research Institute, Umudike, Nigeria (latitude 05° 28′ N, longitude 07° 29′ E, and altitude 122 m above sea level) in the humid tropics of south eastern Nigeria. The location is characterized by a mean annual rainfall of 1,800 to 2,200 mm, which begins in April, peaks in July with a brief dry period in August and ends towards October and early November. The soil of the experimental site is sandy loam (Ultisol) belonging to the order ultisol and classified as Paleulstult. The treatments comprised three cultivars ware-yam (*Nwopoko, Hembamkwase* and *Alumaco*). The experimental treatments were laid out in a completely randomized design and there were three replications.
Clean seed yam tubers of the cultivars were planted in perforated *baggco* pots filled with 15 kg sieved top soil and kept in the field under rain-fed conditions (4th and 7th March, 2014 and 2015 cropping seasons, respectively). The sprouted setts were checked early mornings three times weekly until the vines were properly established. Staking of the vines was done using the trellis method to ensure even distribution of the leaves for better interception of sun light and aeration.
The experimental plots were kept clean by hand picking of the weeds as they appear in the pots while a compound fertilizer (NPK 15:15:15) was applied at the rate of 400 kg ha^{-1} at 8 Weeks after planting. The growing main and lateral vines were periodically and systematically trained on the stakes during the vegetative period. At harvest, data such as number of seed yams $plot^{-1}$, number of ware yam tubers $plot^{-1}$, fresh tuber weight $plot^{-1}$, and fresh tuber yield (t ha^{-1}) were collected. Bulking rate was calculated as the ratio of tuber yield to the duration of tuberization of the ware yam while nematode incidence incidence recorded was calculated thus: [Incidence (%) = Number of tubers infected / Total number of plants on the plot]. The data collected were subjected to analysis of variance procedures using the statistical software Genstat Discovery Edition 4 (Genstat, 2014) while treatment mean comparisons were achieved by following the procedure outlined by Obi (2002) using Fisher's method where a probability level ≤0.05 was considered significant. Correlation was performed using SPSS 17 for windows soft-ware.

Results and Discussion

Analysis of variance (Table 1) indicated that except number of seed yams/plot in 2014, the other variants [number of ware-yams $plot^{-1}$, fresh tuber yield $plot^{-1}$, fresh tuber yield (Mt ha^{-1}) and bulking rate (kg^{-1} day^{-1} ha^{-1})] exhibited different degrees of significance in both years. In 2015, *Alumaco* significantly ($P<0.05$) gave the highest number of seed yams $plot^{-1}$compared to the other cultivars. While in both cropping seasons, it gave the highest number of ware-yams $plot^{-1}$ and weightiest fresh tuber yield $plot^{-1}$ and per hectare. Also, in the two cropping seasons, *Alumaco* yam cultivar exhibited the highest bulking rate, which was higher by 55.8 and 37.3 per cent relative to *Nwopoko* and *Hebamkwase*, respectively (2014) and 56.3 and 22.8 per cent relative to *Nwopoko* and *Hebamkwase*, respectively (2015) cropping season. The mean sequence of tuber yield of the ware-yam cultivars was in the order: *Alumaco* > *Nwopoko* > *Hebamkwase* in both years. The findings from the study corroborate similar works by Balogun *et al*. (2004), Law-Ogbomo (2007) as well as Nwosu and Okoli (2010) in their various studies on white ware-yam in different agro-ecological zones across Nigeria.Nematode incidence on the ware yam cultivars was significant ($P<0.05$) in 2014 cropping season (Table 1). *Nwopoko* ware yam cultivar had the highest incidence of nematode infestation within the cropping season compared to the other cultivars. Fresh tuber yield exhibited highly significant ≤ and positive association with weight of yam tubers/plot and bulking rate in both years (Table 2). However, there was highly significant correlation between fresh tuber yield and number of ware-yam tubers/plot and with number of seed yam tubers/plot in 2014 and 2015, cropping seasons, respectively. Also, in 2014 cropping season, weight of yam tubers/plot and bulking rate exhibited highly significant association with number of ware-yam tubers/plant contrary to 2015 while in both cropping seasons, bulking rate had very strong and positive association with weight of yam tubers/plot. The results of the correlation evaluation of the variants were similar to previous reports by Quin (1998), NRCRI annual report (1998), Balogun *et al*. (2006) in their studies on mini-tuberization of white-yam as well as Muamba *et al*. (2013) in their studies on the use of vine cuttings in the production of yam tubers. The relationship between nematode incidence and fresh tuber yield was poly-linear and positive (Figs. 1a and b) indicating decline in fresh tuber yield·ha^{-1} as incidence of nematode infestation increased before a slight plateau and then a slight upward increment in yield with increased incidence of nematode indicating minor degree of resistance by the yam cultivars to the pest. Furthermore, this indicates that increase in nematode incidence does not automatically relate to linear decline in tuber yield amongst the ware yam cultivars.

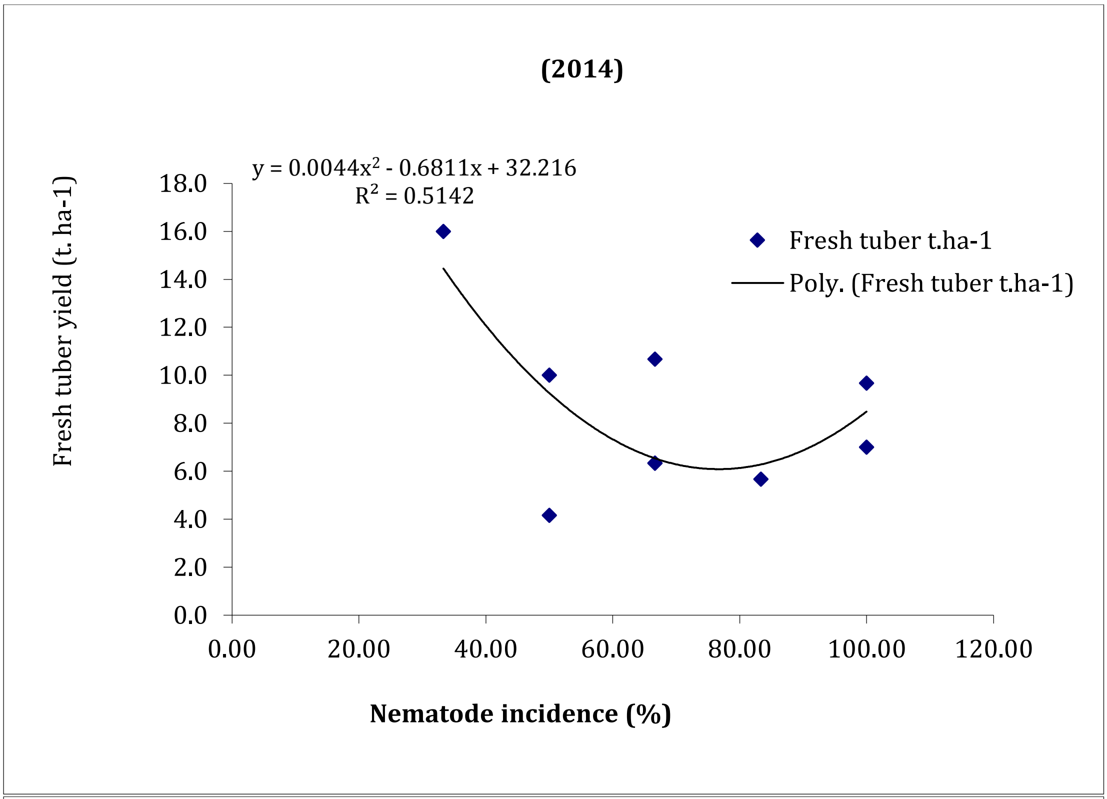

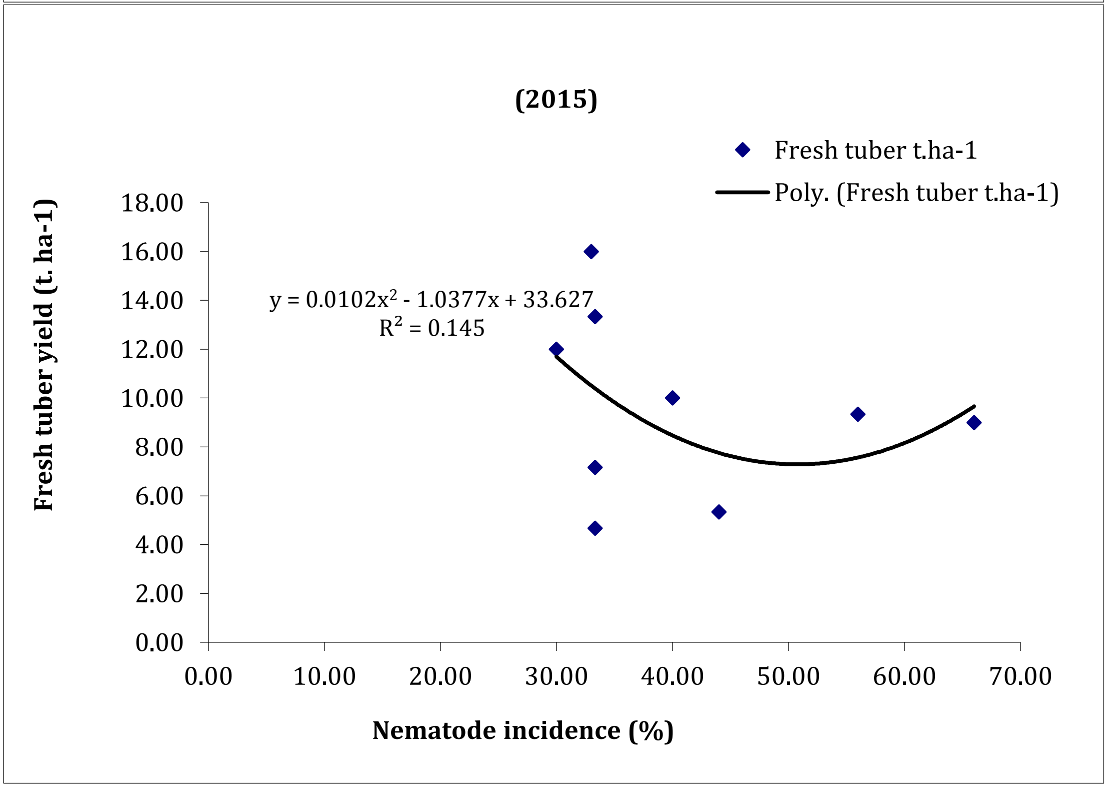

Figs. 1a and b: Relationship between nematode incidence and fresh tuber yield (Mt·ha^{-1}) in 2014 and 2015 cropping seasons with quadratic regression lines.

Conclusion

In both years, tuber yields of the tested cultivars were significant. *Alumaco* had the highest tuber yield relative to *Nwopoko* and *Hebamkwase* other cultivars studied and exhibited the least percentage of nematode incidence in both years. The mean sequence of tuber yield of the ware-yam cultivars in the order: *Alumaco* > *Nwopoko* > *Hebamkwase* in 2014 and 2015 cropping seasons. Fresh tuber yield (t ha^{-1}) indicated highly significant ($P \leq 0.01$) and positive correlation with all the yield attributes, especially weight of tubers/plot and bulking rate in both years with correlation coefficients (r) ranging from 0.55 to 1.00 (2014) and 0.61 to 1.00 (2015). Also, the regression analysis showed a poly-linear and positive relationship between nematode incidence and fresh tuber yield of ware-yam in both years. *Alumaco* ware-yam cultivar was the highest yielder, hence adjudged to be better endowed genetically to be recommended to farmers within the agro-ecological zone of the study area.

Abstract
This study was carried out in the dry season of 2017 at the Teaching and Research Farm of Federal University of Dutsin-Ma, Katsina State, Nigeria, to determine the influence of nitrogen and poultry manure application on cucumber (Cucumis sativus L) performance. The treatments consisted of three levels of nitrogen (0, 40 and 80 kg N ha^{-1}) and four levels of poultry manure (0, 5, 10 and 15 t ha^{-1}) arranged in a randomized complete block design and replicated three times. Application of 40 and 80 kg N ha^{-1} was not significant on growth and yield performance of cucumber. However, application of 80 kg N ha^{-1} gave the highest response on fruit yield of cucumber. Fertilization with poultry manure significantly increased number of leaves per plant, number of branches per plant, fruit length per plant, fruit diameter per plant and fruit yield of cucumber. Application of 10 t ha^{-1} of poultry manure seems to be appropriate for growth and yield of cucumber in this area of study. Application of 5, 10 and 15 t ha^{-1} of poultry manure produced 548, 816.1 and 985.3% increases in cucumber fruit yield when compared with no poultry manure application, respectively.

Introduction
Soil infertility has been an unabated challenge in the growth and yield of any crop in Savanna zone of Nigeria. It has been reported that that Nigerian savanna soils are low in organic carbon, total nitrogen, available phosphorus, effective CEC and exchangeable cations as well as clay and silt contents (Singh, 1987). They are generally poorly buffered and structured and hence they have major chemical, physical and biological limitations (Acquaye, 1974; Jones and Wild, 1975; Kowal and Kassam, 1978). The afore mentioned constraints make it necessary to employ an addition of inputs like inorganic fertilizers such as nitrogen and organic fertilizers such poultry manure worthwhile especially when growing cucumber. It should be of note that crop nitrogen requirement is a physiological component which has a direct relationship to the genetic potential of a crop and its plant growth condition (Zotarelli *et al*., 2009). The use of organic manures like poultry manure is one of the most environmental friendly agricultural technologies which improve the soil physical properties, fertility level and micro flora (Seo *et al.*, 2000). Poultry manure has been reported to contain high percentage of nitrogen and phosphorus for plant healthy growth (Ewulo, 2005). A proper plan of organic and inorganic fertilizer program will definitely improve soil fertility status and consequently enhance crop growth and development for better crop yield and hence, a better income for farmers. It has been observed that maximum net returns in crop production can adequately be sustained with adequate fertilizer program that will supply the amounts of plant nutrients needed (Leonard, 1986). However, the use of chemical fertilizers like nitrogen is very low in Nigeria because of high cost of these inputs while organic manure, which should serve as alternative, is also required in a very large quantity which farmers always find difficult to meet the required quantities for their farms. Although, importance of organic manure in general well-being of soils cannot be over emphasis. Organic manure enables a soil to hold more water, improve the drainage and organic acids that help to dissolve soil nutrients and then make them available for the crops (Deskissa *et al*., 2008). Ologunde (1987) reported that nitrogen is the most limiting factor for production of crops on soils around the world. Hence, there is a need for constant addition of this nutrient especially in

semi-arid environment where this experiment was carried out. Soils of semi-arid environment of Nigeria is known for low organic carbon content which makes addition of poultry manure a good measure of correcting this deficiency. Therefore, this study was conducted to evaluate the influence of application of nitrogen and poultry manure on cucumber performance.

Materials and Methods

The trial was conducted in the dry season of 2017 at the Research Farm of Federal University Dutsin-Ma, at Badole (Longitude $07^0$29'29" E and Latitude $12^0$27'18" N) with altitude of 605 m in the Sudan savanna ecological zone of Nigeria. The treatments consisted of three levels of nitrogen (0, 40 and 80 kg N ha^{-1}) and four levels of poultry manure (0, 5, 10 and 15 t ha^{-1}). The treatments were arranged in a randomized complete block design with various factorial combinations and replicated three times. The experimental plot consisted of four rows of 1.5m apart and 2m long (gross plot) and net plot was 1m x 2m ($2m^2$).The experimental field was harrowed and consequently watered by flooding method. The field was further harrowed to give fine tilths and prepared into raised beds (plots) of 1.5m x 2m in basin form for irrigation purpose. Poultry manure was added to various plots by thoroughly mixing the manure with soil according to the treatments at two weeks before planting. Seeds of exotic variety named PIONSETTE 44 were planted with two seeds per hole at a spacing of 50cm x 50cm on the beds at two weeks after poultry manure incorporation. The cucumber seedlings were thinned to one seedling per stand at two weeks after sowing. Nitrogen fertilizer as urea (46%N) was applied to the cucumber at 2 weeks after sowing (WAS) according to treatments. The field was irrigated twice a week using basin method. Weeds were controlled using hoe at 3 and 6WAS. Samplings on number of leaves and branches per plant were done at 4 ad 6 weeks after sowing (WAS) while fruit length, fruit diameter and fruit yield were obtained at harvest. Data collected from the observations were subjected to statistical analysis of variance (ANOVA) as described by Gomez and Gomez (1984) using SAS package version 9.0 of statistical analysis (SAS institute, 2002). The differences among treatment means were separated using Duncan's Multiple Range Test (Duncan, 1955). Effects were considered statistically significant at 5% level of probability.

Results and Discussion

Application of nitrogen was not significant on number of leaves per plant and number of branches per plant (Table 1). Application of poultry manure had significant effect on number of leaves of cucumber per plant at both 4 and 6WAS (Table 1). Application of 5 and 10 t ha^{-1} of poultry manure at 4WAS, and 5 and 15 t ha^{-1} at 6WAS significantly increased number of leaves per plant which was statistically similar with application of 15 t ha^{-1} at 4WAS and 10 t ha^{-1} at 10WAS (Table 1). Application of 5 t ha^{-1} of poultry manure significantly increased number of branches per plant at 4 and 6WAS which was statistically similar with application of 10 and 15 t ha^{-1} of poultry manure (Table 1). Plots that received poultry manure produced significantly higher number of branches per cucumber plant than plots that received no poultry manure. Plots that received nitrogen fertilization did not show significant effect on fruit length per plant, fruit diameter per plant and fruit yield (Table 2). Application of 5 t ha^{-1} of poultry manure significantly increased fruit length per plant and fruit diameter per plant which was statistically similar with application of 10 and 15 t ha^{-1} of poultry manure (Table 2). Plots that received poultry manure produced significantly longer fruit and fruit diameter than plots that received no poultry manure. Application of 5 and 10 t ha^{-1} of poultry manure significantly increased fruit yield of cucumber (Table 2) but there was no significant difference between application of 10 and 15 t ha^{-1} of poultry manure on cucumber fruit yield. Application of 5, 10 and 15 t ha^{-1} of poultry manure produced 548, 816.1 and 985.3% increases in cucumber fruit yield over zero poultry manure control, respectively (Table 2). Interaction between nitrogen and poultry manure was not significant on the parameters measured in this experiment.

NS: Not significant
Means followed by the same letter(s) within the same column and treatment are not significantly different at 5% level of probability using DMRT

Similarity observed among nitrogen levels on all the parameters measured could be that the soil total nitrogen of the experimental field was adequate for the growth of cucumber. Hence, fertilizing the soil with nitrogen produced similar effect on the cucumber irrespective of the various rates of the added nitrogen. It could also be that the rates of the nitrogen were not adequate to exert significant influence on the measured parameters. Similarly, Van Eerd and O'Reilly (2009) observed that application of nitrogen did not significantly increase cucumber fruit which was attributed to sufficient soil mineral N over the growing season.
Significant increases observed on number of leaves per plant and number of branches per plant could be attributed to the ability of poultry manure to increase the organic matter (OM) content of soil and in turn releases the plant nutrients in available form for the use of the plants (Okoli and Nweke, 2015). Similarly, Nweke et al. (2014) and Okoli and Nweke (2015) reported an increase in cucumber growth after poultry manure fertilization. The mark increases observed on fruit length and fruit diameter following poultry manure application could be attributed to the positive effect of poultry manure on number of leaves per plant and number of branches per plant which culminated in marked increase observed on these yield components. Hamma *et al*., (2012) and Enujeke(2013) observed similarly that poultry manure significantly increased yield parameters of cucumber. Significant increase observed on fruit yield of cucumber after application of poultry manure could be attributed to the increases observed on growth and yield parameters which translated to the better fruit yield. The significant fruit yield after poultry manure fertilization could also be as a result of the improvement in the soil organic matter, release of embedded soil nutrients, increase in soil microbial population and improvement in soil quality. Okoli and Nweke (2015) made similar observation of significant increase in cucumber fruit yield which was attributed to the nutrient content of poultry manure which translated into high vegetative growth resulting in high photosynthetic activities which culminated into high yield observed in plants that received poultry manure. The not significant interaction between nitrogen and poultry manure on the measured parameters could be that both nitrogen and poultry manure did not exert significant effect on each other.

Table 2: Influence of nitrogen and poultry manure on fruit length per plant, fruit diameter perplant and fruit yield of cucumber

Conclusion

Based on the results obtained from this study, it can be concluded that that application of 40 and 80 kg Nha^{-1} did not significantly influence growth and yield of cucumber. Poultry manure fertilization at the rates of 5, 10 and 15 t ha^{-1} exerted significant influence on growth and yield performance of cucumber. However, application of 10 t ha^{-1} of poultry manure seems to be appropriate for the production of cucumber in Sudan savanna ecological zone of Nigeria. Poultry manure must have made available its embedded nutrients through mineralization, created conducive environment for soil microbial activity and exerted big influences on soil physical, chemical and biological properties for enhanced cucumber performance.

Abstract
This study was conducted to evaluate bulking rate as an index of maturity in yam varieties (Dioscorea rotundata). The experiment was conducted at the National Root Crop Research Institute (NRCRI) Umudike, Southern Nigeria. Planting materials include: - 001, 002, 003, 006, and 008, all Dioscorea rotundata white cultivar. These materials will be Sett sizes 50 – 150 g. The experiment was laid out in a randomized complete block designed (RCBD) with five replications. The experimental subjects, (the yam varieties) become the treatments. The planting space will be: 1m x 1m while The sett sizes will be: 50 g – 150 g. Pot size depth will be 10 m x 15 m width. Plot size was 5 m x10 m (50 m). Results showed that no statistical significant (p>0.05) variations were obtained in bulking rate of the five varieties with respect to variety to variety interaction. However, bulking rate increased from 8WAP through 24 WAP across all yam varieties. The variety interaction showed no statistically significant (p>0.05) difference, however, the average tuber weight across the sampling dates was highest in Adaka and lowest in Hembakwase, specifically at 8weeks sampling date. Fresh tuber weight was highest in Amula in 2017 and least in Hembakwase in 2016. At 16 weeks sampling date Adaka recorded the highest fresh tuber weight, while Ame had the least tuber weight in 2016. At 24 week sampling date fresh tuber was highest in Adaka and lowest in Ame both in 2017 cropping season. The bulking rate of the five varieties has reveal time and physical characters which may aid in easy identification of maturity in yam. Yam varieties performed differently in in the Yam yield although the growth parameters did not vary a lot. Adaka from this study showed the best bulking rate and yield values. Hence, it is not out of place to recommend that its adaptation properties may aid good yam production.
Keywords: Yams, Dioscorea, Maturity, Bulking rate and Yield

Introduction
Yams (*Dioscorea* species of family Dioscoreaceae) are important for food, medicine, income and socio-cultural events. They are a leading source of calories for over 300 million people in the tropics and subtropics (Degras, 1993). The crop is grown in Africa, Asia, parts of South America, as well as the Caribbean and the South Pacific islands. In West Africa, about 48 million tons of yams are produced annually on 4 million hectares of arable land. Out of the more than 600 species, 10 are generally cultivated as food: *D. alata*, *D. rotundata, D. cayenensis, D. bulbifera, D. esculenta, D. opposita-japonica, D. nummularia, D. pentaphylla, D. transversa* and *D. Trifida* (Lebot, 2009). *D. rotundata* and *D. cayenensis*, (together also referred to as *D. cayenensis–rotundata* complex) are indigenous to Africa, and represent most of global yam production. They have the highest market value owing to the superior suitability of their tubers to the preferred food uses for the crop in West Africa. High yield potential and early maturity are important characteristics for production. Cultivars that are high yielding and early maturing will enhance production, and may also permit double cropping within a year. This will enable food yam to be available in the market for most of the year. However, crop yield is determined by several related factors, and tuber maturity in yam is difficult to measure directly. Bulking rate refers to the rate of tuber initiation and development; it is also one of the major determinants in the measurement of earliness in maturity, high tuber yields, high forage yield and productivity per unit time in Sweet potato ((Degras, 1993).). The yams (*Dioscorea* spp.) have several botanical peculiarities of their

own. One of these peculiarities is that the tubers which they produce originate neither from the stem; instead they arise from the hypocotyl region of the plant (Lebot, 2009). It is not surprising therefore that the tuber itself exhibits several unique morphological and physiological characteristics. Many of these characteristics profoundly influence the productivity of the crop on the field, and determine how best the crop can be managed for optimum yields.

Materials and Methods

Study Area

The experiment was conducted at the National Root Crop Research Institute (NRCRI) Umudike, Southern Nigeria to study the use of bulking rate as an index of maturity in yam varieties. Umudike is located at Latitude 5° 29' N and Longitude 7°33' E in the rainforest agro-ecological zone of South Eastern Nigeria. It has an annual rainfall that ranges between 1800 mm - 2200 mm. This lies at about 122m above sea level.

Planting Materials

Planting materials include: - 001, 002, 003, 006, and 008, all *Dioscorea rotundata* white cultivar. These materials will be Sett sizes 50 – 150 g.

Field Preparation and Soil Sampling

The site was slashed, harrowed, ploughed and ridged at the onset of the raining season in April. A composite soil samples were collected with a soil auger to the depth of 20cm before ploughing the land. The samples were air dried, passed through 2mm sieve and analyzed for their physical and chemical properties. The experimental area was marked out into replicates and each replicates were divided into five experimental units (plots). Each plot was measured 5m x 10m ($50m^2$).

Experimental Design, Treatments and Treatment Allocation

The experiment was laid out in a randomized complete block designed (RCBD) with five replications. The experimental subjects, (the yam varieties) become the treatments. The planting space will be: 1m x 1m while The sett sizes will be: 50 g – 150 g. Pot size depth will be 10 m x 15 m width. Plot size was 5 m x10 m (50 m)

Data Collection

Data will be collected on the following parameters:

1. Tuber initiation or bulking at 2, 4, 6, and 8 months.
2. Selection index at 8 month
3. Yield component at harvest include :-
4. Tuber yield: it was obtained by converting the mean tuber weight of each plot in tons per hectare.

Data Analysis

The data collected will be subjected to ANOVA and means will be compared using LSD.

Results and Discussion

Bulking Rate of yam varieties in 2016/ 2017 cropping seasons

Bulking rate shortens the period of growth from planting to harvesting. The bulking rate of five yam varieties over a two year cropping season (2016/2017) is presented in table 1. Results showed that no statistical significant (p>0.05) variations were obtained in bulking rate of the five varieties with respect to variety to variety interaction. However, bulking rate increased from 8WAP through 24 WAP across all yam varieties.

Table 1: Bulking rate of Yam varieties in 2016 and 2017 cropping seasons

Treatment	2016 8WAP Tuber yield (kg)	16WAP Tuber yield (kg)	24WAP Tuber yield (kg)	2017 8WAP Tuber yield (kg)	16WAP Tuber yield k(g)	24WAP Tuber yield (kg)
Adaka	1.97	3.22	3.37	2.78	4.05	12.7
Ame	0.9	2.0	3.16	1.01	2.29	7.8
Amula	1.12	3.42	4.91	1.81	3.19	9.7
Hemba	1.22	2.63	3.78	2.19	3.51	8.3
Yandu	1.45	4.08	3.73	1.5	2.3	11.3
$LSD_{0.05}$	1.615^{NS}	2.057^{NS}	1.6^{NS}	1.732^{NS}	2.217^{NS}	8.38^{NS}

Yield of five varieties at different yield component stages in 2016 and 2017

Table 2 is a presentation of the tuber weight of five varieties and showed a general sharp increase in tuber weight from 4WAP through 24WAP. The variety interaction showed no statistically significant (p>0.05) difference, however, the average tuber weight across the sampling dates was highest in Adaka and lowest in Hembakwase, specifically at 8weeks sampling date. Fresh tuber weight was highest in Amula in 2017 and least in Hembakwase in 2016. At 16 weeks sampling date Adaka recorded the highest fresh tuber weight, while Ame had the least tuber weight in 2016. At 24 week sampling date fresh tuber was highest in Adaka and lowest in Ame both in 2017 cropping season.

Table 2: Yam tuber yield of five varieties at different yield component stages in 2016 and 2017 cropping seasons

Treatments	2016	2017	2016	2017	2016	2017
	8WAP (kg)		16WAP (kg)		24WAP (kg)	
Adaka	0.029	0.0348	0.155	0.159	0.019	1.09
Ame	0.0089	0.0127	0.138	0.160	0.145	0.68
Amula	0.0088	0.0219	0.288	0.172	0.186	0.81
Hemba	0.0086	0.0274	0.176	0.165	0.144	0.60
Yandu	0.0151	0.0187	0.328	0.100	0.043	1.13
LSD 0.05	0.0330^{NS}	0.02178^{NS}	0.1583^{NS}	0.0843^{NS}	0.2645^{NS}	1.176^{NS}

The general observation of early tuber formation across the varieties may be due to similarity in fertilizer application, as this may have aided tuber formation. Similar claims on the effect of fertilizer on tuber formation were made by Law-Ogbomo and Osaigbovo (2014). They concluded that the yam plant showed the usefulness of fertilizer application in improving its productivity as the tuber yield was reduced where fertilizer was not applied at all. This may be related to insufficient nutrient uptake as the plants have to rely on the on the native fertility of the soil which has been shown to be deficient in primary nutrients (N, P and K). This soil condition may be the reason why the leaf area was high and in turn aided the early initiation of tubers. Law-Ogbomo and Remison (2008) reported that the significant correlation between fresh tuber yield and the leave area ($r = 0.65$; $p < 0.05$). the increase in the bulking rate over time and the observe higher bulking rate of in 2017 over that of 2016 across the periods of observation may be as a result of difference in the grow factors such as leave area index, vine length, leave number, which may have ensured better utilization of the solar radiation. Adaka, Amula, and Yandu in 2017 recorded tuber numbers that increased with growth period respectively. The reduction in number of tuber yield over time as observed in this study was also reported by Marie-Vianney *et al*. (2008) were at 40 WAP the yam varieties started showing a reduction in the number of tubers counted, this may be a pointer to the knowledge that yam may not increase its tuber number if the maximum number has been reached irrespective of the time and go further to suggest that at its peak of tuber number maturity and other subsequent physiology of the tuber may set in.

Conclusion

The Bulking rate of the five varieties has reveal time and physical characters which may aid in easy identification of maturity in yam. Yam Varieties performed differently in in the Yam yield although the growth parameters did not vary a lot. Adaka from this study showed the best bulking rate and yield values. Hence, it is not out of place to recommend that its adaptation properties may aid good yam production. Yam agronomy requires further research on Better ways to monitor responses and the effectiveness of Yam varieties to agronomic practices and maturity.

Abstract
A field experiment was conducted at the Research farm of Imo state Polytechnic Umuagwo – Ohaji, owerri, Nigeria in 2016 cropping season. The objective of the study was to evaluate the effect of cow dung and poultry manure on the growth and yield of A. hybridus. The experiment was laid out in a Randomized complete block design (RCBD) with four replicates the treatment were 10t/ha of cow dung manure 10t/ha of poultry manure, a mixture of 5t/ha each of cow dung and poultry manure and the control, result shoed that amending soil with poultry manure greatly improved the soil fertility and subsequent growth and yield of a. hybridus. This as due to the high level of nitrogen present in it. The mixture of cow dung and poultry also performed well. The cow dung manure gave a good growth and yield of A. hybridus but not as the mixture the control gave the least performance as it lacked the nutrients required for proper growth and yield of A. hybridus. Thjis work has shown that a good soil amendment especially with poultry manure is needed for a good growth and yield of A. hybridus.

Introduction
Plants depend on some essential elements for proper growth and development. However natural disasters like erosion, leaching and run-offs have really been a problem to farm crops especially vegetables as they cause the depletion of soil nutrients (Ewulo, 2005). Animal manure is known to be effective in the maintenance of adequate supply of organic material in the soil with improvement in soil physical and chemical condition and enhanced crop performance (Ikpe and Poel, 2002). Organic manure consists of natural and biodegradables components and elements which can be easily worked upon by microorganisms and reach plants safely. It reduces soil acidity and does not cause leaching. Organic manure is a source of major nutrients – nitrogen, phosphorus and others as well as some micronutrients. It increases the ability of the soil to hold water and nutrients and keeps improving soil even after the crops are removed. Amaranthus hybridus is a leafy green vegetable which is very rich in vitamins it belongs to the family Amaranthaceae and is a native of tropical America (Budin et al, 1996). Since the cost of producing this vegetable using inorganic fertilizer is expensive, the fertilizer itself is not ecofriendly among other factors this work is aimed at investigating the effect of cow dung and poultry manure on the growth and yield of Amaranthus hybridus

Materials and Methods
The experiment was conducted at the research farm of Imo state Polytechnic, Umuagwo Ohaji, Imo state. The experimental materials ere procured from imo state Agricultural Development office owerri. 10t/ha of cured poultry manure, 10t/ha of cured cow dung manure and 10t/ha of a mixture of both were applied to the already prepared beds two weeks before planting. Seedlings raised in the nursery were transplanted into the field measuring 49m2. The parameters used were plant height, number of leaves, number of branches, stem girth and mean leaf yield were measured at 2, 4, 6 and 8 WAP using plants which were randomly selected. Leaf weight was obtained by weighing the leaves on a salter weighing balance. The data obtained were subjected

to analysis of variance for a randomized complete block design (RCBD) and the means ere separated using least significant difference (LSD) at 5% level of probability

Results and Discussion

Table 1 shows a significant difference in the mean plant height of A. hybridus at 2 WAP between the control and the other treatments and the same trend continued till 8 WAP. This agrees with the report of Ayoola and Adediran, 2006 that organic manure can be used to improve the fertility of soil. Tables 2, 3 and 4 shows that there is no significant difference in the mean number of branches, mean number of leaves and mean stem girth of A. hybridus at 2, 4, 6 and 8 WAP although the T2 and T3 gave the best results. The good performance given by poultry manure agrees with the report of Smith and Ayenigbara, 2001, which showed that poultry manure contains a higher value of Nitrogen when compared to cow dung manure. Table 5 shows a significant difference in the mean leaf yield of A. hybridus under different manure application between t2 (poultry) and t1 (cow dung), a significant difference also existed beteen t2 and t3 indicating that combining poultry and cowdung manure can improve the soil better than using only cow dung manure. A significant difference existed also beteen the control and each of the treatments showing that amending soil using organic manure has a positive influence on the soil (Ano and Agwu, 2005; Joann Nwajiuba and chimezie, 2000). The control (To) had the leastr performance owing to the fact that it lacked the required nutrients for proper growth and yield of A. hybridus. This agrees with the work of Hague and Lupwayi, 2003 who reported that poor nutrient availability to the soil produces low yield. Thus poultry manure (t2) performed better than all the other treatments and this agrees ith the work of marere and Nonga, 2001 who reported that poultry manure has a high level of soil organic properties such as nitrogen and potassium which makes it better than cowdung manure.

Table 1: Mean plant height of *Amaranthus hybridus* at 2, 4, 6 and 8 WAT under different manure application

Table 5: Mean leaf yield (Kg/ha) of *A. hybridus* under different manure application

Manure Treatment	Mean Leaf Yield(Kg/Ha)
T0	133.62[a]
T1	233.59[c]
T2	304.27[a]
T3	242.74[b]
LSD 0.05	0.61 0.41 0.41 0.41

Means in the same column having the same letters are not significantly different at $p \leq 0.05$ according to LSD test

Conclusion

In conclusion, amending soil with organic manure improved the fertility of soil, for the growth and yield of A. hybridus though poultry was more effective than cow dung manure due to high level of organic Nitrogen and carbon present in it.

Agronomic Strategies towards Sustainable Cowpea Production in Nigeria: Effects of Variety and Weeding Regime

E.C. Offor and C.C. Nwokocha
National Root Crops Research Institute Umudike, P.M.B. 7006 UmuahiaAbia State
E-mail: esychinma@gmail.com

Abstract
The field experiment was conducted at the Eastern Research Farm of Michael Okpara University of Agriculture Umudike to investigate the suitable weeding regime to enhance yield of 4 varieties of vegetable cowpea (Vignaunguiculata (L). Walp). The experiment was set up as a split-plot in randomized complete Block Design (RCBD) with the vegetable cowpea varieties (ITO3K-324-9, IT98K-692, 1T99K-377-1 and IT04K-399-1) occupying the main plot and the weeding regime (weed X1, weed X2, weed free and NO weeding) occupying the subplot. Variety 1T04K-339-1 significantly improved plant height, number of branches, number of leaves and leaf area of vegetable cowpea at 4 WAP, while at 8 WAP, variety 1T99K-377-1 proved superior over other varieties in plant height, leaf area and number of seeds/pod. Yield parameters were maximized when variety 1T03K-324-9 was grown, despite its poor growth characteristics. The study identifies single weeding at 4 WAP as being most conducive for optimum yield of vegetable cowpea varieties under Umudike conditions.

Introduction
Cowpea (*Vignaunguiculata (L).Walp*) is an annual legume with lots of common names, such as Crowder pea, black-eyed pea and southern pea, lubia, niebe, coupe or frijoles (Adediran*et al.,* 2005). The largest production of cowpea is in African with Nigeria and Niger predominating, but Brazil, India, Australian and U.S. all have significant production. There are two types of cowpea, the seed type and vegetable type (for leafy greens, green pods fresh shelled green peas and shelled dried peas) (Adediran*et al.,* 2005; Ekeleme and Nwofia, 2005; Umaharam*et al.,* 1997) in the humid forest fringes,. The most widely grown varieties are the vegetable types whose immature succulent pods are eaten by humans. (Ekeleme and Nwofia, 2005). It is usually grown as companion crop in yam, cassava and their mixtures. Cowpea is a food legume that plays a critical role in the lives of millions of people in Africa and other parts of the developing world. Both the grain and the haulm, which serves to improve the nutrient level of the crop, are valuable dietary proteins for the African human population and their livestock (Fatokun, 2002). Cowpea is a deep rooted crop and does well in sandy soils and more tolerant to drought than soybean. The crop is a major component of the tropical cropping system because of its ability to improve marginal lands through nitrogen fixation and as a cover crop (Sanginga *et al.,* 2003; Abayomi, 2009).The crop is of major importance to the livelihoods of millions of people in the tropics. For resource-poor small-holder farmers, the crop serves as food, animal feed, cash and manure. Weed infestation is a major constraint to crop production. Cowpea is generally susceptible to weed infestation at all periods of growth; the most damaging effects occurring during the early stage after planting (Onochie, 1975). Its competition with weeds depends, to some extent, on how long after planting the crop stays weed-free before the canopy covers the ground. Weeds are removed by hand pulling and traditional hoe. This method is labor intensive and often not appropriate during flowering stage (Ekeleme*et al.,* 2003). A experiment was carried out to determine the growth, yield and yield components of four vegetable cowpea cultivars when subject to different weeding regimes in Umudike, Southeastern Nigeria.

Materials and Methods
Four varieties of vegetable cowpea (IT98K-692, IT03K-324-9, IT99K-1 and IT04K-339-1) obtained from the International Institute of Tropical Agriculture (IITA) Ibadan were used in the

study. The experiment was conducted at the Eastern farm of Michael Okpara University of Agriculture Umudike (MOUAU). The location falls within latitude 05°2° N and longitude 07°32° E, with a nearly level to gently undulating topography and slopes ranging from 1% to 3%. The experiment was laid out as a split plot in a Randomized Complete Block Design (RCBD) with the main plots being the vegetable cowpea varieties, while four weeding regimes (no weeding (NW), weed free (WF), weeding once (WXI) and weeding twice (WX2)) occupied the sub-plots. The experiment was replicated three times. Each sub-plot measured 2 m × 3.5 m with 1 m alley between sub-plots and replicates. Two seeds were sown per hole on the flat at a spacing of 25 cm × 50 cm. Insect pest was controlled with *Cypermetherin* (EC) at 150 ml in 20-liters of water from bud initiation stage. Pre-cropping soil samples were randomly collected from four locations at 0 – 30 cm soil depth, and bulked together as composite soil sample. The soil sample was air dried in a room temperature for 48 hours, and subsequently sieved with a 2 mm sieve before being analyzed.

Growth data (plant height, numbers of leaves, number of branches, leaf area) were obtained at 4 and 8 weeks after planting (WAP). Number of fresh pods per plot was obtained by counting the number of pods from each plot at every harvest made twice a week from a 1m quadrant. Fresh pod yield/m^2 was obtained by harvesting the pods from 1 m quadrants at every harvest twice a week. Fresh and dry pod weights were obtained by weighing fresh/dry pods harvested per **m^2** with electric sensitive measuring scale. The average length of the pod was obtained by collecting 10 pods from each plot and determining their average length using a meter rule in centimeter. The numbers of seeds/pod extracted from dry pods collected from each plot was used for the calculation of 100 seed weight (g).

Results and Discussion

Initial soil test results

Results of the initial physico-chemical properties of the study soil showed that the study soil had a sandy clay loam texture, and a slightly acidic soil reaction (pH 5.0). Percentage total nitrogen was low (0.063%) with a moderate value of available phosphorus (19.35 mg/kg). Percentage soil organic matter was medium (1.272%).

Growth parameters

Average plant height

Results on plant height showed that plant height was very significantly ($P < 0.01$) influenced by variety at 4 and 8 WAP. Weeding regime and variety x weeding regime interaction did not significantly ($P > 0.05$) affect plant height at both 4 and 8 WAP (Table 2). Planting of IT04K-339-1 produced tallest plants (12.53 cm) which did not differ significantly with plant height (12.37 cm) of IT03K-324-9 at 4 WAP. However, at 8 WAP, variety IT99K-377-1 which recorded the lowest plant height (9.84 cm) at 4 WAP, returned the tallest plant (73.03 cm) that differed significantly only with plant height (52.58 cm) obtained from IT03K-324-9 variety (Table 1).

Average number of branches

Number of branches of vegetable cowpea was significantly ($P < 0.01$) affected by cowpea variety. Varieties ITO3K-324-9 and IT04K-339-1 recorded significantly highest number of branches (3.97 and 3.48, respectively), which did not differ significantly from each other. Lowest number of cowpea branches (1.95) was recorded by IT99K-377-1 variety at 4 WAP (Table 1). At 8 WAP, IT04K-339-1 maintained the highest number of branches (4.05), significantly over other varieties. Two varieties, ITO3K-324-9 and IT98K-692 suffered reductions in average number of branches at 8 WAP compared with number of branches recorded by the varieties at 4 WAP.

Average number of leaves

In terms of number of leaves, variety IT04K-339-1 recorded significantly ($P < 0.01$) highest number of leaves both at 4 WAP (11.94) and at 8 WAP (24.83) over all other varieties at 4 WAP and over IT99K-377-1 at 8 WAP. Variety IT99K-377-1 maintained lowest number of leaves at both 4 and 8 WAP.

Average leaf area

Average leaf area of vegetable cowpea was significantly ($P < 0.01$) influenced by variety at 4 and 8 WAP. Variety IT04K-339-1 recorded the highest leaf area (514.1 cm2) at 4 WAP, while IT99K-377-1 variety, which recorded the lowest leaf area (326.8 cm2) at 4 WAP, surpassed other varieties at 8 WAP by recording significantly highest leaf area (2271.3 cm2) (Table 1).

Weeding regime and variety x weeding regime interaction did not significantly ($P > 0.05$) influence any of the growth parameters measured

Yield and yield parameters

Fresh pod weight (t/ha)

The effects of variety, weeding regime and variety x weeding regime interaction on fresh pod weight (t/ha) of vegetable cowpea are as shown in Table 2. Variety and variety x weeding regime interaction did not significantly ($P > 0.05$) influence fresh pod weight. However, weeding regime very significantly ($P < 0.01$) influenced fresh pod weight of vegetable cowpea. All weeding regimes (weeding X1, weeding X2 and weed free) significantly yielded higher fresh pod weight than when vegetable cowpea was not weeded (No weeding (5.04 t/ha)). Optimum fresh pod yield (6.30 t/ha) was obtained from when weeding was carried out once (Weeding X1).

Number of seeds/pod and number of pods/m^2

Analysis of variance conducted showed that number of seeds/pod and number of pod/m^2 were highly significant ($P < 0.01$) among the varieties, while weeding regime did not show any significance ($P > 0.05$) for number of seeds/pod, but significantly ($P < 0.05$) influenced number of pods/m^2. Variety x weeding regime interaction did not significantly influence both parameters (Table 2). The results showed that variety IT99K-377-1 had the highest number of seeds (14.69/pod) while variety IT04K-339-1 had the least number of seeds (11.83/pod). Varieties IT98K-692 and IT03K-324-9 had the highest number of pods (158.75 and 138.42 pods/m^2, respectively) while variety IT99K-377-1 recorded the least number of pods (61.08 pods/m^2). The result also showed that optimum number of pods (107.50 pods/m^2) was obtained from plots that were weeded once, which did not differ significantly with values obtained from plots that were weeded twice (127.75 pods/m^2) and plots that were maintained weed free (124.33 pods/m^2).

100 seed weight (g) and pod weight (g) of vegetable cowpea

Results shown in Table 2 showed that 100 seed weight (g) and pod weight (g) among the vegetable cowpea varieties were highly significant ($P < 0.01$),while weeding regime and variety x weeding regime interaction did not significantly ($P > 0.05$) affect 100 seed weight and pod weight. Variety IT03K-324-9 had the biggest 100 seeds weight (18.24 g) among the vegetable cowpea varieties while variety IT98K-692 had the smallest 100 seeds weight (12.93 g). Significantly highest pod weights were obtained from varieties IT03K-324-9 (6.83 g) and 1T99K-377-1 (6.38 g), while variety IT04-339-1 had the smallest pod weight (4.73 g).

The result obtained in this study consistently showed that cowpea varieties, significantly influenced average plant height, average number of branches, average number of leaves, leaf area at 4 and 8 WAP, average number of seed/pod, number of pod/m^{2}and 100 seed weight (g). In terms of growth parameters, there were differences in varietal performance at different periods of observation. Variety 1T04K-339-1 showed consistency in improving plant height, number of branches, number of leaves and leaf area at 4 WAP. However, at 8 WAP, variety 1T99K-377-1 produced tallest plants with highest leaf area. It showed thatimprovements in growth parameters at 4 WAP by 1T04K-339-1 did not translate into improvement in yield parameters; instead variety 1T99K-377-1 which improved growth parameters at 8 WAP produced highest number of seeds/pod. Variety 1T03K-324-9, though it performed poorly in growth parameters, recorded the highest number ofpod/m^2 and highest 100 seeds weight. The study demonstrated that weeding is a critical farm operation that improved fresh pod yield (t/ha), while no weeding suppressed fresh pod yield (t/ha). Optimum number of pod/m^{2}was obtained when weeding was done once at 4 WAP (Weeding X1). It study identifies single weeding at 4 WAP as being most conducive for optimum yield of vegetable cowpea at Umudike. Reduction in number of pods/m^2 caused by increased length of weed interference (No weeding) was accompanied by a simultaneous reduction in fresh pod yield (t/ha). Similar result was reported by A L-Thaihabi*et al* (1994) in chickpea, where weed interference also caused reduction in number of pods and branches per plant and reduced seed size. The significant reduction in yield parameters obtained in weed free and weeding X2 regimes over the weeding X1 regime reflect the reduced effect of weed competition in weeded plots (Akobundu, 1978, Ojo, 1997).

Conclusion

Based on the results of this study, yield is maximized when weeding X1 regime is maintained throughout the life cycle of vegetable cowpea (*Vignaunguiculata L. walp*). Yield is also maximized under Umudike condition when variety 1T03K-324-9 is grown, despite its poor growth characteristics.

Pesticides Application Practices Adopted by Cocoa Farmers in South-Western Nigeria

M.O. Okeniyi and S.B. Orisajo
Cocoa Research Institute of Nigeria, P. M. B. 5244, Idi-Ayunre, Ibadan, Oyo State
E-mail: sambukki@yahoo.com

Abstract
The wrong use of the pesticide application equipment in cocoa production has attracted a global concern about the impact of these pesticides on public health. Proper technique of pesticide application is very vital just as the selection of equipment, knowledge of pest behaviour and skilful dispersal methods. This study was aimed at assessing pesticide application practices and sprayer types adopted by cocoa farmers in South-western Nigeria towards ensuring minimum pesticide usage and appropriate choice of sprayer for different farm operation for sustainable cocoa production in the study area. A set of pre-tested questionnaire was used to collate information from farmers, while multistage sampling procedure was used to select 50 respondents each from two villages in Idanre Local Government of Ondo State and 45 respondents each from two villages also in Ogo-Oluwa Local Government Area of Oyo State. Results showed that 100% of the respondents make use of manually operated sprayer, while 55.9% uses knapsack sprayer. 74.7% of the respondent increased the frequency of application above the recommended rate while 68.4% increased dosage above recommended rate. 95.7% spray pesticide in the morning, 86.3% select a small-hole nozzle (low volume) for application and only 43% of the respondents ensure constant mixing of pesticide during operation. Most farmers apparently used spraying equipment and application practices based on what are at their disposal without basic knowledge and recourse to guiding principles for effective and efficient use of pesticide for controlling pests and diseases. It is recommended that for sustainable cocoa production, training and re-training of farmers on Good Agricultural Practices and Pesticides Usage is needed for efficient use of pesticide and choice of sprayer.

Keywords: application practices, pesticide, sprayer, farmers

Introduction
The nature of cocoa production has changed considerably over the last century, with enormous shifts, not only in how the crop is produced, but also where it is grown. Recent cocoa production has been relatively stable, but over longer periods, dramatic changes have occurred (Bateman, 2015). Nigerian cocoa production has suffered a major problem of pests and disease invasion. Most cocoa farmers are small-holders, who usually minimise inputs for pest and disease management, and may not be willing or able to invest their time or resources in any pest management when cocoa prices are low. However, pod diseases such as *Phytophthora megakarya* (black pod in West Africa) have the capacity to reduce yields by more than 80%. Farmers spray pesticides on a regular basis to contain the disease. Pesticide use in Nigeria has been on the increase since its introduction in the early 1950's for cocoa production. Many farmers believe that pesticides work, at least against some cocoa pest problems, and continue to use them depending on the pest and country (Bateman, 2015; Aikpokpodion *et al,* 2012). There are essentially two types of equipment commonly used for spraying cocoa trees: motorised mist-blowers (or air-blast sprayers) and manual (hydraulic) sprayers. Almost all small-holder farmers use manual (hydraulic) sprayers, which are globally the main method of pesticide (especially fungicide) application to cocoa. Motorised mist-blowers now have many uses, but they were originally developed for obtaining good droplet coverage in the tall cocoa trees of West Africa. For portable equipment (as used by most farmers and especially small-holders), specifications are given for sprayer tanks, pumps, etc., with specific requirements on nozzles. FAO envisaged

that member countries should put sprayer quality standards into law as with pesticides, but sadly, few countries have implemented this. Hydraulic nozzles remain the most widely used method of spraying chemical pesticides. They are fitted to a wide range of spraying systems ranging from the very basic hand-held 'trombone' sprayers, side-lever knapsack sprayers, compression sprayers (originally designed for vector control, but used by some cocoa farmers). There are guidelines on minimum equipment standards for manual sprayers that include various aspects relating to weight, durability, leakage, ease of cleaning and maintenance, instruction manuals, etc. (Bateman, 2015). Many manual sprayers used by smallholder cocoa farmers world-wide are fitted only with variable cone nozzles, and few farmers know which setting to use (Bateman *et al*., 2010). These sprayers are typically maintained by farmers themselves: although there have been Government or cooperative support initiatives. It can be difficult to convince smallholders that it usually pays in the long-term to choose a good quality, robust sprayer and always ask the question "Will I be able to find spare parts for it?" (Bateman, 2015). The wrong use of pesticide application equipment in cocoa production has attracted global concern about the impact of these pesticide on public health with respect to pesticide residue on cocoa and its products: problems of over-or-under-application include crop injury, poor pest control and injury to subsequent crop when using residual pesticide application practices (Malik *et al,* 2012; Takagi *et al,* 2012). Proper maintenance and storage of sprayers are very important for correct performance of pesticide application (Malik *et al*, 2012). The study was carried out to assess pesticide application practices and sprayer types among cocoa farmers.

Materials and Method

The study was carried out in Oyo and Ondo States. A multi-stage sampling procedure was used to select the sample for the study. In the first stage, Ondo and Oyo States were purposively selected due to their cocoa production records. Also, one Local Government Area (LGA) well noted for cocoa production was selected from each of the two states. Idanre and Ogo-Oluwa were selected from Ondo and Oyo States, respectively. Two villages were also chosen from each LGA. They are Owena and Onikokojiya from Idanre; Otamokun and Ibere from Ogo-Oluwa LGA. Fifty (50) and forty-five (45) cocoa farmers were selected from Idanre and Ogo-Oluwa LGA, respectively resulting in Ninety-five (95) farmers. A well-structured questionnaire was individually administered to ninety-five farmers (45 in Oyo and 50 in Ondo State). Data collected was analysed using descriptive statistics such as frequency counts and percentage. The variables considered include farmer's characteristics (age, sex, marital status, education and group membership) sprayer types and application.

Results and Discussion

Personal characteristics of cocoa farmers

Personal characteristics of farmers in the study area are described in Figure 1 to 3. Ages of farmers ranges between 20 and above 70 years. Those within the ages 20-50 years were relatively young being 57.9% of the total population studied while 42.1% were 51-90 years old (Fig. 1). The implication of this is that substantial percentage of farmers in South-western Nigeria was relatively old. This does not encourage sustainable cocoa production since most of the farmers were aging. More male (77.9%) were involved in cocoa production than female (data not shown). This was corroborated by Agbongiarhuoyi *et al,* (2013) in coffee production (that shares the same agroecology with cocoa). This is a good trend as men are regarded to be more energetic to handle herculean tasks such as land clearing better than women.

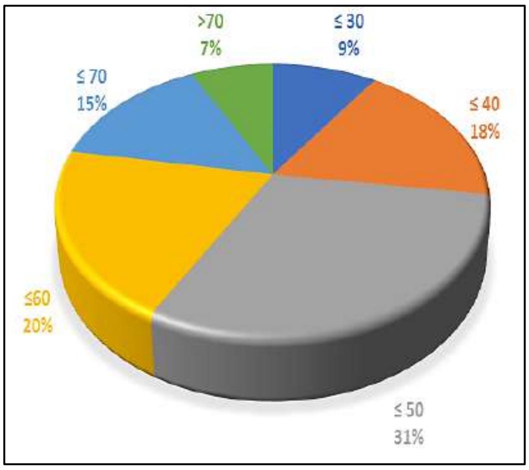

Figure 1: Age range of cocoa farmers

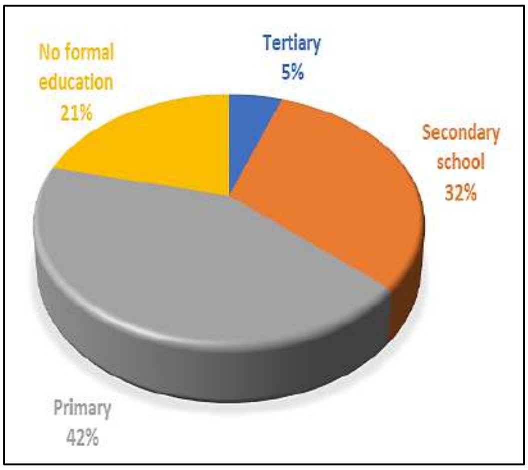

Figure 2: Educational status of cocoa farmers

The educational status of farmers is very important for interpreting and accepting new innovations and technologies in agriculture. However, very low percentage of farmers (5.3%) possessed higher certificates while 31.6% were holders of SSCE and substantial number of 21.0% had no formal education at all (Fig. 2). It had been reported that most of the cocoa farmers are not literate (Asogwa, 2008); hence they indulge in serious malpractices in pesticide application such as wrong use of nozzles, wrong formulations and doses, inability to distinguish one pest from the other and wrong timing of application. Education is positively associated with pesticide use, indicating that highly educated use more pesticides. It may be difficult for farmers without formal education to interpret, understand and accept information on new techniques in farming.

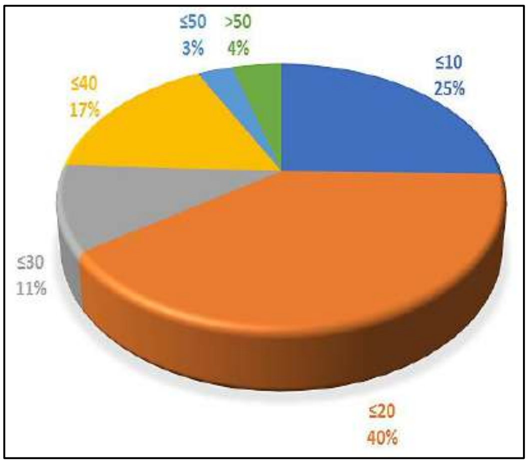

Figure 3: Farming experience (years)

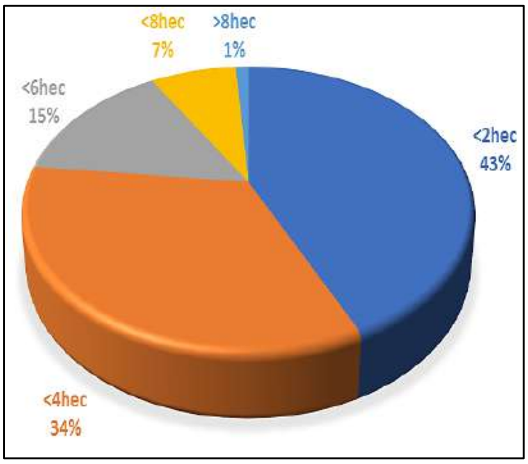

Figure 4: Size of cocoa farm (hectares)

Results showed that about 75% of the farmers sampled had more than 10 years farming experience (Fig. 3). This will help promote knowledge transfer and boost productivity. 76.8% of farmers had small area of farm between 0.1-4 hectares (Fig. 4). This is an indication that majority of cocoa farmers are incapacitated in one way or the other and should be encouraged to increase their farm size through provision of incentives.

Application practices

Significant number of respondent (56.8%) spray cocoa trees at 4-6 weeks' interval, 41% 1-3 weeks' interval while 1.1% sprayed before fruiting and on-setting of rain. Majority (71.6%) of the respondent followed the recommended label dose while 10.5% used fraction of recommended rate and 17.7% adopted indiscriminate pesticide usage. The implication of this is that most farmers are adopting approved pesticide application standards which will ensure quality cocoa beans for local and international market. It will also ensure minimum pesticide residue levels and promote good health for consumers of cocoa products. 86.3% of the farmers selected a low volume nozzle for spraying pesticides as against 5.3% that were indifferent about nozzle selection. Selecting correct spray nozzle type and size is essential for pesticide application (Malik *et al*, 2012). High Volume spraying, mostly obtained through hydraulic nozzles, is the most common and popular method of pesticide application; but Low Volume (LV) and Ultra Low Volume (ULV) are preferred for economic pest control. However, Asogwa *et al.*, (2009) reported that relative higher deposition of spray fluids on cocoa trees by the use of High Volume spraying compared with the use of Low Volume spraying by motorized mist blower in Ghana and fogging sprayers in the Cameroon accelerated the development of resistance. It may, therefore, imply that majority of cocoa farmers in the study area were using the appropriate nozzles for applying pesticides. Notwithstanding, Malik *et al,* 2012 stated that majority of the Nigerian Cocoa farmers still use substandard and inappropriate spraying pumps while attention was not paid to the use of appropriate jets and extension lances where recommended pumps were used. This trend is not encouraging for good pesticides spraying as high volume nozzles are recommended. Reasonably, number of farmers (95.7%) apply pesticides in the morning which is popularly acceptable while 4.3% were indiscriminate about choice of time. 44.2% half fill the tank with water before adding pesticide which is the acceptable method/practice, 20% of the farmers fill up the tank before adding pesticides, a total of 31.55% would either pour the pesticides and add water or mix separately in a container while 4.3% mix as convenient. This implies that a reasonable number of farmers are yet to understand the best procedure for mixing pesticides when loading the sprayer tank. Of the respondents only 43.5% take cognizance of important requirements like mixing the pesticide in the tank periodically after mounting the sprayer which ensures optimum results.

Table 1: Pesticide application practices

Variable	Frequency	Percentage
Spraying interval		
1-3 weeks	39	41.0
4-6 weeks	54	56.8
Before fruiting	1	1.1
Immediately rain set in	1	1.1
Pesticide concentration		
Recommended label dose	68	71.6
Fraction of label dose	10	10.6
Dose used by others	17	17.9
Nozzle selection for pesticides application

Half-filled tank with water and add pesticide	42	44.2
Pouring water and add water	14	14.7
Mix pesticide separately before pouring into tank	16	16.8
As it is convenient	4	4.3
Ensuring constant mixture of pesticide in the tank		
During operation		
Shaking immediately after mounting	41	43.1
Shaking periodically	43	45.3
Shaking at convenient time	9	9.4
Not necessary	1	1.1
None	1	1.1

Source: Field Survey, 2017

Relatively high number of respondents (74.7%) increased the frequency of pesticide application while 68.4% increased the dosage as a result of high level of infestation of diseases and pests (Table 2). This an attitude that does not support sustainable cocoa production in Nigeria. This corroborates Aikpokpodion *et al,* 2012 that indiscriminate use of pesticides by farmers without following manufacturer's instructions ultimately affects the quality of cocoa beans. It is noteworthy that European Union (EU) has set Maximum Residue Limit (MRL) for cocoa beans for consumption among her citizens (Bateman, 2015) which is considered important for exportation and safe local consumption of Nigerian cocoa beans. Higher percentage (64.7) of the farmers wait until there is a serious leakage from sprayer before rectification. Only 26.3% of the farmers always rectify sprayer leakages whenever it is observed in the flow line. This may be detrimental to spraying efficiency as well been injurious to farmers' health if keen attention is not paid to leakages and prompt rectification during spraying operation. Substantial number of respondent 22.1% and 42.1% did not understand the importance of precaution and maintenance of sprayer such as spraying in the direction of the wind and washing of sprayer before and after use. Lack of maintenance and mismanagement has been reported as one of the problems of pesticide application among Nigerian cocoa farmers (Asogwa & Dongo, 2009). Steps such as cleaning the sprayer and nozzle thoroughly after each use, using clean water and inlet net will ensure effective performance and prevent damage to subsequent crops sprayed and undesirable reaction between residual and new CPPs.

Table 2: Pesticide spraying intervals

Variable	Yes		Never		Occasionally		Always	
	Freq	%	Freq	%	Freq	%	Freq	%
Spraying interval								
Application of pesticide for pest and disease control	95	100	-	-	5	5.3	90	94.7
Do you increase the frequency of application during high infestation	71	74.7	24	25.3	51	53.7	20	21.0
Do you increase the dosage for high level of infestation	65	68.4	30	31.6	59	62.1	6	6.3
It is good to rectify leakage in the flow line of the sprayer only if it is serious	64	67.4	31	32.6	39	41.1	25	26.3
Spraying against the wind gives good result	21	22.1	74	77.9	21	22.1	-	-
Washing sprayer before and after use Is not important for good spraying result	40	42.1	55	57.7	34	35.8	6	6.3

Source: Field Survey, 2017

Conclusion

Most sprayer used by farmer are not suitable for the spraying of cacao but were adopted for use and this pose serious challenges to the health of farmers and eventual consumers of the produce. It is noteworthy that most farmers adopted the recommended dose as stipulated by the manufacturer. However, some of the farmers still lack good knowledge of the best practices for effective pesticide spraying this could probably be due to their low level of education on inadequate information on the right techniques of pesticide application and this implies that training and retraining of farmers is required on pesticides usage and the attendant health risks.
It is therefore recommended that efforts should be made by relevant bodies involved in the agrochemical business to engage in sensitization and training programme that will ensure the right choice of sprayer, strict adherence to safety precaution and optimum use of pesticides.

Abstract
This study investigated the influence of low and sub-optimal nitrogen fertilizer rates on growth and yield of five maize (Zea mays L.) varieties on an ultisol in Omoku, Rivers State Nigeria. It was carried out at the Teaching and Research Farm of the Federal College of Education (Technical), Omoku; in the late cropping season of 2015 and early cropping season of 2016. Omoku lies on latitude 6° 40' E and longitude 5° 21' N in the tropical rainforest zone of South-South, Nigeria; its soil is classified as ultisols (regosols) of the typic kandiudult derived from the alluvial plain of the upper Sombreiro-Warri Delta. Varieties of maize planted were DMR-ESRY, Bende white, Mangu white, Oba super II and Oba super 4. Bende white and Mangu white are local varieties while DMR-ESRY, Oba super II and Oba super 4 are hybrids. The experiment was laid out in a Randomized Complete Block Design (RCBD) fitted into a split plot arrangement with three replications. The main plots were N- rates and the sub-plots were the five varieties of maize. Basal application of 30 kg P_2O_5 ha^{-1} as single super phosphate and and 15kg K_2O ha^{-1} as muriate of potash were done at at planting. N fertilizer was applied as urea in two equal split doses at 1WAP and 6WAP, respectively. Growth parameters collected were plant height and leaf area while, yield parameters were grain yield, cob length and 1000-seed weight. N-uptake of maize was determined by the formula: N content (%) x dry matter yield (kg ha^{-1}) / 100. Analysis of variance (ANOVA) was performed using PROC GLM on all the agronomic, yield and yield components identified above for each season using the Statistical Analysis Software (SAS) version 9.4. Treatment means were separated using the Fischer's protected Least Significant Difference (LSD) at $P < 0.05$. The least heights were obtained in the control plots while the highest heights were at 60 kg N ha^{-1}. Interaction between season and N-rates on plant height at 6WAP indicated that it was significant at $P < 0.05$. N uptake at the level of 60 kg N ha^{-1} was significantly higher than that obtained at 30 kg N ha^{-1} and control. There were significant differences among the five (5) varieties of maize at the different levels of N fertilizer application. Grain yield was similar to the level of N-uptake by each maize variety. Mangu white and Bende white performed better than the other varieties. It is recommended that urea fertilizer rate of 60 kg N ha^{-1} can be applied to maize cultivation on Omoku soil.
Key words: Growth, Maize, N-rates, N-uptake and Yield

Introduction
Maize (*Zea mays* L.) is a popular cereal crop grown in all agro-ecological zones of Nigeria. Its cultivation has increased in recent times and many scientific efforts have been put in place to increase its production. This increase in cultivation is occasioned by high demand in its usage for human consumption and industrial products. According to USAID (2010), maize is one of the three most important economically valued cereals grown in Nigeria along with sorghum and millet. It principally provides calories in human diet and animal feeds. In most Nigerian communities it is consumed as roasted or boiled cobs, breakfast cereal, pudding, soup or fermented paste, among others. Oladejo & Adetunji (2012) asserted that maize is a cereal plant that produces grains that can be cooked, roasted, fried, ground, pounded or crushed to prepare various food items like pap, "tuwo", "gwete", "dokunnu", and a host of others. These different

kinds of foods are available among the various ethnic groups in Nigeria such as the Yorubas, Hausas, Igbos, Ibiras, Ishan, Efiks, Binis, among others. The importance of this multipurpose cereal crop cannot be over emphasized as every part of its plant has economic value: the grain, leaves, stalk, tassel and cob can all be used to produce a large variety of food and non food products (IITA, 2009). Maize production requires high nutrients for its growth and yield. Among other soil nutrient required by the crop, nitrogen (N) plays a vital role in its metabolism and productivity. Although it is major nutrient required by plants, its level in the soil is often limited in supply because it is high volatile and readily leached (Anjorin, 2013). Several efforts have been put in place to checkmate this volatility and leaching potentials to enhance crop usage. One of such strategies is to select cultivars with high genotype for nitrogen use efficiency (NUE) under low soil nitrogen condition. This is achievable by the use of cultivars with superior N-use efficiency either by possessing a high N-uptake efficiency or enhanced N-utilization efficiency. Thus, under low soil N a maize variety with good performance should exhibit increase total biomass production, and plant height, leaf area and chlorophyll concentration, little affected by N deficiency, as well as, an efficient partitioning of biomass and n to the grain (Abe, *et al.,* 2013). It is against this backdrop that this study sought to evaluate the growth and yield performance of five maize varieties under low and sub-optimal N-rates on an ultisol in Omoku, Rivers State, Nigeria.

Materials and Methods

The experiment was conducted at the Teaching and Research Farm of Federal College of Education (Technical), Omoku Rivers State. Omoku is the headquarters of Ogba/Egbema/Ndoni Local Government Area (ONELGA) located on the North-Eastern fringe of Rivers State. Geographically, it lies on latitude 6°40´ East and longitude 5°21´ North in the tropical rainforest zone of South-South Nigeria. The soil of Omoku had been classified as Ultisol (regosols) of the upper Sombriero-Warri deltaic plain series (Ayolagha & Onuegbu, 2001). The dominant soil is typic kandiudult. The town which lies on an elevation of 17.69 m (58 feet) above sea level has two main seasons- rainy and dry seasons. The rainy season occurs between April – October with a bimodal pattern, ranging from 2040 to 3000 mm per annum. The break which occurs in August is commonly termed August break. The mean ambient temperature is 28.8°c with a maximum of 38.3°C with a relative humidity of 68 – 80% for large part of the year; the town has a monthly sunshine of 4.2 hours during the raining season. The experimental site was geo-referenced on these coordinates: Length 1 (L1): 05.37699^0 N, 006.67405^0 E; 05.37680^0 N, 006.67394^0 E and 05.37662^0 N, 006.67389^0 E. Width 1 (W1): 05.37662^0 N, 006.67389^0 E; 05.37658^0 N, 006.67398^0 E and 05.37657^0 N, 006.67406^0 E. Length 2 (L 2): 05.37657^0 N, 006.67406^0 E; 05.37673^0 N, 006.67418^0 E and 05.37695^0 N, 006.67424^0 E. Width 2 (W 2): 05.37695^0 N, 006.67424^0 E; 05.37696^0 N, 006.67413^0 E and 05.37699^0 N, 006.67405^0 E. The site located on a middle part toposequence (slope 0-2%), was well drained. The site had previously been under fallow for at least three years before the commencement of the experiment. The site was ploughed and harrowed two weeks after. The prepared site was marked out into plots and sub plots. The main plots measured 24 x 5m = 120m^2 while the sub plot measured 8 x 3m = 24m^2. Five cultivars of maize were obtained from the National Seed Service, Umudike near Umuahia, Abia State. The cultivars were DMR-ESRY, Bende white, Mangu white, Oba super II and Oba super 4. These cultivars have been marketed in Nigeria for sometimes, each having its own level of N requirement, either as N-sufficient or N-insufficient. The experiment was laid out in a randomized complete block design (RCBD) fitted into a split plot arrangement with three replications. The main plots were the rates of N-fertilizer (urea) while the sub-plots were the five maize cultivars. Each main plot had three levels of N-application labeled as no-N (control), low-N (30 kg N ha^{-1}) and sub-optimal - N (60 kg N ha^{-1}). Each level was separated from one another by 2.0 m to minimize possible movement of N from one treatment to another. There were fifteen sub-plots in each main plot. With three levels of N-application we had a total of 45 sub-plots in the entire experimental setup. At planting P in the form of single super phosphate and K as muriate of potash were based-applied at the rate of 30 kg P_2O_5 ha^{-1} and 15 kg K_2O ha^{-1} respectively. Three seeds of maize were planted per hole at a spacing of 0.75m x 0.50m and later thinned to two seedlings to maintained uniform number of plants in each sub-plot. Nitrogen fertilizer was applied in the form of urea in two split of equal doses, at one and six weeks after planting (WAP), respectively. The experiments were established on 29th August, 2015 and 16th April, 2016. Weeding was done manually twice with weeding hoe. Insect pests were controlled using the insecticide *lambdashi* applied through knapsack sprayer at 2l ha^{-1}. The field borders were kept clean to minimize encroachment by insects and rodents. The inner rows in each sub-plot were used for the destructive sampling. Prior to planting 20 top soil (0-15 cm) samples were randomly collected for routine analysis, using soil auger. The sampled soils were collected in a clean plastic bowl properly mixed to obtained composite sample. The composite sample was taken to the Agricultural Education laboratory of the Federal College of Education (Technical), Omoku where it was air dried, crushed and sieved through 2mm sieve to remove large particles, debris and stones. Routine soil analysis was carried out using the procedure described in the laboratory manual of the International Institute of Tropical Agriculture (IITA, 1989). Growth parameters , plant height and leaf area, were measured at 4 and 6 WAP, while N-uptake was measured at tasseling and harvest; and was determined by the formula: N content (%) x dry matter yield (kg ha^{-1}) / 100. Fresh biomass and dry matter (stover) weight on the other hand, were measured at tasseling while, cob weight, cob length, 1000-seed weight and total grain yield were measured at harvest. Analysis of variance (ANOVA) was performed using PROC GLM on all the agronomic, yield and yield components measured for each season using the Statistical Analysis Software (SAS) v 9.4 (SAS Institute, 2014). The treatment means were separated using the Fischer's protected Least Significant Difference (LSD) at $P<0.05$. The results obtained are presented in tables and bar charts.

Results and Discussion

Analysis of the pre-cropped soil indicates that it was slightly acidic (pH 6.10) with cation exchang capacity (CEC) of 7.90 Cmol kg^{-1} and effective cation exchange capacity of 8.01 Cmol kg^{-1}, medium total N (0.23%), organic carbon (2.13%) but high in available P (13.12 ppm) and very high percentage base saturation (98.63%). All of these indicate that the fertility of the soil was inherently moderate to high. The soil textural class was sandy soil (Table 1). Analysis of data generated from plant height at both 4WAP and 6WAP revealed that there were significant differences in the plant height in accordance with the N-rate of application. The least heights were obtained at the control while the highest heights were at 60 kg N ha^{-1}. At 6WAP the highest height was observed in Mangu white variety (Fig.2). This finding is in tandem with the report of Gul *et al.* (2015) who posited that nitrogen availability throughout the growing period of the crop is very important because, it is very essential for plant growth and make up 1 to 4 percent of dry matter of maize. Nitrogen being the major structural constitute of cells, as its level increases, the rate of vegetative and reproductive growth also increases in plants due to increase in assimilatory surface of plants as well as photosynthesis (Shrikanth *et al.,* 2015). From the foregoing it can be asserted that maize respond positively to N fertilizer application. So, at 60 kg N ha^{-1} the maize plants had more N to absorb hence their heights increased. The analysis of the leaf area was positively influenced by the N-rates of application. Leaf area was significantly influenced by the rate of N application. The finding that urea levels increases the leaf area of maize plants is in agreement with the study of Olowoboko *et al.* (2017) who asserted that leaf area of increased with N application rate of 120 kg ha^{-1} and a decrease was recorded for the control. Also, Anjorin (2013) reported that nitrogen fertilizer had significant effect on plant height, leaf area, number of kernels per cob, weight of 100 grains and grain yield. Nitrogen (N) uptake of the maize cultivars at tasseling stage and harvest is presented in Fig. 3. The result revealed that N uptake in the five maize cultivars increased with the level of application of N fertilizer from 0 to 60 kg N ha^{-1}. Uptake in plots applied with 30 and 60 kg N ha^{-1} were significantly higher than the control, while the uptake in 60 kg N ha^{-1} was significantly higher than 30 kg N ha^{-1}. It was also observed that N uptake levels differ significantly among the five varieties of maize at the different levels of urea application. Bende white was significantly higher in the N uptake at tasseling than the other varieties. That was followed by DMR-ESRY, Mangu White, Oba Super II and Oba Super 4 respectively. Similarly, grain yield of the maize varieties (Fig.4) was significantly different in accordance with N-rates. The least grain yields were obtained in the control while the highest grain yields were gotten in plots treated with 60 kg N ha^{-1}. The result of the interaction between the varieties and N rate revealed that it was significant at $P < 0.05$, indicating that at least the yield of one variety of maize was influenced by the rate of N application. The local varieties of Mangu white and Bende white performed better in terms of grain yield than the hybrids across the various seasons of the experiment. This may be caused by their less desire for more nitrogen than the hybrids. The observation that the hybrid varieties of DMR-ESRY, Oba super II and Oba super 4 could not yield as much as the local varieties of Mangu white and Bende white, could be attributed to their desire for more nitrogen application. It has been argued that maize hybrids need more nitrogen than the local varieties. This finding is in agreement with the report of Onasanya *et al.* (2009) that the results of various fertilizer experiments carried out in Nigeria showed that hybrid maize cultivars were found to require high fertilizer rate for optimum yield. Analysis of variance further indicated that there was significant different in the yield components of cob lengths and 1000-seed weight at the rates of N application (Figs.5-6). Maize grain yield depends on the yield contributing characters As it were, the weight of 1000-seed increased with the rates of urea application throughout the seasons of the experiment. This implies that the weight of 1000-seed of maize was significantly influenced by the N rates. This finding is in agreement with the observation of Ahmad *et al*. (2018) who posited that thousand grain weights of maize were significantly affected by cultivars and nitrogen levels. This finding is also consistent with the finding of Hokmalipour & Darbandi (2011) who reported that 1000-grain weight was affected by cultivars and nitrogen levels.

Conclusion

The results of this study show positive relationship between N-rates and growth and yield of maize varieties. Application of 60 kg N ha^{-1} significantly enhanced better plant growth and yield of all maize varieties planted. Among the varieties of maize used in the study, the local varieties of Mangu white and Bende white performed better than the hybrid varieties of DMR-ESRY, Oba super II and Oba super 4. It is therefore recommended that urea fertilizer rate of 60 kg N ha^{-1} can be applied to maize cultivation on Omoku soil.

Abstract

Late leaf spot (LLS) Phaeoisariopsis personata (Berk. and Curtis) Deighton is one of the most important foliar diseases of groundnut worldwide including Nigeria. Repeated application of fungicide could contribute to greater production cost and environmental pollution. The deployment of resistant cultivars offers a better option for the management of the disease in groundnut. Information on the genetic control of resistant to LLS will aid in the development of appropriate breeding methodology that will result in the development of resistant genotypes with high yielding potentials. The objective of this study was to determine the mode of gene action controlling LLS in some groundnut genotypes. Nine parental groundnut genotypes comprising of five LLS resistant (ICGV 12991, ICGV 7878, FDR-F7 82, FDR-F7 67 andß FDR-F7 61) and four LLS susceptible (SAMNUT 23, SAMNUT 24, SAMNUT 25 and SAMNUT 26) genotypes obtained from IAR were used to generate F_1 hybrids using 4 x 5 North Carolina design II mating design. The 20F_1s and the parental genotypes were evaluated for LLS in a randomized complete block design with three replications at the screen house of the Department of Plant Science under artificial inoculation. High relative humidity was maintained by covering the plants with polyethylene bags for 24 hours before and after inoculation. Data were collected on pod yield, disease severity, disease incidence and other agronomic traits. The results of the analysis of variance indicated highly significant ($P \leq 0.01$) differences for the traits of the genotypes evaluated. Negative GCA effects were recorded for disease incidence in SAMNUT 25 (-0.05), indicating the genotype is a good general combiner for LLS disease incidence. The ratio of the GCA and SCA variances indicated the preponderance of SCA variance over GCA variance for disease incidence and severity, indicating the role of non-additive gene effect and it may be due to difference in genotypes used as parents. Hence, selection has to be delayed to when the gene for LLS is fixed.

Keywords: Late leaf Spot, GCA and SCA

Introduction

The cultivated groundn0ut (*Arachis hypogaea* L.) is an important food legume highly adapted to tropical and subtropical climates of the world. It is grown primarily as an oil crop, and largely grown in over 100 countries, with a world total production of 43.98 million tons on 21.8 million hectares (FAO, 2016). In West Africa, Nigeria is the largest producer of groundnuts with production of 3.0 million tons on about 2.4 million hectares (FAO, 2016). Groundnut is valued as a rich source of energy whose oil content stood at 48–50% and protein 25–28% in the kernels (Janila *et al.*, 2013). The cake obtained after extraction of oil is used in animal feed industry, infant feed preparation and as soil amendment as it resist lead absorption (Liu and Nie, 2013). Despite the socio-economic and cultural importance of groundnut, its productivity in Nigeria is below 1 ton/ha because of number of abiotic (droughts) and biotic (especially due to pests and diseases) stresses (Reddy *et al.,* 2003). Late leaf spot is the most devastating fungal disease accounting for yield loss of over 60% (Okello *et al.*, 2010). The disease is caused by *Phaeoisariopsis personata* with symptoms that are seen as small necrotic flecks that enlarge and become light to dark brown. Previous studies have shown that efforts have been made to control late leaf spot disease using a combination of cultural and chemical measures with limited success (Page *et al.*, 2002). Use of fungicides to control leaf spots usually increases production costs by

10% (Coffelt and Porter, 1986). Effective chemical control is heavily reliant upon multiple fungicide applications (Jordan *et al*., 2012) that are costly for resource poor farmers in Nigeria, and as well raises environmental and health concerns with a significant decrease in crude protein and fiber contents with increasing disease severity (Coffelt and Porter, 1986). These factors coupled with health hazards associated with the use of insecticides suggested the use of host plant resistance as the most effective and environmentally friendly control measure for the management of LLS. Genetic information on inheritance of LLS will help in the development of LLS resistant cultivars that will reduce production costs and boost groundnut production in Nigeria. The objective of this study therefore was to determine the mode of gene action controlling late leaf spot resistance in groundnut genotypes.

Materials and Methods

The research was conducted at the Institute for Agricultural Research (IAR), Samaru, Ahmadu Bello University, Zaria ($11^0$11'N, $07^0$38'E), 600m above sea level in the Northern guinea Savannah. The research was carried out during the 2015/2016 raining season.

Experimental Materials: The experimental materials for this study comprised of nine early maturing groundnut genotypes representing a range of resistance levels to Late Leaf Spot (LLS) obtained from IAR Samaru. The resistant genotypes were validated in the 2013/2014 growing season IAR at the farm, Samaru. Five genotypes: ICGV 12991, ICGV 7878, FDR-F7 82, FDR-F7 67 and FDR-F7 61 were resistant to Late Leaf Spot (LLS and four others: SAMNUT 23, SAMNUT 24, SAMNUT 25 and SAMNUT 26 were commercially grown genotypes developed by IAR, which were susceptible to the Late Leaf Spot.

***Population Development*:** Two seeds from each of the groundnut genotypes were sown in plastic pots measuring 50.91m^3 in June 2015. The susceptible genotypes were used as female parents while the resistant genotypes as male parents. The parents were crossed in a 4 x 5 North Carolina mating design II as described by Comstock and Robinson (1948) to generate 20 F_1 progenies.

***Evaluation of F_1 for response to LLS*:** The 20 F_1 progenies and the 9 parents were evaluated for LLS in the screen house using randomized complete block design (RCBD) with three replications. Two pots were allocated for each genotype and two seed were sown per pot. Agronomic practices; weeding; was carried out three times, fumigating; was done once, watering; were carried out to ensure proper growth and development of the groundnut genotypes.

***Inoculation*:** Inoculum was obtained from groundnut leaves infected with LLS collected from IAR field. Fungal isolation was done using scheduled isolation trials at the IAR groundnut farm as described by (Riker and Riker, 1936; Khan *et al.,* 2013). The diseased portion of leaves was cut into small pieces of 1-2 mm and surface sterilized with 0.1% mercuric chloride solution for 1-2 minutes. The small pieces were rinsed twice in sterilized water and transferred to sterilized paper in petri dishes for drying. Plating of these dried pieces was done on Petri plates containing potato dextrose agar (PDA) medium in a laminar hood. The petri plates were then incubated at $27^oC\pm2^oC$ for 57 days to allow the fungi to grow. After five days the margins of the developed mycelium were sub-cultured on PDA at 25^oC for seven days to get the pure culture of LLS. Single spore method was used for the identification of the LLS on the basis of morphological characters. Mycelial growth of the LLS in petri plates was blended with sterilized distilled water in a blender. Numbers of spores were diluted with sterile distilled water to reach 3.3×105 CFU ml^{-1}. The spores were used as inoculum, which was sprayed on all the treatments except control. To provide favorable environment for disease development, watering was carried out regularly (Ijaz, 2011). Thirty-five days old plants were inoculated with LLS at 106 conidia/ml inoculum concentrations. Hand held sprayer was used for the inoculation; 0.1 ml spore suspension was dropped on the leaves. High relative humidity around the plants was maintained by covering the plants with wet polythene bags 24 hours before inoculation. Inoculated plants were covered for another 24 hours to maintain high humidity. Plants were observed weekly for development of disease after inoculation and disease score was recorded using 1-9 scale describes by Subrahmanyam *et al*. (1995).

***Percent disease incidence* (PDI):** PDI scale for groundnut LLS of less than 10% are highly resistant), 11-30% (Resistant), 31-50% (Moderately resistant) and More than 50% (Susceptible)

Data collection: Data were collected on number of mature pods per plant, number of seeds per pod, LLS disease severity at 65 and 90 days after sowing (DAS) as described by Wambi (2014) using a modified nine-point scale as described by Subrahmanyam *et al*. (1995) as showed in

Table 1 and **LLS** disease incidence; The per-cent disease incidence was scored using the scale recommended by ICRISAT (Waliyar *et al*., 2007)

Data Analysis: Data collected on disease severity and incidences were transformed using log10 and were all subjected to analysis of variance and estimates of genetic effects were obtained using General Linear Model procedure of Statistical Analysis System (SAS) package (SAS, 2002). Broad sense (H^2) and narrow sense (h^2) heritability were estimated from broad sense (H^2) and narrow sense (h^2) heritability (Kearsey and Pooni, 1996). (Kearsey and Pooni, 1996). The heritability values were categorised as low, moderate and high as suggested by Robinson *et al.* (1949), where 0 - 30% (Low), 30-60% (Moderate) and >60% (High).

Results and Discussion

Analysis of Variance for Late Leaf Spot

The mean squares from analysis of variance showed highly significant ($P \leq 0.01$) differences among the genotypes for all traits evaluated in this study (Table 1). The presence of highly significant difference suggests the existence of sufficient variability in the material used and provide opportunity for improving groundnut for LLS resistance. The amount of improvement that can be achieved by selection among a number of crosses is dependent on the amount of variation between the crosses. The crosses between SAMNUT 23 x ICGV 7878, SAMNUT x FDR-F7 67 and SAMNUT 24 x FDR-F7 82 showed tolerance to LLS disease incidence ( ) with low severity ( ). This result corroborated with the findings of John *et al*. (2008) who reported moderate incidence of LLS in F_2 population of the Kadiri-3 × ICGV-88083, confirming the possibility of transferring the LLS traits in groundnut.

Mean performance of the genotypes

The mean performance of groundnut genotypes studied for late leaf spot and other agronomic traits are presented in Table 2. Disease severity among the parents; FDR-F7 61 with 19% on a score of 4 (lesion on the lower middle leaves, but severe on lower leaves, defoliation of some leaflets evident on lower leaves), SAMNUT 26, ICGV 12991, ICGV 7878, FDR-F7 82, FDR-F7 67 with 21- 30% on a score of 5 (lesion on lower and middle leaves, over 50% defoliation of lower leaves), SAMNUT 25 with 40% on a score of 6 (lesion severe on lower and middle leaves, defoliation of some leaflet evident on middle leaves), SAMNUT 23 with 42.7% on a score of 7 (lesion on all leaves but less severe on top leaves, defoliation of all lower and some middle leaves). Among the crosses, SAMNUT 24 x FDRF7 82, SAMNUT 24 x FDRF7 61,SAMNUT 25 x FDR-F7 82, SAMNUT 26 x ICGV 12991, SAMNUT 26 x FDR-F7 82 and SAMNUT 26 X FDR-F7 61 with 21-30% on a score of 5 (lesion on lower and middle leaves, over 50% defoliation of lower leaves), and SAMNUT 24 x ICGV12991 and SAMNUT 25 x FDR-F7 61 with 41- 60% on a score of 7 (lesion on all leaves but less severe on top leaves, defoliation of all lower and some middle leaves). Generally, there were wide variations were observed for disease severity.

General combining ability (GCA) effects

The estimates of GCA effects of male and female parents for some agronomic traits and groundnut genotypes are presented in Table 3. Results indicates that ICGV12991, FDR-F7 82 and FDR-F7 61 have significant GCA variance for number of matured pods, and seeds, in addition the exhibited negative GCA variances for disease incidence and percent disease severity. This is confirming that these male parents are truly resistant to LLS and therefore justified their use as a source of pollen for development of LLS resistant groundnut varieties. Among the female parents, only SAMNUT 23 and SAMNUT 24 showed variation in susceptibility to LLS with significantly positive GCA variance for percent DI and DS (11.93 and 6.00, respectively). The other two parents; SAMNUT 25 and SAMNUT 26 however, depicted significantly negative GCA variance for LLS.

Specific combining ability (SCA) effects

The specific combining ability (SCA) effects for some agronomic traits and Late Leaf Spot of groundnut genotypes are presented in Table 4. Negative and significant SCA effects for disease incidence were exhibited by SAMNUT 25 x FDR-F7 67 (-0.08) and SAMNUT 24 x FDR-F7 61 (-0.10). SAMNUT 23 x ICGV 12991 (-0.74), SAMNUT 24 x FDR-F7 82 (-0.12), SAMNUT 24 x FDR-F7 67 (-0.09), SAMNUT 24 x FDR-F7 61 (0.11), SAMNUT 25 x ICGV 7878, SAMNUT 25 x FDR-F7 67, SAMNUT 26 x FDR-F7 67 (-0.08) while SAMNUT 26 x ICGV 7878 (-0.13) showed a negative significant SCA effects for disease severity. The progenies with negative SCA effects for disease incidence and disease severity SAMNUT 24 x FDR-F7 61 and SAMNUT 25 x FDR-F7 67 were identified as the most promising genotypes in breeding programme for LLS tolerance traits. These progenies originated from parents with negative and positive GCA values. This suggest the difficulty in predicting the *P. personata* tolerance level of the progenies based on GCA alone and should necessitate testing of specific male x female combinations. Arunga *et al.* (2010) reported that the SCA effect alone has limited value for parental choice in breeding programmes. They, therefore suggested that SCA effects should be used in combination with other parameters, such as hybrid means and the GCA of the respective parents such that hybrid combination with both high mean and favourable SCA estimates and involving at least one of the parents with high GCA, would tend to increase the concentration of favourable alleles; which is desired by any breeder.

Conclusion

The study revealed ample genetic variability for the agronomic traits in the parents used for the study. Both additive and non-additive gene actions were important in controlling the inheritance of LLS. There was however, the preponderance of non-additive gene action to the inheritance of LLS, therefore selection for LLS resistant has to be delay to further generation whenvthe genes are fixed.

Abstract
In this field study conducted at the Teaching and Research Farm of Department of Agricultural Education, Federal College of Education(Technical) Omoku, Rivers State Nigeria to determine the bioremediation potentials of rumen- based wastes (RBW) on crude oil polluted soils, Cassava (Manihot esculenta Crantz.) was used as test crop. The soil was contaminated with Bonny Light crude oil obtained from OB/OB Nigeria Agip Oil Plc. Fresh RBW was obtained from an abattoir in Omoku, Rivers State. Cassava stems were obtained from the NAOC Green River Project, Obrikom. The soil was pulverized, made into raised seed beds, then contaminated with crude oil at the rates of 0litre m^{-2}(Control), 1.5litre m^{-2} (Mild), 3litre m^{-2} (Moderate) and 4.5litre m^{-2} (Severe). Two weeks after contamination RBW were applied as mulches at the rates of 0, 2, 4 and 6kg/m^{-2}. Results show that RBW increased nickel, lead and copper accumulations in cassava leaf and tuber. It is recommended that RBW should not be used in augmenting crude oil polluted soils as it enhanced accumulation of heavy metals in cassava leaf and tuber.
Keywords: Augmentation, Crude oil, Heavy metal, Remediation and Rumen-based waste

Introduction
The environment which can be described as the world around us is constantly under threat due to various human activities. Natural processes such as earthquakes, floods, tsunamis, drought, and volcanic eruptions pollute and degrade the environment, but human activities are the greatest culprits and drivers of environmental degradation. A typical substance arising from human activities and released into the environment is petroleum hydrocarbons (crude oil). Crude oil is a vital non-renewable natural resource that has emerged as a prominent commodity in the local and international market with numerous benefits for producing nations like Nigeria where it is an important part of the Nigerian economy since 1958 (Oyedeji et al., 2015). Demand and utilization of petroleum products have increased its exploration in Nigeria and globally. Oil spills is one serious environmental problem associated with petroleum exploration with consequent environmental contamination, degradation and negative impacts on ecosystems. Typical constituents of petroleum hydrocarbons are heavy metals that are poisonous even at low concentrations. Heavy metal contamination is one major issue faced throughout the world, requiring attention because heavy metals above their normal ranges are extremely threatened to both plant and animal life (Nazir et al., 2015). Over the years, chemical dispersants and physical or manual scooping are methods adopted to decontaminate the environment after oil pollution. According to Frick et al., (1999), these processes are expensive and still have some adverse effects on the environment. However, in recent times, efforts have focused on biological techniques such as bioremediation and phyto-remediation in ameliorating conditions created by crude oil spills (Gupta and Sinha, 2007; Njoku et al., 2009). These techniques are environmentally-friendly and is already being practiced in many countries like United States of America, Britain and Brazil with significant positive results (Oyedeji et al., 2015). These techniques are non-destructive and cost effective in-situ technology that uses plants and associated microbes to clean up contaminated soils.(Nie et al., 2011). Plant based bioremediation

technology have received increased attention in the recovery of polluted environment but studies on the use of animal based organic substance such as RBW in bioremediation is scanty. RBW has high pH and is a large store house of microbial organism, enzymes and elements some of which may be necessary for plant growth and development (Isirima, Akonye & Iyagba 2017). Each time ruminant animals are slaughtered in the abattoir the product of the rumen are heaped and carelessly abandoned with little or no regard for its possible used in augmentation and remediation of crude oil polluted crop lands. It is on this premise that this study aims at determining the effectiveness of rumen-based waste in reducing heavy metal accumulation in leaf and tuber of the test crop (cassava).

Materials and Methods

The experiment was conducted at the Teaching and Research Farm of the Federal College of Education (Technical) Omoku. The land for the experiment was fallowed for four years after cassava grown on it was harvested. The loamy soil was ploughed and plant thrash removed. The experiment was laid in a split plot fitted into completely randomized design with 3 replications. Crude oil pollution levels (0litre m^{-2} , 1.5litre m^{-2}, 3litre m^{-2} and 4.5litre m^{-2} constituted the main plot while, rumen-based waste(0, 2, 4 and 6kg/m^{-2}) formed the subplot. Each sub-plot measuring 2m x 2m was made into raised bed of 30cm high. Bonny light crude oil was obtained from OB/OB plant of Nigeria Agip Oil Company (NAOC), measured and applied at the rates of 0ml, 1500ml 3000ml and 4500ml with the aid of a watering can. Watering can was preferred to ensure uniform distribution of the crude oil. Care was taken to avoid splash effect. Rumen-based waste freshly obtained from an abattoir in Omoku was applied at the rates of 0, 2, 4 and 6kg/m^2 two weeks after crude oil treatment. Cassava stems (TMS/80/001935) were then planted on the soil earlier polluted with the crude oil and augmented with rumen-based waste. Stems were planted at 1m x 1m spacing two weeks after crude oil and rumen-based waste treatment. Atomic Absorption Spectrometer (AAS) was used to analyze cassava leaf and tuber samples for heavy metals (nickel, lead and copper). The instrument setting and operational conditions were set according to manufacturer's specifications.

Results and Discussion

Table 1 shows that nickel accumulation increased with increasing rumen based waste augmentation at all crude oil levels except at the severe level where it decreased with increasing rumen based waste augmentation. Lead accumulation also decreased with increasing rumen-based waste augmentation at 3MAP and 6MAP at all spill simulation levels. Mean copper concentration at the double control treatment (0ml crude oil and 0kg rumen based waste) was 5.75mg/kg. This value is lower than mean copper levels obtained at various crude oil simulation levels with 0kg rumen based waste. Mean values decreased at 6MAP as quantity of rumen-based waste increased from 2kg, 4kg to 6kg, at various simulation levels showing the potency of rumen-based waste in reducing copper accumulation in cassava leaf.

Table 1: Heavy Metals (Nickel, Lead and Copper) concentrations in cassava leaf

Treatments		Metal concentration in cassava leaf(mg/kg)					
Crude oil levels	Rumen Based Waste	Nickel (Ni) 3MAP	Nickel (Ni) 6MAP	Lead (Pb) 3MAP	Lead (Pb) 6MAP	Copper (Cu) 3MAP	Copper (Cu) 6MAP
	0 kg/m^2	8.95	8.49	6.40	9.76	4.63	6.86
Control	2 kg/m^2	11.28	8.50	7.20	9.50	5.23	5.20

	6 kg/m^2	6.30	2.50	5.00	4.00	9.15	4.22

Heavy metals adversely affect soil ecology, quality of agricultural produce and human health (Nazir et al., 2015). In the current study, nickel, lead and copper accumulation levels in cassava leaf and tuber were ascertained. The observed high nickel concentration in cassava leaf with application of highest (6kg/m^2) rumen-based waste treatment level suggest that degradation of rumen-based waste promoted availability and uptake of nickel in the cassava tissue under control experiment. Decrease in lead and copper concentration in the leaf with increasing levels of rumen-based waste augmentation shows the potency of the organic manure to reduce accumulation of the lead and copper in cassava leaf.

Table 2 shows that nickel was not detected in cassava tuber at the double control and across various levels of RBW treatment of the control experiment, but crude oil + RBW augmentation enhanced accumulation of nickel in the cassava tuber. Greater Nickel accumulation was recorded at higher rumen-based waste augmentation. Lead value of the cassava tuber under double control (No crude oil + No rumen-based waste) was 1.00mg/kg, whereas highest rumen-based waste (6kg) augmentation recorded a lead value range of between 1.40 and 1.80 across mild, moderate and severe crude oil treatment. Copper status of the cassava tuber was 1.02mg/kg at the double control experiment but increased with increasing augmentation to 2.81mg/kg at severe crude oil level. Again copper value obtained across mild, moderate and severe crude oil treatment was higher than mean copper value of 1.02mg/kg obtained at the double control treatment. In this case, rumen-based waste enhanced copper accumulation in cassava tuber.

Table 2: Heavy Metals (Nickel, Lead and Copper) concentrations in cassava tuber

Treatments		**Concentrations in cassava tuber at 6MAP (mg/kg)**		
Crude oil levels	**Rumen Based Waste**	**Nickel (Ni)**	**Lead (Pb)**	**Copper (Cu)**
Control (0ml/m^2)	0 kg/m^2	Not Detected	Not Detected	1.02
	2 kg/m^2	Not Detected	1.00	1.62
	4 kg/m^2	Not Detected	1.40	2.70
	6 kg/m^2	Not Detected	1.40	2.73
Mild (1500ml/m^2)	0 kg/m^2	2.50	1.00	2.50
	2 kg/m^2	2.58	1.00	2.53
	4 kg/m^2	2.70	1.00	2.54
	6 kg/m^2	2.75	1.40	2.55
Moderate (3000ml/m^2)	0 kg/m^2	2.78	1.10	2.40
	2 kg/m^2	2.80	1.40	2.50
	4 kg/m^2	3.00	1.40	2.65
	6 kg/m^2	3.17	1.41	2.67
Severe (4500ml/m^2)	0 kg/m^2	3.02	1.20	2.60
	2 kg/m^2	3.00	1.50	2.60
	4 kg/m^2	3.14	1.80	2.71
	6 kg/m^2	3.17	1.80	2.81

Nickel has been considered to be an essential trace element for human and animal health (Zigham *et al.,* 2012). Absence of nickel in cassava tuber across levels of rumen-based waste in the control experiment and the observed increase in the level of nickel in the crude oil + rumen-based waste augmentation implies that activities of hydrocarbon and degradation process of RBW enhanced deposition of the heavy metal in cassava tubers. Nickel level was within WHO permissible limits of 10mg/kg (Zigham *et al.,* 2012; Nazir *et al.,* 2015). Lead as a soil contaminant is a widespread issue; It accumulates with age in bones aorta, and kidney, liver and spleen. Lead levels increased from not detected (ND) to 1.80mg/kg at the highest levels of severity and rumen-based augmentation. However, lead levels were within WHO permissible limit of 2mg/kg (Zigham *et al.,* 2012; Nazir *et al.,* 2015). Lead is especially accumulated in surface soil horizon because of its low water solubility and mobility especially within an environmentally relevant pH range. Lead is a non essential element and its presence in very toxic levels could lead to neurological problems, it could endanger health and cause enzymatic changes, anaemia and hyperactivity (Barkirdere and Yaman, 2008). Copper, though an essential trace element, may be toxic to both humans and animals when concentration exceeds safe limits. Copper levels increased from 1.02mg/kg at double control to 2.81mg/kg at highest levels of severity and rumen-based augmentation. Copper levels above permissible limits could lead to blood shortage, abdominal pains, nausea, diarrhoea, headache, dizziness and liver cirrhosis (Iqbal *et al.,* 2011;

Chinedu *et al.,* 2011). Copper levels were within WHO permissible limits of 10mg/kg (Zigham *et al.,* 2012; Nazir *et al.,* 2015). Findings of this study agrees with Akonye and Onwudiwe (2007) who observed high accumulation of heavy metal (lead) lead at 2% pollution with saw dust augmentation

Conclusion

Cassava tubers showed increased heavy metals (Nickel, Lead and Copper) content as rumen based waste augmentation increased. While rumen based waste reduced accumulation of heavy metals in leaf of cassava at specific crude oil levels, it enhanced the accumulation of these metals in cassava tuber that is mainly utilized in cassava crop production. Rumen-Based Waste is therefore not a very good material for remediation of crude oil polluted soils as it enhances the accumulation of heavy metals that are dangerous to human health.

Effect of Seed Size on Growth and Yield Development of Fluted Pumpkin (*Telfairia occidentalis* Hook f)

A. Musa Ahmad
Department of Biological Sciences, Federal College of Education, Kano – Nigeria PMB 3045
Email- aminamusabio@gmail.com Phone: 08039257176

Abstract
Fluted pumpkin popularly known as Ugwu is a tropical rain forest crop. Production in the drier zone of the Nigeria has been faced with constraint such seed size, seed placement, fertilizer application among others as such making it costly. Field and pot experiment were therefore conducted at the teaching and research farm of Faculty of Agriculture, Bayero University Kano. The aim of the experiments is to determine the effect of seed size on the vegetative growth and yield of fluted pumpkin (Telfairia occidentalis Hook F). The treatments were seed size, Large, Medium and Small which were laid out in a randomized complete block design (RCBD) for the field experiment and completely randomized design (CRD) for the pot experiment. These were replicated four (4) times. The results obtained shows that seed size had a significant effect on days to emergence, vine length, number of leaves, number of branches, number of male and female flowers and total fresh shoot yield. Large and medium size fluted pumpkin seed produced longer length of vine, higher number of leaves, more branches, flowered earlier and produce higher marketable fresh shoot yield than small seed. It is therefore recommended that large and medium size Telfairia occidentalis seed should be used for the production of fluted pumpkin in the Savanna region of Nigeria.

Introduction
Vegetables constitute essential components of human nutrition because they are very rich in vitamins, protein, minerals, oil among others (Akoroda, 1990). *Telfairia occidentalis* (Fluted pumpkin) is a perennial, dioecious herb. The crop is one of the most important vegetables grown in southern Nigeria. It is generally regarded as a leaf and seed vegetable. Common names of the crop include fluted guard, fluted pumpkin, iroko and Ugwu, mainly cultivated by Igbo people (Akanbi *et al.,* 2007). The leaf of *Telfairia occidentalis* has a high nutritional, medicinal and industrial uses being rich in protein (29%), fat (18%) and minerals and vitamins (20%). In the recent time, *Telfairia occidentalis* has gained medicinal recognition. It has been discovered to be blood purifier (Aletor *et al*., 2002) and could therefore be useful in maintenance of good health more especially among poor resource people in developing countries. The rind and pulp of *Telfairia occidentalis* as reported by (Akanbi *et al.*, 2007), can be used as fodder for livestock. Pregnant women and patients suffering from anaemia use the leaf juice to strengthen their blood.Despite the importance of *Telfairia* in Nigerian diet, farmers are facing a lot of problems concerning its production in the field, more especially here in the Northern regions. These problems include inadequate researches which will recommend appropriate size of seed to be used during planting. Research efforts are therefore, required to formulate the recommended seed size on the growth yield and development fluted pumpkin. There is therefore, need to look into the agronomic practices, since there is no much work done on the crop in this region and thus, the objective of this paper is to determine the effect of seed size on the vegetative growth of *Telfairia occidentalis*.

Materials and Methods
Matured pods of *Telfairia occidentalis* obtained from the National Horticultural Research Institute, Bagauda were split to obtain the seed. A total of 360 seeds were used for both field and pot experiment. For the pot experiment, one seed per pot was directly planted at the depth of 0.5 cm on 36 prepared pots of soil mixture consisting of river sand, top soil and organic manure at

the ratio of 2:1:1 while for field experiment nine (9) seeds were planted per plot at a spacing of 1m between plants, giving a total of 324 seeds. The experimental treatments applied during the planting were placing Large, Medium and Small seeds. The seed size was obtained by weighing the seeds and categorized into small, medium and large 9.19, 14.51 and 18.95g respectively. NPK (15:15:15) fertilizer at the rate of 200kg/ha i.e. 80g per plot was applied at three weeks after planting (WAP) for the field experiment while 0.2g/ha was applied per pot for the potted experiment. Field management was done by hoe weeding at 2, 4 and 6 WAP and pots management was done by picking at subsequent time. Watering at 2-3 times per week and spraying of Superplus® 280EC (a combination of cypermethrin and Dimethoate) to control pest at the rate of 1.5L/ha at 7 WAP. Long Bamboo stakes of 2m were used to make trellis for the plants to climb at 4 WAP. At 5 WAP tips of the plants were decapitated to avoid apical dominance that may allow the plants to spread on the trellis.Three plants were randomly sampled from each plot in the case of field experiments for better precision and the mean was calculated for each parameter under investigation. While in the case of pot experiment observation was carried out on every pot. Data were collected on Number of Days to Emergence (DTE), Vine length, Number of Leaves and Number of Branches (NOB) per plant at 6, 9 and 12 WAP. Number of flowers (Male and Female) was recorded at 9 and 12 WAP on field plant (Table 6) and Fresh Shoot Weight (FSW) was collected at 12, 14 and 16 WAP (Table7). The data collected were analysed using the procedure described by Cochran and Cox (1967), general linear model of SAS (SAS, 1989) and significant differences among the treatment means were evaluated using Duncan's multiple Range test (DMRT) as described by (Duncan, 1955).

Results and Discussion

Seed size was observed to affect plant germination in both field and pot experiments. The results showed that large and medium seeds germinated earlier than smaller seeds. This could probably be due to the fact that large seeds had enough food reserve which always allow the seed plumule to penetrate through deep layer of the soil.Similar observation was reported by Brady,(1990) that small seed do not germinate earlier because of the little reserved nutrients, as such they do not have the ability to penetrate through a deep layer of soil because of the insufficient stored materials to generate the osmotic gradient necessary to overcome the pressure exerted by the soil. Lang and Holmes, (1964) also found germination and early growth to be enhanced by size of the seeds.The length of vine, number of leaves and number of branches was significantly affected by seed size in both experiments.Large seeds produced significantly longer vine, more number of leaves and branches than medium sized seed (Table 2,3 and 4) respectively. This is in line with the work of Akoroda, (1990) on Telfairia that large seed gave higher number of leaves, branches and vine length which may be due to seed vigour or the size of the seed. Similar observation was reported by Barry *et al.*, (2001) on potatoes crop that seed size has significant effect on growth and yield of the plant. Number of Male and Female flowers was found to be significantly affected by seed size. Large and medium seed flower earlier and the ratio of male to female flower is higher. This could be due to the fact that large and medium seeds germinated earlier and attained higher number of leaves, branches and longer vine length as such flower earlier when compared with small seed. Similar results were reported by Brown, (1994) that large or heavier seed of tomatoes produced plants that flowered earlier and gave better yield than small or lighter seed. Fresh shoot weight was significantly affected by size of the seed (Table 7). It was observed that large and medium seed gave better yield than small seed. This could be due to the fact that large and medium seed had earlier germination as such gave higher yield. This is in line with the work of Alam and Locascio,(1965), Akoroda,(1990), Tafi *et al.,* (2003) and Ojeifo and Ajekenrenbeaghan, (2006) that plant height, fresh shoot weight and yield increased with the seed size of vegetable crops.Flowering as one of the reproductive characters of development is not set in the pot experiment. This is due to the fact that the root of potted plants are restricted from the soil nutrient (Table 6).

Conclusion

Result of this study revealed that the seed size of Telfairia seeds had a significant effect on days to emergence, length of vine, number of leaves, number of branches, number of Male and Female flowers and Total fresh shoot yield. Based on the finding of this study, peasant farmers are therefore advice to use large and medium size fluted pumpkin seed (*Telfairia occidentalis)* for better marketable fresh shoot yield.

Effect of Municipal Solid Waste and NPK Fertilizer on Yield of Maize and Groundnut Intercrop in Asaba, Delta State, Nigeria

I.S. Chukwukelu
Department of Agricultural Education, Federal College of Education (Technical) Asaba.
Ifychuks77ng2003@gmail.com

Abstract
Field experiment on effect of municipal solid waste and NPK fertilizer on yield and yield parameters of maize and groundnut intercrop in Asaba was carried out in the Demonstration farm of Federal College of Education (Technical), Asaba during. The objective was to compare the effect of combine and sole application of Municipal Solid Waste (MSW) and NPK fertilizer rate on yield and harvest index of Maize and groundnut intercrop A 6 X 3 factorial experiment in randomized complete block design (RCBD) was used. The two factors studied were nutrients and cropping system. The six nutrients applied were 0 control 100%MSW, 100%NPK, 50%MSW +50%NPK, 75%MSW+ 25%NPK, 25%MSW+ 75%NPK,while cropping systems used were sole maize, sole groundnut and maize/groundnut intercrop. MSWC at 100% and combination of 75% MSW+ 25% NPK recorded the highest yield of 1967kg and 1833kg for maize and 4900kg and 4700kg for groundnut respectively. The use of sole cropping system gave greater yield than intercropping system.

Key words: Municipal Solid Waste, NPK, Maize Yield, Groundnut Yield and Harvest Index

Introduction
Soil is a natural body upon the earth on which crops grow, and its quality varies widely, ranging from very old, weathered and leached rocks to soils inherently law in nutrient because of their clay and organic matter content (DFID 2002) According to UNU-INRAL World Bank report, (1999), nutrient level have declined over the past 30years, resulting to low levels of minerals like nitrogen (N), phosphorus(P) and potassium (K). It is patent to note that bulk of our crop productivity can be traced to a large extent to soil infertility. However many research have identified the usefulness of compost and farmyard manure in the maintenance of organic matter status, amelioration of physical chemical and biological properties of the soil (Stevenson, 1992, swift and Sanchez, 1994). Municipalities are facing a growing problem of how to dispose their solid waste. Municipal solid waste is primarily organic waste, such as leaves, skins and unsold food, discarded at or near food markets (United Nations Environmental Programme (UNEP 2009). Bryan and Morton (2007), sees municipal solid waste (MSW) as waste from multifamily, commercial and industrial e.g. Schools. In most developing countries like Nigeria waste from markets and other public places are used as landfills or dumped where people no longer use. Organic compost account for about 75% of total MSW in Nigeria (Oyinlola, 2001). In order to minimize environmental impacts and loss of organic resources composting is a measure that must be employed to convert MSW into organic manure for plant growth. Composting is one of the major recycling processes by which nutrients present in organic materials are returned by to the soil in plant available from (Incket *et al* ; 1996). The low fertility status of most tropical soils hinders crop production as most crops have exhausting effect on the soil.(Onwudiwe 2014).Inorganic fertilizers such as NPK , exerts strong influence on plant growth, development and yield (Stafano,Dris and Rapparini 2004). However excessive or continual application of NPK fertilizer will lead to loss of soil fertility due to improper use and this has adverse effect on crop productivity. Groundnut can be planted sole or intercropped. However, it performs better as sole crop (Dania, Fagbola and Alabi, 2014). Limitation in groundnut production ranges from land availability, labour, fund, availability of appropriate fertilizers dosage, disease control, post harvest challenges, proper storage to marketing. Groundnut is an excellent source of organic nitrogen and nutrient recycling. It increases organic nitrogen and nutrient recycling. It increases

organic matter and improves soil structure and quality and can be intercropped with maize, sorghum, cassava, and melons (Tabo, Ezuch, Ajayi, Asiegbu, Singh, 1995). Therefore maize (Zea mays .L) is an important cereal crop grown in most tropical African countries for human consumption, livestock and for industrial purposes. Alabi and Esobhawan (2006) states that maize is often planted in intercropping system in many tropical countries like Nigeria. Dania, Fagbola and Alabi, (2014) proved that intercropping maize with groundnut is an insurance against crop failure, erosion control, and efficient use of land, stability of yield, risk minimization, continuous and diversified food supply and higher yield.

Materials and Methods

Field experiment was carried out in the Demonstration farm of Federal College of Education (Technical) Asaba . Asaba is located at latitude 06^2 25^1 N and longitude 06^0 49^1 E of the equator. This location lies in the tropical rainforest zone and it is characterized by rainfall periods of between April and October with bimodal rainfall distribution (NIMET, 2016). Municipal solid wastes used for the study were collected from waste bins in markets and within the college hostels. Biodegradable materials were sorted out and decomposed aerobically. The compost materials used for the study were free from dour and dark in colour. The chemical fertilizer used for the study was NPK (15:15:15). The experimental design used was 6 X 3 factorial in randomized complete block design (RCBD). The two factors studied were nutrients and cropping system the six nutrients applied were 0 control, 100% MSW, 100% NPK, 75% MSW+ 25% NPK, 25% MSW+ 75% NPK, 50% MSW+ 50% NPK. MSWC and NPK were combined to produce 18 treated combinations which were replicated three times. The treatments were applied two weeks after planting (WAP) in ring from (10 to 15cm from the plant) and mixed properly with the soil at the plants base. Harvest index was obtained by calculating from the formula:

$$\frac{\text{Seed weight (g/plant)}}{\text{Total dry matter of plant material (g/plant)}}$$

Data was subjected to analysis of variance (ANOVA); means were separated using fishers least significance (F-LSD) Procedure as described by Obi (2002). Test of significance was at 5% probability level.

Results and Discussion

The result presented in Table 1 showed that treatment of MSW and NPK fertilizer and cropping system had significant ($p<0.05$) effects on the yield of maize. Sole cropping system significantly (p<0.050 effect on maize yield when compared to intercrop while 100% MSWC had the highest yield 1967kg/ha, 17.77g and 1867kg/ha, 17.7kg. Nutrient x cropping system had significant effect on yield at all levels of interaction. Groundnut yield was significantly ($p<0.05$) influenced by MSW, NPK and cropping system, while 100% MSW gave significantly ($p<0.05$) highest plant yield (4900kg/ha) when compared with other treatment combination sole cropping system gave highest yield (3233kg/ha) than intercropping system (3189kg/ha), while nutrient x cropping system had no significant effect on grain yield of intercrops.

Conclusion

The use of sole cropping system had greater yield. However, intercropping of maize and groundnut increased the productivity per unit of land of the experimental sight. Intercropping of maize and groundnut helped in effective utilization of nutrients, weed control and erosion control. This is in line with the findings of Thayamini *Saran and Brinth* (2010) and Shrikishnah,Umaraijini and Seran (2008). It is recommended that farmers should combine 75%MSW and 25%NPK rather than sole application of NPK fertilizer for better yield; also, intercropping maize and groundnut should be encouraged for effective utilization of available land resources.

Abstract
A pot experiment was carried out in 2016 at the screen house of the University of Calabar Teaching and Research Farm, Calabar, Cross River State, Nigeria to evaluate the effects of rates of NPK and neem based organic fertilizer on soil properties and the performance of okra. Seven (7) treatments including the control (no amendment) and two nutrient sources (neem based organic fertilizer and NPK 20:10:10) each applied at 3 levels of nitrogen (80,100,120 kg N/ha) were fitted into a completely randomized design (CRD) and replicated three times. Data were subjected to analysis of variance and means compared with Duncan New Multiple Range Test at 5 % level of probability. The soil used for the study was extremely acid (4.38), loamy sand in texture and low in fertility. The results of the trial revealed that application of NPK and Neem based organic fertilizer significantly (P<0.05) improved the soil properties with the organic sources recording higher values. The use of fertilizer either organic or inorganic source improved the number of leaves, leaf area, stem girth, plant height and number of fruits of okra. The improvement increased as the rate of application increased but neem-based organic fertilizer treated soils produced higher fruit weight of okra than the NPK treated soils. The highest okra fruit weight of 6400 kg/ha was obtained in pots treated with 120 kg N/ha Neem and is therefore recommended for sustainable production of okra in Calabar and other regions with similar climatic conditions.
Keywords: Neem based organic fertilizer, NPK 20:10:10, soil properties, okra performance and Ultisol

Introduction
Okra (*Abelmoschusesculentus (L) Moench*), is an important vegetable crop that is widely cultivated and consumed in Nigeria and other tropical countries of the world. It is the only vegetable crop of significance in the malvaceae family and is grown both in tropical and sub-tropical regions of the world (Ahmed *et al.*, 2006).It has been observed that farmers are facing a lot of problems on its sustained productivity as soil tends to be highly weathered and have low inherent fertility. The applications of inorganic and organic fertilizers are the usual approach of soil fertility maintenance. Organic and inorganic fertilizers have their merits and demerits for instance; organic fertilizers are slow release nutrient sources. This implies that crops can suffer initial starvation from nutrient immobilization prior to mineralization. They are also required in large quantities which may not be readily available to small scale farmers (Iren *et al*., 2016).In an organic fertilizer use, production of crops free from heavy metal contamination will be guaranteed (Asadu and Unagwu 2012). On the other hand inorganic fertilizer ensures quick availability of nutrients to crops but they have limited residual effect of the applied nutrient (Iren *et al*., 2015).Reckless use of these nutrient sources without knowing the appropriate rate to apply can create nutrient imbalance that limits the uptake of other essential nutrients and cause soil acidity leading to low crop yields. Neem-based organic fertilizer is a natural organic fertilizer produced from neem-seed kernel (OrgoNeem, 2015). It is a non-synthetic soil amendment that enhanced soil quality, thereby improving the vegetative and seed parts of crops (Subbalakshmi *et al*., 2012).Therefore; this study was designed to assess the effects of rates of NPK and neem-based organic fertilizers on soil properties and the performance of okra in Calabar.

Materials and Method

Description of the study location: The experiment was conducted at the screen house of the Teaching and Research Farm of the University of Calabar, Calabar in Cross River State. The area lies between latitude 5° 32' and 4° 27' N and longitude 7° 15' and 9° 28' E. The total rainfall ranges from 2000- 3500 mm annually while the mean temperature ranges from 23 -33 °C. The mean relative humidity is 60- 90 %.

Collection and preparation of material/ Experimental design and treatments: Plastic buckets (7Litrecapacity) were perforated at the bottom to allow for easy drainage and facilitate aeration. Surface soil samples (0-15 cm) collected randomly from the Teaching and Research Farm of the university were thoroughly mixed, air dried and passed through a 4 mm size sieve and 6 kg of the soil was measured into each of the plastic buckets.Seven (7) treatments including the control (no amendment) and two nutrient sources (neem based organic fertilizer and NPK 20:10:10) each applied at 3 levels of nitrogen (80,100,120 kg N/ha) were fitted into a completely randomized design (CRD) and replicated three times. The neem – based organic fertilizer treatments were applied to specified pots based on the calculated N rate and thoroughly mixed with the soil, watered to field capacity and kept for a period of five days before sowing the okra seed while the NPK fertilizer was applied to specified pots three weeks after sowing.

Planting and crop management / Data collection: Four (4) okra seeds were planted in each pot and were later thinned down to two plants per pot two weeks after planting (WAP). The pots were watered at regular intervals to maintain soil moisture at field capacity. The growth parameters measured after one month of planting were number of leaves per plant, leaf area, stem girth and plant height and these continued at two weeks interval. Number of fruits and fruit weights were taken per harvest and the average recorded at the end of the experiment.

Soil sampling/Laboratory analyses: One composite soil sample was taken before experiment and at the end of the experiment; soil in each pot was sampled for analysis. The soil samples were air dried, ground and sieved with 2 mm size sieve and physicochemical properties analyzed following standard procedures as outlined by Udo *et al*. (2009). The properties analyzed include particle size distribution, pH (H_2O), organic carbon, total nitrogen, available phosphorus, exchangeable bases and exchangeable acidity. Effective cation exchange capacity and base saturation were calculated.

The neem-based organic fertilizer was also subjected to chemical analysis.

Data analysis: Data collected were subjected to analysis of variance (ANOVA) using statistical package of Social Science software programme (SPSS) version 18 (2009) and the means were compared using Duncan New Multiple Range Test (DMRT) at 5% probability level.

Results and Discusion

Physico-chemical properties of the soil before the study: The physico-chemical properties of the soil before the study and nutrient composition of the neem-based organic fertilizer are presented in Table 1. The soil texture was loamy sand with 84.3 % sand, 8.7 % silt, and 7.0 % clay. The soil was extremely acid with a pH value of 4.38 as rated by Adaikwu and Ali (2013). The soil organic carbon, total nitrogen, exchangeable bases, exchangeable acidity and ECEC were low; the available phosphorus content of the soil was high while base saturation was moderate. The low fertility status of the soil necessitates the need for application of soil amendments.

Influence of NPK and neem based organic fertilizer on soil chemical properties: The chemical properties of the soil after experiment are shown in Table2. The results showed that the treatments applied significantly ($P< 0.05$) improved the soil pH relative to the control. The highest pH value was obtained from soil treated with 120 kg N/ha Neem (4.98) followed by100 kg N/ha Neem (4.91). The least pH value of 4.40 was obtained in control plot and was not lower than the value of 4.44 obtained from plot treated with 120 kg N/ha NPK.The organic carbon, total nitrogen, total exchangeable bases, ECEC and base saturation levels of the soil were significantly ($P < 0.05$) improved by the treatments applied with the highest values mostly obtained in soils treated with 120 kg N/ha Neem. The available phosphorus contents of all the amended soils weresignificantly reduced relative to the control. These reductions might be attributed to the uptake of phosphorus by the okra plant. The exchange acidity level was also significantly ($P< 0.05$) reduced in the amended soil while the base saturation level was significantly ($P < 0.05$) increased.

Table 1: Physicochemical properties of soil before experiment and characteristics of the crude oil used

Soil property		Nutrient content of the neem-based organic fertilizer	
Parameter	Value	Parameter	Value
Sand (%)	84.3	pH (H_2O)	7.8
Silt (%)	8.7	pH (KCl)	6.4

ECEC (cmol/kg)	8.27	NH_4^-(mg/kg)	65.7
Base saturation (%)	41.35		

Influence of NPK and neem based organic Fertilizer on growth parameters of okra

Table 3 shows that there were significant ($P < 0.05$) influences of NPK and neem- based organic fertilizer on growth parameters of okra plant. Number of leaves per okra plant was significant across all the growth stages measured with the amended soils producing more leaves relative to the control except at 4WAP where only the 120 kg N/ha Neem treated plot was significantly higher than the control.The highest number of leaves per okra plant was obtained from the plot amended with 120 kg N/ha Neem in all the growth stages measured (Table 3). This agrees with the findings of Olatunji and Oboh (2012) and Iren *et al*. (2016) who reported increases in the number of okra leaves with the application of organic based fertilizer.The leaf area of okra was significant ($P < 0.05$) across all the growth stages withthe broadest leaf obtained from plants treated with 120 kg N/ha Neem. At 12 WAP, the broadest leaf of 53.87 cm^2 obtained by plants treated with the highest rate of neem –based organic fertilizer was not wider than those obtained by other rates but was more than the NPK treated plants. There were significant ($P < 0.05$) increases in stem girth of okra plants across all the growth stages with the soils treated with neem-based organic fertilizer producing biggest stem than NPK fertilizer and the stem girth increases as the rate of application increases. There was significant increase in plant height of okra at different growth stages (Table 3). At 4 WAP, only the plants treated with 120 kg N/ha Neem was significantly taller than the control but at other stages of growth, plants treated with 120 and 100 kg N/ha Neem were taller than the plants in the control pots. Generally, the untreated plants were shorter than the treated plants at all the growth stages. This agrees with the findings of Odiete *et al*. (1999) and Iren *et al*. (2016) who reported increase in okra plant height by the application of amendments. The influence of NPK and neem-based organic fertilizers on number of fruits and fruit weight of okra was significant (Table 4) with the highest number of fruits (19.00) and fruit weight (6400 kg/ha) of okra obtained from the application of 120 kg N/ha Neem which was significantly more than other treatments. All the other treatments did not differ significantly from one another but were more than the control.

Conclusion

The use of fertilizer either organic or inorganic source improved the soil nutrient availability, growth and yield of okra. The improvement increased as the rate of application increased but neem-based organic fertilizer treated soils produced higher fruit weight of okra than the NPK treated soils. The highest okra fruit weight of 6400 kg/ha was obtained in pots treated with 120 kg N/ha Neem and is therefore recommended for sustainable production of okra in Calabar and other regions with similar climatic conditions.

Abstract
Phosphorus is a major nutrient required for cowpea growth, nodulation, root development, maturity and tolerance to field pests and diseases. Cowpea's yield in farmers field are below average of the genetic potential partly due to poor soil fertility of dry savannah areas, where the crop is majorly cultivated. It provides food over 200 million people, feed for livestock and cash for all the value chain actors. The use of phosphorus-based (P) fertilizer to provide cowpea with needed amount of P to complement the low-P from soil comes with financial and environmental cost, as P fertilizers are relatively expensive, not readily-available and excessive use of P could result in pollution of water bodies. In addition, global reserves of rock phosphate, a crucial ingredient for producing phosphorus fertilizers are limited and fast depleting. Therefore, breeding cowpea that acquire and use P from sub-optimal soils would reduce these costs. The variation in shoot yield and its correlation with root dry matter was quantified among 30 cowpea genotypes with varying performance. Genotypes were grown at zero, low and high P soils in a ratio 1:1 of low-P field soil to river-sand in three replications under screen house conditions using Hoagland nutrient solution. Results have showed existence of genotypes with above average performance under varying P levels as estimated via biomass production, and was associated with root development, as root biomass increased with increasing P content. This work provides information demonstrating potential of developing varieties with improved P acquisition and use efficiency in cowpea.

Introduction
Cowpea (*Vigna unguiculata* [L.] Walp) is an important legume crop which provides food and feed for human and livestock. The grains are rich in essential amino acids, thereby making it an important supplement to cereal-based meals for most families (Boukar *et al.*, 2018; Ojiewo *et al.*, 2018). Realized yield of the crop among farmers is low partly due to poor soil fertility especially low nitrogen and phosphorus in soils of most growing areas in West and Central Africa that accounts for substantial share of global production (Abate *et al.*, 2012). Phosphorus (P) is an essential nutrient for cowpea (Armstrong and Griffin, 1991; Adusei, 2015; Hussain, 2017), and the concertation of available P in the soil is often time low leading to slow diffusion of P to the root surface (Miguel, Postma and Lynch, 2015). P is one of the most limiting nutrient for cowpea and use of inorganic P fertilizer is advocated for achieving high yield and stability (Hammond *et al.*, 2009). Application of P fertilizers for higher gains appears to be unsustainable due to the financial and environmental costs associated with heavy fertilization. In the low inputs systems, these fertilizers are beyond reach of most local farmers while in the high input systems of the developed nations, intensive P usage could lead to excess soluble P ending up in the water bodies and polluting the aquifers that may result in loss of biodiversity. Developing cowpea varieties with ability to efficiently acquire and use P is an important strategy to reduce the use and reliance on synthetic P fertilizers, such that crop plants would produce above average yield with minimal use of inorganic P and higher returns when is sufficiently applied. This study used shoot biomass under low and high P conditions as a measure of P acquisition and use efficiency respectively. There is considerable within crop species genetic variation in the measure of P use

and acquisition (Hammond *et al.*, 2009). However, they observed that differences in the response of yield to P fertilization do not appear to correlate with P uptake efficiency (PUtE). Thus, selection for greater PUtE does not appear to be an effective strategy for developing crops that yield well on soils with low P availability. However, genotypes of crop plants that yield well and have lower tissue P concentrations can be used to reduce P-fertilizer inputs. There is a body of literature that pointed to variation in cowpea to various measures of P use efficiency (Kolawole, Tian and Singh, 2000; Sanginga, Lyasse and Singh, 2000; Mahamane, 2008; Olaleye *et al.*, 2011) and root hairs (Krasilnikoff, Gahoonia and Nielsen, 2003). The main object of this work was to investigate variation in shoot yield of cowpea to varying P levels and strength of association with root dry matter, this will provide critical information required for selecting cowpea for improved root system development.

Materials and Methods

Plant material

Thirty cowpea genotypes of which 20 are parents of recombinant inbred lines previously described (Muchero *et al.*, 2009; Huynh *et al.*, 2013, 2018; Muñoz-Amatriaín *et al.*, 2017) and 10 popular Nigerian lines were used to quantify the varying levels of P nutrient for shoot yield.

Screening experiment

A subsoil (20-40 cm) was collected from Institute for Agricultural Research-Ahmadu Bello University low-P research field and analyzed for physiochemical properties. The collected subsoil was mixed with acid washed river sand in the ratio of 1:1 and 5kg of the final mixture was weighed into pots (24 x 24 cm) for planting. A modified Hoagland nutrient solution used by (Johnson, Vance and Allan, 1996) on lupin and (Rothe, 2014) on some cowpea lines with little modifications on P concentration was adopted. Stock solutions were prepared for each of the nutrient salts ad defined quantities of stock solution were then measured out (see experimental procedure) into a 20 litre bucket, and reverse osmosis (RO) was used to make up the required volume for watering various P treatments, the pH was adjusted to 6.5 with NaOH or HCl. P was supplied as $Ca(H_2PO_4)_2.H_20$ at 0 mg, 1.5 mg and 30 mg for the zero, low and high P treatments, which were equivalent to 0 M, 25.0 μM and 0.5 mM of $Ca(H_2PO_4)_2.H_2O$ in the nutrient solution.

Experimental procedure

The thirty (30) cowpea lines were planted in a total of 270 pots as a factorial arrangement under three (3) P levels; 0 mg, 1.5 mg and 30 mg P/kg, with genotypes and P levels as treatments arranged in a randomized complete block design with three replications. All pots received 3.0 mM KNO_3, 2.5 mM $Ca(NO_3)_2$, 1.0 mM $MgSO_4$, 12.0 μM FeEDTA, 4.0 μM $MnCl_2$, 22.0 μM H_3BO_3, 0.4 μM $ZnSO_4$, 0.05 μM $NaMoO_4$, 1.6 μM $CuSO_4$ except and $Ca(H_2PO_4)_2.H_2O$ that was applied to only low and high P pots (Johnson et al., 1996; Rothe, 2014). Prior to planting, seeds were treated with a commercial fungicide (AllStar) according to manufacturer's recommendation and pots were watered to field capacity with 1000 ml of RO water. Two seeds were planted per pot, and were later thinned to one per pot at ten days after sowing (10 DAS). Pots were watered with nutrient solution described earlier as follows; 300 ml of dilute nutrient solution per pot at planting, and subsequently 300 ml was applied at 3 DAS, 6 DAS, 9 DAS, 16 DAS, 23 DAS, 30 DAS, 37 DAS, 44 DAS, and 51 DAS, these quantities of nutrient solution were dispensed using graduated beakers. Pots were periodically watered with RO water to prevent wilting and accumulation of salts in the soil. Plants were protected against insect pests by spraying Karate (50 g/l lambda- cyhalothrin, Syngenta Crop Protection AG, Basle, Switzerland) at a rate of 1.0L ha-1 as at when insects were found on plants.

Data collection and analysis

At eight weeks after sowing (WAS), plant height was measured, and all the genotypes were uprooted; the shoots were detached from the roots at above soil surface using secateurs. Roots were cleaned by repeated washing under a running tap to remove soils under a 1mm mesh opening. Fresh shoot and root samples were dried for 24 hours in the screenhouse under ambient temperature, and later moved to an incubator (Percival, Boone IOWA 50036) set at 60-65^{o}C for 36 hours and weighed using a digital scale (Scout^{tm} pro SPU202, Ohaus Corporation). In addition to plant height, shoot dry biomass (g), root dry biomass (g) were measured while total biomass, shoot to root and root to shoot ratios were computed. Prior to weighing, dried roots were checked for any soil particles, which were removed if found. Data were analyzed for differences in the parameters recorded and means were generated from SAS proc GLM (SAS 9.4, licensed to West Africa Centre for Crop Improvement) while graphical representation of the results were made using principal component analysis with built-in R functions *prcomp* on the pooled means of ANOVA (Kassambara, 2017).

Results and Discussion

Principal component analysis (PCA) was performed to reduce the dimensionality of the data by removing its redundancy, identify hidden patterns and correlated variables. The results showed that the first component which was mainly influenced by shoot, root and total plant biomass explained 49.9% of total variance (Figure 1), while the second component with main contributions from root to shoot and shoot to root ratios accounted for 22.6% of total variability. The graph of correction circle (Figure 2) revealed positively correlated variables pointing to the same direction, namely; shoot, root and total plant biomass, and these were negatively correlated with root to shoot ratio that was projected in the opposite side of the map. Variables that were far away from the origin of the PCA plane implies good representation on the map while those close to the origin are least represented on the components plane and may be better explained by other components. Measuring dry biomass has proven as the most potent criteria (Armstrong and Griffin, 1991; Hammond *et al.*, 2009; Korkmaz and Altıntaş, 2016) for estimating P response and use, this is because P deficiency slows down utilization of carbohydrate by plants and it is easily manifested as amount of biomass produced under sub-optimal conditions. Loss in yield is another obvious symptom associated with P deficiency for most field grown plants. Similarly, P deficiency results in delayed maturity, reduced fruit size and quality, and decreased tolerance to diseases (Armstrong and Griffin, 1991; Armstrong, 1999). Results from the present study supported reports of earlier works that P contained in the growth medium is critical for optimum yield in cowpea (Kolawole, Tian and Singh, 2000; Sanginga, Lyasse and Singh, 2000) and shoot yield is correlated with root dry matter production (Li *et al.*, 2009), as root system responds to P availability in the soil.

Conclusion

The differential performance of cowpea under varying soil P levels was successfully demonstrated. Shoot biomass production among same genotypes treated with different P concentration has showed role of P nutrition in supporting normal growth and development. Effect of P nutrient was more apparent on the shoot system than the root system leading low shoot to root ratio. Root dry weight was equally reduced in treatments with no to low P, and dry weight was associated with shoot dry weight. These findings will provide important information for selecting desired parents to initiate breeding programmes to develop cowpea varieties with improved P use and acquisition efficiency.

Abstract
Laboratory experiments were conducted to determine the effects of aqueous extracts of Terminalia mantaly H. Perrier (Combretaceae), Fragaria vesca (L) (Rosaceae), Ficus thonningii Blume (Moraceae) and Ribes nigrum (L) (Grossulariaceae) at 2.0, 4.0 and 6.0 ml/100g of raw extracts against Callosobruchus maculatus on stored cowpea seeds. Untreated control was also set up. Efficacy of the aqueous extract was assessed based on adult mortality at 1, 3 and 5 days after treatment (DAT) and progeny production. The experiment was conducted under ambient laboratory conditions at temperature of 32.2 ± 3°C and 33.9 ± 5% relative humidity. The results revealed that adult mortality increased with an increased concentration and exposure intervals. The percentage adult mortality ranged from 10.0 to 76.7% and was highest at 6.0 ml of Black Currant aqueous extracts; which was significantly different ($p < 0.05$) from untreated control at 1 day after treatments (DAT). Similar trends were observed at 3 and 5 DAT. On the other hand, all the treatment significantly ($p < 0.05$) reduced F_1 and F_2 progeny production compared to the untreated control. The results suggest that these plant materials tested have the insecticidal potential. Hence, it should be incorporated into post-harvest protection against, C. maculatus, the major insect pest of stored cowpea seeds.

Keywords: Callosobruchus maculatus, Cowpea seeds, Aqueous extracts, Adult mortality and Progeny production

Introduction
Cowpea (*Vigna unguiculata*) is a food and animal feed crop grown in the semi-arid tropics covering Africa, Asia, Europe, United States and Central and South America (IITA, 2016). The grains contain 25% protein, and several vitamins and minerals. More than 5.4 million tons of dried cowpeas are produced worldwide, with Africa producing nearly 5.2 million (IITA, 2016). Nigeria, the largest producer and consumer, accounts for 61% of production in Africa and 58% worldwide (IITA, 2016). One of the major constraints to cowpea storage is attack by an insect pest. *Callosobruchus maculatus* Fab. (Coleoptera: Chrysomelidae), is the most important insect pest of cowpeas (Ileke *et al*., 2013; Ahmed *et al*., 2014). It is a cosmopolitan pest that causes considerable economic damage. (Profit, 1997; FAO, 2004). Adults may be found outdoors in flowers in early spring and colonize the cowpea field at the end of the rainy season carrying the bruchid populations into the stores where they continue to develop (van Huis, 1996; FAO, 2004). Eggs laid by females hatch in 5 to 20 days. Larvae typically feed inside the cowpea, taking from 2 weeks to 6 months to develop before pupating. Six or seven generations may occur per year. Larvae chew near the surface and leave a thin covering uneaten which appears as a "window". Later the adult emerges from the ""window" (FAO, 2004). They prefer dried cowpeas but will attack other beans and peas in storage. Adults move about readily and can infest seeds in the field, but can also breed continuously in stored dry cowpeas. Larvae typically develop inside the dried peas (FAO, 2004). Damages caused by these storage pests include weight loss, loss in quality and market value. This causes quantitative and qualitative losses, reduced seed germination and nutritional value (Jackai, and Daoust, 1986; FAO, 2004). The damage cause by *C. maculatus* and other storage insect pests can be effectively control by the use of synthetic

insecticides like Rambo powders, Pestox powders, Malathion powders and Actellic dust. However, several problems are associated with their usage such as health hazard, increasing costs of the insecticides, development of resistance by the insect pests, scarcity and environmental hazard (EPA, 2001). In view of that, efforts are being focused on the use of plant materials that are relatively cheap, readily biodegradable, less toxic to other beneficial organism (Niber *et al*., 1994; Mukanga *et al*., 2010; Adedire *et al*., 2011; Ahmed *et al*., 2014; Chudasama *et al.,*2015; Longe, 2016). Therefore, the present study was conducted to evaluate insecticidal potentials of *Terminalia mantaly* H. Perrier (Combretaceae), *Fragaria vesca* (L) (Rosaceae), *Ficus thonningii* Blume (Moraceae) and *Ribes nigrum* (L) (Grossulariaceae) aqueous leaves extracts against *C. maculatus* on stored cowpea seeds.

Materials and Methods

Study site

The experiment was conducted in the Entomology Laboratory, Department of Crop Protection, University of Maiduguri. Maiduguri is located in the Sahel Savanna region of North-Eastern Nigeria at latitude 11°05' North and longitude 13°05' East (Daura, 2002). The temperature and relative humidity in the laboratory were recorded with Omson's hygrometer.

Rearing of *C. maculatus*

The adult *C. maculatus* used to establish the insect culture was obtained from infested stocks cowpea seeds purchased from Maiduguri Monday Market, Borno State - Nigeria and kept in Entomology Laboratory, Department of Crop Protection, University of Maiduguri. C*. maculatus* was subsequently reared on cowpea seeds (cv. Borno brown) in 1- Litre glass jars. The jars were covered with perforated lids to permit ventilation and prevent escape of adult insects. The culture was maintained under ambient laboratory conditions (temperature of 32.2 ± 3°C and 33.9 ± 5% relative humidity).

Source of cowpea seeds

Two kilograms of cowpea *Vigna unguiculata* (cv. Borno brown) used for the study was purchased from the Maiduguri Monday Market, Borno State - Nigeria. It is the most preferred variety, brown in colour. The seeds were fumigated with aluminum phosphide (Phostoxin® tablet) in an air tight container for 7 days. The seeds were later air dried in the laboratory bench for three days to allow for dissipation of the fumigant.

Collection of plant material

Fresh leaves of *T. mantaly* (Madagascar almond), *F. vesca* (Wood strawberry), *Ficus thonningii* (Common wild fig) and *R. nigrum* (Black currant) were collected from Ornamental Plant Garden Opposite Total Filling Station, Bama road, Maiduguri and authentication of the plant was done by a Botanist. The leaves of these plant materials were subjected to washing to remove all dust particles then dried to remove moisture. It was then milled into powders using pestle and mortar. The powders were further sieved using 1mm^2 metallic sieve to obtain fine powder. The powders were preserved in air tight glass jars until needed.

Preparation of Plant extracts

Twenty grams each of dried leaf powder was soaked in 100 ml of distilled water for 24 hours. Extract was filtered through a double layered muslin cloth followed by Whatman No. 1 filter paper and used for the experiment immediately.

Bioassay Procedures

One hundred grams of cowpea seeds were weighed into 500 ml glass jars using Mettler weighing balance and admixed with 2.0, 4.0 and 6.0 ml/100g of each aqueous extract and an untreated control was also included. After treatment, all the jars, except the untreated control, were vigorously shaken to ensure an effective admixture and the contents were allowed to settle for an hour. Thereafter, each jar was infested with twenty 1-2 days adult *C. maculatus* of mixed sexes. Each jar was then covered with a lid, which was cut at the middle but sealed with a mesh to facilitate ventilation and prevent escape of the insects. Each treatment was replicated three times. The jars were labeled and arranged in a completely randomized design on the laboratory table under ambient conditions for 90 days. Mortality assessment was conducted 1, 3 and 5 days after treatment (DAT), by emptying the contents of each jar on a plastic tray, where dead and live insects were counted and recorded. The dead insects were removed while the live ones were returned into their respective jars. Insects were considered dead if appendages did not move when touch with a blunt object. Thereafter, the jars were left undisturbed for the emergence of the F_1 (30 - 40 days after treatments), F_2 generation (70- 80 days after treatments). The number of adults that emerged from each jar was counted and recorded.

Statistical analysis
Mortality data were corrected for control mortality using the Abbott's (Abbott, 1925) formula. Prior to the statistical analysis, an arcsine transformation of the adult mortality data as well as a square root transformation of the progeny production data was performed to standardize the data. The data was subjected to one-way ANOVA using Minitab Statistical software (version 17) and Tukey - Kramer (HSD) tests at $p < 0.05$ was used for the post hoc separation (Zar, 1999).

Results and Discussion

The effects of some aqueous extract on the mortality of adult *Callosobruchus maculatus* are presented in Table 1. Results indicated that the highest adult mortality percent (76.7%) occurred at the highest concentration (6 ml) of Black Currant aqueous extracts, while the lowest mortality percent (10.0%) occurred at the lowest concentrations (2 ml) of Woodland Strawberry aqueous extracts, Madagascar Almond aqueous extracts and, Common Wild Fig aqueous extracts, compared to (6.7%) for the untreated control at 1 DAT. Similarly, complete adult mortality (100%) was caused at the highest concentration (6 ml) of Black Currant aqueous extracts, meanwhile the lowest value (10.0%) occurred at the lowest concentration (2 ml) of Madagascar Almond aqueous extracts and Common Wild Fig aqueous extracts, compared to (6.7%) for the untreated control at 3 DAT. Similar trend of mortality was observed at 5 DAT. In the present investigation the insecticidal activity of aqueous leaves extract of *T. mantaly*, *F. vesca*, *F. thonningii* and *R. nigrum* have been evaluated for the control of *C. maculatus* on stored cowpea seeds. The results indicated that the extracts of the four plant species exhibited high level (10-100%) of insecticidal activity against *C. maculatus* and proved significantly different from the untreated control. The insecticidal activity of these plant materials could be attributed to the phytochemical constituents of various the plant materials. These results confirmed the previous work conducted by (FAO, 2004; Adedire *et al*., 2011; Ahmed *et al*., 2014; Longe, 2016) which reported that plant materials can be used effectively as grain protectants against cowpea bruchids and other storage insect pests. The effect of some aqueous extracts on *Callosobruchus maculatus* adults emergence are presented in Table 2. The results indicated that the Black Currant aqueous extracts at (6 ml) recorded the lowest number of F_1 adults progeny (2.0), which was significantly different ($p < 0.05$) from the untreated control (303.0). On the other hand, the number of F_2 adult emergence recorded from the aqueous extracts ranged between 12.0 to 213.7 which was significantly different ($p < 0.05$) from the untreated control (470.0). Aqueous leaf extracts of *T. mantaly*, *F. vesca*, *F. thonningii* and *R. nigrum* clearly suppressed the emergence of *C. maculatus* adult populations on stored cowpea seeds. The reproduction potential was greatly reduced but not completely inhibited and this could be attributed to the toxic effect of these extracts as well as to oviposition deterrent effects, delayed egg-hatching and growth disrupting effects of these extract. Several studies (Niber *et al*., 1994; Mukanga *et al*., 2010; Adedire *et al*., 2011; Ahmed *et al*., 2014; Chudasama *et al.,*2015; Longe, 2016) have also reported the ability of some leaf extracts to inhibit the reproductive capacity of stored product insect pests including *C. maculatus*. The effects of these extracts may also blocked the insect spiracles leading to asphyxiation and death. This finding are in agreement with Adedire *et al*. (2011) who reported that plant materials prevented insects from breathing through blockage of their spiracles.

Conclusion

From the study, it is concluded that application of *T. mantaly*, *F. vesca*, *F. thonningii* and *R. nigrum* aqueous leaf extracts on stored cowpea seeds may control the damage caused by the cowpea bruchids *C. maculatus* and more studies are needed to isolate and extract the active compounds in these plant materials.

Abstract
A field experiment on the effects of poultry droppings and NPK15:15:15 on the growth and yield of carrot was carried out at the Faculty of Agriculture demonstration farm, University of Port Harcourt. The experiment was laid out in a completely randomized design of four treatments (Poultry dropping, NPK15:15:15, combination of Poultry droppings + NPK15:15:15, and control) with three replications. The result showed that the application of the treatments had significant influences (P=0.05) on all parameter studied (number of leaves, plant height, diameter of root, length of root, fresh weight of root, dry weight of roots, fresh weight of leaves, dry weight of leaves, gross yield, and marketable yield). The result revealed that the application of the Poultry droppings was found to be suitable for maximum gross yield and marketable yield (14.79 tha^{-1} and 14.65tha^{-1} respectively), while NPK 15:15:15 had better gross and marketable yield (17.14 tha^{-1} and 17.02 tha^{-1} respectively) and the combination of poultry droppings and NPK15:15:15 resulted in the best performance in gross and marketable yield (22.15 tha-1 and 22.04 tha-1 respectively).The net return (₦6,211,800 ha^{-1}) and benefit cost ratio (3.37) were maximum in the treatment with the combination of poultry droppings and NPK15:15:15.
Keywords: Poultry droppings, NPK, growth, yield and Carrot

Introduction
Carrot (*Daucus carota* L.) is an important vegetable which is ranked third among the succulent vegetables in world production (Yamaguchi, 1983). The edible roots are nutritious and contain water, protein, ash, vitamins and mineral (Norman, 1992). Carotene which is extracted from the roots is used in colouring margarine and for improving the colour of egg yolk when added to layer feed. The leaves and mature roots are used in the preparation of animal feed (Kahangi, 2004). Carrot which belongs to the family Apiaceae is a biennial and is usually cultivated as an annual crop in the tropics (De Lannoy, 2001). The crop is tolerant to soil pH of 5.5 to 6.5 and it requires a deep and well-drained loamy soil with high amount of organic matter (Yayock *et al*., 1988). Carrot production can be a beneficial enterprise for small-scale farmers because it is a short duration crop and higher yields can be obtained per unit area (Ahmad *et al*., 2005). However, Sarkindiya and Yakubu (2006) reported low average yields in Nigeria. In most developing countries, carrot yield per unit area remains below the world average (FAO 1999). One reason for low yield is low soil fertility and low technological know-how in production methods. In order to obtain high and sustainable carrot yields, good soil fertility and constant growth are required to facilitate production and translocation of carbohydrates from leaves to roots. The key limiting factors in crop growth, development, and yield are nitrogen, phosphorous, potassium, and water. In most cases, carrot growers use chemical fertilizers as the major supply of nutrients to attain higher growth and yield (Hochmuth *et al*., 1999; Amjad *et al*., 2005). Continuous application of synthetic fertilizer may lead to soil acidity, human health problems, and soil degradation because they release nutrients at a faster rate. Increasing costs of synthetic fertilizers have made them generally unaffordable to most small-scale farmers. Fordham and Biggs (1985) recommended the application of 70-120 kg/ha N, 30- 35 kg/ha P and 0-55 kg/ha K for high yield of carrots. Application of 300 - 450 kg/ha NPK (15:15:15) before planting has been recommended for improved growth and yield of the crop (Norman, 1992). Kahangi (2004) has

recommended the application of 10-20 t/ha poultry manure for improved growth and yield of carrot in the tropics. However, there is not much work on this study in Nigeria. The present research was therefore, undertaken to determine the effects of inorganic fertilizers and organic poultry droppings on the growth and yield of carrot.

Materials and Methods

The experiment was carried out at the Faculty of Agriculture demonstration farm, University of Port Harcourt. Soil samples of the experimental plot were collected and analyzed. The seeds were sourced from Songhai farm Sapele Delta State. The carrot seed is a Thema variety and the fertilizers (NPK 15:15:15 and poultry droppings) used were provided by the Faculty of Agriculture demonstration farm, University of Port Harcourt. The experiment was laid out in a completely randomized design of four treatments with three replications. The four treatments used in this experiment are as listed thus;
Treatment 1: poultry droppings (organic fertilizers)
Treatment 2: NPK 15:15:15 (inorganic fertilizers)
Treatment 3: combined effect of organic and inorganic fertilizers (poultry droppings and NPK)
Treatment 4: no fertilizer (control)
Carrot seed were soaked in water for 24hrs and wrapped with a cloth for 5 hrs (Shahid *et al.*, 2011). Beds were made and seed were sown at a spacing of 25cm x 25cm at a depth of 1.5cm. 35days after sowing, the treatments were applied; poultry dropping, NPK and combined effect of poultry droppings and NPK were applied on the plot using mechanical ring method. Two thinning operations were done at 25 and 35 days after sowing of seed to maintain the spacing. The experimental plot was kept free from infestation by weed. Intercultural and irrigation operations were carried out when required. The carrots were harvested 90 days after sowing. The crop was disease free and no fungicide were used. The following parameters were analyzed: number of leaves, plant height, diameter of root, length of root, fresh weight of roots, dry weight of roots, fresh weight of leaves, dry weight of leaves, gross yield, and marketable yield. The leaves of the plant of the various treatments were counted visually. The number obtained was then recorded appropriately against each sample. The plant height was measured with a metre tape in centimetres from the soil surface to the plant apex. The diameter of the root was measured at the thickest portion of the root at harvest. This was done using slide clippers. Marketable yield of the root was computed from conversion of the total marketable roots per plant and was recorded in hectares. Data collected for each parameter were subjected to analysis of variance (ANOVA) using Microsoft Excel 2010 version. Means were compared using the least significant Difference (LSD) (Steel and Torrie,1960).

Results and Discussion

The results of the effects of Poultry dropping and NPK 151515 on the number of leaves are shown in fig.1. From the result, after application of treatments, there was significant P=0.05 difference in number of leaves. At week 12, the highest number of leaves was recorded in the combination of NPK 15:15:15 and Poultry droppings (11.97), followed by NPK 15:15:15(11.63) and poultry dropping (11.27). The effect of increased number of leaves was as a result of the quick release of nutrients from the combination of NPK15:15:15 and poultry droppings that enhanced the soil conditions, which might have increased the number of leaves. Generally the control showed lowest number of leaves.

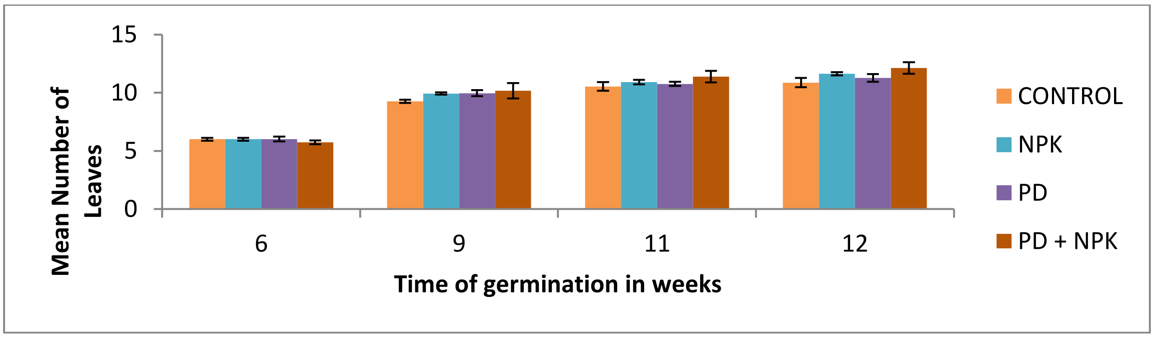

Fig.1: Eefects of Poultry Droppings (PD) and NPK15:15:15 on number of Leaves

The Plant height varied significantly P=0.05 with the application of the poultry droppings, NPK 15:15:15 and their combination (poultry droppings and NPK15:15:15). At 12 weeks the highest plant height (61.67cm) was found with NPK15:15:15 and poultry droppings treatment, followed by poultry dropping (59.50 cm), NPK 15:15:15 (56. 33cm) and the shortest height were found in control (53.33cm) Fig. 2.

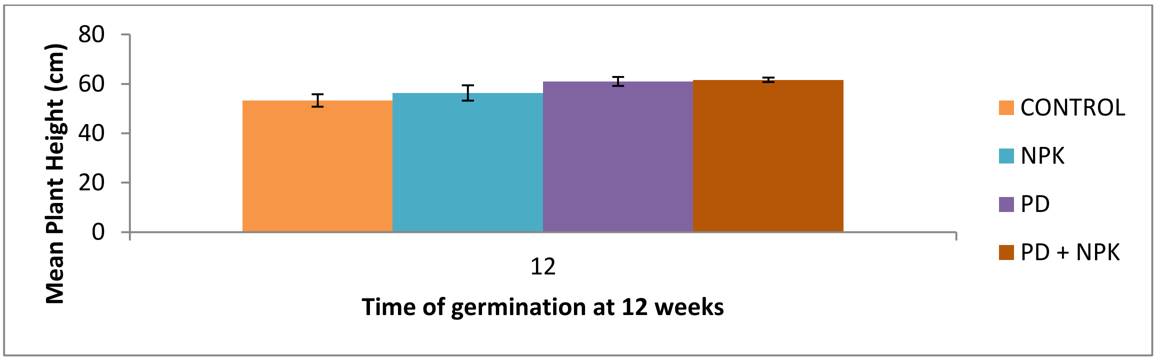

Fig 2: Effect of Poultry Droppings (PD) and NPK 15:15:15:15 on Plant Height

The maximum leaf weight per plant was recorded in the combination of poultry droppings and NPK15:15:15 (138.44g) followed by NPK15:15:15 (107.15g) and poultry droppings (92.43g) and the control were recorded to have the minimum weight (84.91g). The combination of poultry droppings and NPK15:15:15 were found to have the maximum weight; this is due to the adequate supply of nutrient leading to higher vegetative growth of the plant. The fresh weight of root per plant was significantly P=0.05 different with respect to the treatments (Table 1). The highest fresh weight of root per plant was found in the combination of poultry droppings and NPK15:15:15 (64.55g) followed by NPK15:15:15 (53.54g) and poultry droppings (46.04g) while the lowest weight (38.09g) was found with control. This may be due to the fact that the combination of the fertilizers supports the soil physical condition for better development. The maximum dry weight of leaves was found in control (17.94%) followed by poultry droppings (16.94%) and NPK15:15:15 (16.29%) while the combination of NPK 15:15:15 and poultry droppings (15.15%) was the minimum dry weight. The maximum dry weight was found in the combination of poultry droppings and NPK15:15:15 (16.65%), followed by NPK15:15:15 (14.98%) and poultry droppings (13.86%) while the control (11.71%) had the minimum percentage of dry weight. The provision and supply of adequate nutrient for better growth by the combination of the poultry droppings and NPK15:15:15 enhanced the production of maximum amount of dry weight of the root.

Table 1: Effect of Poultry Droppings and NPK15:15:15 on the Growth and Yield of Carrot

Treatments	Length of root/plant (cm)	Diameter of root/plant (cm)	Fresh wt. of root/plant (g)	Fresh wt. of leaves/plant (g)	Percent dry wt. of roots	Percent dry wt. of leaves
NPK15:15:15+PD	16.04±0.34	5.95±0.46	138.44±5.23	64.55±3.21	15.15±0.48	15.65±3.11
POULTRY DROPPINGS (PD)	13.60±1.5	6.10±0.02	92.43±5.6	46.04±3.64	16.94±1.18	13.86±0.47

CONTROL	11.70±0.4	5.98±0.58	84.91±6.45	38.09±5.81	17.94±2.66	11.71±1.56

Mean±Standard Error

The cracked root production was significantly P=0.05 influenced by the application poultry droppings and the NPK15:15:15 (fig. 3). The maximum number of cracked roots (0.08) was obtained from the treatments of poultry droppings followed by NPK15:15:15 (0.07) and the combination of NPK151515 and poultry droppings (0.04) while the control had the lowest (0.03) number of cracked roots. The branched root production was significantly P=0.05 influenced by the application of poultry droppings and the NPK15:15:15. The maximum number of cracked roots (0.12) was obtained from the control followed by treatments of poultry droppings (0.07) and NPK15:15:15 the combination of NPK151515 and poultry droppings (0.04) while the combination of NPK151515 and poultry droppings had the lowest (0.03) number of branched roots.

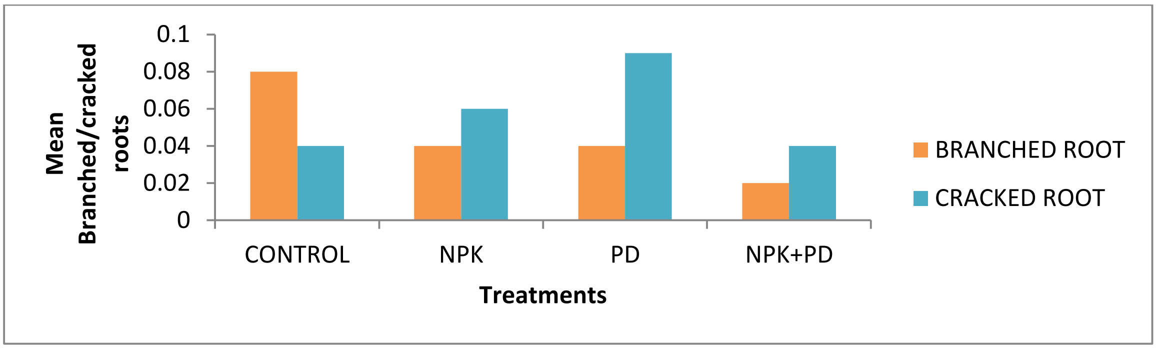

Fig. 3: Mean Branched and Cracked Roots of Carrot

Conclusion

Organic manures helps to improve the soil fertility and productivity, inorganic fertilizers also supply adequate nutrients in known proportion but on the other hand creates problem to the environment when use indiscriminately From the results of the present study, it can be concluded that the combination of poultry dropping and NPK15:15:15 is suggested for maximum carrot production.

Abstract
Hausa potato is an underutilized root crop with edible root and foliage. It is not only important for its significant contribution to nutrition but also a source for traditional medicine used in the treatment of dysentery. This informed our search for its antimicrobial use against Food-borne pathogens. The antimicrobial activity of Hausa potato was investigated against three Gram-negative bacteria strains; Escherichia coli, Salmonella typhi and Pseudomonas aeruginosa, two Gram-positive bacteria strains: Enterococus fecalis and Staphylococcus aureus. The antibacterial activity was evaluated by agar diffusion, minimum inhibition and bactericidal concentration methods. The antibacterial activity of the plants studied demonstrated clear zones of inhibition. The data obtained for the antibacterial activity of Hausa potato leaf is the first reported to the best of our knowledge. The extract showed sensitivity to both Gram negative and Gram positive tested bacteria strains. The results suggest that Hausa potato has potential as an antimicrobial agent

Introduction
Antibiotics have been part of animal feed since the 1950s. They are given in the form of supplement or mixed in their drinking water. There is no doubt that there is great improvement in animal growth and performance but routine use of antibiotics on farm animals can promote drug resistant bacteria. Although the drugs maybe effective against most of the bacteria killing them but there are some that could survive, proliferate and colonize in human (Linton *et al.*, 1977). In recent years the use and search for drugs and supplements of plant origin has increased tremendously. Traditional healers depend on plant sources for treatment and prevention of bacterial infection, also plants rich in phytochemicals such as terpenoids, tannins, alkaloids and flavonoids have been found to possess antimicrobial potentials. (Cowan, 1999). Hausa potato (*Solenostemon rotundifolius*) leaves possess high content of tannins and moderate amount of alkaloids and flavonoids (Harbor, *et al.,* 2016). These aromatic hydrocarbons have been shown to possess antibacterial activity (Murugan, *et al*., 2013). In view of search for antimicrobial of plant origin to be used in order to reduce the incidence of drug resistance, we carried out *in vitro* studies of antimicrobial potential of Hausa potato. The objective of the study was to determine the susceptibility of enteric microorganisms to Hausa potato leaves' extract in search of potent antimicrobials from natural product.

Materials and method
The leaves of *S. rotundifolius* was dried under room temperature, pulverised and extracted with ethanol. The anti-microbial activity of ethanol extract of Hausa potato leaves were examined against some two gram positive and three gram negative enteric micro-organisms: *Staphylococcus aureus* (+), *Enterococcus faecalis* (+), *Escherichia coli* (-), *Salmonella typhi* (-) and *Pseudomonas aeruginosa* (-). Stock solutions were prepared by dissolving 0.2 g (200 mg) each of the crude extract in 2 ml of DMSO to give concentration of 100 mg/ml. Further concentrations were obtained by performing serial dilutions to obtain 10 mg/ml and 1mg/ml. These concentrations used to evaluate the inhibitory effect of Hausa potato leaves against the selected enteric organisms. The test organisms were reactivated from nutrient agar slants onto freshly

prepared nutrient agar plates and these were inoculated into prepared Mueller-Hinton agar plates. The Kirby-Bauer disc diffusion technique was employed for the determination of the sensitivity of microorganisms to the extract. Greater drug efficacy yields larger microbe-free zones surrounding drug-containing disks after overnight growth on solid media. The broth dilution method described by Andrews (2001) was followed for the determination of the minimum inhibitory concentration (MIC), while minimum bactericidal concentration (MBC) was determined by sub-culturing MIC to culture plates that do not contain test microorganisums. Complete absence of growth was indicative of MBC. Gentamicin was used for the positive control while the negative control was DMSO.

Results and Discussion

Our earlier studies on the phytoconstituents of Hausa potato leaves reveal high content of flavonoids and tannins (Harbor *et al.,* 2016). Both tannins and flavonoids have been associated with antimicrobial activity. Flavonoids are said to be synthesized by plants in response to microbial infection (Dixon *et al.,* 1983) and have been found *in vitro* to be effective antimicrobial substance against a wide array of microorganisms. Their activity is probably due to their ability to complex with extracellular and soluble proteins and with the peptidoglycan of bacterial cell walls. However more lipophilic flavonoids are thought to disrupt microbial membranes (Cowan, 1999). Tannins antimicrobial activity may include inhibition of extracellular microbial enzymes, deprivation of the substrates required for microbial growth or inhibition of oxidative phophorylation. The extract of Hausa potato leaves showed antimicrobial activity against *S. aureus, E. faecali* and *S. Typhi* strains. No antimicrobial activity by the crude extract was observed against *E. coli* and *P. aeruginosa* strains most likely; fractions of the extract may have activity against these strains when tested. The leaves of Hausa potato can be described as broad spectrum antibiotic agent since it has anti-microbial activity on both the Gram positive and the Gram negative bacteria strains. The activity and potency of the positive control, gentamicin, is seen to be significantly higher than that of the extract and could be because it is a pure compound. Moreover in traditional use, medicinal plants are not used as single therapy, rather are used in combination with other herbal remedies thereby acting in synergistic manner and raising the potency.

Abstract
The response of an improved soybean variety (TGX-1448-2E) to bradyrhizobium inoculation under different tillage systems and maize-soybean-based cropping systems in the Northern Guinea Savanna of Nigeria was evaluated at Institute for Agricultural Research, Ahmadu Bello University Research Farm, Samaru. Treatments consisted of two tillage systems; conventional tillage (CT) and reduced tillage (RT) and Bradyrhizobium inoculation [inoculated (IN) and uninoculated (UNIN)]. These were tested in a split-plot experimental design with three replications. The results showed that data obtained for dry matter yield were consistently higher in inoculated plots compared to the uninoculated plots at significant level of $P < 0.001$). Results of grains yield were similar and consistent with that of the dry matter yield (DMY). Grain yield (2481.88 kg/ha), grain N (3.98 %) and protein content (24.89 %) obtained under inoculated plots were significantly higher than uninoculated plots with 14.04 % difference. No significant difference was observed between the RT and CT in terms of grain N and protein content while reverse is the case in grain yield. The findings tend to suggest the need for Rhizobium inoculation to improve soybean growth and grain yield under good management systems.

Keywords: Tillage, Rhizobium inoculation, grain legume and Savanna Alfisol

Introduction
Tillage, one of the most important practices in agriculture, performed primarily to mix the soil with organic residues and fertilizer, to loosen the upper layer of soil, to check weeds and to create a suitable seedbed for germination and plant growth (Rasmussen 1999). Soil physical and biological characteristics are influenced by tillage practice, which in turn lead to alter plant growth and yield (Wasaya *et al*., 2011, Rashidi and Keshavarzpour 2007). Reduced soil disturbance, for example, improves soil physical parameters such as structure, and also the chemical and biological parameters that affect nitrogen fixation. Soil moisture and temperature, are known to be influenced by tillage, all of which affect biological nitrogen fixation (Salvagiotti *et al.,* 2008). According to Kemal, (2011), No-Tillage with Direct Seeding (NTDS) plots gave root weights (6.9 g/plant), number of nodules (96 number/plant) weight of nodules (0.318 g/plant) and root nitrogen content (% 0.71) which were found to be statistically higher than with the other tillage methods. In the Reduced tillage with rotary tiller (RTR) plots, the values of root dry weight (51.3 g/plant), mean nodule weight (3.91 mg/nodule), root N content (2.38%), and are found to be higher than in the NTDS plots. However, legumes such as soybean that transport N fixed from roots to shoots in the form of ureides (allantoin and allantoic acid) are particularly susceptible to water stress (Sinclair *et al*., 2007) and conservation practices involving reduced tillage and surface crop residue application, are expected to positively influence nitrogen fixation (Kihara *et al.,* 2011). Similar studies have also shown that zero and reduced soil tillage methods have increased the soil microbial activity and population. The average yield increase over ten years of research in soybean inoculation has returned a profit of over 300 percent (Beuerlein, 2004). Increases in fresh weight, dry weight and seed weight were also observed as compared to the control in several instances (Jalaluddin, 2005). The high N fixing property of soybean can be

seen in the plant coloration. Colour differences were obvious in a study, as inoculated plots appeared much greener compared to the uninoculated (Thelen and Schulz, 2009). In view of the above discussion, a field study was conducted with a view to evaluate the effect of tillage and *Rhizobium* inoculation on the performance of soybean, in a savanna Alfisol of Nigeria.

Materials and Methods

Experimental site

Field experiment was conducted at research farm of the Institute for Agricultural Research (IAR) Ahmadu Bello Univeristy, Samaru, in 2011 cropping season. Samaru (11° 11' N, 7° 381E) 686 m above sea level is located in the Northern GunieaSavanna of Nigeria with an annual rainfall of 1100 mm distributed between April and October (Kowal and Knabe, 1972) and monomodal rainfall pattern. While the longitudes (11^{o} 10' N) and latitudes (7^{o} 36' E) of the actual experimental field were determined by use of a Global Positioning System (GPS) receiver. Samaru has a long-term mean temperature of 21.05^{o}C (minimum), 33.47^{o}C (maximum), and relative humidity of 55.23 % (Oluwasemine and Alabi, 2004). The soil type is an Alfisol derived from Pre-Cambrian Crystalline basement complex rocks with some quanternary (quarternary) Aeolian deposits. The main soil sub-group is TypicHaplustalf (Awujoola, 1979).

Field experiment

The experiment was a split plot arrangement in a randomised complete block design with three replicates. The treatments were tillage practice as main plot (reduced and conventional tillage) and bradyrhizobium inoculation as sub plot (inoculated and uninoculated). The conventional tillage was ridged manually using hoe while reduced tillage was planted directly without ridging. Soybean (TGX 1448-2E) was used as a test crop. Phosphorus and potassium fertilizers were applied to all the plots at the rate of 60 kg P_2O_5 ha^{-1} and 60 kg K_2O ha^{-1} respectively, at planting without nitrogen fertilizer. Weeds were controlled by the application of glyphosate at two weeks before land preparation. Subsequently, manual weeding was employed two times before harvesting.

Inoculation and planting

The soybean seeds were surface sterilised as reported by Vicent (1970) and inoculated with commercial bradyrhizobial strain described Somasegaran and Hoben (1994). Soybean seeds were drilled in open grooves on the ridges and covered lightly with soil. The uninoculated soybean treatment rows were planted first before uninoculated plots. The seedlings were thinned to one plant per hill at 5 cm within row spacing at two weeks after planting. Subsequent field operations such as weeding were cautiously done manually to avoid transfer of rhizobia from inoculated rows to uninoculated rows.

Sampling and Analysis

Soil samples were collected at 0-20 cm depth from the experimental field before planting for determination of physicochemical properties of the studied soil. Plant within the net ridges of each plot at harvest were cut at ground level, bagged, air-dried and manually threshed. The following measurements were obtained: weight of dry haulms, grain yield and 100 grain weight, as well as the shoot weight, root weight per plot. Grain was grounded in a hammer mill, passing through a 0.5 mm sieve and stored at -5 ^{0}C in bags for analysis nitrogen as described by micro-kjeldahl digestion method (Bremner and Mulvaney, 1982) and multiplied by a factor (5.7) to obtain protein content (Halvorson *et al.,* 2004).

Statistical analysis

Data were subjected to analysis of variance (ANOVA) using mixed linear model MIXED Procedure of SAS, (Institute Inc., 2009). The effects of various factors and their interactions were compared by computing least square means and standard errors of difference (SED) at 5 % level of probability.

Results and Discussion

Dry Matter Yield

Effects of tillage systems on root dry matter yield were not significant (Table 3). However, effect of inoculation resulted in significant different in root dry mater weight. The percentage difference between inoculated soybean and uninoculated ones was found to be 11%. The interaction effects, was not significant. There was also no significant difference between the tillage systems on shoot dry matter of the soybean plant. There was however, highly significant difference ($P<0.001$) as a result of inoculation effect on shoot dry matter. The obtained difference as 16% inoculated soybean was always superior in all cases. The haulm dry matter on the other hand recorded a highly significant difference (P<0.01) as influenced by the tillage systems, with CT being 11% higher than RT. More dramatic ways the highly significant difference (P<0.05) recorded as a result of Rhizobium inoculation. Inoculated soybeans recorded a higher haulm dry matter compared to the uninoculated with percentage difference of 10.79%. There was also significant difference between (P<0.05) the Tillage*Rhizobium inoculation interaction (Fig.2). The percentage contrast was 18.14%. A significant differences observed in the dry matters yield of the inoculated soybean over uninoculated plots were due to the effectiveness of the Rhizobium inoculant used. The findings are in conformity with that of Bai *et al*. (2002) and Okereke *et al.* (2004) reported 29% and 2 - 130% increase in SDW following the inoculation with *Rhizobium*, respectively. Egamberdiyeva et al. (2004) reported that *Rhizobium* inoculation increased soybean SDW and RDW by 7-23% and 57-78%, respectively. Sobral *et al.* (2004) explained that use of r*hizobia* isolates were able to produce IAA, solubilize phosphate and fix nitrogen which could be used for soybean growth promotion.

Table 3. Effect of tillage and Rhizobium inoculation on dry matter yield

Treatment	Root Dry Matter (kg/ha)	Shoot Dry Matter (kg/ha)	Haulm Dry Matter (kg/ha)
Tillage systems

± SE	30.26**	31.48**	102.91**
Tillage*Rhizobium Inoculation			
Significance	NS	NS	*

NS= not significant, * = Significant at 5 % probability, SE= standard error, CT= conventional tillage, RT= reduced tillage

Hundred seeds weight was significantly differenced (P<0.05) by the tillage system (Table 4). Also, significant difference (P<0.05) was between Rhizobium inoculation and uninoculated soybeans plots in terms of 100-seeds weight. The Tillageand Rhizobium inoculation interaction was not significant. However, tillage systems significantly influenced grain yield, Inoculated soybeans gave much higher grain yield compared to the uninoculated ones. The percentage difference between the inoculated and uninoculated soybeans was 35.51% (Table 4). The Tillageand Rhizobium inoculation interaction was not significant on grain yield. The final grain yield of a crop is a function of cumulative contribution of its various growth and yield parameters which are influenced by various agronomic practices and environmental conditions. Higher grain yield (2481.88 kg ha^{-1}) was obtained from soybean seed inoculated with *Rhizobium* compared to the un-inoculated (1357.11 kg ha^{-1}).

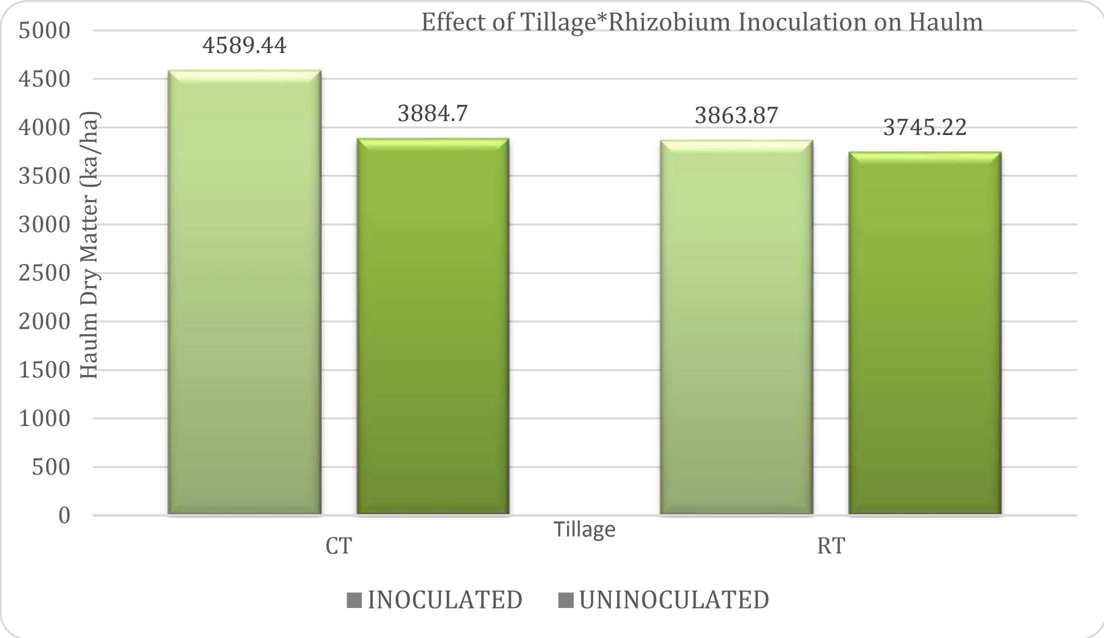

Fig. 2 Interaction Effect of Tillage and Rhizobium inoculation on Haulm Dry Matter
100-Seed Weight and Grain Yield

Symbiosis between soybean and *Rhizobium* inoculation can be the possible explanation to the above findings. Increased nodulation resulted in more N fixation that led to increased yield components. Increase in pods number, seed and dry matter yield due to *Rhizobium* inoculation was well documented in literature. Okereke *et al.* (2004) reported 14 – 100 %, Egamberdiyeva *et al.,* (2004) 48 - 55%, (Majid *et al.,* 2009) 41-62 % increases in seed and dry matter yield due to inoculation. Similarly, Ashraf *et al.,* (2002), Oad *et al.,* (2002) and Abbasi *et al.,* (2008) in Pakistan, reported increase in seed yield due to *Rhizobium* inoculation. Mendels *et al.,* (2003) reported higher yield of soybean (3514 kg/ha) in conventional tillage than that of No-tillage (3224 kg/ha).

Grain Nitrogen (N) and Protein Content

The computed total grain N and protein content are presented Table 4. The result shown that tillage system did not significantly ($P<0.05$) influence the grain N concentration as well as protein content. However, there was highly significant difference ($P<0.0001$) between the inoculated and uninoculated soybeans in terms of total grain N and protein content. The magnitudes of the difference were 14.04% total grain N and 14.50 % protein with inoculation stimulating the higher performance. The Tillageand Rhizobium inoculation interaction was not significant. The higher total grain N and protein content recorded in inoculated plots was due to effectiveness of the Rhizobium inoculant used. The significant increase in nodulation resulted in greater N fixation (Seneviratne *et al*., 2000; Sarr *et al.,* 2005; Majid *et al.,* 2009). Similar observation was recorded by Majid *et al.,*(2009). They reported that Rhizobium inoculation increased soybean seed N by 9 % over uninoculated control and 10% increase in protein content and 19% increase in oil content of soybean following the inoculation of *Rhizobia.*

Table 4. Effect of treatment on grain yield and 100-seed weight

Treatment	100-Seeds weight (g)	Grain Yield (kg/ha)	Grain N (%)	Protein (%)

Conclusion

It can be concluded from the study that the data computed for grain yield (2481.88 kg/ha), root dry weight (690.71 kg/ha), shoot dry weight (1735.56 kg/ha), haulms dry weight, grain N (3.98 %) and protein content (24.89 %) were consistently higher in Rhizobium inoculation plots compared to the uninoculated ones. While the influenced of reduced tillage system was lower in terms of nodulation, yield and dry matter yield but higher in root dry matter weight (657.50 kg/ha) compared to conventional tillage system with root dry matter weight of 653.86 kg/ha. There was interaction effect of tillage and rhizobium inoculation on haulm dry matter only. The study revealed the agronomic important of using Rhizobium inoculation in soybean production under tillage system in other to boast smallholder farmers income in northern Guinea savanna of Nigeria who are characterised by intensive cultivation coupled with low input use and low capital base.

Abstract

Salicylic acid and Benzoic acid are antitranpirantsusually used to reduce the rate of moisture loss and increase productivity of irrigated crops. To test antitranspiracy of Salicylic and Benzoic acids, field experiments were conducted during the two successive dry Seasons of 2011/2012 and 2012/2013 at the Teaching and Research Farm of Faculty of Agriculture Bayero University, Kano (11° 97' 98.6" N, 8°42' 03.7" E) 475 m elevation. The aim was to study the effects of antitranspirants and moisture stress on crop growth and development stages of tomato. The treatments consisted of two antitranspirants at four concentrations each (0, 200, 400 and 600 ppm) and three moisture stress stages (vegetative, flowering and fruit setting). Antitranspirants and moisture stresses were assigned to the main plot and concentrations were used as sub–plot treatment. These were replicated three times and laid out in a split-plot design. The gross plot size was 3.6m x 3.0m (10.8m^2) consisting of 6 rows of 3m length, while the net plot size was 1.2 m x 1.8 m (2.16 m^2) consisting of 2 inner most rows. Data were taken on some tomato growth attributes. Data generated were analysed using SAS. The results of the study revealed that application of Salicylic acid at 600 ppm significantly enhanced leaf area, total dry matter, crop growth rate and relative growth rate than application of Benzoic acid.Interaction between antitranspirant and stress was significant on dry matter. Flowering and fruiting stages were found to be the critical growth stages for moisture stress of tomato.

Keywords: Antitranspirant, moisture stress, growth characters and tomato

Introduction

Besides chilling and freezing temperatures, drought is one of the most important limiting factors of crop production all around the world.Cultivation of tomato is now widespread throughout the temperate and tropical climate (Harlan, 1984). It is among the most important vegetable crops in Nigeria. Large scale tomato production in Nigeria is mainly under irrigation during the dry season. Tomato is a rich source of vitamin A, B and C with acidic properties that bring out other flavour (Rakesh and Adarsh, 2010). Tomatoes require a high water potential for optimal vegetative and reproductive development. Therefore, irrigation is required for profitable production.There is a critical need to balance water availability, water requirement and water consumption in conserving water which has become a decisive consideration for agricultural expansion, particularly in arid and semi- arid regions.One way to achieve this goal is by reducing the transpiration rate using Antitranspirant materials to minimize the amount of irrigation water. Foliar application of antitranspirant seams an attractive method for regulating transpiration and maintaining a favourable plant water status.

Materials and Method

The experiment was conducted for the two successive dry seasons of 2011/2012 and 2012/2013 at the Teaching and Research Farm of Faculty of Agriculture Bayero University, Kano (11° 97' 98.6" N, 8° 42' 03.7" E) 475 m above sea level. The treatments consisted of two antitranspirants (Benzoic and Salicylic acids) at four concentrations each (0, 200, 400 and 600 ppm) and three moisture stress stages (vegetative, flowering and fruit setting). The experiment was laid out in a split-plot design and replicated three times.The land was ploughed, harrowed and prepared into plots of slightly sunken beds of 3.6 m x 3.0 m (10.8m^2) sizes. Paired rows of beds were separated by 0.75m wide irrigation channels between the plots.Before removing the seedlings from the nursery, thebedswere thoroughly irrigated and seedlings were uprooted using a small hand hoe and then transplanted at a spacing of 60 cm x 60 cm.Salicylic and Benzoic acids were sprayed to the foliage using a hand sprayer at vegetative, flowering and fruit setting stages at the rate of 0, 200, 400 and 600 ppm equivalent to 0.2, 0.4 and 0.6 g L^{-1} of water.

Results and Discussion

Table 1 shows that Antitranspirant had significant effect on the leaf area and dry matter of the moisture stressed tomato where plants that were foliar sprayed with salicylic acidhad wider leaf area (9.48cm^{-2}) than those sprayed with benzoic acid (8.89cm^{-2}). The effect of stress was observed to be significant where plants that were stressed at fruiting stage had wide leaf area (9.27cm^{-2}) while those stressed at flowering and vegetative stages had narrow leaf areas (7.42cm^{-2}) and (7.42) respectively. Application of 600ppm resulted into plants with wider leaf area (9.85cm^{-2}), although statistically at par with 200ppm (9.53cm^{-2}).Similarly, foliar applied salicylic acid produced plants with higher dry matter (100.47g) than benzoic acid (98.22g). Plants stressed at fruiting stage had higher dry matter (103.45g) while those stressed at vegetative stage had lower dry matter (79.12g) and plants sprayed with 600ppm concentration had higher dry matter (110.66g) than the control 0ppm (80.22g). Interaction between antitranspirant and stresson the dry matter of moisture stressed tomato was significant (Table 1). Table 2 shows the interaction between Antitranspirants and stress stages on dry matter of moisture stressed tomato. In 2012 season, looking at the Antitranspirants under different stress stages, application of Benzoic acid at all the stress stages significantlyhad plants with higher dry matter (107.41 g) even though at par with application of Salicylic acid at flowering (96.50 g) and fruiting stages (105.75 g).When the stress stagesare considered,stressing theplant at vegetative stage with application of Salicylic acid had significantly lower dry matter (65.41 g). Table 3 shows that there was significant difference between the antitranspirants on the crop growth rate and relative growth rate of moisture stressed tomato where application of salicylic acid resulted into plants with higher crop growth rate (3.47) while those sprayed with Benzoic acid had lower crop growth rate (2.75)in both seasons and combined. Plants stressed at fruiting stage had higher crop growth rate (9.99) than those stressed at vegetative stage (2.72). Effects of concentration of antitranspirant was observed to be significant where plants that were foliar sprayed with 600ppm had higher crop growth rate (8.17), although statistically at par with 400ppm (7.53) while the control 0ppm resulted into plants with lower crop growth (3.35). Interaction between the treatments was not significant. Similarly plants sprayed with salicylic acid had higher relative growth rate (0.49) while those sprayed with benzoic acid had lower relative growth rate (0.39) in both seasons and combined.Stress had significant effect where plants that were stressed at fruiting stage had higher relative growth rate (0.78) than those stressed at vegetative stage (0.40) and application of 400ppm concentration produced plants with higher relative growth rate (0.69), although at par with 600ppm (0.63) while plants sprayed with 200ppm had lower relative growth rate (0.47) which was at par with the control 0ppm (0.53). Interaction between treatments on relative growth rate was no significant. Table 4 shows the effect of the antitranspirants on the net assimilation rate of moisture stressed tomato. There was significant difference between the two antitranspirants on the net assimilation rate of moisture stressed tomato where foliar applied salicylic had resulted into plants with higher net assimilation rate (0.12) than those sprayed with benzoic acid (0.09). There was no significant difference between the stress stages, concentrations as well as the interactions between the treatments on the net assimilation rate of the moisture stress tomato.

Salicylic acid gave higher leaf area at in both seasons than Benzoic acid. Higher performance of Salicylic acid than Benzoic acid could be attributed to the differences of the active ingredient in the formulation of the antitranspirants. The active ingredient in Benzoic acid was 0.3 kg a.i while that of Salicylic acid was 0.95 kg a.i. Similar result was observed by Latimer (1992) who reported that application of GA_3 increased leaf area. This findings are in contrast with the results of El-Kobbia and Ibrahim (1986) who did not observe any effect on leaf area of tomato plants sprayed with Epoxylin seed oil and vapour guard antitranspirants. Total dry matter increase with Salicylic acid than Benzoic acid in both seasons. This may probably be due to the fact that, Salicylic acid might have affected assimilate transportation to the various organs positively than the Benzoic acid. Irmak *et al.* (1999) found that plant development and dry matter production for the vegetative parts of tomato plants were increased by antitranspirants. Application of Salicylic at fruit setting stage had higher dry mater possibly because of higher number of branches recorded by this antitranspirant at this stress stage. Gu*et al.* (1996) had earlier reported that water stress and antitranspirant GLK-8924 interacted on tomato to affect plant growth rate and hence dry matter. Salicylic acid had higher crop growth rate than Benzoic acid. This higher performance of Salicylic acid than Benzoic acid could be attributed to the higher leaf area and higher total dry matter obtained from plants that were sprayed Salicylic acid. Salicylic acid had produced plants with the highest relative growth rates than Benzoic acid. This results supported the findings of Goreta*et al.* (2007) who reported thatrelative growth rate of pepper was reduced by aminoethoxyvinlglycinetreated plants to 40% and 50% respectively, compared with control plants while enhanced relative growth rate was found after aminoethoxyvinlglycine and vapour guard application.The higher performance of Salicylic acid in terms of net assimilation rate of tomato than Benzoic acid could be attributed to the net effect of Salicylic acid on crop growth rate and the relative growth rate.This result is in contrast with that of Cantore*et al.* (2009) who reported that applicationof Kaolin based particle film on tomato reduced net assimilation rate by 26%.

Abstract
A 5X2 factorial experiment was conducted at the screen house of the National Root Crops Research Institute, Umudike, Nigeria (latitude 05⁰, 29′ N and Longitude 07⁰ 33′ E) to evaluate the effect of different irrigation frequencies for sustainable sweetpotato pre-basic seed production in the humid rainforest zone of Nigeria. The factors were five irrigation frequencies (daily, 2 days interval, 3 days interval, 4 days interval, and 5 days interval) and two varieties of sweetpotato (TIS 87/0087and UMUSPO/3 (Mothers Delight) laid out in completely randomized fashion (CRD) and replicated 3 times. Five kilogram of the soil sample used for the experiment was weighed into 30 plastic buckets to which 1.6 liters of water was added to irrigate to field capacity. Subsequent irrigations were carried out as specified above. Growth parameters and vine multiplication rates were assessed at 4, 8 and 12 WAP. Results of the study showed that irrigating every three days interval proved to be superior in all the parameters assessed. Delaying irrigation beyond 3 days resulted in drastic reduction in the number of branches, vine length and number of cuttings. The number of cuttings and number of branches increased significantly in the 2nd cutting. The number of cuttings of TIS 87/0087 was greater than that of UMUSPO/3. For sustainable pre-basic seed production in the study area irrigating every three days is recommended. This will not only save cost but reduce the labour involved in vine production as well as other physiological defects that might arise due to over or under irrigation

Keywords: Irrigation frequency, vine production, sweetpotato and Nigeria

Introduction
Sweetpotato (*Ipomoea batatas* (L.) Lam) is a root crop widely grown in different parts of the world. It is an important food crop in tropical and sub-tropical regions of the world, particularly in Asia, Africa, and the Pacific (Osiru *et al*., 2009; Amante and O'Sullivan, 2012). Within the African cropping systems, sweetpotato has several advantages. It produces food in a relatively short time, gives reliable yields in sub-optimal growth conditions, requires lower labour inputs (appropriate for vulnerable households) than other staples, serves as an alternative food source for urban populations facing increasing prices of cereals, and provides a potential option to reduce vitamin A deficiency (Andreas *et al*.,2009). Constraints to production of sweetpotato include pests and diseases, drought, vine scarcity, lack of capital, high labour requirements, poor yields, low prices, destruction of crops by animals, lack of land and crop rotting. Of all the highlighted problems, the third most important constraint often mentioned by farmers was the availability of vines. Vines cannot be preserved for long without losing its quality. Principal sources of vines for farmers are 46% from their previous crop, 31% from friends and neighbours and only 14% are purchased (Yanggen and Naguja, 2006). According to Nabiswa and Wesonga (2009), cuttings cannot be kept for more than seven days beyond which condition that leads to large reduction in storage root yield sets in. Sweetpotato has been reported to be sensitive to water deficits, particularly during the establishment period including vine development (Indira and Kabeerathumma, 1988). Farmers often use the same amount of water and intervals, regardless of crop species and growth stage. But excessive irrigation of soils results in water loss and significantly increases runoff (soil erosion) from production fields, enhances soil nutrient leaching which leads to contamination of the groundwater due to fertilizers and other chemical

products (Al-Jamal et al., 2001). In addition, excessive water use increases production costs, reduces yield by affecting soil aeration, and favors the occurrence and severity of diseases and pests. On the other hand, deficient irrigation promotes a reduction of sweetpotato root quantity and lower yield due to reduced leaf area and/or reduced photosynthesis per unit leaf area (Van Loon, 1981) .Therefore for sustainable sweetpotato vine availability, determining the best time and frequency of irrigation will not only make vines available to farmers but will save the cost and drudgery involved in vine production.

This study seeks to determine the effect of different irrigation frequencies on sweetpotato vine production at Umudike, southeastern Nigeria and effect of variety on sweetpotato vine production attributes.

Materials and Methods

This study was conducted at the Research Farm of National Root Crops Research Institute Umudike, Nigeria (Latitude 05^0, 29'N and Longitude 07^0, 33'E). The experiment was a 5x2 factorial laid out in completely randomized design (CRD) and replicated three times. The treatment comprises of five irrigation frequencies (daily, 2 days interval, 3 days interval, 4 days interval, and 5 days interval) and two varieties of sweetpotato (TIS 87/0087and UMUSPO/3 (Mothers Delight). The field capacity of the soil used was determined by adding known volume of water to 1kg of soil sample until saturation and collecting the excess water until draining ceased. The quantity of water retained was then deducted by subtraction. 5kg of soil was weighed into plastic buckets to which 1.6 liters of water was added to irrigate to field capacity. Two vine cuttings were planted per bucket. After initial watering before planting, subsequent irrigations were carried out based on the frequencies specified above. Growth parameters such as: number of branches was assessed at 4, 8 and 12 WAP and vine length assessed at 4 and 8 WAP only. The establishment count was done at **2**WAP and number of vine cuttings per stand at 8 and 12WAP. Data collected were subjected to analysis of variance (ANOVA) using Genstat discovery edition 4. And significant means separated using Fishers least significant differences at 5% level of probability.

Results and Discussion

Vine establishment

Irrigation frequency significantly affected the rate of establishment. Irrigating the crop daily, at 2 and at 3 days intervals gave the same rate of establishment. However, the establishment rate declined when the crop was irrigated at 4 and 5 days intervals. Varietal differences and variety by irrigation frequency interaction did not affect the rate of vine establishment.

Number of branches

The results of the effect of irrigation frequency on the number of branches at 4, 8 and 12 WAP are shown on Tables 2, 3 and 4. The results showed that no significant difference was observed on the number of branches at 4WAP. However, irrigation frequency significantly influenced number of branches at 8 and 12 WAP. Irrigating every 3 days gave the highest number of branches at both 8 and 12 sampling periods. Variety did not significantly influence mean number of branches though TIS 87/0087 had more branches than UMUSPO/3. The number of branches of each variety seems to increase across sampling periods.

Vine length (cm)

The results of the effect of irrigation frequency on the vine lenght of sweetpotato at 4 and 8WAP are presented in Tables 5 and 6. The results showed that there were no significant irrigation frequency, variety and their interaction influences on vine length at 4 WAP, while only irrigation frequency significantly affected vine length at 8WAP with irrigating every 3 days giving the highest vine length (174.9 cm) across varieties.

Number of vine cuttings

The effects of irrigation frequency, variety and their interaction on the number of cuttings per stand at 8 and 12 WAP are presented in Tables 7 and 8. The result showed that both variety and irrigation frequency significantly affected the number of cuttings at 8 and 12 WAP. Irrigating at every 3 days interval gave the highest number of cuttings at 8 WAP (6.94) and 12 WAP (11.28). Stands of variety TIS 87/0087 gave higher mean number of vine cuttings (8.69) compared to UMUSPO/3 (7.44).

Varietal differences observed in most of the parameters studied could be attributed to differences in morphology of the varieties**.** Reduction in growth parameters of the varieties when irrigated daily or two days interval could be as a result of soil Co_2 concentrations which increases with increasing soil volumetric water content and have been reported to suppresses growth and root yield of sweetpotato (Siquinbatu *et al*, 2012)**.**With this increase in water and reduction in redox potentials, toxic compounds such as soluble Fe, Mn and acids appear which reduce growth (Yabuki and Kitaya, 1984; Wegner, 2010). Reduction in vine length, number of branches and cuttings at different sampling periods when the crop was irrigated every 4 and 5 days might be due to water deficit as reported by Van Heerdeen and Laurie (2008). Sweetpotato has been reported to be sensitive to water deficit particularly during establishment phase including vine development (Indira and Kabeerathumma, 1988), This explains why delaying irrigation up to 4 and 5 days interval had significant effect on vine establishment even when vigorous and disease free planting materials were used, Likewise, excess water during stand establishment phase can lead to reduction in growth and subsequently number of cuttings per plant. According to Ravi and Saravanan (2012), water logging impedes growth by restricting availability of oxygen in the root zone.Watering daily or at 2 days interval often created water-logging scenarios at times, and this could explain the observed lower mean vine length and mean vine cuttings between the two irrigation regimes and watering at 3 days interval. It is important to note that watering daily or at two days interval had better performances than 4-5 days interval watering. This suggests that sweetpotato plants could physiologically prefer water-logging scenario than drought occurence at early plant establishment stage.

Conclusion

Irrigating every three days interval proved to be superior in all the parameters assessed. Delaying irrigation beyond 3 days will likely result in drastic reduction in the number of branches, vine length and number of vine cuttings. Varietal differences abound in the number of cuttings that could be got from a sweetpotato stand. For sustainable pre-basic seed production in the study area, irrigating every three days is recommended. This will not only save cost but reduce the labour involved in vine production as well as other physiological defects that might arise due to over or under irrigation. This result needs to be further confirmed on-field.

Abstract
A 3x2 factorial experiment was conducted at the screen house of National Root Crops Research Institute, Umudike, Nigeria (latitude 05^0, 29ʹ N and Longitude 07^0, 33ʹ E) to determine the effect of staking and non-staking on sweetpotato vine multiplication ratio. The factors were three varieties of sweetpotato (UMUSPO/1, UMUSPO/3 and TIS 87/0087) and two production methods (staking and non-staking) laid out in completely randomized design (CRD) and replicated three times. Two vine cuttings were planted per pot from which one was sampled for data collection. Growth parameters such as: number of vine branches, vine length and number of vine cuttings were assessed at 8 and 12 weeks after planting (WAP). Data collected were subjected to analysis of variance (ANOVA), while treatment means were separated using Fishers Least Significant Difference at 5% level of probability. Results of the study showed that variety significantly affected the growth parameters and number of cuttings at different sampling periods. Production method (staking and non-staking) has no significant effect on the growth parameters studied except vine length at 12 WAP which was significantly affected by staking. Generally, non-staking proved to be superior to staking in the number of cuttings produced at different cutting intervals. Variety TIS 87/0087 produced the highest number of cuttings at different cutting intervals followed by UMUSPO/3 with UMUSPO/1 producing the least.
Keywords: Staking, non-staking, vine production and sweetpotato

Introduction
Despite the fact that sweetpotato is a crucial root crop with increasing annual consumption per capita in most Sub Saharan African countries, its production is limited by shortage of planting materials. According to Low *et al.* (2009), nurseries owned by smallholder farmers are small and most of them are located at small backyard spaces or near washing areas where they are irrigated by hard water. A strategy sometimes adopted by farmers to cope with the shortage of vines is to plant only a portion of their field with available vines and when these plants are well established, vine cuttings are taken from them and used to plant the next portion (Belehu, 2003). To overcome this challenge, scientists are exploring various ways of developing simple and affordable technologies that will lead to increase in the multiplication ratio of the vine cuttings. Alam *et al*. (2016) reported that staking enhances photosynthetic activities of plants due to better exposure of the foliage to sunlight and subsequent accumulation of higher assimilates. And increased the tuber yield in Dioscorea plants compared to non-staked plants (Norman *et al., 2015*) and fruit yields of tomato and cucumber compared to the yields from non-staked stands (Alam *et al., 2016*; Soweley and Damba, 2013). In sweetpotato, Afolabi *et al*. (2013) noted that staking induced flowering and can be used to facilitate hybridization for improved hybrid seed production. However, there is limited empirical information on the effect of staking and non-staking on sweetpotato vine production and hence the need for this study

Materials and Methods
This study was conducted at the screen house of National Root Crops Research Institute, Umudike, Nigeria (latitude 05^0, 29ʹ N and Longitude 07^0 33ʹ E*).* The experiment was a 3x2 factorial arrangement laid out in completely randomized design (CRD) and replicated three times. The treatments comprised of three varieties of sweetpotato (UMUSPO/1, UMUSPO/3 and

TIS 87/0087) and two production methods (staking and non-staking). Two vine cuttings were planted per pot from which one was used for data collection. Growth parameters such as: number of branches, vine length (cm) and number of cuttings were assessed at 8 and 12 WAP. The establishment count and staking was done at **2**WAP. Data collected were subjected to analysis of variance (ANOVA) using Genstat Discovery Edition 4. Treatment means were separated using Fishers Least Significant Difference at 5% level of probability.

Results and Discussion

Number of branches

The results of the effect of staking and non-staking on the number of branches at 8 and 12wap are presented in Tables 1.The results showed that variety significantly (p<0.05) affected the number of branches at 8WAP with UMUSPO/1 having the highest number of branches (2.56) followed by TIS 87/0087 with 1.78 mean number of branches. The varieties no longer exhibited significant differences in their number of branches at 12 WAP. Production method and the interaction of production method and variety did not affect the number of branches at the different sampling periods. However, production method means ranged between 1.78 and 2.04 at 8 WAP, and 2.81 and 2.96 at 12 WAP. For production method X variety interaction means, number of vine branches ranged 1.22 - 2.67 at 8 WAP, and 1.78 - 3.44 at 12 WAP.

Vine length

Variety significantly (p<0.05) affected vine length at 8 WAP with both TIS 87/0087 (220.7 cm) and UMUSPO/3 (217.4 cm) significantly longer than the vines of UMUSPO/1 (91.3 cm) (Table 2). Both means of production method and production X variety interaction showed no significat influence on on vine length. However, at 12 WAP, variety, production method, as wel as the interaction of variety and production method significantly affected vine length (Table 2). Variety TIS 87/0087 (111.8 cm) produced the highest mean vine length, followed by UMUSPO/3 and UMUSPO/1 in that order with mean vine lengths of 74.1 and 38.4 cm, respectively. Unlike as observed at 8 WAP, mean vine length was higher in staked stands (89.9 cm) compared to non-staked plants (60.7 cm). Overall, staked vines of TIS 87/0087 gave the highest mean vine length of 146.1 cm.

Number of cuttings

At 8 and 12 WAP, only variety significantly (P<0.05) influenced mean number of vine cuttings per stand (Table 3). At 8 WAP, TIS 87/0087 had the highest mean number of cuttings (16.28), followed by UMUSPO/1 (13.94) and UMUSPO/3 (11.50). At 12 WAP, same variety, TIS 87/0087 also had the highest mean number of vine cuttings of 10.72, which was significantly (P<0.05) higher than only UMUSPO/1 with 6.94 mean cuttings. At both sampling periods, production method and production method X variety interaction had no major influence on number of vine cuttings. However, production method had mean number of vine cuttings ranged 13.85 - 13.96 at 8 WAP, and 8.81 - 8.89 at 12 WAP.

Vine length or plant height of crops varies according to cultivar characteristics or genetic make-up (Soweley and Damba, 2013).This explains the significant differences observed in the vine length and number of cuttings of the three cultivars used. The non significant differences observed in the production method could be attributed to the non-conferment of any significant advantage on photosynthesis, and by extension, assimilate production, by either of the two production methods. Generally, sweetpotato often arranges its leaves in such a manner as to expose each leaf to maximum insolation as it creeps on the ground. This prevents shading. This same effect in naturally creeping sweetpotato plants is what staking confers on it. However, one would have expected the non-staked plants to have higher vine length and number of branches as it is a more natural growth environment for sweetpotato than the staked environment.

Conclusion

Results of this study showed that different sweetpotato cultivars responded differently to staking and non-staking. The erect sweetpotato type like UMUSPO/1 does not respond to staking while the spreading types (UMUSPO/3 and TIS 87/0087) respond to staking even though there are no significant differences in the vine length and number of cuttings among the production methods. This implies that farmers can adopt any of the two methods depending on the cultivar.

Abstract
The study was carried out to determine the resistance-breaking ability of six RYMV isolates collected from the north central Nigeria. Seven rice genotypes obtained from AfricaRice Center were used for the experiment in a Split-plot design with three replications in the screenhouse at Badeggi, Niger State. The result showed that the resistant alleles - rymv1-1 and rymv1-2, were circumvented by the six virus isolates; whereas rymv1-4/rymv2 and rymv1-3 only broke down with Mararaba-Obi and Gulu isolates at 42 DAI respectively. The breakdown of resistance appeared first as hypersensitivity reaction and later (≥ 42 DAI) as symptom expressed breakdown. Rymv1-5 found in Tog 5674 was not affected by the six virus isolates in terms of symptom expression; although, saps from earlier inoculated test plants also elicited symptoms at SES score of 5 on highly susceptible Bouake 189 during back inoculation test. Virus isolates from Obubu-Ofu and Makurdi, belonging to Ser1 reacted differently and circumvented the resistance in the conventional resistant check (Gigante) with obvious yellow mottle symptoms of RYMV at 42 DAI. The result of serological profile analysis indicated that the six virus isolates belonged to Serogroups 1 and 2 (Ser1 and Ser2). The present study has reported significant differences in the aggressiveness of isolates of same serogroup, and the overall RYMV isolates existing in north central Nigeria.
Keywords: Rice yellow mottle virus, Resistance-breaking, isolates and Nigeria

Introduction
Rice yellow mottle sobemovirus is fast becoming endemic virus disease of rice in Nigeria. Baker (1974) first reported the virus in Kenya, East Africa in mid 1960s, and numerous reports of the virus have emerged from major lowland rice growing countries in Africa (Kouassi *et al*., 2005). In Nigeria RYMV has been reported virtually in all rice growing areas in the country. The virus has been reported in rice fields at tillering and panicle initiation stages in Niger, Kano, Bauchi, Gombe, and Benue States in the north-central zone of Nigeria between 2000 and 2008 (Abo *et al*., 2002; Onwughalu *et al*., 2009). The disease survey in five southwest states of Nigeria, indicated disease incidence of 15 – 70% on farmer's fields in Lagos, Oyo, Ogun, Ekiti and Ondo States (Onasanya *et al*., 2011). Singh *et al*. (1997) also reported the disease in Akwa-Ibom, Ebonyi and Sokoto States; whereas Alegbejo *et al*. (2006) reported the virus disease incidence in Zamfara State. Moreover, the rice-leaf samples from the southeastern states of Delta, Imo and Anambra were earlier found with the virus (Awoderu, 1991). There are other reports of RYMV incidence on farmers' fields in the Northern Nigeria (Abo, 2010; Alkali *et al*., 2014); and the serogroups commonly reported like in other west African countries are the Ser 1, 2 and 3 (Fargette *et al*., 2002; Kanyeka *et al*., 2007). The characteristic symptoms of RYMV include yellow mottles, height reduction, spikelets' sterility; and in severely infected plants, dispersed and bunchy tiller formation may occur with orange coloration (Onwughalu *et al*., 2017). The top management strategies for RYMV in the field include good farm sanitation to eliminate weed hosts and vectors; and also, maintaining clean working implements. Other approaches involving cultural manipulations are also being adopted in an integrated management system. Earlier studies have identified RYMV resistance in traditional *Oryza glaberrima* subspecies, especially the cultivars Tog 5681, Tog 5672, and Tog 5675 (Ndijiondjop *et al.*, 1999; Traore *et al.*, 2006). N'Guessan *et al.*

(2001) reported negligible yield losses with the resistant cultivars Gigante and Tog 5675, when challenged with 15 isolates of RYMV in field condition. However, in the early and mid-2000s', reports of resistance breaking isolates of RYMV have emerged in some countries of Africa (Fargette *et al*., 2002; Hebrard *et al*., 2006; Traore *et al*., 2006); hence, the growing concern is the challenge that this might pose to the development of durable resistance to RYMV in the region. It is therefore necessary to identify, characterize and determine the resistance-breaking ability of RYMV isolates commonly found in Nigeria.

Materials and Methods

The experiment was conducted in a screenhouse at NCRI, Badeggi in 2016. The rice genotypes used – TOG 5681, TOG 5674, TOG 5672, IR 64, BG 90-2, Bouake 189 and Gigante, were obtained from the genetic resource unit of AfricaRice Center, Benin. Genes for resistance found with these rice genotypes were given as follows: IR 64 (rymv 1-1), Tog 5681 (rymv 1-3), Tog 5672 (rymv 1-4 & rymv 2), Tog 5674 (rymv 1-5) and Gigante (rymv 1-2) (Ndjiondjop *et al*., 1999; Silue Drissa, personal communication). The experiment was laid out in a Split-plot design, with virus isolates (RYMV) and rice genotypes constituted the two factors A (Main-Plot) and B (Sub-Plot). The levels of factor A (RYMV isolates) included a control (i.e. pure distilled water). The level of Factor B (Rice genotypes) included Bouake 189, which was used as a susceptible check, and Gigante (resistant check). The 7 x 7 factorial composed of 49 experimental units, which was replicated three times. Fresh leaves extracts from each disease isolate earlier multiplied on Bouake 189, were harvested, crushed and the sap obtained was finger-rubbed on test plants when plants were 5 weeks old (35 DAP). Carborundum (600 mesh) was added to extracts to aid virus penetration to test plants. For the control, only pure distilled water with an abrasive (carborundum) was used to rub on the plants. Visual assessment and scoring for RYMV symptom expression was done at 14, 28 and 42 Days After Inoculation (DAI) following the SES (1 – 9) score for rice at 35 DAI according to IRRI (1996). Disease severity and other agronomic data were determined following Salaudeen *et al*. and Michel *et al*. (2008). Data analysis was done using Cropstat Windows Version 7.2 (IRRI, 2007), and significant differences between means were determined using Fishers Least Significant Difference Test at 1 and 5 % probability levels.

Results and Discussion

The result of serological analysis using TAS-ELISA, and the characterization of the six RYMV isolates indicated that four isolates from Obubu-Ofu (Kogi State), Wuya (Niger State), Makurdi (Benue State) and Mararaba-Obi (Nasarawa State), belonged to Ser1, while isolates from Edozhigi (Niger State) and Gulu (Niger State) belonged to Ser2 (Table 1). The identification of Ser1 and Ser2 in the four north-central states is in agreement with earlier reports that these serotypes are common in West African Countries (Fargette *et al*., 2002; Kanyeka *et al*., 2007). The result of Table 2 showed that disease severity increased progressively on the susceptible rice genotype (Bouake 189) from 14 Days after inoculation (DAI); whereas the *O. indica* cv Gigante infection trend indicated a slow disease development at early infection stage, which peaked at 42 DAI (Table 2). The breakdown of resistance among resistant genotypes was observed in early infection stage as hypersensitive reaction and later (≥ 42 DAI), as either clear mottle symptoms (Gigante) or symptom of localized infection (Tog 5681 and Tog 5672) at 42 DAI. The report of symptom expression on Gigante by Makurdi and Obubu-Ofu isolates in the present study, and virus disease severity (%) of 6.22 – 7.43% based on SES score at 42 DAI recorded on Tog 5681 and Tog 5672 with Gulu and Mararaba-Obi isolates are also indications of virus pathogenicity, and ability of virus strains reacting differently on different cultivars. Ochola and Tusiime (2011) had reported no significant differences in aggressiveness between islolates of RYMV in eastern Uganda. The expression of yellow mottle symptom on the resistant Gigante subspecies in the present study shows that the resistant alleles - rymv1-1 and rymv1-2, were circumvented by the six virus isolates; whereas rymv1-4/rymv2 (Tog5672) and rymv1-3 only broke down with Mararaba-Obi and Gulu isolates at 42 DAI respectively. Rymv1-5 found in Tog 5674 was not affected by the six virus isolates, but sap extract from the plant elicited characteristic symptoms of RYMV at SES score of 5 on highly susceptible Bouake 189 during back inoculation test (Table 2). Plant yield (g) at harvest was significantly low on the susceptible genotype (Bouake 189), which produced zero yield with Gulu, Makurdi and Edozhigi isolates. Plant yield (g) also varied significantly (P = 0.01) across the levels of virus isolates inoculation on Tog 5674, Tog 5672 and Tog 5681 at harvest (Figure 1). The result also indicated yield losses (%) at harvest (up to 100%)

in the highly susceptible Bouake 189 due to virus inoculation with Gulu, Makurdi and Edozhigi isolates. Moreover, virus isolates from Makurdi and Obubu-Ofu, belonging to S1 strains reacted differently and circumvented the resistance in Gigante, producing obvious mottling symptoms of RYMV in an artificial condition.

Conclusion

The present study has reported significant differences in the aggressiveness of isolates of RYMV isolates existing in north-central Nigeria, and confirmed the resistance breakdown in the conventional resistant Gigante subspecies. Rymv1-5 found in Tog 5674 was not affected by the six virus isolates, but sap extract from the plant elicited characteristic symptoms of RYMV at SES score of 5 on highly susceptible Bouake 189 during back inoculation test.

Abstract

Plant tissue analysis of Zea mays was conducted at Yaba College of Technology, Epe Campus (Southwestern Nigeria) during 2017 cropping season. The experiment was a Randomized Complete Block Design(RCBD) with 4 replicates covering different locations of the campus. The maize crop was evaluated for its proximately and mineral composition after maturity. Data obtained were analyzed using Analysis of variance (ANOVA) and treatment means were separated using Duncan multiple range test(DMRT). Result indicated increased values for macro nutrients such as potassium (150-125%), sodium (40-28%), calcium (32-25%), and magnesium(8-6%) as well as micronutrient such as zinc (21-19%), while micronutrients including iron (4-3%), copper (1.3-8.84%) and manganese (0.13-0.05%) were significantly low. Proximate composition revealed that carbohydrates has the highest component (46.63%). Followed by ash (22.06%), protein (17.26%), moisture content (10.34%), and crude fibre(6.15%), while the lowest component was fat (4.95%). Thus, effort aimed at obtaining high yield of maize would necessitate the augmentation of nutrient status of the soil particularly micronutrients to meet the crop requirement for optimum productivity and maintaining soil fertility with the use of organic or inorganic materials.
Keywords: Plant tissue analysis, Zea mays, Proximate and mineral composition

Introduction

In Nigeria, maize (*Zea mays*) is a major cereal crop for human nutrition, livestock feed and raw materials for industries. It is primarily an energy giving food because of its high starch content. It is grown either as mono or mixed crop in the backyard garden, as a field or plantation crop. It is Nigeria's third most important cereal crop after sorghum and millet (FAO, 1996). Maize is an important cereal crop due to its high yielding, ease of processing, readily digested and cost less than other cereals (Jaliya et. al. 2008) and therefore, it will continue to play a large and important role in Nigeria food production. Nweke and Nsoanya (2013) observed that, maize cultivation has immense potential in the tropics and yield of 7.5 tonnes per hectare can be obtained if the crop is properly managed. Unfortunately, yield are still below 5 tonnes per hectare (FAO, 2007) and this has caused inadequacy of maize production. One of the major problems associated with maize in tropical ecology is poor soil fertility. This is due to intensive cropping system, which has now become a characteristicfeatures of Nigeria arable agriculture. This practice depleted the soil nutrient over short period of time as a result of continuous cropping on a particular land. Maize is an exhaustive crop and has a very high nutrient requirement (Nweke and Nsoanya, 2013). It fails to provide good grain in plots without adequate nutrients (Adediran and Banjoko, 2003) and therefore productivity depends on nutrients management. The removal of nutrients from the soil by crop harvest has to be balanced by the addition of manure (Ofusu-Amin et. al. 2006). One of the method by which nutrient status of the soil can be determined for soil nutrient management is by plant tissue analysis. It is used to confirm suspected nutrient deficiencies after visual symptoms has been observed and uncover potential problems. It is complimentary to soil testing and thus reference concentration of mineral nutrients in a specific part are established and used to the well-being of the plant and effectiveness of the soil fertility programme (Uponi and Adeoye, 2000).*Zea mays* is used in this study (plant tissue analysis) due to its nutritional and industrial potential in Nigeria. However, Omofunmi*et al*, (2017) carried out assessment of land suitability for crop production and irrigation in the study area. This present work therefore corroborates the effort of Omofunmi*et al*, (2017). The information provided would help to correct nutrient problems and monitor the effectiveness of soil fertilityprogramme and ascertain the nutrient status of the soil in the study area.

Materials and Methods

Field work: The experiment was carried out at Yaba College of Technology (YABATECH), Epe Campus at 4 different locations (North, South, East and West of the campus) in March and May, 2017. The Polytechnic is located at km 16 along Epe-Ijebu Ode road, Odoragushin in Epe Local Government Area of Lagos State (06^{o} 47^{o}N and 03^{o} 58^{o}E). Epe lies in lowland rain forest vegetation with bimodal rainfall pattern between April and October while dry season is between November and March. The plot size was 3 meters by 4 meters(12meter square). The soils were tilled after marking out the site into plots. The maize seeds (TMRS6) used were improved variety obtained from Lagos state Agricultural Input Supply Company, Epe depot. They were planted at two seeds per hole at a depth of 2 centimeters deep spaced at 75 centimeter by 25 centimeter and were laid out in a randomize complete block design with four replications. Cultural operations such as watering (in the morning and evening prior to rainfall) and manual weeding at 4 and 8 weeks after planting) were carried out to ensure good growth of maize. Harvesting was done manually at 12 weeks after planting.

Laboratory work (Proximate and mineral analysis of sampled *Zea mays*): 5 plants from each plots were randomly selected from the harvested *Zea mays* for laboratory analysis. The roots were carefully washed with running water, air dried, grinded manually with porcelain mortar and pestle and milled to pass through 0.5mm sieve, stored in plastic bottles and labeled appropriately and thereafter analyzed in triplicate for its proximate analysis following the method of Association of Analytical Chemist (2012). For moisture (using auto moisture analyzer model ML-50), ash (using carbolite model), protein (kjeldahl digestion and steam distillation method with model KJELTEC 8200), fibre (using FIBRETEC hot/hydrolysis unit, model 1020) and fat (using Soxtec Extraction System, Soxtec model 2005). Protein content was obtained by multiplying the Nitrogen value by a factor of 6.25 (kjeldahl Nitrogen) while available carbohydrate (Nitrogen Free Extract) was calculated using differentiation method. To determine the mineral composition of *Zea mays,* the mineral content was determined by digestion and wet oxidation methods (Association of Analytical Chemist, 2012) using $HCLO_3/HNO_3/H_2SO_4$ mixture. Sodium and Potassium was assayed by flame photometry (Model AAS 200A, Busch Scientific). Calcium and Magnesium was determined by Atomic Absorption Spectrophotometry (AAS) while Phosphorus was determined by Colorimetric Spectrophotometer using Vanadomolybdate reagent. Nitrogen in the digestion was evaluated using auto analyzer.

Data analysis

Data were subjected to analysis of variance with SAS Software (2001). Significant means separated using Duncan Multiple Range Test (DMRT) statistics.

Results and Discussion

Table 1 summarizes the result of proximate composition of the maize seeds.

Carbohydrate*:Zea mays* have higher proximate value for carbohydrate (46.63%) followed by ash(22.06%),protein(17.26%),moisture(10.34%),crude fibre (6.15%) and fat(4.95%).Carbohydrates are the major chemical component of the maize grain. This notion is in agreement with Ijabadeniyi and Adebolu(2005). which reported 65.63-70.23% of the carbohydrate content for the maize varieties grown in Nigeria.Ikram et.al (2010)also reported higher carbohydrate content(69.65-74.54%)for maize in Pakistan.

Ash: It can be defined as the quantity of mineral matter which after application remains as incombustible residue of the tested substances (Ikram, 2010).The second largest chemical component of the kernel is ash(22.06-18.70%).Percentage content of different maize varieties were found in the range of 1.3 and 1.20% by Ikram(2010)which is lower than the present study.Thus,the grain with high ash (as in this study) contained a greater proportion of non-endosperm material (Ikram, 2010).Hence,Evers (2011) opined that ash values are determined in order to indicate the level to which non-endosperm components are present.

%Protein: Percentage protein were in the range of 17.26 and 13.84% and is the third largest chemical present in the maize grains after carbohydrate and ash.Ijabadeniyi and Adebolu(2005)found the percentage of protein content of three maize varieties in the range of 10.67-11.27% which were lower than the result of the present study. According to

Ikramet.al(2010),maize kernel contains albumin,globulin,prolamins and glutelins with two types of storage protein predominant in the seed, the embryo contains globulin and the endosperm(the major site of storage protein accumulation)contains predominantly prolamins,the so called zein fraction.

%Moisture content: Values for seed moisture content were determined in the range of 10.34-8.78% and was the fourth largest chemical found in kernel.Ikram et.al(2010)found the moisture value between 10.98 and 9.20%,which is in close agreement with this present study.

% Crude fibre: This was the fifth largest chemical component found in the range of 6.15-4.80%.Ijabadeniyi and Adebolu(2005) showed percentage crude fibre of maize varieties grown in Nigeria between 2.07-2.77% and that of Ikram et.al(2010) between 0.80-2.32% in Pakistan which are lower values compared with result of the present study.

%Fat: The level of fat were found between 4.95 and 3.87% which is in close consistent withthe Ijabadeniyi and Adebolu(2005) which reported percentage fat between 4.77 to 5.77% for the grains.

Table 1: Proximate composition (mg/100g) of *Zeamays* harvested from experimental plots at YABATECH

Sample	Moisture	Ash	Fat	Protein	Crude Fibre	Carbohydrate
A (North Location)	10.34±0.08^{a}	20.16±0.03^{b}	3.87±0.01^{c}	13.84±0.06^{b}	6.15±0.07^{a}	45.65±0.12^{a}

Values represent the Mean ± SEM. The value with the different letters in a column are significantly different from one another @ ($p<0.05$) according to DMRT

The mineral composition of the plant tissue analysis of the maize is shown on table 2.Presence of minerals in hierarchical order are K(between 150-125%),Na(between 40-28%),Ca(between 32-25%),Zn(between 21-19%),Mg(between 8-6%),Fe(between 4-3%),Cu(between 1.3-0.84%) and Mn (0.13-0.05%).Thus, the concentration of potassium was the highest while Manganese was the lowest.This confirmed the result of Omofunmi*et al,* (2017) which revealed that macro-nutrients such as K,Ca,Na,Mg are adequate while micro-nutrients such as Fe,Cu and Mn are also present but significantly low in the soil of Yaba College of Technology,Epe Campus.Thus,effort aimed at obtaining high yield of maize would necessitate the augmentation of nutrient status of the soil to meet the crops requirement for optimum productivity and maintaining soil fertility. Increasing the nutrients status of the soil may be achieved by boosting the soil nutrient content with the use of inorganic fertilizer or the use of organic materials.(Agba et.al.2012).The maize requires an adequate supply of nutrients particularly N.P.K for optimum growth and yield. The most important micro-nutrients particularly in the savannah zone and under continuous cropping in the forest ecology are Sulphur,Zinc and Magnesium (Iken and Amusa,2004).

Table 2: Minerals composition of *Zea mays*harvested from experimental plots at Yaba College of Technology, Epe Campus

Sample	Mg	Ca	Na	K	Fe	Mn	Cu	Zn
A (North Location)	8.77±0.21^{a}	28.80±1.07^{b}	32.85±0.35^{a}	150.52±0.18^{b}	4.59±0.05^{d}	0.13±0.01^{a}	1.33±0.04^{b}	19.12±90^{c}
B (South Location)	8.12±0.08^{a}	25.44±0.30^{c}	40.33±0.35^{b}	135.16±0.23^{a}	4.08±0.05^{c}	0.08±0.01^{b}	1.04±0.04^{c}	15.19±0.72^{b}
C (East Location)	6.96±0.12^{b}	32.72±0.46^{d}	28.52±0.35^{c}	125.72±0.23^{d}	3.78±0.05^{b}	0.05±0.00^{c}	1.16±0.06^{d}	21.27±0.71^{c}
D (West Location)	6.21±0.011^{d}	26.74±0.31^{a}	35.64±0.29^{d}	140.75±0.18^{c}	3.42±0.05^{a}	0.09±0.01^{b}	0.84±0.04^{a}	16.97±0.36^{d}

Values represent the Mean ± SEM. The values with the different letters in a column are significantly different from one another ($P<0.05$).According to (DMRT).

Conclusion

Finding in this study have shown the proximate composition of *Zea mays*has havingcarbohydrate asthe highest value while fat is significantly low compared to other nutrients.The study also shown that the mineral content of the soil are higher in K,Na, Ca,Zn and lower in Mg, Fe, Cu and Mn. Therefore, this result will be useful in providing information about the nutritional properties of the soils of Yaba College of Technology,Epe Campus and may guide us in designing strategies that maximize the utility and production of different crops. It is therefore, recommended that the result of soil survey and analysis by Ibrahim et.al.(2013) and the result of this study (Plant tissue analysis) be strictly adhered to and areas that needs to be augmented by fertilizing and manuring should be done, because fertilizer add nutrient to the soil which are lacking in it and adopting a good fertilizer programme is a major way of improving yield in crops, and as such the optimum dose that gives the highest earning on the investment must be used.

Abstract
An experiment on the influence of crop establishment methods and weeding regimes on the yield and yield components of hungry rice (D. exilis) was carried out during the cropping season of 2016 and 2017 at the research field of the National Cereals Research Institute, Badeggi (Lat. 9^o 45^1 N and Long 6^o 97^1 E). The treatments consisted of two crop establishment methods (broadcasting and drilling at 30cm inter-row spacing and four weeding regimes (weeding once (w_1), weeding twice (W_2), weeding thrice (W_3) and a weedy check (w_o). A split-plot design was used such that crop establishment methods were allocated to the main plots and weeding regimes were assigned to the sub-plots. The experiment was replicated four times. The land was prepared manually but ensured to be leveled properly. The plot size was 3.0m x 4.0m leaving a distance of 1.0m between replications and 0.5m between plots as alleyways. Hungry rice (Vakahal (Local) accession was used. Fertilizer (NPK 15:15:15) was used to supply 30kg N ha^{-1}, 30kg $P_2O_5gha^{-1}$ and 30kg K_20 ha^{-1} basal. Weed management was by manual hand pulling of weeds 4 weeks after sowing (WAS). Data taken include number of tillers, plant height, length of spikes and grain yield respectively. Results showed that drilling method of sowing produced more tillers, taller plants and higher grain yield in both years compared to broadcasting method. While crop establishment methods had no significant influence on length of spikes in both years of experimentation. Among the weeding regime treatments, weeding thrice had significantly higher tillers, plant height and grain yield over the other treatments in both years. From this study, the best method of sowing hungry rice (D. exilis) is by drilling and weeding thrice.
Key words: Digitaria exilis, crop establishment, hungry rice, sowing methods and weeding regime

Introduction
At this time of climate change and its influence on Food Security and Insecurity, many people in the dry environments of Nigeria and Africa will depend on cereals that are grown in drought water stress and marginal environments such as millet, sorghum and finger-millet, among other dry land crops (CGIAR, 2002). The poor rural farmers whose major occupation is still farming require crops of low input demand and can also give appreciable and stable yields on their poor environments. Hungry rice (*D. exilis*) is an important candidate crop for food security in West Africa and is assuming greater importance in the context of changing climate and increasing demand or highly nutritious food with low cost of input (Animasaun *et al.,* (2014). Hungry rice (*D. exilis*) has high potentials for fighting hunger in the Sub-Saharan Africa (Vietmeyer *et al.,* 1996). The crop is grown as human food and as forage (Aliero and Murakinyo, 2001) in the Savanna Zones of West Africa and also as a staple. The crop is traditional, well adopted to local conditions and possesses good nutritional culinary properties (Cruz, 2004). The tiny grain of hungry rice (D. exilis) can be used to make tuwo, couscous, porridge, malt drinks, in pharmaceutical industries as a binder in the production of Paracetamol (Musa *et al.,* 2008), good for human health, recommended for people with diet challenges. It is reported that dishes of hungry rice (*D. exilis*) show higher preference than those of rice, millet maize, among growers (Cruz, 2004). The production of hungry rice (*D. exilis*) in Nigeria and elsewhere is faced with a number of problems such as weed control, seeding rate, establishment methods, small seed size,

low yield and its post-harvest transformation (Ukwungwu *et al., 2003*; Dachi, 2014). Hungry rice (*D. exilis*) has the potential of producing higher grain yield with good agronomic practices such as appropriate establishment method, seed rate and proper weed control. Few studies have been conducted as regards appropriate establishment method and weeding regime in hungry rice (*D. exilis*). The objective of this study was to obtain the best establishment method and weeding regime for growth yield and yield components of hungry rice (*D. exilis*).

Materials and Methods

The experiment was conducted at the National Cereals Research Institute, Badeggi (Lat. 9^0 45^1 N and Lon. 6^0 07 E) during 2016 and 2017 cropping season. The soil of the site was sandy loam. The treatments consisted of two crop establishment methods (broadcasting and drilling at 30cm inter-row spacing) and four weeding regimes (weeding once (W_1), weeding twice (W_2), weeding thrice (W_3) and a weedy check (w_o). The experimental design was a split-plot with four replications. Establishment methods were allocated to the main plots and weeding regimes to the sub-plot. Plot size was 3.0m x 4.0m. Hungry rice (D. exilis) Vakahal accession (local) was sown by broadcasting and drilling into each of the plots. Weed weeding regime was carried out according to treatments by manual hand pulling of weeds. Basal fertilizer application of 30kg N ha^{-1}, 30kg $P_20_5ha^{-1}$ and 30kg K_20ha^{-1} using NPK 15:15:15 fertilizer, source. Data were taken on number of tillers, plant height, leaf area, length of spikes and grain yield. The data were subjected to analysis of variance and treatment effects were compared using least significant difference at 0.5 percent level of probability.

Results and Discussion

The influences of crop establishment methods and weeding regimes had significant effects on number of tillers and plant height in both years of studies. Significantly higher number of tillers, and plant height were produced in drilling method of sowing and weed free (w_3) than broadcasting method and no weeding (w_o). The increase in these parameters recorded in drilling method of sowing and weed free (w_3) conditions than in broadcasting method and no weeding conditions (w_o) could be attributed to better micro environment in the drilling method of sowing and weed free conditions compared to those in broadcasting method and no weeding (w_o) conditions. Also, the better crop stand establishment in drilling method of sowing and weed free (w_o) conditions might have been responsible for the increase in number of tillers and plant height due to less competition for growth factors (Tables 1 and 2). This finding is in line with Dachi (2014) and Mondal *et al*., (2013) who reported similar results in drilling method of sowing than in broadcasting in acha (*D. exilis*) and weed free (w_o) in Aus rice respectively. In both years, crop establishment methods had no significant influence on length of spikes. This might be due to genetic factor of the crop (Table 3). Crop establishment methods and weeding regimes had significant influence on grain yield in both years. The highest grain yields were found in drilling method of sowing and weed free (W_3), followed by weeding twice (W_2) in both years and the lowest grain yields were recorded from broadcasting method of sowing and no weeding (W_0) condition (Table 4). This could be attributed to the fact that in drilling method of sowing and weed free (W_3) conditions, plants got higher nutrients, light, water and less competition from weeds which resulted in higher grain yields. The obtained result is in close agreement with Dachi (2014) and Mondel *et al*, (2013) who reported highest grain yields in drilling method of sowing in acha (D. exilis) and weed free (W_3) condition in AUS rice respectively (Table 4).

Conclusion

From the result of this study, it is conclusion is that drilling method of sowing and weeding thrice are best for acha (D. exilis) production at Badeggi, Nigeria.

ASN 52nd Annual Conference Proceedings

Effect of Garden Egg Population on Growth and Yield of Component Crops in Sweetpotato/ Garden Egg Intercropping System in South Eastern Nigeria

[1]C.N. Ebeniro, [2]C.O. Muoneke, and [2]D.A. Okpara
[1]National Root Crops Research Institute, Umudike, Abia State, Nigeria
[2]Department of Agronomy, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
christyebeniro@yahoo.com

Abstract
The experiment was conducted at Umudike (latitude 05° 29' N, longitude 07°33' E) in 2014 to determine the effects of garden egg (Solanum gilo) population on growth and yield of sweetpotato /eggplant intercrop. Four populations of eggplant 10,000, 20,000, 30,000 and 40,000 plants/ha were intercropped with two varieties of sweetpotato (Umuspo 1 and TIS 87/0087), and sweetpotato planted at spacing of 1m x 0.30m in randomized complete block design. Data on plant height, leaf number, and branch number for garden egg; and vine length, leaf number and branch number for sweetpotato were taken at 8 and 10 WAP. Sweetpotato roots yield was assessed at 16 WAP. The yield of garden egg fruits was sum from 60 to 90 DAP. The results showed that intercropping significantly reduced growth and yield attributes of both plants as the population increases from 10000 plants/ha to 40000 plants/ha. The yields of sole crops were higher than individual crops in the intercrop. Garden egg at 10,000 plants/ha + sweetpotato at 33,333 plants were significantly better than other populations. Land equivalent ratio of intercrops were above unity, and gross monetary returns were higher in intercropping than sole implying that there were higher productivity in intercropping which means that farmers can make more income by intercropping.

Introduction
Intercropping is an agricultural practice of growing two or more crops simultaneously on the same field during a growing season in definite pattern or arrangements (Francis, 1989, Filho, 2000). It is a scientific application of mixed cropping in terms of crop spacing, time of planting and quantity and quality of fertilizer application (Muoneke, 2017). Sweetpotato, *Ipomoea batatas* (L.) Lam) is one of the world's most widely grown and variable crops, and farmers in more than 100 countries rely on its ability to produce high yield in marginal soil with little investment (Horton *et al*, 1989). It is used for poverty alleviation and food security due to its high productivity per unit land area and time which makes it a crop for the survival of resource poor farmers in Nigeria. Garden egg *Solanum gilo* (L.) is a small-size dessert fruit type, fruit vegetable that belongs to the Solanaceae family of flowering plants. It is also an important crop grown in Nigeria for both its leaves and fruits which has cultural, social and economic importance. Both sweetpotato and garden egg feature prominently in the cropping systems in many agricultural zones of Nigeria. They may be grown as monocrops or intercrops but mixed cropping or intercropping is the predominant cropping system (Ekwere *et al*., 2009).
Optimum plant population ensures crop growth, development and yield. Maximum productivity in intercropping could be obtained when inter and intra specific crop competition are minimal for growth limiting factors and the density of each crop adjusted to minimize competition (Okpara *et al*., 2004). Over population results in excessive plant competition for production factors which could reduce the overall productivity of the crop and under populations reduce potential crop yield per unit area (Hector, 2010). Generally, high yields per unit area are obtained from high populations because of maximum use of light, although the performances of the individual plants decrease. Therefore the objective of study was to determine the effect of garden egg (GE) population on growth and yield of component crops in sweetpotato/garden egg intercropping system.

Materials and Methods

The field experiment was carried out at the National Root Crops Research Institute, (NRCRI), Umudike experimental field during the 2014 cropping season. Umudike is located on longitude 07˚ 33 E and latitude 05˚ 29 N and at an elevation of 122 m above sea level in the rainforest agro-ecological zone of Nigeria. The experimental field was cleared, ploughed, harrowed and ridged in May. The experiment was laid out in factorial arrangement using randomized complete block design (RCBD) and replicated three times. The plant population for the two sweetpotato varieties (TIS 087/0087 and Umuspo 1) were 33,333 plants/hectare while the populations for garden egg were 10,000, 20,000, 30,000 and 40,000 plants/ha. Data were collected on vine length, number of leaves and branches for sweetpotato while for garden egg height, number of leaves and branches at 8 WAP and 10 WAP. Sweetpotato roots yield was assessed at 16 WAP. The yield of garden egg fruits was sum from 60 to 90 DAP. Data collected from the crops in the field experiment were subjected to analysis of variance according Genstat Discovery Edition 1 and means compared using Fisher's least significance difference (LSD) at 5% level of probability.

Results and Discussion

The results showed that intercropping significantly reduced sweetpotato vine length, number of leaves and number of branches. Vines were longer in sole than intercropping at 8 WAP and 10 WAP (weeks after planting). TIS 087/0087 vines were longer than Umuspo 1 while Umuspo 1 had higher of leaves than TIS 87/0087. Sweetpotato varieties did affected plant vine length, number of leaves and number of branches of sweetpotato. Garden egg height, number of leaves and number of branches were reduced by cropping system. Increase in garden egg population significantly decreased vine length, number of leaves and number of branches (Tables 1 and 2). Garden egg population reduced plant height, number of leaves and number of branches at 8 WAP and 10 WAP as the population increased from 10,000 plants/ha to 40,000 plants/ha. There was no interaction between the cropping system X sweetpotato varieties and sweetpotato X garden egg population. The yields of sole crops were higher than individual crops in the intercrop; this finding is in agreement with the report of (Arubalueze, 2016) on cassava and cowpea intercrop. Cropping system significantly reduced weight of root/plant and root weight/ha which agreed with (Njoku *et al.*, 2010). Garden egg at 10,000 and sweetpotato populations at 33,333 plants/ha were better than other populations. In crop mixtures plant population should be adjusted to avoid over crowding. Abolhassan, (2005) reported that high plant density results in excessive plant competition for production factors which could reduce the overall productivity of the crop. In higher population, low fruit yield of garden egg were obtained, which could be as a result of higher intra specific competition for growth resources like light, water, soil nutrient by high population (Amih, 2013). Land equivalent ratio of intercrops were above unity, and gross monetary returns were higher in intercropping than sole implying that there were higher productivity in intercropping. Farmers can make more income by intercropping. The higher productivity per unit area due to intercropping over sole in all the populations confirmed the works of Muoneke and Mbah, 2007 and Ekwere *et al*., 2009). For maximum productivity, planting sweetpotato at 33,333 + garden egg at10,000 plants/ha should be practiced by farmers.

Abstract
Limiting water availability is one of the major factors that affect the productivity in crop plants. Generally plants manage to survive water deficit to a certain extent either by morphological or physiological modifications that enable them to avoid or postpone desiccation stress. Hevea brasiliensis is a tropical tree crop that is valued for its latex. The latex is referred to as natural rubber. Demand for natural rubber is expected to increase once more with increasing crude oil price and automotive industry in several countries. Ten clones of Para rubber in Nigeria were evaluated for adaptability to water stress. The clones were obtained from Rubber Research Institute of Nigeria Iyanomo, Benin City Edo State and evaluated at the research farm of National Root Crop Research Institute Umudike, Abia State using fresh and dry weight of whole plant and root as indices for adaptability. Among the various growth and productivity limiting factors, the negative impact of drought on root growth has been well established in different Hevea clones.

Introduction
The rubber tree is a native of the Amazonian rainforest of South America. Rubber tree *(Hevea brasiliensis* Muell. Arg.) is the only commercial source of natural rubber and the species is well suited to the equatorial region with plenty of well distributed rainfall of 1800-2000mm per year and minimum fluctuations in temperature (Pires *et al.,* 2002). With increasing global demand for natural rubber, attempts have been made to extend the cultivation of this tree crop to agro-climatically marginal lands such as drought and cold prone areas Nair *et al.* (2010). The crop does not perform well if there is a long dry season. It also does badly if the climate is excessively humid, as this encourages leaf diseases. The rubber tree can tolerate a wide range of soil conditions from sandy to loamy soils provided the soils are deep, fertile, well drained and slightly acidic with a soil p^h of 4-8 or 4-6. The rubber tree is a perennial and deciduous crop with an economics life span of 25-30 years. But the very narrow genetic base of the cultivated *Hevea* resulted from the development of the species from a limited number of seeds introduced by Sir Henry Wickham, limits the scope of extending the clone to such marginal areas. A broad genetic base is a prerequisite for developing new genotypes tolerant to various stress conditions. Plant genetic resources provide the requisite genetic variability and are the most important and vulnerable basic materials to meet the current and future needs of plant breeding programmes Gonçalves *et al.* (2006). The wild germplasm accessions collected by an expedition of International Rubber Research and Development Board (IRRDB) during 1981, into the primary centre of origin of the crop, the Amazon forests provide a rich source of natural variability in this tree species. Introduction of genes from such wild progenitors is an ideal method of broadening the genetic base of cultivated *Hevea* species (Omokhafe and Alika, 2003). The objective of this study was to evaluate *hevea* clones that will adapt to water stress.

Materials and Methods
Hevea genotypes used in this evaluation were sourced from Rubber Research Institute of Nigeria, Iyanomo, Benin City, Edo State. The experiment was conducted at the research farm of the National Root Crops Research Institute (NRCRI), Umudike (latitude 05^0, 29'N; longitude 07^0,

33'E) in 2013 planting season. Umudike is in the tropics and has a total rainfall of about 2177 mm per annum with an average temperature of about 26^{0}C. The predominant vegetation type is rain forest (NEST, 1991), while the soil has been classified as sandy loam ultisol (Agboola, 1979). Climatic conditions during the period of this research work are shown in Table 2. Soil samples were collected at the experimental site using soil auger at a depth of 0-15cm and was analyzed for its physico-chemical properties in the National Root Crops Research Institute Laboratory. The genotypes used were: RRIM 600, NIG 800, NIG 801, NIG 802, NIG 803, NIG 804, PR 107, RRIM 628, GT I, and PB 5/51. Sprouted seedlings were transplanted to the main nursery at one month old on October, 10, 2013 in a randomized complete block design (RCBD) with three replications. Each plot size was 6m^2 (3 x 2m) with 1m apart and contained 30 plants spaced 30cm within and 1m between the rows to give a seedling population of 33,333 seedlings per hectare. The seedlings were watered twice daily (morning and evening) during the dry spell, about three to four manual weeding were done to keep the field weed free. Data on each stand were taken as follows: Weight of whole plant was taken by uprooting the plant at 40 days after exposure to drought stress, taking the fresh weight after uprooting and the dry weight after 7 days of sun drying using sensitive weighing balance (Model 333, manufactured by Acculab Electronic Digital Scale). Weight of root was also taken by cutting off the root of the uprooted plant, washing off the sand, fresh and dry weight were taken at 40 days after subjection to drought stress and at 7 days after sun drying respectively.
Data collected were summarized and subjected to statistical analysis using SAS software (SAS 1998)

Results and Discussion

Soil Physico-chemical Properties of the Experimental sites
The result of the soil analysis of the experimental site for the year 2013 is presented on Table 1. The soil texture of the site was sandy loam with sand, silt and clay having the proportions of 71%, 17.5% and 11.5%. The soils were moderately acidic with pH of 4.35. The percentage organic carbon was 0.95; total percentage nitrogen was very low 0.12. Extractable phosphorus was moderate 43.6 mg/kg while exchangeable potassium was found to be very low.

Table 1: Soil physico-chemical properties of the experimental site in 2013

The result of average monthly rainfall at the experimental site in 2013 is presented on table 2. Average monthly rainfall ranged from75.0 to 466.1mm in 2013. The total rainfall in 2013 was 2210 with a mean monthly rainfall of 184.17mm. In 2013 average monthly rainfall was highest in May with 466.1mm. There was no rainfall in January and February 2014.

Fresh and Dry Weight of Whole Plant and Roots

The fresh weight of the whole plant and fresh weight of roots of each genotype at 40 days of drought stress in the field varied from 6.515 to 18.131g and 3.0387 to 8.5213g respectively. Their dry weights at 7 days after uprooting and drying ranged from 1.9377 to 7.3413g and 0.9723 to 3.1367g respectively. Even though there were significant differences ($p<0.05$) among the genotypes, GT1 had the highest fresh weight of 18.131g and dry weight of 7.3413g followed by RRIM 600 with fresh weight of 16.829g and dry weight of 6.7840 while RRIM 628 had the least fresh weight of 6.515g and dry weight of 1.9377g. Meanwhile GT 1 and RRIM 600 showed more tolerance to drought stress whereas RRIM 628 and Nig 800 showed the highest effect of drought when compared with other genotypes (Table 2). The same trend observed in the fresh weight of roots and dry weight of roots where also observed here, the same GT1 had the highest fresh root weight of 8.5213g and dry roots weight of 3.1367g followed by RRIM 600 with fresh root weight of 7.7540g.

Table 3: Mean fresh weight of whole plant, dry weight of whole plant, fresh weight of root and dry weight of root of 10 rubber genotypes evaluated in the field in the year 2013

Genotypes	Fresh weight(g) of whole plant 40 days after drought	Dry weight(g) of whole Plant 40 days after drought	Fresh weight (g) of roots 40 days after drought	Dry weight(g) of roots 40 days after drought
GT1	18.131	7.3413	8.5213	3.1367
Nig 800	6.720	2.5880	3.2843	1.1133
Nig 801	9.329	3.610	4.6303	1.9563
Nig 802	11.181	3.2010	5.1540	2.2037

PR 107	10.997	4.3407	4.9987	1.6847
RRIM600	16.829	6.7840	7.7540	2.9400
RIMM628	6.515	1.9377	3.0387	0.9723
$FLSD_{0.05}$	3.9588	1.6354	1.6347	0.7532

The water requirement for plant growth is met from soil water stored in the plant root zone. The reduction in root growth in some genotypes may be due to soil water deficit that decreased the efficiency of plants ability to absorbed soil water and nutrients. Moreover, there were significant differences in roots development between various genotypes of *Hevea brasiliensis* (Samarappuli *et al.,* 1996). Genotypes like GT1, RRIM 600, Nig 800 and PR107 had the highest root density and this particular clones exhibited better performance under moisture stress conditions. Prolonged drought periods with distinct dry season leads to soil moisture stress differential magnitude, adversely affecting the growth and productivity of natural rubber clones (Lalani, 1998). This study concludes that RRIM 600 and Nig 804 are physiologically better adapted to water stress. Screening of clones for better root growth is an important tool to identify clones with intrinsic drought tolerance potential which may become increasingly relevant in a future climate when water becomes highly scarce.

Studies on the Effect of Different Fertilizer Application on Soil Microbial Community, Activity and Yield of Livingstone Potato (*Plectranthus esculentus*) in NRCRI Umudike

E.F. Iwoh., O.D. Onyegbula and A.E. Ezimmadu
National Root Crops Research Institute Umudike, Abia State
Email: georgeiwoh1@gmail.com

Abstract
A field study was conducted to evaluate and analyze the short term impacts of mineral and organic fertilizers on soil microbial community, activity and crop yield. The experiment was set up as a randomized block design in four replications at the experimental field of the NRCRI Umudike, in 2016 planting season. Livingstone Potato (Plectranthus esculentus) was used as the test crop. The trail involved four treatments: non-fertilized (control), Nitrogen Phosphorous potassium (NPK) fertilizer, Poultry manure (PM), Lime (LM) and combination of (NPK+PM+LM). Soil samples were collected from the experimental soil before and after treatments at monthly interval for 3months. The results obtained suggest that the bacterial count at initial stage were low compared to treated soil, which showed that bacterial and fungal counts increased at the second month compared to first and third months, and bacterial count was higher than the fungal count in all the treatments which has a stimulating effect on bacterial micro-flora variation during the growing period. Poultry manure (PM) which induced the highest increase in microbial counts of ($128.33 x10^6 \pm 2.51$ cfu/g), followed by NPK and treatment combination (NPK+PM+LM), while Lime (LM) gave the lowest of ($73.33\ x10^6 \pm 2.51$ cfu/g) during the first month. A similar effect was seen on fungal counts which PM gave the highest of ($19.00\ x10^2 \pm 1.73$), followed by NPK, NPK+PM+LM and significantly reduced with Lime LM ($5.66x10^2 \pm 1.15$) and control ($8.33x10^2 \pm 1.12$). The trend was same in the second and third month respectively. The result of the yield showed that PM gave the highest yield of 24.0 t/ha, followed by treatment combination (NPK+PM+LM) with a yield of 19.7 t/ha. Lime (LM) gave the lowest yield of 5.5 t/ha. The effects of different amendments were observed, thereby confirming that some effects of integrated fertilizer strategies may occur in the short term.
Keywords: Microbial diversity, Fertilization, Microorganisms, Soil, Organic/Inorganic Manure and Livingstone Potato

Introduction
Fertilization is one of the most significant cultural practices in modern agricultural production and these fertilizers play a vital role in food safety in Africa over the past years. However, application of chemical fertilizers caused the degradation of soil quality, such as soil acidification and soil hardening (Blake *et al.,* 1999). Mineral fertilizer and organic manure maintain or improve crop yields and induce changes in soil chemical, physical and biological properties. These changes, in the long-term, are believed to have significant influences on the quality and productive capacity of the soil (Zhang and Wang, 2006). Soil microorganisms are involved in various biochemical processes and play a vital role in maintaining soil fertility and plant yields (Nannipieri *et al*., 2003). Changes in the activity and diversity of soil microbes may reflect changes in soil quality. Therefore, the judicious and efficient use of mineral fertilizers (e.g. Nitrogen, Phosphorus, Potassium (NPK), Lime (LM) etc.) and organic fertilizers (Poultry Manure (PM), cow dung etc.) can be practicable and adopted by farmers when the approach has considered some microbiological studies. Microorganisms are critical to the maintenance of soil function because of their contributions to soil structure formation, decomposition of organic matter, toxin removal, and the biogeochemical cycling of carbon, nitrogen, phosphorus, and sulphur. The extent of soil microbial diversity in agricultural soils made it critical for the maintenance of soil health and quality, growth and yield of crops (Mele and Crowley, 2008). A

study was carried to investigate the effect of fertilizer sources on microbial structure and root yield of livingstone potato on an Ultisol of southeastern Nigeria.

Materials and Methods

A field experiment was established on a loamy soil at the agricultural experimental field of National Root Crops Research Institute Umudike, Abia State to study the short-term effect of different fertilizer amendments on soil microbial activity and root yield of Livingstone potato (*plectranthus esculentus*). The research plots were established on 22nd april 2017, in a randomized complete block design (RCBD) with four replications. Each plot size measured 15m^2 (3 m x 5 m) and the spacing between the plot was 1 m. The test plant used in the experiment was Livingstone potato (*plectranthus esculentus*). Treatments which comprised: Control (without fertilization); NPK) fertilizer at 400 kg/ha; Poultry manure (PM) at 5 t/ha; Lime (LM) at 2t/ha; and treatments combination (NPK + PM + LIME) were applied two days before planting. Livingstone potato was planted at a spacing of 0.7 m between rows and 0.25 m within row.

Soil Sampling and Bioassay

Soil sampling was done in accordance with the method of (Saeki and Toyota, 2004). Soil samples were collected from the plots before treatment and after treatments at monthly intervals, and the top soil sample was collected from depth of (0-20 cm) at four randomly selected locations in each of the plot. Composite samples were collected from each plot and stored in a sterile polypropylene bag and kept cool using coolers during field sampling. The composite samples were homogenized and sieved twice using meshes (2.0 and 0.2 mm) in order to remove stone and plant debris. Samples were subsequently processed within 24 - 48 hour for further analysis. Microbial analysis was carried out four times at monthly intervals: 1st month (before treatments application); 2nd month (after plant emergence on 31st June); 3rd month (after flowering on 29th July); and 4th month (at the end of the growing season on 22nd August).

Microbiological Analysis and Enumeration

One gram (1g) of each of the soil samples was weighed and agitated in 9 ml of distilled water, to dislodge the organisms from the soil particles. An aliquot of 1 ml was serially transferred from each sample into series of test tubes containing sterilized distilled water to obtain dilution of 10^{-1} and 10^{-10}. The microbial population was enumerated which involved determination and count of total viable microorganisms in the experiment using the method of dilution on specific solid media spread plate technique series of 10-fold serial dilution. Aliquot (0.1ml) of 10^{-2}, 10^{-4}, 10^{-6} and 10^{-8} was inoculated into nutrient agar plated in triplicates (Chikere *et al*., 2009). Total soil fungi were enumerated by inoculating aliquots (0.1ml) and determined using Sabouraud dextrose agar (SDA) supplemented with streptomycin (1 mg/100 ml) to suppress bacterial growth with the diluted soil samples of 10^{-3}. The plates were all incubated aerobically at room temperature (30^0C) for 24hours (bacteria) and fungi for 96 hours. The resulting colonies were counted and recorded as colony forming units per gram (CFU/g) using colony counter (Onifade *et al*.,2007). The counts were characterized based on cultural characteristics, staining reaction and biochemical tests.

Yield determination*:* Harvesting was done at the end of the growing season (4 MAP). Root yield of Livingstone potato were weighed and recorded per plot.

Statistical Analysis: The data was subjected to an analysis of variance (ANOVA Statistica SPSS 5), using a GENSTAT and the significant effects between individual-factor level and interaction means were separated using DNMR Test level ($p \le 0.05$).

Results and Discussion

The results obtained suggest that soil microbiological characteristics, Livingstone potato yield were significantly affected by fertilization and the growing period. Initial soil microbial counts indicated that bacterial count in the soil before treatments application was 78.33 x 10^6 CFU/g, while fungal count was 5.53 x 10^2 CFU/g (Table 1). Among all the treatment, the highest significant differences is in bacterial population, recorded across the periods of sampling (115.33 x106±1.15 CFU/g for 1st month, 128.33 x106±2.51 CFU/g for 2nd month and 114.00 x106±2.00 CFU/g for 3rd month), and these were obtained from plots that received PM treatment (Table 2). Poultry manure (PM) provided organic substrates that proliferated bacterial population and activities in the soil, as they breakdown soil organic matter and multiply in the soil, which accounted for the highest bacterial count that peaked in the 2nd month of sampling. Mandal *et al*. (2007) had posited that organic substrates intensify mineralization processes in the soil and increase enzymatic activities of soil microorganisms. The ability of PM to increase bacterial count in the soil was followed by the application of NPK fertilizer which accounted for 107.33x10^6±1.52, 144.33 x10^6±2.88, and 105.00 x10^6±1.73 CFU/g at 1st month, 2nd month and 3rd month of sampling, respectively. The activity of NPK highlighted the significant roles nitrogen and phosphorus play in symbiotic and mycorrhzal relationships with soil micro-organisms. The positive effects of chemical fertilizer on soil biological parameters during the first months of application have been reported (Park *et al*., 2005; Emtsev *et al*., 2010). Lowest values of bacterial count where obtained from plots that were treated with lime. (LM) except at 2nd month of sampling, when the Control recorded the lowest bacterial count (84.00x10^6±2.00 CFU/g) significantly. This may be attributed to the modification of the soil rhizosphere to and alkaline condition by the lime applied which is antagonistic to bacterial growth Results obtained from the study also showed that sampling at 2 months of application of fertilizer materials resulted in the highest mean bacterial count of 96.1 x 10^6 CFU/g. Application of PM also gave the highest yield of 24.0 t/ha. Application of lime at 2 t/ha did not improve yield, as it yield 5.5 t/ha of Livingstone potato roots.

Table 1: Initial soil microbial count.

Microbial soil sampling	Microbial counts (CFU/g)
Bacterial	78.33 x10^6
Fungi	5.53x10^2

Table 2 Effect of different fertilizers applications on soil bacterial mean count (CFU/g) and root yield of Livingstone potato in 2016

	Sampling period			
Treatments	**1st month**	**2nd month**	**3rd month**	**Root yield (t/ha)**
NPK	107.33 x10^6±1.52 ^{d}	144.33 x10^6±2.88 ^{d}	105.00 x10^6±1.73 ^{d}	10.5
PM	115.33 x10^6±1.15 ^{e}	128.33 x10^6±2.51^e	114.00 x10^6±2.00 ^{e}	24.0
LM	73.33 x10^6±2.51 ^{a}	87.66 x10^6±1.52 ^{b}	76.66 x10^6±2.30^a	5.5
NPK+PM+LM	102.66 x10^6±1.50 ^{c}	110.00 x10^6±2.00 ^{c}	95.33 x10^6±1.52 ^{b}	19.7
Control	88.70x10^6±3.05 ^{b}	84.00x10^6±2.00 ^{a}	86.66x10^6±2.51 ^{c}	6.8

Values show mean of triplicates analysis ± standard deviation. Figure with different superscripts down the column were significantly different at $P \leq 0.05$

Results obtained from the study also showed that sampling at 2 months of application of fertilizer materials resulted in the highest mean bacterial count of 128.33 x10^6±2.51 CFU/g. Application of PM also gave the highest yield of 24.0 t/ha. Application of lime at 2 t/ha did not improve yield, as it yield 5.5 t/ha of Livingstone potato roots. Table 3 showed effect of the fertilizer materials on fungal count and root yield of Livingstone potato at different months of sampling. Results obtained showed that PM significantly increased fungal count more than other treatments at any period of sampling. Lowest values of fungal count were recorded on plots that received LM treatment, at all sampling period. This indicates that PM promotes fungal growth in the soil, while LM inhibits fungal growth in the soil. The mean values of fungal numbers per gram of soil across the 3 sampling periods, due to treatments applied increased in this order: PM (19.00 x10^2±1.73), NPK+PM+LM (14.33x10^2±0.57 CFU/g), NPK (12.33 x10^2±1.15 CFU/g), Control (8.33x10^2±1.15 CFU/g), LM (5.66x10^2±1.15 CFU/g). Fungal load induced by PM was highest at the 1st month (17.0 x 10^2 CFU/g) and least at the 3rd month (10.33 x 10^2 CFU/g) significantly. Similar trend was observed for effect due to NPK treatment. Yield response of sweet potato to different sources of fertilizers showed that PM promoted bacterial and fungal growth and activities at all stages of Livingstone potato growth with a resultant highest increase in root yield of 24.7 t/ha. Lime treatment alone depressed yield of Livingstone potato in the studied soil.

Table 3 Effect of different fertilizers applications on soil fungal mean count (CFU/g) and root yield of Livingstone potato in 2017

Treatments	Sampling period			Root yield (t/ha)
	1st month	2nd month	3rd month	
NPK	12.33 x10²±1.15	9.66 x10²±0.57 c	7.66 x10²±0.57 b	10.5
PM	19.00 x10²±1.73	16.66 x10²±1.15 e	12.33x10²±1.15 d	24.0
LM	5.66x10²±1.15	6.66x10²±0.5 7b	8.66x10²±0.60 c	5.5
NPK+PM+LM	14.33x10²±0.57 d	12.00x10²±1.00 d	11.66x10²±0.57 e	19.7
Control	8.33x10²±1.15 b	6.66 x10²±1.15 b	6.33 x10²±0.57 a	6.8

Values show mean of triplicates analysis ± standard deviation; Figure with different superscripts down the column is significantly different at P≤0.05.

Conclusion

The study showed that bacterial and fungal counts increased at the second month compared to first and third months, and bacterial count was higher than fungal count in all the treatments which has a stimulating effect on bacterial micro-flora variation during the growing period. A positive effect of NPK fertilizer on soil biological parameters during the first months of treatments application was also observed. Poultry manure induced the highest increase in microbial count and yield of livingstone potato. Lime gave the lowest microbial counts in all the months compared to control as well as the lowest yield, this might be as a result of changes in environmental conditions for microbial growth, and lime is effective in increasing soil pH, which reduces soil acidity at the detriment of the soil microorganism.

Abstract
Rice blast caused by fungus Magnaporthe oryzae is one of the major fungal disease affecting rice (Oryza sativa) cultivation. Currently, the use of pesticides has proven to be successful in the control of this disease to a very large extent, but these results in increase in the cost of production and these chemicals are sometimes not eco-friendly. Therefore, the deployment of blast-resistant cultivars is the most important method of combating the disease because it is considered as a no-cost technology especially to the poor farmers. Therefore, this study was carried out to evaluate rice genotypes for resistance to natural population of blast pathogens and there agronomic performance. Fifteen NCRI advance rice breeding lines and two released (BR1-17) varieties (checks) were collected from the breeding unit of the National Cereals Research Institute (NCRI), Badeggi, Nigeria. These genotypes were screened for resistance to blast disease caused by Magnaporthe oryzae in the blast hot spot and water stress environment. The results on agronomic performance reveal different reactions. Genotype BR3 was highly resistant and has the least disease incidence of 28%. BR2 is moderately resistant and also gave the highest grain yield 6tons per hecter. The blast incidence and severity did not affect the agronomic performance of the rice genotypes as most of the genotypes yield above the average grain yield of 3tons/hectare. BR3 may therefore be utilized by incorporating it into the breeding programme strategy to control blast disease of Magnaporthe oryzae .

Introduction
Rice is an extremely important food in Nigeria with a total annual production of about 2 million metric tons. It is a staple food for both rural and urban dwellers in Nigeria and it is ranked the fourth most important cereal crop in terms of production (after sorghum, maize and millet)(Abo *et al.,* 2003). Nigeria is the largest rice importer in West Africa despite having about 5.0 million hectares of land suitable for rice cultivation (Smith, 2007). Rice production in Nigeria is faced by several biotic and abiotic limitations, and prominent among the biotic factors is yield loss due to diseases. Among these diseases, leaf blast caused by *Magnaporthe oryzae* remains a particular threat because of its unpredictable outbreaks as well as breaking down of genes in resistant cultivars over time (Jamal-U-deen *et al.,* 2012). Leaf blast is one of the most serious and widespread constraint of rice cultivation in Nigeria. It occurs in upland and rainfed rice field. Water deficiency predisposes the rice field to severe infection in all environments (Akator *et al.,* 2013). Currently, the use of pesticides has proven to be successful in the control of this disease to a very large extent, but these results in increase in the cost of production and these chemicals are sometimes not eco-friendly. Therefore, the deployment of blast-resistant cultivars is the main methods of combating the disease because it is considered as a no-cost technology especially to the poor farmers (skamnioti and Gurr, 2009). Therefore the objective of this study focused on field evaluation of seventeen rice genotypes to confirm their resistance to natural population of blast pathogen under water stress environment. The agronomic performance of the rice genotypes and their resistance to diseases will facilitate their selection and incorporation into the breeding programs in Nigeria. It is on this note that the study on evaluation of Rice Genotypes for the Agronomic Performance and Resistance against *Magnaporthe oryzae* was investigated.

Materials and Methods

Collection of Materials

Fifteen NCRI advance rice breeding lines and two released varieties (checks) were collected from the breeding unit of the National Cereals Research Institute (NCRI), Badeggi.

Study Area

The study was conducted at hydromorphic field (latitude N9^{o}.04'02.05 and longitudes E6^{o}.01'30.31) of the National cereals research institute, Badeggi, Niger state, Nigeria during 2017 cropping season.

Experimental Design

The experiment was laid out in a randomised complete block design and replicated 3 times and each entry was planted to a 2 x 5m^2 plot size.

Other Agronomic practices

Fertilizer application was at 80, 40, 40kg per ha of N, P_2O_5 and K_2O, with N applied in two splits at 21 and 42 days after planting. Weeds were controlled using two herbicides (propanol and 2-4-D formulation) at 4 litres per hectare of Orizo plus with supplementary hand weeding.

Data collection and Analysis

The data regarding the occurrence of the blast disease were collected at seventh week after planting using the Standard Evaluation System developed by International Rice Research Institute (IRRI, 2013) and then converting into percentage disease by using the formula thus:

$$\text{Disease (\%)} = \frac{\text{Average of the disease score X 100}}{9}$$

Other data collected include agronomic traits such as Plant Height measured using metre rule, number of tiller per metre square, number of panicle per metre square, days to 50% flowering, 1000 grain weight and yield. Data was analyzed using CropStat7.2. version. Analysis of variance was carried out and significant means was separated using LSD @0.05% probability level

Results and Discussion

The rice genotypes showed different reactions in response to blast. Scoring of 1 in the susceptible local check (FARO 52) indicated probably that there is genetic mutation of the variety against blast as the environment was suitable for disease screening. There were 2 resistant (R) varieties, 5 moderately resistant (MR) and 9 moderately susceptible (MS) varieties (Table 2). Barnwal *et al.,* (2012), singh *et al.,* (2010) and Ali *et al.,* (2003) also observed variation in the reaction of rice genotypes to leaf blast. Significant difference at 5% level of probability was also observed for percentage blast incidence and blast severity (Table 3). Significant difference at 5% level of probability was also observed for number of tiller/m^2 and grain weight across the means of all the rice lines evaluated. Means of plant height, panicle/m^2, 50% flowering and grain yield were significantly different at 5% level of probability (Table). Highest number (78.6 and 280) of plant height and tiller/m2 were recorded in BR8 respectively. BR12 recorded the highest number (450g) of panicle/m2 followed by BR6 (431) (Table 4) though has the highest percentage blast incidence 43% and severity scoring of 5 across all the genotypes (Table 3 & 4). The susceptibility of this genotype may be as result of genetic makeup from the parents. Most of the genotypes gave grain yield above 3t/ha, though BR2 significantly at 5% gave higher grain yield of 6190kg/ha than all other entries (Table 4). Lowest grain yield was recorded in BR 11.

Majority of the genotypes yield above 3tons which is the average expected yield under the natural blast infection. The resistant genotype is therefore recommended for incorporation in to the breeding program in Nigeria.

Abstract

Two field experiments were conducted at University Putra Malaysia (UPM), Selangor, Malaysia during off season (May to September) and main season (September to December) of 2015 to evaluate the effect of biofertilizer on physiological characteristics, growth and biomass yield of aerobic rice genotypes. The experiment consisted of five (5) fertilizer combinations (chemical fertilizer recommended rate (CFRR) (150 N; 60 P_2O_5; 60 K_2O kg ha^{-1}) 100%, biofertilizer 1 ton ha^{-1} + 75% CFRR, biofertilizer 2 tons ha^{-1} + 50% CFRR, biofertilizer 3 tons ha^{-1} + 25% CFRR and biofertilizer 4 tons ha^{-1}) and three aerobic rice genotypes (MRIA1, MR219-4 and MR219-9) laid out in a split-plot design in randomized complete block arrangement with 3 replicates. Results revealed that application of biofertilizer 1 ton + 75% CFRR produced plant height (90.75 cm) and a number of tillers (321.42 no. m^{-2}) at 12 weeks after sowing (WAS), the highest photosynthesis rate (16.34 µmol CO_2 m^{-2} s^{-1}) and transpiration rate (6.13 µmol CO_2 m^{-2} s^{-1}) than the other biofertilizer treatments. MR219-4 produced the highest leaf area (25776.00 cm^2 m^{-2})), plant biomass (764.22), leaf photosynthesis (16.29 µmol CO_2 m^{-2} s^{-1}) and transpiration rate (6.13 µmol CO_2 m^{-2} s^{-1}) while MR219-9 produced the highest number of tillers (358.29 no. m^{-2}) and crop growth rate (85.47 g m^{-2} $week^{-1}$) at 12 WAS. The trend in these results indicated that biofertilizer tend to be more effective with limited chemical fertilizer. These results concluded that 1 ton biofertilizer + 75% CFRR and MR 219-4 enhances rice growth in aerobic condition.

Introduction

Aerobic rice production system is an innovative way of cultivating rice in highly drained, non-puddled, and non-saturated soils without standing water. This method uses specialized rice varieties those respond to inputs and balanced management practice to achieve a minimum of 4 to 6 tons per hectare yield with just fifty percent (50%) to seventy percent (70%) of the water requirement for rice production under irrigation (Akter et al., 2016).In this method, the land is prepared under dry condition and brought to a fine tilt, the seeds are sown by dibbling in a determined ratio of rows with adequate spacing and soil moisture condition is retained almost close to field capacity (Shanmuganathan, 2006). Biofertilizers are progressively becoming popular in many countries, for many crops and are one of the complementary sources for the inorganic fertilizers. It enhances growth by increasing the primary nutrients to the host plant or supplying phytohormones to the plant (Vessey, 2003). The collective phytohormone, produced by the bacteria is indoleacetic acid, which promotes plant root growth. Additionally, biofertilizer as the organic fertilizers comprises beneficial microbes which increased crop production (15 to

50%) (Panhwar, *et al*., 2014). Biofertilizer application increases the population of microorganisms that can convert plant nutrients to the available form in soil (Vessey, 2003). It is found that application of organic and biofertilizer enhances the growth and yield of rice and able to reduce inorganic fertilizer application (Ngoc *et al*., 2001). Biofertilizer can be an effective approach to minimize chemical fertilizer sources and ultimately develop soil fertility. The main mechanisms of biofertilizer for improving plant growth include; increases nitrogen availability by fixing atmospheric nitrogen, solubilizing insoluble organic and inorganic P by producing organic acids and enzymes, and promoting root growth by indoleacetic acid (IAA) (Naher *et al*., 2009; Panhwar *et al*., 2012). To face the upcoming challenges of food production, energy consumption, and adverse environmental consequences, biofertilizer, which is prepared with the residue of plant material and beneficial environment-friendly bacteria can be a supplement to chemical fertilizer. It can be assumed that biofertilizers could offer an opportunity for rice farmers to increase yields and productivity. This study was conducted to determine the effect of biofertilizer in combination with chemical fertilizer on physiological characteristics, growth and biomass yield of three aerobic rice genotypes in field condition.

Materials and Methods

Experimental site: Field 10 University Putra Malaysia (UPM), (latitude 3^0 02'N; longitude 101^0 42' E and on the altitude of 31 m above sea level) Selangor, Malaysia. The experimental site was previously planted with sweet corn and was cleared of the debris prior to land preparation. Sweet corn was previously planted at the experimental site and the debris was cleared off prior to land preparation. Soil analysis of the experimental site revealed that the soil was clay loam with pH value of 6.50 and 6.42, total carbon (C) 0.79 and 0.77%, total nitrogen (N) 0.06 and 0.07%, total sulphur (S) 0.02 and 0.0.2%, phosphorus (P) 84.7 and 165.2 µg g-1, potassium (K) 41.24 and 55.07 µg g-1 were recorded in off and main season, respectively. The total rainfall received during the experimental periods was 548 and 1438 mm in the off and main season respectively. Maximum and minimum temperatures recorded in the off and main season were 33. 5 and 33°C, 25.25 and 24.5°C, average 29 and 28.5°C respectively

Experimental materials Aerobic rice varieties: MRIA1 aerobic rice genotypes obtained from Malaysian Agriculture Research and Development Institute (MARDI) and; MR219-4 and MR219-9 obtained from Malaysian Nuclear Agency were used for the experiments.

Preparation of biofertilizer: The prepared biofertilizer used constituted a nitrogen-fixing bacteria conglomeration (*Bacillus sp.* Sb35 and 42) and bacteria for the solubilization of phosphate (*Bacillus sp.* PSB16). One liter of each inoculum was diluted in 4 liters of distilled water (dH_2O) + molasses in soil microbiology laboratory (bacteria). Preparation of the biofertilizer was done in the biofertilizer processing laboratory glasshouse field 2 using empty fruit bunch (EFB) and peat moss in the ratio of 1:1:1. For the bacteria to multiply prior to application, the prepared biofertilizer was stored at ambient room temperature for one month.

Treatments and experimental design: The treatments comprised of five (5) biofertilizer combinations (chemical fertilizer recommended rate (CFRR) (150 N; 60 P_2O_5; 60 K_2O kg ha^{-1}) 100%, biofertilizer 1 ton + 75% CFRR, biofertilizer 2 tons + 50% CFRR, biofertilizer 3 tons + 25% CFRR, biofertilizer 4 tons) and three aerobic rice genotypes (MRIA1, MR219-4 and MR219-9). The experiments were laid out in a split-plot design in a randomized complete block arrangement with 3 replicates, with biofertilizer in the main plot and aerobic rice genotypes in the sub-plots.

Crop husbandry practices: Land was ploughed and rotovated to obtain a fine tilth and then marked out as required plot sizes with 1.0 meter space between blocks and 0.50 m spacing between plots. The gross and net plot sizes were 2.5 m × 1.5 m (3.75 m^2) and 2.0 m × 1 m (2.0 m^2), respectively constituting 6 rows in the gross plots and 4 rows in the net plots, respectively. Sown seeds were speciously treated with 70% chlorox (5.25% sodium hypochloride solution) for 30 minutes then rinsed with sterile water (Amin *et al*., 2004). Sowing was done on 24th May 2015 and 3rd September 2015 at an intra and inter-row spacing of 25 cm × 25 cm. Ten (10) dry treated rice seeds were sown $hill^{-1}$ that was later thinned to 5 seedlings $hill^{-1}$ at 14 days after sowing (DAS). 'Butachlor' herbicide (1.2 kg a.i ha^{-1}) was sprayed 2 DAS in main season only. In both seasons, 'Basagran' herbicide (bentazone 0.8 kg a.i ha^{-1} and MCPA 0.12 kg a.i ha^{-1}) was sprayed 21 and 28 DAS in off and main season, respectively followed by manual weeding throughout the growing seasons to control weeds. A day before crop establishment, biofertilizer was incorporated into the soil. Compound fertilizer (NPK 15:15:15) was applied at the rate of 400 kg ha^{-1} as basal; and Urea at the rate of 196 kg ha^{-1} in two split doses by side placement at 28 and 56

DAS to supply total recommended nutrients of 150 N; 60 P_2O_5; 60 K_2O kg ha^{-1}. Both were applied as prescribed by the treatments. The crop was grown rain-fed but supplemental irrigation was carried out using a sprinkler to keep the soil at field capacity throughout the growing season.

Parameters measured

Agronomic parameters: Five (5) rice hills from each net plot of all the treatments were randomly sampled and their height was measured at 4, 8 and 12 weeks after sowing (WAS). A number of tillers were counted manually following the same interval. Leaf area and plant biomass were determined at 4, 8 and 12 WAS. One rice hill $plot^{-1}$ was randomly sampled, uprooted and washed to remove all soil particles adhering to the shoot and root. The samples from the field were then brought to the laboratory for leaf area measurement using leaf area meter (MODEL: LI-3100 AREA METER, USA). A constant weight was achieved by oven drying the samples at 70 ^{0}C for 72 hours after the measurement, the plant biomass was then weighed using digital balance and readings were recorded.

Physiological parameters: The chlorophyll content was measured from fully expanded healthy leaves 4 weeks interval starting from 4 weeks after sowing using a portable chlorophyll meter (MINOLTA ™ SPAD-502, Minolta camera Co, Osaka, Japan). The youngest fully expanded leaf (YEL) of each plant an average of 15 leaves $plot^{-1}$ (5 leaves $hill^{-1}$) SPAD readings were recorded. A portable photosynthesis system (LI-6400XT, LI-COR Inc. Lincoln, Nebraska, USA) was used for the measurement of single leaf net photosynthesis and transpiration at 75 and 65 DAS in off season and main season respectively. The measurements were carried out under full sunlight and at constant CO_2 of 380 µmol CO_2 mol^{-1} in the chamber. Crop growth rate (CGR) at 4, 8 and 12 WAS was calculated using the equation CGR = $\frac{w2 - w1}{t2 - t1}$ (g $hill^{-1}$ $week^{-1}$)

Where w_2 and w_1 are dry shoot weight taken at two consecutive harvest time's interval t_2 and t_1

Results and Discussion

Plant height and Number of tillers

Effect of season and biofertilizer on the genotypes of rice and their interaction on plant height and number of tillers is presented in Table 1. At 4 WAS, the tallest plants (43.83 cm) were recorded in the main season. In biofertilizer treatment, the height (37.42 cm) of plants recorded in 100% CFRR was similar ($p>0.05$) to that of biofertilizer 1 ton +75% CFRR (35.98 cm) and biofertilizer 2 tons +50% CFRR (35.59 cm) but significantly ($p\leq0.05$) higher than other biofertilizer treatments. MRIA1 recorded higher (43.65 cm) plant height than the other genotypes. At 8 WAS, the tallest plants (79.32 cm) were significantly produced in the main season. MRIA1 recorded the tallest (90.67 cm) plants. At 12 WAS, the tallest plants (94.58 cm) were significantly produced from CFRR 100% while the shortest (83.73 cm) plants were significantly produced from biofertilizer 4 tons at par with the other biofertilizer treatments except for CFRR 100% and biofertilizer 1 ton + 75% CFRR; and biofertilizer 2 tons + 50% CFRR respectively. Similar to 8 WAS, MRIA1 recorded the tallest (102.66 cm) plants. At 4 WAS, the highest (194.84 no. m^{-2}) number of tillers were significantly produced in main season while MR219-4 significantly produced more (162.28 no. m^{-2}) number of tillers at par with MR219-9. MRIA1 significantly produced the least (99.51 no. m^{-2}) number of tillers. At 8 WAS, more (310.19 no. m^{-2}) number of tillers were significantly produced in the main season. More (313.76 no. m^{-2}) number of tillers were significantly produced by MR219-4. MRIA1 significantly produced the least (115.38 no. m^{-2}) number of tillers. At 12 WAS, biofertilizer 2 tons + 50% CFRR significantly produced more (350.93 no.m^{-2}) number of tillers. Least (259.56 no. m^{-2}) number of tillers were significantly produced from biofertilizer 4 tons. MR219-4 significantly produced more (381.23 no. m^{-2}) number of tillers. MRIA1 significantly produced the least (197.87 no. m^{-2}) number of tillers.

Leaf area and leaf chlorophyll content (SPAD value)

Effect of season and biofertilizer on the genotypes of rice and their interaction on leaf area and SPAD value is presented in Table 2. At 4 WAS, the highest (5056.40 $cm^2\ m^{-2}$) leaf area was significantly produced in the main season. Biofertilizer 1 ton + 75% CFRR ha^{-1} had the highest (3923.30 $cm^2\ m^{-2}$) leaf area. Biofertilizer 4 tons significantly produced the lowest (3200.70 $cm^2\ m^{-2}$) leaf area. The highest (4119.60 $cm^2\ m^{-2}$) leaf area was significantly produced by MR219-4. MRIA1 significantly produced the lowest (2924.19 $cm^2\ m^{-2}$) leaf area. At 8 WAS, the highest (29729. 30 $cm^2\ m^{-2}$) leaf area was significantly produced in the main season. The highest (38397.60 $cm^2\ m^{-2}$) leaf area was significantly produced from CFRR 100%. The lowest (15615.80 $cm^2\ m^{-2}$) leaf area was significantly produced from biofertilizer 4 tons. MR219-4 significantly produced the highest (31258.00 $cm^2\ m^{-2}$) leaf area. MRIA1 significantly produced the lowest (11595.90 $cm^2\ m^{-2}$) leaf area. At 12 WAS, the highest (24935.60 $cm^2\ m^{-2}$) leaf area was significantly produced in a main season. The highest (26196.40 $cm^2\ m^{-2}$) leaf area was significantly produced from CFRR 100%. The lowest (15944.40 $cm^2\ m^{-2}$) leaf area was significantly produced from biofertilizer 4 tons. MR219-4 significantly produced the highest (25776.00 $cm^2\ m^{-2}$) leaf area. MRIA1 significantly produced the lowest (8021.40 $cm^2\ m^{-2}$) leaf area. At 4 WAS, the highest (37.01) SPAD value was significantly produced in the main season. The highest (37.21) SPAD value was significantly produced from CFRR 100%. The lowest (32.58) SPAD value was significantly produced from biofertilizer 4 tons. At 8 WAS, the highest (37.18) SPAD value was significantly produced in the main season while the highest (37.87) SPAD value was significantly produced from CFRR 100%. The lowest (34.76) SPAD value was significantly produced from biofertilizer 4 tons. The highest (42.22) SPAD values was significantly produced by MRIA1. Similar to 8 WAS, at 12 WAS, MRIA1 significantly produced the highest (36.80) SPAD value.

Plant biomass, photosynthesis and transpiration

Effect of season and biofertilizer on the genotypes of rice and their interaction on p biomass and photosynthesis and transpiration rate is presented in Table 3. At 4 WAS, the heaviest (103.27 gm^{-2}) plant biomass was significantly produced in a main season. In biofertilizer treatments, the heaviest (137.23 gm^{-2}) plant biomass was significantly produced from biofertilizer 1 ton + 75% CFRR. Biofertilizer 3 tons + 25% CFRR significantly produced the lightest (62.24 g m^{-2}) plant biomass. The heaviest (92.03 g m^{-2}) plant biomass was significantly produced by MR219-4. MR219-9 significantly produced the lightest (62.66 g m^{-2}) plant biomass. At 8 WAS, the heaviest (455.26 gm^{-2}) plant biomass was significantly produced in the main season. In biofertilizer treatment, the heaviest (538.15 gm^{-2}) plant biomass was significantly produced from CFRR 100%. The lightest (350.65 g m^{-2}) plant biomass was significantly produced from biofertilizer 4 tons. The heaviest (520.30 g m^{-2}) plant biomass was significantly produced by MR219-4 while MR219-9 produced the lightest (368.18 g m^{-2}) plant biomass. At 12 WAS, the heaviest (712.81 gm^{-2}) plant biomass was significantly produced in the main season. In biofertilizer treatment, the heaviest (800.54 gm^{-2}) plant biomass was significantly produced from CFRR 100%. The lightest (580.54 g m^{-2}) plant biomass was significantly produced from biofertilizer 4 tons. The heaviest (764.22 g m^{-2}) plant biomass was significantly produced by MR219-4. MRIA1 significantly produced the lightest (471.69 g m^{-2}) plant biomass. The highest (18.60 µmol CO_2 m^{-2} s^{-1}) photosynthesis rate was significantly produced in the main season. The least (13.71 µmol CO_2 m^{-2} s^{-1}) photosynthetic rate was significantly produced from biofertilizer 4 tons. The highest (14.09 µmol CO_2 m^{-2} s^{-1}) photosynthetic rate was significantly produced by MR219-4 while MR219-9 significantly produced the least (10.23 µmol CO_2 m^{-2} s^{-1}) photosynthetic rate. The highest (6.23 mmol H_2O m^{-2} s^{-1}) transpiration rate was significantly produced in main season while MR219-4, significantly produced the highest (6.06 mmol H_2O m^{-2} s^{-1}) transpiration rate.

Table 1: Plant biomass (g m^{-2}), photosynthesis (μmol CO_2 m^{-2} s^{-1}) and transpiration rate (mmol H_2O m^{-2} s^{-1}) of aerobic rice as influenced by season, biofertilizer, genotype and their interactions for two seasons combined

Crop growth rate

Effect of season and biofertilizer on the genotypes of rice and their interaction on crop growth rate is presented in Figure 1. At 4 WAS, the heaviest (25.82 gm^{-2} $week^{-1}$) crop growth rate was significantly produced in the main season. The heaviest (20.90 gm^{-2} $week^{-1}$) crop growth rate was significantly produced from biofertilizer 1 ton + 75% CFRR. The lightest (19.60 g m^{-2} $week^{-1}$) crop growth rate was significantly produced from biofertilizer 3 tons + 25% CFRR. The heaviest crop growth rate (23.00 g m^{-2} $week^{-1}$) was significantly produced by MR219-4. MR219-9 significantly produced the lightest crop growth rate (15.67 g m^{-2} $week^{-1}$). At 8 WAS, the heaviest (113.76 gm^{-2} $week^{-1}$) crop growth rate was significantly produced from CFRR 100%. The lightest (71.55 g m^{-2} $week^{-1}$) crop growth rate was significantly produced from biofertilizer 4 tons. The heaviest (107.67 g m^{-2} $week^{-1}$) crop growth rate was significantly produced by MR219-4. MR219-9 significantly produced the lightest (76.38 g m^{-2} $week^{-1}$) crop growth rate. At 12 WAS the heaviest (71.64 g m^{-2} $week^{-1}$) crop growth rate was significantly produced from biofertilizer 3 tons + 25% CFRR. The lightest (39.72 g m^{-2} $week^{-1}$) crop growth rate was significantly produced from biofertilizer 4 tons. MR219-9 significantly produced the heaviest (85.47 g m^{-2} $week^{-1}$) crop growth rate while MRIA1 produced the lightest (22.71 g m^{-2} $week^{-1}$) crop growth rate.

Results of this experiment showed that use of biofertilizer increases the growth of rice. It also reduces the consumption of inorganic fertilizer. The helpful influence of biofertilizer on the growth and productivity of soybean, maize, sugar beet, and wheat were emphasized by nitrogen fixation ability, phosphorus solubilization, and production of phytohormones (Naseri and Mirzaei, 2010; Naseri, *et al*., 2013). These potential inoculants, its' application properly combine with inorganic fertilizer could be deliberated in the sustainable and organic cultivation of aerobic rice (Panhwar *et al*., 2011a). The considerable increase in the height of plant, number of tillers and leaf photosynthesis on biofertilizer 1 ton ha^{-1} + 75% CFRR applied plots might be due to microorganisms contained in the biofertilizer helped in the fixation of atmospheric nitrogen and solubilized the insoluble forms of phosphates into available forms thereby making these nutrients available for the crop growth. Panhwar *et al*. (2011b) reported phosphate solubilizing bacteria (PSB) strains increased plant height in aerobic rice. Their findings revealed that aerobic rice inoculation with PSB enhanced microbial phosphate solubilization activity of applied treatments. Similarly, Tambekar *et al*. (2009) reported that symbiotic nitrogen fixing and phosphate solubilizing microorganisms play a significant role in complementing plant's nitrogen and phosphorus requirement, permitting a nitrogen and phosphate fertilizers usage sustainably. From the findings of this study, about twenty-five percent (25%) of the recommended chemical fertilizer is saved. This is contrary to findings of Habibi *et al*. (2011) where they reported fifty percent (50%) of needed nitrogen and phosphorus fertilizers may possibly be substituted by bio- and organic fertilizers, since bio-and organic fertilizers enriched the efficacy of suggested nitrogen and phosphorus fertilizers and decrease chemical fertilizers costs, similarly prevent contamination of the environment from wide use of inorganic fertilizers. Naher *et al*. (2016) stated the application of chemical N and P can be reduced by fifty percent (50%) and increase rice yield with the supplement of 5 tons ha^{-1} bio-organic fertilizer. However, it was reported that when various PSB strains were used along with a half-dose of inorganic fertilizer on lettuce (*Lactuca sativa*), twenty-five (25%) growth increase was achieved in contrast with sole chemical fertilizer treatments and by applying biofertilizer at least fifty percent (50%) of chemical fertilizer could be saved (Young *et al*., 2003). With regards to the increase in chlorophyll contents, leaf photosynthesis rate, leaf area, crop biomass and crop growth rate, biofertilizer 1 ton + 75% CFRR at par with a CFRR 100% seemed to be more effective than the other biofertilizer treatments. The higher values obtained on these parameters in biofertilizer 1 ton + 75% CFRR showed the effectiveness of N-fixing and PSB inoculants in aerobic rice. The biofertilizer used in this study contains N2-fixing and phosphate solubilizing bacteria (PSB) with the capability to produce growth promoting phytohormones (IAA), organic acids and enzymes (Naher, *et al*., 2009). The beneficial features of the biofertilizer directly opinionated the physiology of rice (Panhwar *et al*., 2015a) and improved the chlorophyll contents in its leaves. Application of biofertilizer will, therefore, give rise to the fixation of some atmospheric nitrogen, which else required to be supplied from chemical N fertilizer and bio-available P. Hence, using this biofertilizer, to a certain degree, enhanced the rice growth and yield (Radziah and Panhwar, 2014). Mehrvarz *et al*. (2008) reported an increase in chlorophyll content and photosynthesis rates with inoculation of PSB. Other studies established that biofertilizer promptly enhances crop growth (Kachrooc and Razdiah, 2006; Son *et al*., 2007). Crop growth rate is a simple and important index of agricultural productivity on the rate of dry matter production. The highest crop growth rate recorded in CFRR 100% might be attributed to the larger surface area of the leaves of plants in this treatment. When leaf area is large to intercept 95% of sunlight then plant gets optimum crop growth rate and also greater light interception stimulates crop growth rate which in turn increases total dry matter and leaf area. Datta *et al*. (2012) reported that greater leaf area causes higher light interception which further enhances crop growth rate and thus results in higher yield.

Conclusion

The crop recorded higher plant height, a number of tillers, and photosynthesis rate in biofertilizer 1 ton + 75% CFRR. MR219-4 recorded higher leaf photosynthesis, transpiration, leaf area, plant biomass while MR219-9 recorded higher number of tillers and crop growth rate. Rice growth could be improved by the application of biofertilizer 1 ton + 75% CFRR on MR219- and MR219-9 genotypes in aerobic condition and thus minimizes the inorganic fertilizer application. It was concluded that 25% reduced dose of chemical fertilizer and its combination with biofertilizer was optimum for most of the parameters studied as compared to the sole chemical or biofertilizer at both crop growth stages.

E-mail: nwoghajerrys@gmail.com

Abstract
The objective of the study was to evaluate responses of yield and some yield components of 12 pre-release water yam (D.alata) genotypes in three agro-ecologies within Nigeria yam belt. The trials were established at Umudike , Igbariam and Markurdi. The field was laid out in randomised complete block design (RCBD) and replicated three times. Data were captured digitally using field book app. Genotype x environment interactions determined the performance of each genotype at particular location with regards to number of emerged plant plot^{-1}, number of ware tuber plot^{-1}, ware tuber yield plot^{-1} and total fresh tuber yield plot^{-1}. However, based on yield stability across the agro-ecologies, TDa1100302 and TDa1100264 were the best performing among the genotypes and were better than the national check TDa291.

Keywords: responses, yield, hybrid, water yam, genotypes and agro-ecologies

Introduction
Yam (*Dioscorea spp*) is a tuber crop of great economic importance in tropical regions of the world. It also holds cultural significance among the ethnic tribes of West Africa and South Pacific islands; where it is highly revered and celebrated with many festivities, as the most important cultural food crop (Obidiegwu and Akpabio 2017). Yams serve as one of the most important staple food in West Africa, broadening the food base and bringing food security to about 300 million people in the low-income, food-deficit countries (LIFDCs) of the tropics and providing them with about 200 dietary calories daily (Nwogha, *et al*, 2017). Nutritionally, yams are better than cassava in terms of vitamin C content; yams contain 40-120mg g^{-1} edible portion of vitamin C and crude protein of 40-140g Kg^{-1} dry matter, and do not contain cyanogenic compounds like cassava. It has net dietary protein calorie content of about 4.6% which compares well with 4.7% in maize (Egesi, et al., 2003). In West Africa, yam is also a source of foreign exchange because its consumption is more widely dispersed than its production. It is exported from West Africa to other parts of Africa where it is not produced and to other parts of the world including Europe, North and South America and Asia where it is consumed by increasing West African immigrant populations. In Nigeria, yam contributes 18% of household food crops cash income (BMFG, 2013). It is a multi-species crop which has more than 600 known species that produce tubers, bulbils or rhizomes (Ayenus and Coursey 1972). Among the species, water yam or greater yam (*Dioscorea alata*) is the most widely distributed in the tropics and most cultivated by small holder farmers (Sartie and Asiedu 2014). The wide environments adaptability of water yam (*Dioscorea alata*) across climatic regions and agro-ecologies when compared to other *Dioscorea* species may be link to its advantageous agronomic traits such as; high yield potential, high multiplication ratio, ease of propagation (through production of tubers, bulbils and reliability of sprouting), early growth vigour for weed suppression and long storability of tubers. However, this inherent genetic advantage of water yam compared to other species in terms of yield potential and flexibility in environmental adaptation notwithstanding. The yields are still being influenced by numerous environmental factors such as rainfall (soil moisture), temperature, light, photoperiod and other edaphic factors (Oselebe and Okporie, 2008). These factors in addition to other biotic factors have led to decline in water yam productivity over the years,

prompting yam breeding objectives to be structured towards developing varieties that will be resilient to wide range of environments. Hence, the objective of this study is to evaluate pre-release hybrid water yam (*Dioscorea alata*) genotypes for their yields and yield components responses across three agro-ecologies within Nigeria yam belt.

Materials and Methods

The trials were established in 2017 at National Root Crops Research Institute (NRCRI), Umudike(humid rainforest), NRCRI out-station, Igbariam (derived savannah) and Federal University of Agriculture Markurdi (southern guinea savannah) located at 05^{0}29'09.1"N, 007^{0}32'29.5"E; 06^{0}18.732'N, 006^{0}58.101'E and 07^{0}46.310'N, 008^{0}39.979'E respectively. The locations have mean temperatures (Umudike 27.08^{0}C, Igbariam 32^{0}C and Markurdi 33.2^{0}C) and mean rainfall of 2524mm, 2000mm and 1600mm respectively. The soils of the locations belong to utisols for Umudike and Igbariam each and alfisols for Markurdi and have pH of 4.6-5.1, 5.35-5.47and 5.7-6.79 respectively.

Plant materials comprise of 11 pre-release hybrid water yam (*D. alata*) genotypes which includes; TDa297, TDa11/00204, TDa11/00300, TDa11/00264, TDa11/00193, TDa11/00316, TDa11/00201, TDa11/00302, TDa11/00477, TDa07/00015, TDa11/00203 and TDa291 that was used as check. These materials were sourced from the International Institute of tropical Agriculture (IITA), Ibadan Nigeria. Land preparations were done by tractor, the lands were ploughed, ridged and then marked into a 10m length per a plot to make the total land area of 12mx32m^2 (i e 384 m^2) each location for the experiment. Each genotype were cut into sett size of 200g and planted at space of 1mx1m and depth of 10cm between 27th April and 11th May 2017. The field was sprayed with pre-emergence herbicide 3 days after planting. Subsequently, weeding was done manually at 2 and 5 months after emergence. No fertilizer was applied as the crops were evaluated for their responses to natural soil fertility across the agro-ecologies. Single staking was done using whole bamboo stakes of 3 metres high. The experiments were laid out in randomized complete block design that has four blocks and replicated three times. Data were digitally captured on various agronomic traits of interest using field book App. Data captured were subjected to statistical analysis using Genstat software and means were separated using least significant deviation.

Results and Discussion

Variance estimates for yield components and yield of *D.alata* genotypes across three agro-ecologies within

Nigeria yam-belt

Significant genotype effect at (P<0.001) was recorded on plant vigour, number of seed tuber plot^{-1}, number of ware tuber plot^{-1}, seed tuber yield plot^{-1}, ware tuber yield plot^{-1}, and total fresh tuber yield plot^{-1}. Similarly, location significantly affected all the above traits, in addition to number of emerged plant plot^{-1}(p<0.001). However, genotype x location interaction effect was significant for number of emerged plant plot^{-1}(P<0.05), number of ware tuber plot^{-1}, ware tuber yield plot^{-1} and total fresh tuber yield plot^{-1} at (0.001) respectively.

Mean yield components and yield performance of *D. alata* genotypes

The twelve genotypes were significantly different (P<0.05) with respect to plant vigour, number of seed tuber plot^{-1}, number of ware tuber plot^{-1}, seed tuber yield plot^{-1}, ware tuber yield plot^{-1}, and total fresh tuber yield plot^{-1} (Table 2). TDa1100201, TDa1100264, TDa1100302, were the most vigorous across the locations, these genotypes approximately recorded the highest visual score of 3 and were not significantly different to each other, while, TDa297, recorded the least plant vigour with visual average score of 1.89. The national check TDa 291 recorded the highest of seed tubers plot^{-1}, (15.67 seed tubers), whereas, TDa1100201 recorded the least number of seed tubers plot^{-1}, (9 seed tubers). Similarly, TDa1100264 and TDa297 recorded highest and lowest seed tuber yields of 7.43Kg plot^{-1} and 4.28Kg Plot^{-1} respectively. TDa1100302 recorded the highest number of ware tuber plot^{-1} (15.56 ware tubers) and subsequently produced the highest ware tuber yield plot^{-1} 20.62Kg/plot. While, TDa 297 recorded the least number of ware tubers (10.44 ware tubers) and equally recorded lowest ware tuber yield. Similar trend was observed for total fresh tuber yield, TDa1100302 recorded produced the highest total fresh tuber yield of 26.13Kg plot^{-1} and could be ranked the best among the genotypes in terms of tuber yield across the three agro-ecologies

Table 2: Means of yield components and yield of *D. alata* genotypes across three agro-ecologies in Nigeria yam-belt

Genotype	Number of emerged plant/plot	Plant vigour	Number of seed tubers/plot	Number of ware tubers/plot	Seed tuber yield/plot(Kg)	Ware tuber yield/plot(Kg)	Total fresh tuber yield/plot(Kg)

Effects of agro-ecologies on responses of yield and yield components of *D. alata* genotypes

Genotypes performed better in Southern guinea savannah for all yield and yield components traits phenotyped, except for seed tuber yield (Table 3). Though, in terms of total fresh tuber yield genotypes were responsive to agro-ecologies. The most responsive genotype is TDa1100203, while the non-responsive is TDa1100302. This characteristic is an indication of the genotype fair stability across the agro-ecologies where they were evaluated. Based on yield stability across the agro-ecologies, TDa1100302 and TDa1100264 were the best performing and were better than the national check TDa291. Generally, farmers would prefer high yielding genotype that will perform consistently in wide range of environments.

Table3: Effects of agro-ecologies on responses of yield and yield components of *D. alata* genotypes

Agro-ecology	Number of emerged plant/plot	Plant vigour	Number of seed tubers/plot	Number of ware tubers/plot	Seed tuber yield/plot (Kg)	Ware tuber yield/plot (Kg)	Total fresh tuber yield/plot(Kg)
Humid rainforest(Umudike)	9.89	2.4	9.31	12.94	5.93	14.54	20.47
Derived Savannah(Igbariam)	9.86	2.6	14.67	12.08	6.45	13.14	19.59
Southern Guinea Savannah(Makurdi)	7.39	2.9	9.25	14.92	4.18	19.28	23.46
Mean							
LSD0.05	0.40	0.21	1.86	0.9	0.7	1.48	1.48

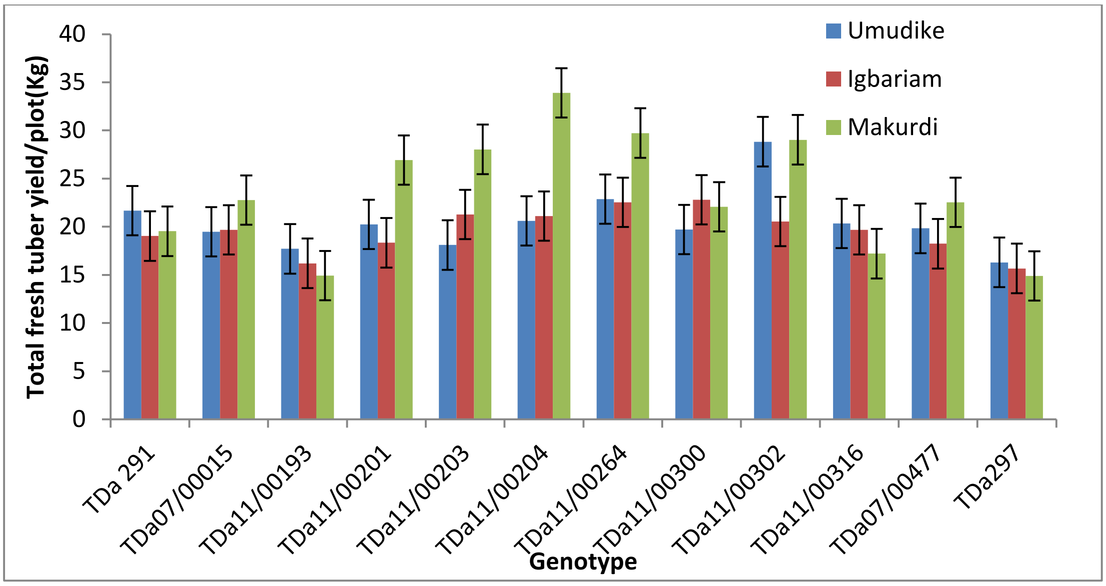

Figure 1: Effect of genotype x environment interaction on total fresh tuber yield plot^{-1} . error standard deviation value was used to insert and customised error bars, means with lower bars above the upper bars comparing means are significantly different at P=0.05

Conclusion

Genotype x environment interactions determined the performance of each genotype at particular location with regard to number of emerged plant plot^{-1}, number of ware tuber plot^{-1}, ware tuber yield plot^{-1} and total fresh tuber yield plot^{-1}. Based on yield stability across the agro-ecologies, TDa1100302 and TDa1100264 were the best performing and were better than the national check TDa291.

Abstract
A field study was conducted at the Joseph Ayo Babalola University Teaching and Research Farm, Osun State Nigeria to investigate the effect of foliar application of MLE and GLE on the vegetative growth and yield performance of Celosia argentea. The results showed that growth and yield of celosia were significantly (P<0.05) influenced by foliar application of Moringa leaf extract (MLE). The result also shows that the foliar application was significant in the evaluation of the plant height, stem girth and numbers of leaves produce the residual effects of this foliar application also improve soil physicochemical characteristics. With improvement in N, P, K, Ca and Mg. that was in moderate form during the pre-planting test. There was significant increase in herbage yield also with the application of Moringa leaf extract with 13.40kg/ha, increased in plant height after 3 weeks of transplanting with a height of 41.02cm, 12leaves, 3.79cm stem grith and leaf area index of 17.23cm^2.

Keywords: Moringa oleifera,Foliar, Fertilizer, Celosia argeata, Leaf, Extract and Growth

Introduction
The daily human intake of synthetic residual chemicals in there dietary component taken up by field crops during fertilizer application has led to various degrees of health challenges that has results to more poisonous, incurable ailments and at times death of the consumer. The idea of organic agriculture where plant and animal origin fertilizer is now trending as a replacement for the dangerous chemicals with serious residual effects. The depletion of soil nutrients due to continuous cropping reduces the soil organic matter, cause significant acidification and yield reduction (Batiano and Makwunye, 1991; Anonymous, 1995; Ajilore, 2008). There is therefore need for adequate fertilization or manuring in order to sustain soil productivity for optimum growth and yield of planted crops to ensure food security for the ever increasing growing population. *Celosia argeanta* commonly known as plumed cocks comb or the silver cock's comb is a herbaceous plant of tropical origin and is known for its very bright colours. *Celosia argeanta* is a tender annual that is often grown in gardens. It blooms in mid-spring to summer. It is propagated by seeds. The seeds are extremely small up to 43,000 seeds per ounce. The flowers are hermaphrodites (Grant and William F., 1954). *Celosia argeanta var. argeanta* or "Lagos Spinach" is one of the main boiled green in West Africa where it is known as *Sokoyokoto*(Yoruba) or *fararalayyafo* (Hausa). (Hanelt*et al*., 2001). Organic produce are found to be of higher nutrient, minerals and healthier (Ayelagbe, 2011). Organic farming has helped in eliminating health hazard caused by residue effect of chemical fertilizers used in inorganic farming. Leaf extracts are organic fertilizers with plant origin and are alternative sources of plant nutrients that are cheaper, eco-friendly and capable of enhancing sustainable crop production. The study was carried out to evaluate effects of *Moringa oleifera* and *Gliricidia sepium* leaf extracts as foliar fertilizer on vegetative growth of *Celosia argentea,* and also provide keen knowledge on the possibility of producing *Celosia argentea* and CO in large scale with little capital and have a healthy and high yield of production with the use of various nitrogen fixer plants leaf extracts.

Methodology

The research was conducted at JABU Teaching and Research farm, Longiude9°84°64° and Latitude 10°32°73° Ilesha-Akure road, Ikeji Arakeji, Osun State. (Google Earth, 2018)). The land was manually cleared of existing vegetation and bed constructed the raised seed bed of 1.5m width by 1.5mlong and about 0.5m high were prepared using hoe and spades. The *Celosia argeantea* L.var. TLV8. seeds to be used in this study will be bought from the National Institute of Horticultural Research (NIHORT), Ibadan. The *Moringa oleifera* and *Gliricidia sepium* leaves was harvested on the teaching and research farm. 100grams of freshly harvested leaves of *Moringa oleifera and Gliricidia sepium* to 1 litres of water during the extraction.

Data Collection

The growth parameters which include height of plant, leaf index rea, number of leaves, stem diameter and weight of plant after harvest were measured at random using three replications. This was carried out every five days. The measurement of the plant and leaf index was done using a ruler which was done using a ruler which was measured in centimeters, the stem was done using vernier caliper and weight was measured using a weighing scale while the number of leaves was done by counting.

Data Analysis

Analysis of Variance (ANOVA) was used to get the mean values of plant height, leaf area index, stem diameter, number of leaves and weight after harvest three weeks after transplanting.

Results and Discussion

Table 1 shows the result obtained from the experiment 3 weeks after transplanting in same environmental conditions but different treatment.

Table 1: **Mineral Evaluation of Moringa Leaf Extract (MLE)**

Parameters	T1 (Control)	T2(Moringa Leaf Extract)	T3 (Gliricidia Leaf Extract)
Plant Height(cm)	33.90	41.02	36.00
Stem Grith(cm)	2.31	3.79	2.31
Leaf Area Index (cm2)	14.94	17.23	16.33
Number of Leaves	10.00	12.00	9.00
Stem Yield/Weight (kg/ha)	5.45	13.40	7.50

Source: Computed from field data, 2018

The result shows that Moringa leaf extract is rich in nutrient such as Potassium, Calcium, Iron and Nitrogen which enhances the vegetative growth and yield of Celosia argentea. It also leads to nutrient accumulation for increase in leaf area index and other growth parameter. This further corroborates the findings of Abdul-Rahman M. A (2017). Plant height increases weekly with respect to treatment. Table above shows Treatment 2 i.e Moringa Leaf extract had the tallest plant 3WAT(Weeks After Transplanting). Stem was significant ($p<0.05$) in all other week with progression and treatment 2 getting the highest stem grith 3WAT with 3.79cm. This corroborates the work of Aliyu and Olanrewaju (1996) on Capsicum annum where they observe that the beneficial effects of N,P and K could be seen in the increase in the increase in the stem grith, where Treatment 1 and 3 has the same value of stem grith throughout the sample periods. Treatment 2 has the highest number of leaves at three WAT with 12 leave and the Treatment 1 has the lowest numbers of leaves with 9 leaves at 3 WAT at ($p<0.05$). This corroborated the study Zhang et al (2010) who noted that Nitrogen generally stimulates vegetative growth. Olaniyi and Ojetayo (2012) and Olaniyi et al (2008) reported that *C. argentea* increases in growth with increasing rate of Nitrogenous fertilizer and vegetative cropping system requires a greater degree of management. They noted that nitrogen increases the cell size and cellular number resulting from cellular number resulting from cell division and expansion that leads to increased number of leaves and other vegetative parts of the plant. Result shows that LAI was at its peak at 3 WAT (17.23cm^2),it is significant in third WAT, with Treatment 2 with the highest leaf area index (LAI) ($P<0.05$). This implies that LAI resulting from increasing fertilizer application due to better utilization of solar radiation which favoured photosynthetic capacity of the plant. This finding corroborates the study of Law-Ogbomo and Egharevba, (2008). The table also shows that treatment 2 has the highest herbage to stem yield, with a yield of 13.40kg/ha. This agrees with the findings of Ojeniyi et al. (2009) who reported that the use of inorganic fertilizer increases the yield of crops and have been found to be effective as a short term solution which demands consistence use on a long term basis.

Conclusion

Based on the results of the experiment, it has revealed that *Celosia argentea* sprayed with *Moringa oleifera* leaf extract was better than others in the same condition. The study has shown that the cultivation of *Celosia argentea* can be possible on foliar application of organic fertilizers with plant origin depending on the vegetative plant growth to measure. Based on the results obtained, Celosia performed best on organic foliar fertilizer of plant origin. Hence, the recommended foliar fertilizer for the cultivation of the Celosia argentea is *Moringa oleifera* leaf extract and alternatively the combination of *Moringa oleifera* and *Gliricidia sepium* leaf extracts can also be used for maximum output.

Abstract
A field experiment was conducted to evaluate the effects of rhizome sizes on the growth and yield of ginger crop in 2012/2013 cropping season at the Teaching and Research Farm, Department of Agricultural Education, Nwafor Orizu College of Education, Nsugbe, Anambra State. The experiment was arranged in a randomized complete block design with three replicate and the rhizome sizes were 10g, 15g, 20g 25g and 30g. Data on growth parameters were taken at 4, 12 and 20 weeks after planting (WAP), on plant height (cm), number of leaves, number of tillers and total leaf area (cm²) while fresh rhizome weight (g), rhizome length (cm) and width (cm) were evaluated at harvest. The results showed that ginger grown from 20g rhizome size had ($P < 0.05$) higher plant height (cm), number of leaves, number of tillers and total leaf area(cm²) than those grown from other rhizome sizes. Ginger grown from 20g rhizome size had higher rhizome fresh weight (118.39g), rhizome length (12.87cm) and width (10.78cm) than ginger yield from other treatments. Therefore for optimum yield of ginger 20g of rhizome size is hereby recommended.
Keywords: Ginger, Rhizome size, Growth and Yield

Introduction
Ginger (*Zingiber officinale* Rosccoe) is monocotyledonous, herbaceous, tropical plant belonging to the family *Zingiberaceae*.. Ginger even though a native to South East Asia, now it is grown commercially in most tropical regions (Abeykera et al., 2005). The top five ginger producer countries are India, China, Nepal, Nigeria, and Thailand. India is the largest producer of ginger accounting for more than 34% of the world production in 2011 followed by China (FAO, 2013). The modified underground stem otherwise known as rhizome is used worldwide as a preservative and as well as a spice for flavoring food and food products (Jakes, 2003). Nutritionally, ginger is an important source of vitamins and minerals in its fresh and dried (powdered) forms. It is known to supply significant levels of calcium, potassium, phosphorus, magnesium, niacin and vitamin C. (Raghavan, 2007). Apart from its nutritional values and flavoring agent, ginger is among numerous herbs known for their health benefits both in traditional and modern medicines. Ginger has a long tradition of being very effective in alleviating symptoms of gastrointestinal distress thereby facilitating digestion and treating stomach upset, diarrhea, and nausea. Furthermore, modern scientific research has also revealed that ginger possesses numerous therapeutic properties including antioxidant effects, an ability to inhibit the formation of inflammatory and carcinogenic compounds, and direct anti-inflammatory effects (UMMC, 2006; Shuka and Singh, 2008; Islam et al., 2008; Ewuziem et al., 2009 and Karna et al., 2012). The fact that ginger cultivation was mostly in the Northern part of the country except at Umudike (NRCRI) who has the mandate as a research institute; it is as an important commercial spice crop in the area and has been a good source of income for farmers who grow it. Despite its remarkable uses and contribution to the livelihoods of smallholder farmers and to the economy of the country, information on different agronomic practices of ginger cultivation such as improved varieties, agronomic practices like spacing, planting date, land preparation system and propagule size are very little in the study area in spite, of the diverse agro-climatic conditions with abundance of natural resources which provide good opportunities for ginger production. Therefore in view of the above factors, the present study was conducted to find out the best

rhizome size that will give the best growth and yield of ginger. The rhizome which is the economic yield as well as the planting material ginger affects the establishment, growth and yield of the crops. The use of large size rhizomes means the loss of the commercial product whereas the use of small seed rhizome leads reduced growth and yield. Therefore, selecting the right size of planting material (length, weight and number of growing buds per seed) is a very critical factor in the cultivation of rhizomatous spices such as ginger and turmeric (Girma and Kindie, 2008). They further opined that rhizome sizes also significantly affected fresh rhizome weight, length of rhizome, number of fingers per rhizome and rhizome yield per hectare. Hailemichael and Tesfaye, 2008) in their study found out that an increase in seed rhizome size (using a rhizome seed size of 9.1 cm) will significantly increase the major growth parameters and dry rhizome yield and using large seed rhizome was also found to be economically profitable. Similarly, Monnaf et al., (2010) in their study reported that rhizome size significantly influenced all the measured parameters like plant height (37.64cm), number of leaves per plant (26.47), number of tillers per clump (15.94), weight of old mother rhizome (11.77 g) per plant, amount of primary rhizome (1971.78 g) per clump. They further stressed that the amount of secondary rhizome (129.12 g) per clump, the highest yield (135.14 g) per plant, the maximum yield (4.57 kg) per plot were produced using 30-35g of rhizome. The lowest were produced by 10-15g of rhizome attributed to larger size which emerged earlier with vigorous and rapid growth using the initial reserve food materials in it. Sengupta and Dasgupta (2011), in a study posited that variations in growth and yields are due to seed rhizome size and further stressed that plants produced from the largest rhizome size emerged earlier and showed vigorous and rapid growth using the initial reserve food materials resulting to maximum yield and yield attributes.

Materials and methods

The experiment was carried out at the Teaching and Research Farm of the Department of Agricultural Education, Nwafor Orizu College of Education, Nsugbe during the 2012/2013 cropping seasons. Nsugbe is located at latitude 06^{o}25'N and longitude 06^{o}82'E of the equator. This location lies in the tropical rain forest zone with the average annual rainfall between 1,500mm and 2000 mm .It has a bimodal, distribution with peak in July and September (NIMET, 2013). The experimental area was cleared and stumped. Hoe was use to prepare 15 beds measuring 2m x 2m, while ginger rhizomes were sown on the beds at a spacing of 20cm x 20cm at the depth of 5cm and covered with top soil. The experimental design was a randomized complete block design (RCBD) replicated three times and the treatments compromised of five rhizome sizes 10g, 15g, 20g, 25g and 30g. The plots were weeded manually three times and other agronomic practices were carried out as the need arises. Data were collected on plant height using a metric rule, number of leaves and numbers of tillers were visually counted while leaf area were measured using graphic method and multiplied by the number of leaves for total leaf area of the plant. Rhizome's fresh weights were obtained using a digital scale while length and width were measured with a ruler and venire caliper. The data obtained were subjected to analysis of variance (ANOVA) using SAS (2010) and the means showing significant difference were separated using Duncan Multiple Range Test at 5% level of probability.

Results and Discussion

The results of the effect of different rhizome sizes on plant height and number of leaves of ginger are presented in Table 1. The plant height was significantly affected by the age of ginger crop. At 4 weeks after planting (WAP), plant heights of ginger grown from rhizome sizes of 20-30g were significantly enhanced than those grown from10-15g rhizome sizes that were significantly depressed. Within a range of 12-20 WAP, 20g rhizome size was significantly higher $P<0.05$ followed by 15 and 25g while 10 and 30g were least significant in plant heights. The results of number of leaves increased significantly across the periods of sampling. Leaf production at 4WAP, was significantly higher in ginger grown from 15-25g (4.65, 4.99 and 4.54) while 10 and 30g rhizome sizes were significantly depressed (4.20 and 4.35). Within a range of 12-20 WAP, numbers of leaves were statistically higher in rhizome size of 20g (16.31 and 19.25) than other treatments that while 30g rhizome size was depressed (14.73). Rhizome size effects on growth parameters of ginger (plant height, number of leaves per plant and number of tillers per plant) is in tandem with the findings of Hailemichael and Tesfaye (2008) and Monnaf et al (2010) who reported that rhizome size significantly influenced all the measured parameters like plant height (37.64cm), number of leaves per plant (26.47) and number of tillers per clump (15.94). They further stressed that the highest yield of (135.14 g) per plant, the maximum yield (4.57 kg) per plot produced using 30-35g of rhizome and lowest produced by 10-15g of rhizome are attributed to larger size which emerged earlier with vigorous and rapid growth using the initial reserve food materials in it. The effects of different rhizome sizes on the number of tillers and total leaf area of ginger are shown in Table 2. The tiller production were statistically similar P=0.05 at 4WAP in all the treatments. At 12 WAP, tiller production were significantly depressed in ginger grown from 10g and 30g rhizome size (3.20 and 3.24) respectively, while 20g rhizome size was significantly higher P>0.05 (4.35) than other treatments. Ginger grown from 20g rhizome size was statistically higher 5.45 than other treatments that are statistically similar 4.05, 4.12, 4.15 and 4.40 as number of tillers at 20 WAP. At 4th - 20th WAP, total leaf areas of ginger planted were significantly higher in 20g rhizome size (162.43, 739.60 and 1008.20cm$^{2)}$ followed by 25g rhizome size while tiller production from 10g rhizome size were significantly depressed (130.28, 677.55 and 816.25cm^2). The variations observed among the different rhizome sizes in growth parameters are in line with the findings of Sengupta and Dasgupta (2011) who reported that variations in growth and yields are due to seed rhizome size and further stressed that plants produced from the largest rhizome size emerged earlier and showed vigorous and rapid growth using the initial reserve food materials resulting to maximum yield and yield attributes. The results of ginger yield and yield characters from different rhizome sizes are presented in Table 3. Ginger yield for crops grown from 20g rhizome size were significantly higher in rhizome fresh weight (118.39g), rhizome length (12.87cm) and width (10.78cm) than ginger yield from other treatments. Between and within rhizome fresh weight, length and width, ginger yield and yield characters were most significantly depressed on ginger grown from 10g and 30g rhizome sizes than other rhizome size. The results are in tandem with the findings of Girma and Kindie (2008) who revealed that rhizome size significantly affected fresh rhizome weight, length of rhizome, number of fingers per rhizome and rhizome yield per hectare. They further stressed that the use of large size rhizomes means the loss of the commercial product whereas the use of small seed rhizome resulted to reduced growth and yield. Hence, they advised that in selecting the right size of planting material (length, weight and number of growing buds per seed) is a very critical factor in the cultivation of rhizomatous spices such as ginger and turmeric. The results are also in agreement with Monnaf et al., (2010) who reported that rhizome size significantly resulted to the highest yield of (135.14 g) per plant, the maximum yield (4.57 kg) per plot produced using 30-35g of rhizome and lowest produced by 10-15g of rhizome are attributed to larger size which emerged earlier with vigorous and rapid growth using the initial reserve food materials in it.

Conclusion

The study has showed that different rhizome size significantly affect the growth and yield of ginger. Therefore, for fresh rhizome weight, length and width, it is recommended that ginger should be grown using 20g rhizome size than other rhizome sizes as rhizome is the economic yield as well as the planting material of ginger.

Influence of Time and Rate of Poultry Manure on Cucumber (*Cucumis sativus* L.) in Semi -Arid Environment

C.B. Ekeoma and A.G. Adesoji*
Department of Crop Production and Protection, Faculty of Agriculture and Agricultural Technology, Federal University Dutsin-Ma, Katsina State, Nigeria
*Corresponding Author E-mail: *aadesoji@fudutsinma.edu.ng*

Abstract
The trial was conducted to determine the influence of time and rate of poultry manure on cucumber (Cucumis sativus L.). Field experiment was carried out in the dry season of 2017 at the Teaching and Research Farm of Federal University of Dutsin-Ma, Katsina State, Nigeria. The treatments consisted of four different times of poultry manure application (T_1=two weeks before planting, T_2=one week before planting, T_3=at planting and T_4=one week after planting) and three rates of poultry manure (0, 10 and 20 t ha^{-1}) and were arranged in a randomized complete block design and replicated three times. Time of poultry manure was significant number of leaves per plant, vine length per plant, number of fruits per hectare, fruit weight per plant and fruit yield. Poultry application at two week before planting of cucumber was found to be appropriate for cucumber production in the study area. [1] was not significant on growth and yield performance of cucumber. Application of poultry manure significantly increased number of leaves per plant, vine length per plant, number of fruits per hectare, fruit weight per plant and fruit yield. Soil fertilization at 10 t ha^{-1} of poultry manure seems to be suitable for growth and yield of cucumber in this area of study. Application of 10 and 20 t ha^{-1} of poultry manure produced 167.7 and 190.9% increases in cucumber fruit yield when compared with no poultry manure application, respectively.

Introduction
Cucumber (*Cucumis sativus* L.) belongs to the family of cucurbitaceae and is one of the important fruit vegetable crops grown in Nigeria. It is grown in commercial quantity in Northern Nigeria, eaten largely in different parts of the country and enjoyed across different ethnic groups (Iyagba and Isirima, 2017). The potential uses of cucumber have made the crop to gain popularity Nigeria. It is used for various culinary purposes and plays important role in maintaining good health because of its minerals and vitamins (Yamaguchi, 2000). It is eaten raw, cooked and used as a salad. It has been reported that minerals and vitamins present in cucumber assists in building up bone and teeth, and protects the human body and promotes major metabolic processes in the body and enhances vitality and good health (Iyagba and Isirima, 2017). Cucumber has been observed to have health benefits like ability to control hypertension in human body and causes human body to escape kidney challenges when taken on regular basis (Vimala *et al.*, 1999). Despite the important of cucumber as a major source of mineral s and vitamins, the production is still is low as result of various factors which include nutrient/water deficiency (Ayotamuno *et al*., 2007). Nigerian savanna soils difficultly support worthwhile crop production without implementing soil fertility strategies of improving fertility carrying capacity through either organic or inorganic fertilizer addition (Adesoji *et al.*, 2018). Therefore, it becomes very necessary to add organic fertilizer to Savanna soils because of its capacity of leaving the soils safer and healthier than inorganic fertilizers. Also, organic manures have been reported to sustain cropping systems by better nutrient recycling and improving physical, chemical and biological properties of soil (Ojeniyi, 2000). The major target of every farmer is better yield for better income which only possible when all production factors including inputs like organic manure are applied or available at optimum levels. The input of organic manures has been a major factor for long term cropping in the tropics because of slow mineralization of organic manures enhance crop yield for a long period of time (Gambo *et al*., 2008). Timing of

when the organic manure should be applied becomes so importance so that the effect can easily be felt by cucumber plants for enhanced growth and development and consequently, improved yield. It has reported that when organic manures are properly added to soil, they can be valuable resources for enhanced production of crops (Ajari, 2003). This study was therefore designed to investigate the influence of time and rate of poultry manure on cucumber.

Materials and Methods

The study was conducted in the dry season of 2017 at the Research and Teaching Farm of Federal University Dutsin-Ma, at Badole (Longitude $07^0 29'29''$ E and Latitude $12^0 27'18''$ N) with altitude of 605 m in the Sudan savanna ecological zone of Nigeria. The treatments consisted of four different times of poultry manure application (T_1=two weeks before planting, T_2=one week before planting, T_3=at planting and T_4=one week after planting) and three rates of poultry manure (0, 10 and 20 t ha^{-1}). The treatments were arranged in a randomized complete block design with various factorial combinations and replicated three times. The gross plot size was 2m x 2m ($4m^2$) and the net plot was 1m x 2m ($2m^2$). The experimental field was harrowed and consequently watered by flooding method. The field was further harrowed to give fine tilts and prepared into raised beds (plots) of 1.5m x 2m in basin form for irrigation purpose. Poultry manure was added to various plots by thoroughly mixing the manure with soil according to the treatments at two weeks before planting. Seeds of exotic variety named PIONSETTE 44 were planted with two seeds per hole at a spacing of 50cm x 50cm on the beds at two weeks after poultry manure incorporation. The cucumber seedlings were thinned to one seedling per stand at two weeks after sowing. Nitrogen fertilizer as urea (46%N) was applied to the cucumber at 2 weeks after sowing (WAS) according to treatments. The field was irrigated twice a week using basin method. Weeds were controlled using hoe at 3 and 6WAS. Samplings on number of leaves and branches per plant were done at 4 ad 6 weeks after sowing (WAS) while number of fruits per hectare (kg), fruit weight per plant (g) and fruit yield (kg/ha) were obtained at harvest. Data collected from the observations were subjected to statistical analysis of variance (ANOVA) as described by Gomez and Gomez (1984) using SAS package version 9.0 of statistical analysis (SAS institute, 2002). The differences among treatment means were separated using Duncan's Multiple Range Test (Duncan, 1955). Effects were considered statistically significant at 5% level of probability.

Results and Discussion

Time of application of poultry manure was not significant on number of leaves of cucumber at 2WAS and 6WAS but was significantly increased at 4WAS where application of poultry manure at 1 week after planting was significantly different from application of poultry manure at 1and 2 weeks before planting on number of leaves per plant (Table 1) but at par with application of poultry manure at planting. Application of poultry manure did not significantly increase the number of leaves per plant of cucumber at 2WAS and 6WAS but significantly increased number of leaves per plant at 4WAS. Application of 10t ha-1 of poultry manure produced significantly more number of leaves than plots that received no poultry manure but was at par with plots treated with application rate of 20t ha-1 poultry manure. Time of application of poultry manure significantly increased number of branches at 4WAS but did not significantly increase number of branches per plant at 6WAS. Application of poultry manure at 2weekks before planting produced significantly more number of branches than application of poultry manure at 1week after planting but there was no significant difference between application of poultry manure at 2weeks before planting, 1week before planting and at planting at 4WAS. Application of poultry manure was not significant on number of branches at both 4WAS and 6WAS. Time of application of poultry manure significantly increased number of fruits per hectare, fruit weight per plant and fruit yield per hectare of cucumber (Table 2). Application of poultry manure at 2weeks before planting produced significantly higher number of fruits per hectare, fruit weight per plant and fruit yield than application of poultry manure at 1week after planting and also at planting on number of fruits per hectare but was statistically similar to application of poultry manure at 1week before planting and at planting for fruit weight per plant and fruit yield of cucumber. Increasing the application of poultry manure from zero (0 t ha^{-1}) to 10t ha^{-1} significantly increased the fruit weight per plant, number of fruit per hectare and fruit yield but a further increase of poultry rate from 10 t ha^{-1} to 20 t ha^{-1} produced no significant difference on both parameters. Application of poultry manure was found to give 167.7 and 190.9% increases in fruit yield over the control for 10 and 20 t ha^{-1}, respectively

The significant increases reported on number of leaves per plant, vine length per plant, number of fruits per hectare, fruit weight per plant and fruit yield as influenced by time of poultry application could attributed to the fact that time is needed for the decomposition and consequent mineralization of the added poultry manure. It has been reported by Adesoji (2015) that the type and quality of organic materials added to soil for nutrient improvement determines the rate of decomposition and nutrient release status of the materials. Better performance of the measured parameters of cucumber observed at two weeks before planting could have been that the time was enough to cure and speed up the decomposition process and consequent mineralization of the manure. Abdulmaliq *et al*.(2015) reported that okra growth responded positively to the application of poultry manure two weeks before planting which was attributed to the decomposition rate of poultry manure applied two weeks before planting that made nutrients available for the growing okra when needed most. Significant increases observed on number of leaves per plant and vine length of cucumber as a result of poultry application could be attributed to the capacity of poultry manure to make available the embedded nutrients especially nitrogen, phosphorus and potassium for the growth and development of the crop. This in line with the report of Okoli and Nweke (2015) where poultry manure was reported to have an ability to enhance the soil organic matter (OM) content and in turn release the plant nutrients in available form for plants to use. The marked increases on number of leaves per plant and vine length of cucumber caused by application of poultry manure could also be that the added poultry manure created a favourable soil physico-chemical environment which enhanced photosynthetic activities of the cucumber plants for increased growth and development. Similarly, Hamma *et al*. (2012), Nweke *et al*. (2014) and Okoli and Nweke (2015) reported that application of poultry manure increased growth of cucumber. The significant increases observed on number of fruit per hectare and fruit weight per plant after fertilization with poultry manure could be attributed to the positive influence of poultry manure on number of leaves per plant and vine length per plant which culminated in significant increases observed on these yield components. Khan *et al*. (2017) reported a significant increase of average fruit weight of cucumber which was attributed to the high concentration of nutrients in high poultry manure level which boost up the growth and yield. It was equally reported that significant increase on number of fruits per plant by Khan *et al*. (2017) was due to Poultry manure ability to improve plant nutrient availability, bulk density and water holding capacity of the soil which in turn increased the vegetative growth, accelerated the division of meristematic tissue and metabolic reactions and caused plants to take more nutrients which increased the number of fruits per plant. Significant increase observed on cucumber fruit yield of cucumber after fertilization with poultry manure could be attributed to the increases observed on growth and yield components which culminated into better fruit yield of cucumber. The significant cucumber fruit yield after application of poultry manure could also be as a result of the capacity of poultry manure to improve biological, physical and chemical properties of soil, which might have created safe and healthy soil for better growth and development of cucumber plants which culminated in marked increase observed on fruit yield of cucumber. Similar fruit yield increase as a result of poultry manure application was observed by Hamma *et al*. (2012), Nweke *et al*. (2014), Okoli and Nweke (2015) and Khan *et al*. (2017).

Conclusion

Based on the results obtained from this study, conclusion can be drawn that time of poultry manure had significant effect on number of leaves per plant, vine length per plant, number of fruits per hectare, fruit weight per plant and fruit yield of cucumber where application of poultry manure at two weeks before planting was found most suitable time to apply poultry manure for cucumber production. Poultry manure fertilization at the rates of 10 and 20 t ha^{-1} exerted significant influence on growth and yield performance of cucumber. Application of 10 t ha^{-1} of poultry manure seems to be appropriate for the cucumber production in Sudan savanna ecological zone of Nigeria.

Abstract
The field experiment was carried out during the 2013 dry season at the College Farm of Federal College of Forestry Mechanization, Afaka-Kaduna located at latitude 10⁰37'N, longitude 07⁰21'E elevation of 644m above the sea level in the northern guinea savannah agro-ecological zone to evaluate the effect of intra-row spacing and the time of harvesting on onion production. The treatments consist of three intra-row spacing of 10cm, 20cm, 30cm and two harvesting time of 77days, 107days respectively and a control (92days) as farmers practice, was laid out in Randomize Complete Block Design (RCBD) and replicated three times. The growth parameters observed are plant height and number of leaves at 7, 9 and 11WAT, while yield parameters are number of bulbs/plant, bulb/plot, weight of fresh bulb/plant and weight of fresh bulb/plot. The intra-row spacing of 30cm and harvesting at 77days gave significantly higher plant height while intra-row spacing of 10cm and 20cm and harvesting at 77days produced more number of leaves and number of bulbs/plot. The results obtained show that the treatments had significant effect on the characters measured. Therefore, for maximum growth and yield of onion production intra-row spacing of 20 cm and harvesting at 77 days should be recommended and adopted in the study area.
Keywords: Onion, Spacing and harvest time

Introduction
Onion (*Alliun cepa* (L) belongs to the family *Alliaceae* and is of immense benefit due to its diet and medicinal values. Onion is one of the most important vegetable crops in Nigeria, where it is exported and is an important condiment in the preparation of curry and spicy dishes, the crop is grown for consumption both in the green state as well as in mature bulb (FAO, 2005). Onion is one of the oldest food sources in the world. Onion is popularly called 'Albassa' in northen Nigeria; it is grown under irrigation with low humidity. Onion exhibits particular diversity in the eastern Mediterranean countries, through Turkmania, Tajikistan to Pakistan and India, which are the most important sources of genetic diversity and believed to be the center of origin (Brewester, 2008). The total area under production of onion in Nigeria is estimated at 0.1- 0.2 million hectares (Dantata, 2008). In Africa, the leading countries are Niger Republic with 36 tons/ha, Egypt 30.5 tons/ha, South Africa 26 tons/ha and Morocco 24.9 tons /ha (FAOSTAT, 2013). Despite the ranking of onion as the second most important vegetable in Nigeria, the present production level does not meet the demand of the teeming populace. Though, the consumption of onion cuts across the country, its production is limited to the northern part of the country, restricted to fadama areas, and grown mostly during the dry season under irrigation. Nigeria is leading in onion production in West Africa with 0.615 million metric tons of dry bulb (FAOSTAT, 2013) but the consumption rate did not meet the continuous market demand; this could be as a result of its nutritional value and medicinal uses. It can be easily assumed that there is always shortage of onion in Nigeria and this is due to improper agronomy practices. Successful onion production depends upon the identification of appropriate agro-techniques that will promote growth, development and bulb production satisfactorily. Varying the spacing between plants has been found to have a great influence on growth and development of the crop, such exploitation can be accomplished when population density of a crop exercise maximizes pressure on all production, such as solar radiation, soil nutrient and water (Khan *et al.,* (2002). Agronomic

practices are the best that will attain the correct amount of food for maximum growth and production; this is usually achieved by using correct intra-row spacing. Khan *et al.* (2002) stated that a uniform distribution of plant per unit area is a perquisite for yield stability. Khan *et al.* (2002) observed that wider plant spacing in onion, resulted in heavier bulb production, they also stated that wider plant spacing would also increase bulb diameter of onion. Delaying in harvesting of onion till after the fall or top down of 80% of leaves resulted in increases in the rate of storage rot. However, result on yield tends to show that early and late harvest lead sprouting, rotting and later to loss in quality of yield (Khan *et al.,* 2002). Therefore, the optimal time of harvest for maximum yield of onion is necessary. In view of these, the trial thus examined the response of onion to intra-row spacing and harvest time with the aim of recommending the most appropriate spacing and harvesting time for the sustainability, vigorous growth and yield in the study area.

Materials and Methods

The experiment was carried out during late 2013 to early 2013 dry season at the Federal College of Forestry Mechanization Afaka, Kaduna experimental site $10^{0}37^{'}$, $07^{0}21$'E and 644m above sea level in the Northern Guinea Savanah agro-ecological zone. The treatments consist of three intra-row spacing 10, 20 and 30cm and two harvesting time, 77 and 107 days and a central of 92 days (Farmers practice) which was arranged in factorial combination. The treatments were laid out in Randomized Complete Block Design (RCBD) replicated three times to give a total of eighteen treatments. A seed of (COMPR4) were used as a test crop and was sourced from the Institute for Agricultural Research, ABU Samaru, Zaria. Nursery beds of 2m x 2m were marked out and cleared. Organic manure (poultry) was incorporated and watered for two weeks before planting. Seeds were drilled into rows of 15cm apart to raise onion seedlings on 8th December 2013. Regular watering was carried out by means of watering can and hand-pulling of grasses until the seedlings were ready for transplanting at the area for 8 WAS. The nursery beds were thatched with dry grass as mulch in order to provide shade for the seeds before germination and prevent loss of soil nutrients. Prior to land preparation, composite soil samples were collected at five different locations within the farm at the depth of 0-15 cm and 13-30cm using soil auger and the soil was subjected to laboratory analysis for physical and chemical properties of the soil. At eight (8) WAS healthy and vigorous seedlings were selected from the nursery. The seedlings were removed carefully with the ball of earth to avoid damage to the root. The sunken beds were prepared and watered before transplanting. The size of the bed was 2m x 1.5m = ($3m^2$). The field was marked out into plots and thereafter leveled. Transplanting was carried out on 8th February, 2013 with one seedling per hole at a depth of 5cm, with spacing of 10 x 2 cm, 20 x 2 cm and 30 x 2cm, respectively. Agronomic practices such as irrigation, fertilizer application, weeding, pests and disease control were properly observed. Harvesting was carried out according to the treatments 77, 92 and 107 days after transplanting. During this time 50 – 80% of the leaves fall over and it was carried out using handing pulling. Four plants were tagged within a plot for data collection. Data were collected on plant height, number of leaves/plant, crop vigor score, number of bulb/plant, number of bulb/plot, weight of bulb/plant and weight of bulb/plot. Plant height was taken using meter rule to measure the centre of leaf from soil level to the top of the leaf, while number of leaves was obtained by counting the number of leaves from the topped plant and average computed at 7, 9 and 11 WAT. The crop vigor score was taken at 4, 9, and 11 WAS using a scale of 1 to 9 where 1 represented dead plant and 9 represented the most vigorous plant. Number of bulbs/plant was taken by counting the number of bulbs in each uprooted tagged bulb during harvesting and average computed. Weight of the bulb/plant and bulb/plot was obtained by using measuring scale graduated in gram (g) to measure the weight and average computed. The data obtained were subjected to Analysis of Variance (ANOVA). Mean separation was done at 5% level of probability using Duncan Multiple Range Test (DMRT) as suggested by Duncan, (1955).

Results and Discussion

Table 1 shows the effect of intra-row spacing and time of harvest of onion on plant height, crop vigor and number of leaves/plant at 7, 9 and 11 weeks after transplanting (WAT) during 2013 dry season at Afaka. The results obtained show that there was no significant difference on intra-row spacing at 7 WAT but significant at 9 and 11 WAT on crop vigor and number of leaves/plant. Intra-row spacing 10cm, 10 and 20cm gave higher crop vigor of (9.78) and produced more number of leaves/plant (62.44) while the least were obtained at 20cm of 3.67 and 30cm of (41.33) respectively. However, harvesting time of 77 days gave higher crop vigor of (9.67) and more number of leaves/plant of (57.44) while the least were obtained from 107 days of (4.78) and (31.56). Significant interaction was observed at intra-row spacing at 30cm and 77 days of harvest time. Table 1 shows the effect of intra-row spacing and time of harvest of onion on number of bulb/plant, bulb/plot, weight of bulb/plant and bulb/plot during 2013 dry season at Afaka. The result obtained shows that there was no significant difference on number of bulb/plant and bulb/plot but significance on number of bulb/plot. Intra-row spacing of 30cm produced more number of bulb/plant of (1.42) and spacing at 10cm produced number bulb/plot of (56.33). The least number of bulb/plant and bulb/plot was produced by spacing at 10cm of (1.00) and 50cm of (19.11) respectively. However, there was no significant difference on harvest time on number of bulb/plant and bulb/plot. Harvesting time of 92 days produced more number of bulb/plant and bulb/plot of 1.53 and 35.78 while the least was produced at 77 days of (1.00) and (33.89). No significant interaction was observed. There was significant difference on weight of bulb/plot. Intra-row spacing at 30cm gave heavier bulb/plant and bulb/plot of (326.58) and (2000.1g) while spacing at 10cm gave the least of (250.5/g) and (1000.72g) respectively. However, there was no significant difference on time of harvest on weight of bulb/plant/plot. Harvest time of 92 days gave heavier bulb/plant and bulb/plot of 35.78 and 77 days had heavier bulb/plot (2000.7g). The least weight bulb/plant was obtained from 77 days of 33.89g and 107 days of (1000.16g). No significant interaction was observed. The higher growth and yield of onion obtained during the trial 2013 dry season was due to the relatively moderate climatic weather condition during the time when the experiment was conducted. The higher number of leaves/plant of (62.44) obtained in plant with 30cm and 20cm spaced followed by plant with 10cm planting spaced (41.33) per plant respectively, shows non-significant behavior during growing period of 5 and 7 WAT but significant at 9 and 11WAT which may be as a result of environment factor and heterogeneous nature of soil. The intra-row spacing of 10cm gave the minimum number of leaves/plant (41.33). This might be due to competition among the plants to achieve the required food for their growth due to the closer spacing. The result obtained is in agreement with Khan *et al.* (2002) who reported that closed plant spacing produced minimum number of leave in plant, due to higher competition between the plants. Significantly maximum bulb weight (326.58g) was recorded in plant spaced at 30cm apart followed by 20cm plant spacing with (293.29g). Production of heavier bulb at wider spacing might be attributed to the fact that, plants widely spaced experienced less or little competition for limited environmental resources compared to closely spaced plants. Similar result was reported by Balraj *et al.* (1998); Khan *et al.* (2002) who observed that wider plant spacing in onion resulted in heavier bulb production. Intra-row spacing also affected the bulb yield/plot, the data obtained shows that maximum bulb yield/plot of (56.33kg) was recorded in plants with closer spacing of 10cm, followed by plants spaced at 20cm and 30cm producing average yield of (29.67kg) and (19.11kg) per plant, respectively. On the other hand close spacing may produce higher yield but the quality of produce may be adversely affected and may not attract better market (Singh, 1984).

Conclusion

The result obtained from the trial shows that intra-row spacing of 20cm and harvest time of 77 days gave higher plant height, produced more number of bulb/plant/plot and heavier weight of bulb/plant/plot than all other treatments on the character measured. Based on the finding, for maximum growth and yield of onion, intra-row spacing 20cm and harvest time of 77 days may be recommended in the study area. For a good growth and yield of onion (*Allium cepa* L.) production during dry season, intra-row spacing at 20cm and harvest time of 77 days could be adequate for maximum production of onion in the study area. Therefore, for maximum growth and yield of onion intra-row spacing at 20cm and harvest time of 77 days may be adopted, and recommended in the study area.

Abstract
The experiment was conducted during 2013 rainy season at the school farm of Federal College of Forestry Mechanization, Afaka-Kaduna, located at latitude 10⁰37'N, longitude 07⁰21'E and elevation of 644m above sea level in the Northern Guinea Savanna agro-ecological zone to determine the effects of inorganic fertilizer application levels and pruning periods on yield and yield components of roselle (Hibiscus sabdariffa L.). The treatments comprised of two levels of inorganic fertilizer application (NPK 20:10:10) 30kg/ha and 60kg/ha, two pruning periods (eight (8) and ten (10) week after planting) and control (unpruned) farmers practices which was arranged in factorial combination laid out in Randomized Complete Block Design (RCBD) and replicated four times. The parameters taken include number of calyx/plant, calyx weight/plant, calyx weight/plot, calyx yield kg/ha, number of seeds/capsule and 100 seed weight. The result obtained showed significant difference on number of calyx/plant, weight of calyx/plant, weight of calyx/plot, weight of calyx kg/ha. Therefore, application of inorganic fertilizer levels at 60kg/ha and pruning period at eight (8) weeks after planting (WAP) manifested significantly higher effects on yield and yield components of Roselle and should be recommended and adopted for use in the study areas.
Keywords: Roselle, fertilizer application and pruning period

Introduction
Roselle (*Hibiscus sabdariffa L.*) is a species of *Hibiscus* native to the West Africa and it is known in different countries by various common names sorrel, karkade, jamaica, rosella, zoborodo, isapa, pupa. It belongs to the family of *Malvaceae* commonly known as "Karkade" (Maunde, 2010). *Hibiscus sabdariffa L.* probably originates from Africa, where it may have been domesticated in Sudan about 6000 years ago, first for its seed and later for leaf and calyx production. The selection for fibre production took place in Asia, where cultivation was reported from the beginning of the 20th century, for example in India, Sri Lanka, Thailand, Malaysia and Java (Babajide *et al.,* 2004). In tropical Africa, it is common in the Savanna regions of the West African, it is often found as an escape from cultivation. However, apparently truly wild plant of *Hibiscus sabdariffa L*. has been collected in Ghana, Nigerian and Angola (Maunde, 2010).
Despite the numerous importance of roselle, the production in Nigeria is still low; this might be as a result of the fact that production is limited to small holding under subsistence practices. Roselle is grown predominately in savanna where there is low inherent low fertility of the soil this result to low productivity of crops. This trial thus investigated the response of roselle to different levels of inorganic fertilizer and pruning periods, with the aim of recommending the most appropriate level of fertilizer requirement and pruning period on yield and yield component of rosselle in the Northern guinea savannah ecological zone of Nigeria.

Materials and Methods
The field trial was conducted during 2013 raining season at the Federal College of Forestry Mechanization Afaka, Igabi Local Government Area of Kaduna state. The experimental farm site is

located at latitude 10 37N & Longitude 7 47E and 644m above sea level situated in the Northern guinea savannah ecological zone of Nigeria. The experimental comprised of two level of inorganic fertilizer application 30 and 60 kg/ha, two pruning periods eight (8) and ten (10) weeks after planting and a control unpruned (farmers practiced). This was arranged in factorial combination and laid out in Randomized Complete Block Design (RCBD) and replicated four times. Prior to land preparation, composite soil samples were collected at five different locations within the farm at the depth 0-30cm using soil auger and the soil was subjected to laboratory analysis for physical and chemical properties of the soil. The meteorological report were obtained from federal Airport authority Kaduna as shown in appendices i and ii respectively. The seeds were sourced from Institute for Agricultural Research, Samaru, Zaria and the variety used was local. It is of medium height with a profuse branching habit with dark stems, petiole and midribs. The local variety product is high quality calyx preferred by consumers and marketers. The seeds were dressed with Apron plus at the rate of 5g per 2kg seeds before planting to protect them from soil borne, pest and diseases. The experimental site was cleared, harrowed twice and ridged at 75cm spacing. The gross plot size was 3.8m x 2.5m (9.5m^2) consisting of six ridges, 2,5m long, spaced 0.75m apart and 1m between the replication and plot. The net plot was 2.3m x 1.5m (3.5 m^2) which made up of four ridges. The seeds were planted 26th July, 2013 manually using hand at the spaced of 50cm x 75cm. Six seeds were planted per hill on a depth of 3-4 cm which was later thinned to two plants per stand at two weeks after planting. Inorganic fertilizer (NPK) 20: 10: 10 was applied in two split doses at two and seven weeks after planting according to the treatments. Pruning of the main stems was carried out at 8 and 10 WAS using razor blade according to the treatments. Weeding was carried out at 3, 6 and 9 WAP using manual hoe-weeding, pest and diseases were monitored and controlled using insecticide Uppercut 500EC (Lambdacyhalothrin) at the rate of 25 ml per 15 litres of water poured into CP-15 knapsack sprayer and sprayed commenced from two weeks after planting as a routine preventive measure against pests and diseases. Harvesting commenced on 29th November 2013 manually using sharp knife during this time the calyx were fully matured. The plant reached full physiological maturity at sixteen weeks after planting and ready for harvest when the lower leaves have been shedded and lower capsules on the stem were about to split. Seeds turned reddish brown and capsules were about to open. The calyx was separated from the capsule, air dried and then the capsule was shelled to obtain the seeds. A destructive sample of five plants was taken at random from the four inner rows of experimental plot at maturity to measure yield and yield components. Observations were carried out on number of calyx and were obtained by counting total number of harvested calyx from five randomly selected plants in each plot and average computed. Calyx's dry weight/plant this was obtained by peeling off the calyx from the capsule of five selected plants using simple hand tools. The calyx were air dried to constant weight, using Denver electronic digital scale model XP 300 weighing at 0.01g precision and then average calyx yield per plant (g) was determined. Calyx dry weight /plot, harvested calyx from each plot was air-dried removed from capsule and weighed. The mean average computed. Calyx yield kg/ha**,** the yield per plot weighed was later converted to per hectare basis using this formula.

$$\text{Calyx yield kg/ha} = \frac{\text{calyx yield kg/plot x } 10{,}000\text{m}^2}{\text{Harvested plot area m}^2}$$

Number of seeds/capsule; ten (10) capsules were randomly selected from tagged plant in each plot and the seeds were shelled from capsule, seeds counted and mean recorded. Seed weight/plant; the number of seeds /capsule obtained were weighed and mean weight computed. 100 seed weight, this was determined by randomly selected 100 seeds from number of seed/plot from each plot, weighing and the means recorded. The data obtained were subjected to Analysis of Variance (ANOVA). Mean separation was done at 5% level of probabilities using Duncan Multiple Range Test (DMRT) (Duncan, 1955).

Results and Discussion

The effect of different levels of inorganic fertilizer and pruning periods of roselle (*Hibiscus sabdariffa* L.) on number of calyx per plant, weight of calyx/plant, weight of calyx/plot and weight of calyx kg/ha is presented in (Table 1). The result obtained revealed there were significant differences on the parameters measured. However, application of inorganic fertilizer at 60kg/ha produced more number and heavier fruit weight than 30kg/ha. Pruning period at 8WAP gave more numbers of calyx while unpruned produced the least. Table 2 shows the effect of different levels of inorganic fertilizer and pruning period of roselle on number of seeds per capsule, weight of seed/capsule and 100 seed weight. The results obtained shows there was significant differences on number of seed/capsule and 100 seed weight. However, application of inorganic fertilizer at 60kg/ha produced more number and heavier weight of seed per capsule. Pruning periods at 8WAP gave more and heavier seed while unprunned gave the least. The significant response of roselle to the application of inorganic fertilizer in this trail explained the importance of the nutrients to yield and yield component of the crop. Number of calyx and calyx weight increased with increases in fertilizer level. This could be attributed to the fact that application of inorganic fertilizer supplied enough nutrients required by plant for vigour growth. The application of 60kg/ha of inorganic fertilizer produced number of calyx/plant and seed/capsule, heavier fruit weight/plant/plot, 100 seed yield and seed weight/capsule than 30kg/ha (Okunsaya *et al.,* (1999). Babajide *et al.* (2007) who observed increased in calyx yield as a result of inorganic fertilizer application, which was attributed to increase in crop photosynthetic ability, as a result of good vegetative growth induced by this treatment. Maunde (2010) reported that application of 60kgNPK, significantly increased number of calyx, and seed yield of roselle. Also, Halimatul *et al.,* (2007) who reported that inorganic fertilizer has positive influence on the yield components of roselle and this could be attributed to the direct effect of nitrogen on meristematic and photosynthetic activities, and partitioning of assimilates to the reproductive sink. Pruning periods at 8 and 10 weeks after planting produced more number of calyx/plant and seed/capsule, heavier weight calyx/plant/plot and seed yield/capsule than unpruned, this was as a result pruning creates more surface area for development of branches and calyx than on pruning.

Conclusion

The results obtained from the trial shows that 60kg/ha of inorganic fertilizer application and pruning at eight weeks after planting gave more numbers of calyx/plant, heavier weight of calyx/plant, weight of calyx/plot, weight of calyx/ha than all the other treatments. The least of roselle was obtained from the unpruned. For good yield and yield component of roselle (*Hibiscus sabdariffa* L.) production during rainy season, application of inorganic fertilizer of 60kg/ha and pruning period at eight weeks after planting could be adequate for maximum production of roselle in the study area. Therefore, for maximum yield of roselle production, application of 60kg/ha of NPK 20:10:10 fertilizer with pruning period at eight weeks after planning may be adopted and recommended in the study area.

Abstract

A study was conducted during the 20132014 dry season to determine the effects of mulch and organic manure on the growth and yield of sweet melon at the Teaching and Research Farm of Federal College of Horticulture, Dadinkowa in the sudan savannah ecological zone of Nigeria. Results indicated that dry rice straw and poultry manure affected growth and yield traits such as vine length, number of leaves plant^{-1}, fresh fruit yield plot^{-1} and fresh fruit yield hectare^{-1} than the other applications. There was no significant effect due to mulch and organic manure on number of vines plant^{-1} and number of fresh fruits plant^{-1}. The effects of dry rice straw mulch and poultry manure application produced significantly higher means of the characters assessed compared to the rest of the treatments; whereas the control treatments of no mulch and no organic manure significantly produced the lowest means of the same traits studied.

Keywords: Sweet melon, mulch, organic manure, growth and yield

Introduction

Melon (*Cucumis melo* L.) belongs to the family Curcubitaceae and originated from the Middle East to the Mediterranean regions (Nkansah *et al.*, 2012). Melon production worldwide in 2009 was 31,053,716 tons, 0.33% more than the 30, 953, 684 tons in 2008 (Nkansah *et al.*, 2012). FAO (2009) reported that melon production in the world was realized from 1.3 million hectares of land. In the same year, melon production in the world was 26.70 million tons (FAO, 2009). China is the leading Country in production about 51% followed by Turkey with 6%, USA and Spain each with 4% (FAO, 2009). Melons are consumed as deserts, fresh cut-fruits and juices (Nkansah *et al.*, 2012). The relishing pulp which is highly nutritional, sweet pleasant aroma, light color, firm flesh texture, high sugar content above 10% and proper shape traits which make melon unique and a relish in the world (Aguyoh *et al.*, 2010). Vegetable production is getting an increase all round the world. Nigeria has favorable ecological conditions for vegetable growth and is one of the most important vegetable producers in the world. Turkey is fourth important producer (25.3 million tons) country regarding of vegetable production in the world. Vegetables commonly grown in Nigeria today consist of annual crops including Solanaceous, Cucurbits, Bulbs, Legumes and other indigenous vegetable species. In terms of economic value, nutrition, consumers preference, general adaptability and extent of cultivation the most commonly grown vegetable crops are tomato, watermelon, cucumber, pepper (hot and sweet), eggplant, onion, melon etc (Oyewole *et al.*, 2012). Melon is one of the most important vegetable in Nigeria (Oyewole *et al.*, 2012). To increase vegetable production, many applications such as mulch and organic manure are applied in different environmental conditions (Nwangburuka *et al.*, 2013). Mulching and organic manure in vegetables can increase yields, promote early harvest and reduce fruit defects (Gordon *et al.*, 2010). This study was conducted to determine the effects of mulch and organic manure on the growth and yield of sweet melon at Dadinkowa.

Materials and Methods

The experiment was conducted during the 2013/2014 dry season at the Teaching and Research Farm of Federal College of Horticulture, Dadinkowa in the sudan savannah ecological zone of Nigeria. The trial was laid out in a split plot design with no mulch (control), black plastic mulch, white plastic mulch and dry rice straw mulch assigned as main plot treatments, whereas organic manure source of no manure (control), goat manure, cow dung and poultry manure assigned as sub plot treatments, replicated three times. Seeds of sweet melon were sown at the beginning of the dry season into multiple trays having growing medium during the 2013 dry season. Beds of 3 x 2 m were prepared 1 m apart from each other. Black plastic mulch, white plastic mulch and dry rice straw mulch were laid down on the beds and holes were opened at 1 m x 1 m for planting seedlings, except the control where no mulch was applied. Seedlings were planted first week of January in 2013 dry season. The required cultural practices were made during the growing period. Parameters such as vine length, number of leaves plant^{-1}, number of vines plant^{-1}, number of fresh fruits plant^{-1}, fresh fruit yield plot^{-1} and fresh fruit yield hectare^{-1} were recorded. Data were tested by analysis of variance and treatments were compared using Duncan's multiple range test (Rangaswamy, 2010).

Results and Discussion

Table 1 shows that the physical properties of the soil in 2013 dry season was sandy-loam with high proportion of sand (86.88%), low silt (7.42%) and clay (11.24%). The chemical analysis revealed that the soil contains low amount of organic carbon (5.44%), pH in water (6.52), total nitrogen (3.56%), total phosphorus (2.24 mg kg^{-1}), potassium (1.58 mg kg^{-1}), magnesium (0.58 mg kg^{-1}), sodium (0.53 mg kg^{-1}) calcium (1.35 mg kg^{-1}) and cation exchange capacity (CEC) (5.23 mg kg^{-1}).

Vine length (cm)

Table 2 shows a significant difference at $P \leq 0.05$ between means due to mulch at 4WAS, 8WAS and 12WAS during the 2013 dry season. The control of no mulch applied significantly produced the lowest means of 12.47, 14.55, and 25.34 on vine length; whereas dry rice straw significantly produced the highest means of 17.36, 25.46 and 28.47 throughout the sampling periods on plant height. Table 2 also shows a significant difference at $P \leq 0.05$ between means due to organic manure at 4WAS, 8WAS and 12WAS during the 2013 dry season. The control of no manure applied significantly produced the lowest means of 12.48, 14.56, and 25.36 on vine length; whereas poultry manure significantly produced the highest means of 17.40, 25.48 and 28.49 throughout the sampling periods on vine length of sweet melon.

Number of leaves plant^{-1}

Table 2 shows a significant difference at $P \leq 0.05$ between means due to mulch at 4WAS, 8WAS and 12WAS during the 2013dry season. The control of no mulch applied significantly produced the lowest means of 8.43, 10.58 and 17.32 on number of leaves plant^{-1}; whereas dry rice straw significantly produced the highest means of 12.46, 14.76 and 22.43 throughout the sampling periods on number of leaves plant^{-1}. Table 2 also shows a significant difference at $P \leq 0.05$ between means due to organic manure at 4WAS, 8WAS and 12WAS during the 2013 dry season. The control of no manure applied significantly produced the lowest means of 8.45, 10.61 and 17.34 on number of leaves plant^{-1}; whereas poultry manure significantly produced the highest means of 12.48, 14.78 and 22.46 throughout the sampling periods on number of leaves plant^{-1}.

Number of vines plant^{-1}

Table 2 shows a no significant difference at $P \geq 0.05$ between means due to mulch and organic manure at 4WAS and 8WAS and 12WAS during the 2013 dry season on number of vines plant^{-1}.

Number of fresh fruits plant^{-1}

Table 3 shows a no significant difference at $P \leq 0.05$ between means due to mulch and organic manure at 10WAS, 12WAS and 14WAS during the 2013 dry season on number of fresh fruits plant^{-1}.

Fresh fruit yield (kg) plot^{-1}

Table 3 shows a significant difference at P≤0.05 between means due to mulch during the 2013 dry season on fresh fruit yield plot^{-1}. The control of no mulch applied significantly produced the lowest mean of 3.54 on fresh fruit yield plot^{-1}; whereas dry rice straw significantly produced the highest mean of 5.36 during the sampling period on fresh fruit yield plot^{-1}. Table 3 shows a significant difference at P≤0.05 between means due to organic manure during the 2013 dry season on fresh fruit yield plot^{-1}. The control of no manure applied significantly produced the lowest mean of 3.51 on fresh fruit yield plot^{-1}; whereas poultry manure significantly produced the highest mean a of 5.31 during the sampling period on fresh fruit yield plot^{-1}.

Fresh fruit yield (tons) hactare^{-1}

Table 3 shows a significant difference at P≤0.05 between means due to mulch during the 2013 dry season on fresh fruit yield plot^{-1}. The control of no mulch applied significantly produced the lowest mean of 3.84 on fresh fruit yield plot^{-1}; whereas dry rice straw significantly produced the highest mean of 4.62 during the sampling period on fresh fruit yield plot^{-1}. Table 3 shows a significant difference at P≤0.05 between means due to organic manure during the 2013 dry season on fresh fruit yield plot^{-1}. The control of no manure applied significantly produced the lowest mean of 3.68 on fresh fruit yield plot^{-1}; whereas poultry manure significantly produced the highest mean a of 4.84 during the sampling period on fresh fruit yield plot^{-1}.

Mulch applications significantly increased plant growth and yield in the experiment. The highest plant growth and yield was obtained from dry rice straw application; whereas the lowest plant growth and yield from the control of no mulch applied. Similar results were reported by Nkansah *et al.* (2012); Aguyoh *et al.* (2010); Gordon (2006). Gordon (2006) recorded that row covers with plastic mulch resulted in increased soil temperatures but had no effect on the yield of muskmelon. In Louisiana, row covers with plastic mulch were credited with increased soil temperatures. The increased soil temperatures were beneficial in producing a greater total yield of a watermelon crop. James (2013) reported similar observation that one important attribute to any organic mulch is its nutrient content. Organic mulch improves the soil over the long term and increases the fertility of soil at a given site. Such mulching methods may actually be preferred in organic farming as a means to increase soil organic matter content, improve long-term soil fertility, and enhance soil biological activity. Organic mulch may be selected for such attributes rather than on the basis of weed control alone. Organic mulch may affect crop yields through other means than the influence on nitrogen in the soil. The effect that organic mulch has on soil temperatures may ultimately impact yields.

Conclusion

Farmers are advised to use dry rice straw as a mulching material alongside with poultry manure for sweet melon production in Dadinkowa metropolis so as to increase its quality and yield.

Effect of Cassava Production with Polluted Irrigated Water from some Water Bodies in Orumba South L.G.A, South-eastern Nigeria

V.N. Okeke
Soil Science Division, National Root Crops Research Institute, Umudike, Abia State, Nigeria.
e-mail: veranonye16@gmail.com

Abstract
The effect of irrigated water used in the production of cassava around the shores of two streams and a river in Orumba South Local Government Area of Anambra state. Three samples from each water body (a kilometer apart) were used for analysis for three months. The samples were analyzed for seven heavy metals using Atomic Absorption Spectrophotometer (AAS). The average result showed that these parameters were above WHO permissible levels for most water bodies.

Introduction
Cassava is one of the well-known poverty alleviating root crops primarily grown in most parts of the world including sub-Saharan African, Asia and the Americans (Rabbi *et al.,* 2014). It is a basic food for over 700 million people in Western and Central Africa (FAO, 2010: 2005) with an average consumption of approximately 500 calories per day (FAO, 2010: 2005). Cassava is a perennial crop which bulking duration ranges from 8 weeks after planting to 24 months after planting. This makes cassava to be available all-round the year. Those planted near water bodies are been irrigated during the dry season to improve its yield capacity. Water is very essential in human lives, animals and plants. Great care has to be taken in monitoring the different water bodies for human consumption. Industrial waste, fertilizers, herbicides and pesticides are directly or indirectly introduced into water bodies. The chemical substances get into water bodies through various sources such as erosion, discharging into the water bodies, waste from farms, domestic sludge and human or animal waste (Okafor, 1985). Heavy metals like iron, cadmium, lead, copper, chromium, manganese and zinc accumulates in water bodies above World Health Organization (WHO) permissible levels. These high concentrations of the heavy metals are as a result of discarded materials from various homes, activities of most industrial wastes and incinerator residue (Pickford, 1978). The objective of this study is to evaluate the effect of using polluted water from three water bodies in Orumba South Local Government Area of Anambra State to irrigate cassava production.

Materials and Methods
Two streams and one river from Orumba South L.G.A were sampled. Each of the water bodies were sampled at three points, a kilometer apart for a period of three months.

Sample Collection

The samples were collected in the months of November and December 2003 and January 2004. A sterilized container was used at each point of the sample collection.

Laboratory Analysis

The samples were analyzed for heavy metals using Atomic Absorption Spectrophotometer (AAS) method. The results were subjected to statistical analysis using their means ± standard deviation.

Results and Discussion
The results of the heavy metals in the surface water bodies were compared to the World Health Organization (WHO) standard with the following permissible concentrations Iron 0.3, manganese 0.5, copper 1.0, zinc 15, cadmium 0.01, lead 0.1 and chromium 0.05 all in mg/l (WHO, 1971). Zinc, cadmium and copper fell within the highest desirable level of the WHO for drinking water standards (WHO, 1971). Manganese level fall within the WHO standard with exception of

samples B_2, B_3 and C_1 in table 1. These three samples are not good for irrigation because manganese is very toxic to living tissues. Lead content of the whole water samples are above the WHO standard of the maximum permissible level. Cassava production in these areas will have high accumulated lead which causes kidney disease, stroke and brain damage. Iron content of the whole water samples is above the WHO standard. Iron is not harmful to the body when consumed but its excess in the soil fixes phosphorus. Chromium content is above WHO standard. Cassava irrigated with these water bodies is a potential carrier of cancer disease.

Conclusion

Comparing the results with WHO International Standards for drinking water, it means that people from Orumba South L.G.A have been using substandard water for the irrigation of their cassava farms. ANSEPA should provide treatment of surface water and restrict the disposal of different waste materials in these water bodies.

Influence of varying rates of Organo-Mineral and NPK Fertilizers on Performance of *Solanum macrocarpon* (eggplant) in Ikorodu Agro Ecological Zone

Sanni, K. O. and Komolafe.A.O
Department of Crop Production and Horticulture, Lagos State Polytechnic, Ikorodu, Lagos State
sunny_kenny2000@yahoo.com

Abstract
The focus of the study was to evaluate the effects of varying rates of organomineral and NPK fertilizers on growth performance of Solanum macrocarpon (eggplant) in Ikorodu area of Lagos state. The treatments include five organomineral fertilizer rates (0, 2.5, 5, 7.5, and 10 t/ha) which were applied at transplanting and NPK 15:15:15 fertilizer (200 kg/ha) applied a week after transplanting. Parameters used for comparison include plant height (cm), stem girth (cm), number of leaves, number of branches, leaf area index (cm$^{2)}$ at 2, 4 and 6 weeks after transplanting (WAT)) and leaf yield at harvest. Findings from the study indicated that application rates of organomineral fertilizer significantly improves the plant height, stem girth, number of leaves, number of branches, leaf area index and yield of S. macrocarpon compared to control plots, as rate of fertilizer increases, growth and yield of S. macrocarpon tends to increases concurrently with 10 t/ha rate resulted in maximum growth performance and shoot yield.
Keywords: Application rates, Growth performance, Organomineral Fertilizer and Solanum macrocarpon

Introduction
The increasing demand for eggplants is due to the increasing awareness toward the benefit of leafy vegetables in fulfilling the nutritional and health benefits of increasing human population in the south west Nigeria. Owing to high demand for eggplant leafy vegetable, the production should be increased as well rather its cultivation has reduced drastically in the last couple of years. One of the main causes of such reduction is the decreasing fertility of the soil and organic matters in the soil (Ullah *et al.*, 2008). Most soils in Sub-Sahara African are used for subsistence farming and are of low and declining fertility (Buresh *et al*., 1997) and adequate soil fertility is essential for sustainable vegetable production especially in urban and peri-urban centres. Thus, the application of fertilizer or manure for amelioration of soil fertility is an integral part of leafy vegetable production. The shortcomings associated with both mineral and organic fertilizers led to the introduction of a new fertilizer called organomineral fertilizers. Recently, some state governments in Nigeria have embarked on industrial production of organomieral fertilizer derived from household waste materials. Various researchers have found organomineral fertilizers to significantly increase the yield of maize and vegetables such as pepper, tomato, okra, melon and amaranthus (Adeoye et al, 2008; Akanni and Ojeniyi 2008; Ojeniyi et al, 2009; Makinde et al 2010). However, in litteratures there appear to be dearth of information on the utilization of organomineral for the cultivation of eggplant in the study area. Therefore, this study aims at evaluate the effect of varying rates of organomineral fertilizer compared with a fixed rate of NPK 15-15-15 fertilizer on the growth and yield performance of *Solanum macrocarpon* (eggplant) in Ikorodu agro ecological zone.

Materials and Methods

Experimental location and land preparation

The experiment was carried out at the Teaching and Research Farms, Lagos State Polytechnic, Ikorodu, Lagos State Nigeria located in the humid tropical rainforest agro-ecological zone. The experimental site has been under continuous cultivation for over three years without any form of soil amendments. The land was ploughed and harrowed to a fine tilt using a disc plough and harrow. Land clearing and marking out were done and suitable beds of equal size of 3m x 2.5m were made with hoe.

Soil analysis

Composite soil samples were randomly collected with auger from ten (10) different locations in the study area and were composited, air dried and sieved through 5mm sieve and their physiochemical characteristics were determined before application of treatment following standard laboratory procedure (Page *et al*., 1989)

Crop establishment and maintenance

S. macrocarpon seeds were sown in nursery via broadcasting and nursery management lasted for four weeks. Transplanting was carried out at a spacing of 50cm x 50cm at 4weeks after sowing with one plant per hole. Irrigation was carried regularly and weeding was carried out as at when due and pest and disease was controlled using chemical method of control.

Experimental Design and treatment application

The experiment was laid out in Randomized Complete Block Design (RCBD**)** on a total land area of 179.5m^2 which was divided into 3 blocks of 21m x 2.5m (52.5m^2), each plot size was 3m x 2.5m (7.5m^2) with a discard of 0.5m which gave a total number of 18 plots. Five (5) rates of organomineral fertilizer: 0, 2.5, 5.0, 7.5, 10t/ha^{1}and NPK 15:15:15 at 200kg/ha respectively was applied to the plots at transplanting, while NPK 15:15:15 was applied a week after transplanting by band placement and replicated 3 times.

Data collection and Statistical Analysis

Six (6) plants were tagged per plot, from which growth and yield parameters were taken at 2, 4, 6 and 11 weeks after transplanting (WAP) respectively. Data collected was analyzed statistically with Analysis of Variance (ANOVA), and significant means was compared with Duncan Multiple Range Test (DMRT) at 5% level of probability using ASSISTAT 7.7 beta statistical software (2015).

Results and Discussion

Initial soil fertility analysis

The pre-cropping physical and chemical characteristics of the experiment soil shows that the soil is sandy clay loam in texture (sand 72.50%, silt 27.0% and clay 0.50%) and slightly acidic with pH 6.47. The soil is low in Organic Carbon (1.02%), Total N (0.08%), Available P (3.42mg/kg^1), exchangeable bases Na (0.74cmol/kg), K (0.01cmol/kg), Ca (0.85cmol/kg) and Mg (1.26cmol/kg).

Effect of organomineral and NPK fertilizers on plant height

Results from Table 1 indicated that both organomineral and NPK fertilizers did not significantly ($p<0.05$) affects plant height. However, at 4 and 6 WAT, 2.5 t/ha produced the tallest plant followed by 10 t/ha, 5 t/ha NPK 200 kg/ha and control had the shortest plant. At 2 WAP plots that received 10 t/ha OMF produced the tallest plants followed by 7.5 t/ha, 2.5 t/ha, 5 t/ha, and control treatment (3.33cm) which still gave taller plant than NPK 200 kg/ha (3.20) which recorded the lowest plant height

Table 1: Effect of varying rates of organomineral and NPK fertilizers on plant height on plots planted with *solanum macrocarpon* at 2, 4, and 6 weeks after transplanting

Treatments	2WAP	4WAP	6WAP
OMF 0/ha	3.33	3.97	4.87
OMF 2.5t/ha	3.90	4.80	6.37
OMF 5t/ha	3.80	4.53	5.93
OMF 7.5t/ha	3.93	4.77	5.93
OMF 10t/ha	3.97	4.73	6.17
NPK 15:15:15 200kg/ha	3.20	4.60	5.63

OMF =Organomineral fertilizer

Effect of organomineral and NPK fertilizers on number of leaves

Table 2 shows the effect of varying rates of OMF and NPK fertilizers on the number of leaves of eggplant. Number of leaves at 2 and 4WAT were significantly ($p<0.05$) affected by varying rates of OMF and NPK fertilizers as the result reveals but no significant effect ($p<0.05$) at 6WAT. Although control treatment produced the maximum number of leaves at 2 WAT and differs significantly compared to other treatments, while there was no significant difference between 7.5, 10 t/ha OMF and NPK. While, at 4 WAT 10 t/ha produced maximum number of leaves (9.40) followed by 2.5 t/ha (8.07), NPK 200 kg/ha (7.70), 7.5 t/ha, 5 t/ha (6.73) and control (5.87). similar trend was observed at 6 WAT.

Table 2: Effect of varying rates of organomineral and NPK fertilizers on number of leaves on plots planted with *Solanum macrocarpon* at 2, 4, and 6 weeks after transplanting

Treatments	2WAP	4WAP	6WAP
Control	4.40a	5.87b	8.70
OMF 2.5t/ha	4.07ab	8.07ab	10.47
OMF 5t/ha	3.33b	6.73ab	8.67
OMF 7.5t/ha	3.97ab	7.67ab	10.00
OMF 10t/ha	4.33ab	9.40a	11.40
NPK 15:15:15 200kg/ha	3.77ab	7.70ab	9.60

Means with different letter(s) in the same column are significantly different at 5% D.M.R.T.
OMF =Organomineral fertilizer

Effect of organomineral and NPK fertilizers on stem girth

Data recorded in Table 3 showed the effect of varying rates of OMF and NPK fertilizers on the stem girth of *S. macrocarpon*. The result obtained reveals that the varying rates of both fertilizers did not significantly ($p>0.05$) affect the stem girth of *S. macrocarpon* at all weeks. Therefore, with regards to the result, the eggplant shows no peculiar trend in the stem girth as the plant progresses. However, the 10 t/ha (0.63) had the widest stem girth followed by 7.5 t/ha (0.53), 5.0 t/ha (0.53) and 2.5 t/ha (0.50), NPK 200 kg per hectare (0.50) and control (0.50) having similar value at 6WAT.

Table 3: Effect of varying rates of organomineral and NPK fertilizers on stem girth on plots planted with *Solanum macrocarpon* at 2, 4, and 6 weeks after transplanting

Treatments	2WAP	4WAP	6WAP
Control	0.23	0.37	0.50
OMF 2.5t/ha	0.20	0.37	0.50
OMF 5t/ha	0.17	0.33	0.53
OMF 7.5t/ha	0.17	0.33	0.53
OMF 10t/ha	0.20	0.40	0.63
NPK 15:15:15 200kg/ha	0.20	0.33	0.50

OMF =Organomineral fertilizer

Effect of organomineral and NPK fertilizer on leaf area index

Table 4 presents effect of varying rates of OMF and NPK fertilizers on leaf area index of *S. macrocarpon*. Varying rates of OMF and NPK fertilizers did not significantly ($p<0.05$) influence the leaf area index throughout the weeks of assessment of *S. macrocarpon* and the leaf area index increases with ageing. Control gave the lowest leaf area index at 2, 4 and 6 WAT and OMF 2.5t/ha and OMF 7.5t/ha produced the maximum leaf area at 2, 4 and 6 WAT respectively.

Table 4: Effect of varying rates of organomineral and NPK fertilizers on leaf area index on plots planted with *Solanum macrocarpon* at 2, 4, and 6 weeks after transplanting.

Treatments	2WAP	4WAP	6WAP
Control	5.00	8.18	11.99
OMF 2.5t/ha	8.26	17.78	17.88
OMF 5t/ha	7.63	15.34	20.25
OMF 7.5t/ha	7.79	17.59	22.66
OMF 10t/ha	7.10	13.35	18.20
NPK 15:15:15 200kg/ha	6.37	13.84	18.02

OMF =Organomineral fertilizer

Effect of organomineral and NPK fertilizers on number of branches

Results from Table 5 indicated that the effect of varying rates of OMF and NPK fertilizers did not significantly influenced number of branches produced by *S. macrocarpon*. In all the treatments, number of branches produced by the *S. macrocarpon* increases with the age of the plant and in responses to the different of fertilizers application.

Table 5: Effect of varying rates of organomineral and NPK fertilizers on number of branches on plots planted with *Solanum macrocarpon* at 2, 4, and 6 weeks after transplanting

Treatments	4WAP	6WAP
OMF 0/ha	1.90	2.83
OMF 2.5t/ha	2.37	3.07
OMF 5t/ha	2.00	2.93
OMF 7.5t/ha	2.77	3.70
OMF 10t/ha	2.57	3.20
NPK 15:15:15 200kg/ha	2.30	3.57

OMF =Organomineral fertilizer

Effect of varying rates of organomineral and NPK fertilizers on marketable shoot yield

Results from Table 6 indicated that marketable shoot yield of *S. macrocarpon* was not significantly influenced by the varying rates of OMF and NPK fertilizers. The results show that 10 t/ha gave the highest marketable shoot yield (0.40kg/ha) followed by NPK 200 (0.35kg/ha), 2.5 t/ha (0.30kg), 7.5 t/ha (0.29kg), 5 t/ha (0.20kg) and control (0.18kg) which had the least marketable shoot yield

Table 6: Effect of varying rates of organomineral and NPK fertilizers on marketable shoot yield (kg) of *Solanum macrocarpon*

Treatments	Yield(kg)
Control	0.18
OMF 2.5t/ha	0.30
OMF 5t/ha	0.20
OMF 7.5t/ha	0.29
OMF 10t/ha	0.40
NPK 15:15:15 200kg/ha	0.35

OMF = Organomineral fertilizer

Cost analysis of *S. macrocarpon* production

The table below showed the total cost incurred on the production of eggplant to be ₦5061. Result from Table7 indicated that the yield obtained from 10 t/ha OMF was the highest with resulting revenue of ₦120 followed by NPK 200 kg/ha (₦110), 7.5 t/ha OMF (₦90), 2.5 t/ha (₦90), 5 t/ha (₦60) and control (₦50). Therefore, all the treatments had gross margins less than ₦1:00 which makes production non profitable or beneficial. However, the low revenue could be attributed to the time the project was terminated.

Table 7: Cost analysis of *S. macrocarpon* production

Variables	control	2.5t/ha OMF	5t/ha OMF	7.5t/ha OMF	10t/ha OMF	NPK 200 kg/ha	Total

The low fertility status observed in the soil can be attributed to continuous cropping and increased land use intensity. This confirmed previous observation by Ojeniyi and Akanni, 2008 that soils in south-west Nigeria which are mostly weathered alfisols were deficient in nutrients especially OM, total N, available P, exchange K and Ca; thus the needs for amendment with organic and inorganic fertilizer sources to improve the availability of these nutrients in soil which was low in the soil. The contents of base elements (K, Ca and Mg) in OMF will serve to reduce soil acidity and it is benefit the soil and in return increase eggplant growth and yield. The improved growth parameters observed was due to nutrient sources and the release of mineral elements such as N, P, K and exchangeable cations (Ca, Mg and Na) to the soil by the different fertilizer sources which established and maintained optimum soil physical condition for plant growth. The result showed that different fertilizers enhanced plant growth; taller plants produced more leaves and capture more light energy and had more photosynthate available for plant growth and development. The increased shoot yield may be attributed to more photosynthetic activities of the plant on the account of adequate supply of nitrogen with increasing rates of fertilizer from different sources. In all the treatments, eggplants responded directly proportional to the varying levels of OMF applied and this supported the finding of Jibrin (2011) who opined that the quantity of organic manure applied determines the level of productivity of the plant. The differences in the variable cost observed are attributable to the different rates of fertilizers used. This is supported by the findings of Ngbede et al (2014) on urban vegetable production. This is in agreement with the report of Akanbi et al (2006) that the yield obtained from the optimum application of organo-mineral fertilizer on okra was high enough to compensate for the high cost of production incurred.

Conclusion

Apparently the results from the study show that organomineral fertilizer application is of great benefits for crop vegetative growth. In all the rates applied, 10 t/ha resulted in maximum growth performance and shoot yield. *S. macrocarpon* farmers in the study area should be encourage to adopt organomineral for the crop cultivation since its readily available and not bulky compared to inorganic organic fertilizers respectively.

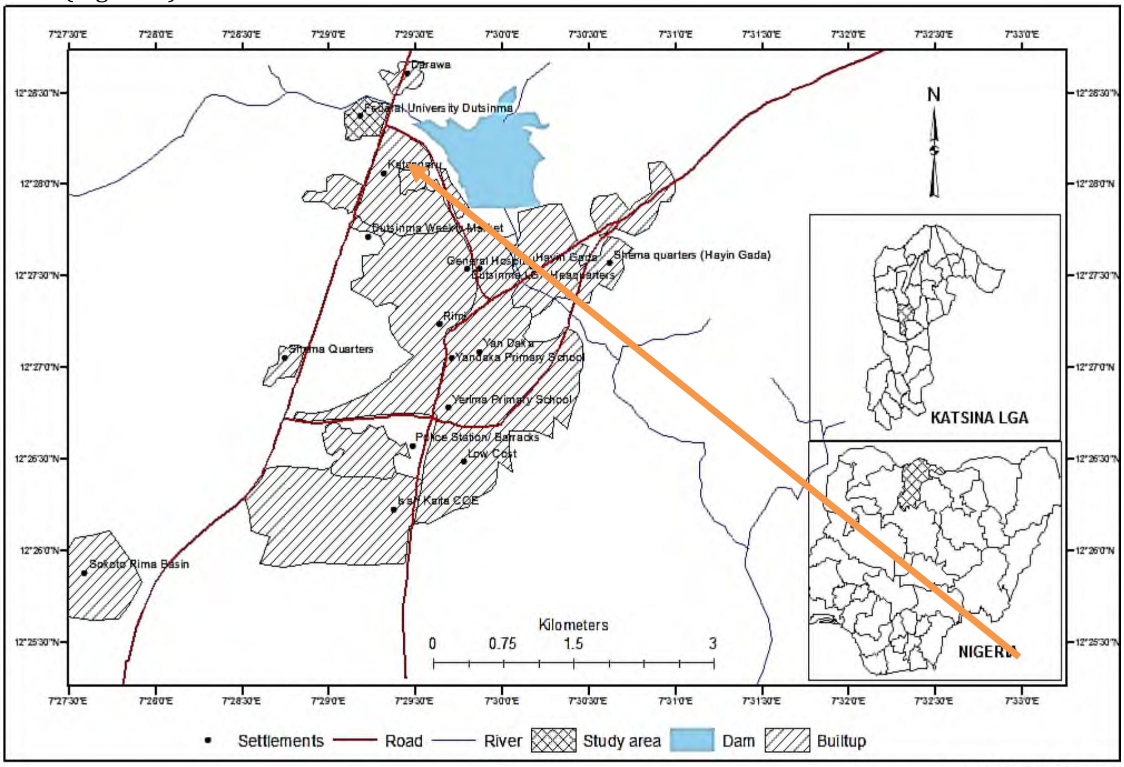
Abstract
Varieties of pearl millet were tried for two growing seasons to assess their response to downy mildew. In the first year the pearl millets were evaluated using infector row system. The infector rows were made of bulk of local varieties which were inoculated with downy mildew inoculum. The indicator rows were Jirani variety of pearl millet which are very susceptible Downy Mildew disease. In the second year, the infector rows were not inoculated with downy mildew inoculum. The Maiwa varieties that were found to be resistant to downy mildew infection were selected and crossed with Gero varieties that showed some level of susceptibility to downy mildew infestation during the off season in a screen house. The hybrids generated were then evaluated along with their parents on downy mildew infested plot with the aim of testing their resistance and susceptibilities. 2 female parents are highly resistant, 12 hybrids were highly resistant, 6 genotypes were resistant and 5 were moderately resistant.

Introduction
Pearl millet [*Pennisetum glaucum* (L.) R.Br.] was domesticated as a food crop in the tropical region of West Africa at least 4000 years ago. Its use as a food grain has grown over the centuries, with an estimated 64 million acres of pearl millet being grown in Africa and India (Robert 2018). Millets are nutritionally superior as their grains contain high amount of proteins, essential amino acids, minerals, and vitamins (Vinoth and Ravindhran, 2017). The crop is used for a variety of food products, and is even made into a type of beer. In resource-poor countries of Asia and Africa, millets provide 75% of total calorie intake next to cereal grains with an average annual production of 14.2 and 12.4 million tons (Belton and Taylor, 2004; O'Kennedy *et al*., 2006). India is the Leading producer of millets accounting for about 80% of the global millet production (Food and Agricultural Organization (FAO, 2015). Among the millets, pearl millet occupies 95% of the production (Yadavetal., 2012; Yadav and Rai, 2013; Agricultural Statistics, Government of India, 2014; Nedumaran *et al*., 2014). Downy mildew (DM) or 'green ear' disease caused by *Sclerospora graminicola* (Sacc.) Schroet. occurs most destructively in Asia and Africa (Arya HC and Kumar A. (1976), Nene YL and Singh SD. (1976), Rachie and Majmudar, (1980) and Singh, (1995)). The disease was considered of minor importance till 1970, as its incidence was sporadic on local cultivars. The first epidemic of downy mildew occurred in 1971 on the first popular pearl millet hybrid, HB 3, resulting in severe grain loss of about 4.6 million metric tons (Singh, 1995), Singh *et al*., (1993). As a result of continued large-scale cultivation of the susceptible hybrids, the disease caused serious epidemics during 1974, 1984, 1987 and 1988 (Arun *et al*., 2012). It is important to determine the effect if this disease on some varieties of pearl millet.

Materials and Methods

Study Area

This experiment was conducted at the Agroforestry farm layout, Federal University Dutsin-Ma, Katsina State, Nigeria. Dutsin-Ma lies between latitude 12º 27' and 22''N and longitude 7º 30' and 83''E (Figure 1).



Source: FUDMA GIS Lab.

Figure 1: Map of Katsina State showing Dutsin-Ma LG.A. / Federal University, Dutsin-Ma
Source: Modified from the Administrative Map of Katsina State.

The daily minimum and maximum temperatures range from 32ºC to 43ºC. Dutsin-Ma, in Katsina State experiences unimodal rainfall pattern with an annual rainfall of about 1100 mm, with a single peak in August. Dry season lasts for a minimum of seven months (November-May) while the wet season spans June to October.

Design of the Study

Crosses were obtained using a factorial mating scheme of North Carolina Design II, where each male was mated to each of the female (Comstock and Robinson, 1948; Hallauer and Miranda, 1981). The field evaluation was done using complete Randomized Block Design (CRBD) two replications. Hybrids and parents were allocated to plots using random table number.

Data Analysis

Downy mildew incidence was calculated as:

$$\text{DMI}=\frac{\text{Number of diseased seedlings}}{\text{Total number of seedlings per pot}}\times 100$$

where DMI =Downy mildew incidence

Downy mildew incidence data were analyzed using Statistical Analysis System (SAS, 9.1, 2003). For classifying the pearl millet genotypes the rating scale of Ball (1983) was adopted:

0-5% disease incidence = Highly Resistant (HR)
5-10% disease incidence = Resistance (R)
10-25% disease incidence = Moderately Resistant (MR)
25-50% disease incidence = Moderately Susceptible (MS)
50-80% disease incidence = Susceptible(S)
>80% disease incidence = Highly Susceptible (HS)

Results and Discussion

Table 1 presents the results of thirty genotypes comprising of parents and hybrids for downy mildew infestation. The results indicated two of the male parents that were resistant in the first two seasons became moderately susceptible in the third season at the same location. This indicates either a shift in virulence of the pathogen or a shift in resistance of genotypes used. Similar results were obtained in Ati *et al*., (2013) and (2015). Thakuret *et al*., (2009) found that a major change in disease incidence of pearl millet line over time at the same location reflected virulence shift in the pathogen population. Downy mildew pathogen is heterothallic and frequent recombination leads to genetic diversity and evolution of new virulent population. Hence identification of resistance to new virulence population is a prerequisite for resistance breeding (Thakuret *et al*.; 2009). Among five female parents only one maintained it status of being susceptible to the pathogen, the remaining 4 female parents gained resistance to the pathogens while among the male parents, one was resistant, two moderately resistant and two were moderately susceptible. Fourteen of the genotypes were highly resistant to the pathogen (3 parents and 11 hybrids). The rest of the hybrids were resistant to the pathogens except one (GMC17001XMMC17006, the only susceptible genotype among the 30 genotypes study).

Table1: Mean Performance of Downy Mildew Rating for twenty Hybrids and Their Parents

S/N	GENOTYPES	NHE	PltVig	DMI	DMI RATING

The means followed by the same letter(s) along the same column are not significantly different (Duncan's Multiple Range Test at P< 0.05). *S =Susceptible, HS= highly susceptible, MS= moderately susceptible, MR= moderately resistance.*

Conclusion

Thirty genotypes were evaluated for downy mildew infestation. twenty-six of them were resistant to the pathogen (2 female parents (GMC17004 and GMC17002) are highly resistant, 12 hybrids(GMC17001 X MMC17010, GMC17005 X MMC17007, GMC17001 X MMC17007, GMC17005 X MMC17008, GMC17002 X MMC17010, GMC17002 X MMC17009, GMC17004 X

MMC17008, GMC17003 X MMC17006, GMC17003 X MMC17008, GMC17004 X MMC17009, GMC17003 X MMC17009 and GMC17002 X MMC17006) were highly resistant, 6 genotypes were resistant (MMC17007, GMC17003 X MMC17007, GMC17003, GMC17004 X MMC17010, GMC17001 and GMC17004 X MMC17006, and 5 were moderately resistant (GMC17004 X MMC17007, MMC17008, MMC17010, GMC17002 X MMC17007 and GMC17005 X MMC17006) while four were susceptible. Among these four, two were male parents (MMC17009 and MMC17006) that are resistant to the pathogen during the first two years of evaluation; one female parent (GMC17005) maintained her susceptibility to the downy mildew while one hybrid (GMC17001XMMC17006) was susceptible. These twenty-six genotypes were identified as downy mildew resistant varieties.

Abstract
This study was conducted at the Teaching and Research farm of Adamawa State College of Agriculture, Ganye, Nigeria, to evaluate the effect of applied animal manure from different sources of plant materials on growth and yield performance of maize (Zea mays L.) in Ganye, Adamawa state, Nigeria. The experiment was laid out in Randomized Complete Block Design (RCBD), with three replications having five treatments: T_1 = manure obtained by feeding West African dwarf goat with brewer's dried grain + cowpea husk, T_2 = brewer's dried grain + Ficus sycomorous, T_3= brewer's dried grain + Vitellaria paradoxa, T_4 = brewer's dried grain + Anogessus leiocarpus, while T_5 was the control with no manure applied. The parameters measured were plant height, leaf length, number of leaves, girth width, cob length, cob width, 1000 grain weight and tones/hectare. The analysis of variance shows that there were significant difference ($p<0.05$) among the treatments applied on the parameters measured. It was discovered that treatment T_1, T_2, T_3, and T_4 produces better difference among the treatments. Therefore, based on the findings, brewer's dried grain + cowpea husk, Ficus sycomorous, Vitellaria paradoxa, and Anogessus leiocarpus leaves when fed to West African dwarf goat as fodder, their dropping can be used by farmers as animal manure for optimum growth and yield of maize production.
Keywords: Organic Manure, Growth, Yield and Mineral Nutrients

Introduction
Maize remains one of the most important grain crops and is geographically the most widely cultivated species all over the world. Maize contributes 62% in the total cereal production. Maize is multipurpose crop and provides food for human beings, fodder for livestock and feed for poultry. It has great nutritional value as it contain about 66.7% starch, 10% protein, 4.8% oil, 8.5% fiber, 3% sugars, and 7% ash (Chaudhary, 1983). It is a major source of income in several developing countries and one of the best sources for bio-fuel in developed countries (Ali et al., 2014). Declining fertility of Nigeria soil is becoming increasingly critical to secure sustainable agricultural productivity. Hence soil productivity maintenance is important in order to enhance agricultural crop production. Soil low organic matter content and erosion problems have predisposed the soils to productivity. Nutrient balance is always an important consideration for crop response to applied fertilizers. Use of inorganic fertilizers can improve crop yield and nutrient availability, but its unwise use can cause nutrient imbalance and environmental pollution in addition to high production cost (Das *et al*., 1991; Oad *et al*., 2004; Ali, 2005; Mbah and Mbagwu, 2006; Mbah *et al*., 2006; and Ali, 2012). The application of N.P.K fertilizer to the soil actually boosts the performance of maize. Nevertheless, its persistence application destroys soil reaction and impedes the activities of soil micro organisms thereby making the soil acidic and toxic for maize production (Omisore 2010). The increasing cost of mineral fertilizers coupled with the inability to condition the soil has brought attention to organic manure in many parts of the developing countries in recent times (Baoteng *et al*., 2006). The application of manures to soil provides potential benefits and serve as soil conditioners through improving soil physical properties including soil structure, water infiltration, soil water holding capacity, aeration and

permeability, soil aggregation, decreased soil crusting, bulk density, and erosion and increasing rooting depth, improving soil organic matter microbial biomass and soil fertility, reducing the amount of synthetic fertilizer needed for crop production (Allison, 1973; Sumner, 2000; Phan et al., 2002 and Blay et al., 2002) . Therefore with increasing demand for sustainable agriculture, and maize production in particular, the study was designed to examine the effects of applied animal manure from different sources of plant materials on growth and yield of maize in the study area.

Materials and Methods

The study was carried out in the teaching and research farm of the Adamawa State College of Agriculture Ganye; it lies between latitude 8^0 24′ and 8^0 25′north and longitude 12^0 04′ and 12^0 05′east. The mean annual temperature of the study area is 26.7^{o}C while the mean annual rainfall ranges between 1100mm and 1600mm with a distinct dry season which begins in November and ends in April and the wet season begins in April and ends in October or sometimes in November (Adebayo, 1999). The major economic activity in the area is agriculture, food crops grown in the area are Maize, sorghum, cowpea, Cassava and Potatoes. While Cash crops such as Ground nuts, Rice, Yam and Sugarcane are produced in large quantities. The major livestock reared in the Zones are cattle, sheep and goats. (Ad seeds, 2004).
The experimental field has been under fallow since 2008, before then sorghum was planted, with no of history of manure application.

Field Preparation

The total land area for the experiment was 135m^2, prepared manually by clearing and marked out using basin formation according to the experimental layout Each plot was 3 m × 3 m (9m^2), with 1.5 m between replication and 0.5 m between each plot and composite soil samples collected from the plots at 0-15cm depth in order to assess the initial phyisco-chemical properties of the soils.

Soil Analysis

The samples were analyzed for pH as described by Bates (1954); particle size was determined using hydrometer method as described by Bouyoucos (1951). Available Phosphorus was be extracted with 1N NH_4F and 0.5N HCl (Bray and Kurtz, 1945). The titrimetric method was used for the determination of Calcium and Magnesium in the soil as described by Black (1965) while the regular Macro-Kjeldahl Method as described by Black (1965) was be used for the determination of soil total Nitrogen. Potassium and Sodium were be determined in 1N neutral NH_4OAc soil extract using Flame Photometry and Exchangeable acidity was determined using the titration method as described by Mclean (1965). The cation exchange capacity was be determined by summation method.

Experimental Design and Treatments

The experiment was carried out in a Randomized Complete Block Design (RCBD) with three replicates and five treatments. Prior to seed sowing, animal manures were applied at the rate of six (6) tons per hectare one week before sowing. Treatment used are:- T_1 = manure obtained by feeding West African dwarf goat with brewer's dried grain + cowpea husk, T_2 = brewer's dried grain + *Ficus sycomorous*, T_3= brewer's dried grain + *Vitellaria paradoxa*, T_4 = brewer's dried grain + *Anogessus leiocarpus,* while T_5 was the control with no manure applied.

Seed collection and sowing

Improved maize seeds (Ife hyb-6 maize variety by Wacot L t d) was purchased from seed vendor in the study area and sown on the plots at the rate of 2 seed per hole at a depth of 3-5 cm, using 75 cm x 25 cm. The seedlings were later thinned to one plant per stand two weeks after emergence making a total of 44 plants per plot.

Weeding

Weeding commenced at two weeks after sowing and subsequent weeding was carried out at 7 and 11 weeks after sowing to minimize weed interference respectively.

Data Collection

Four (4) plants each per plot were randomly selected for determination of growth and yield parameters. The parameters assessed included, plant height at 2, 4 and 12 weeks after sowing (WAS), number of leaves per plant at 12 WAS, days to 50% flowering, number of cobs at harvest, plant length (cm), weight of 1000 grain (g) and yield of maize per hectare (kg/ha). Plant height was measured with tape from the base of the plant to the top of first tassel, number of leaves and grains/cob were obtained by direct counting; grain weight was measured using weighing scale.

Statistical Analysis

Data collected were subjected to analysis of variance (ANOVA) and means were separated with Duncan Multiple Range Text (DMRT) according to Wahua, (1999)

Results and Discussion

Table 1 presents the results of physic-chemical soil properties of the study area. The values of particle size distribution indicate that the soil belongs to sandy clay loam textural class and the soil pH measured in water fell within the medium acid class type. The percentage organic carbon content was 1.10%. The percentage nitrogen value of the soil was 0.13%, available phosphorus 4.60 g kg^{-1}. The exchangeable potassium value was 1.05 Cmol (+) kg^{-1} soil and the value of exchangeable calcium was 15.23 Cmol (+) kg^{-1} soil respectively. Exchangeable values of magnesium, sodium and the cation exchange capacity were 8.90, 0.53 17.70 Cmol (+) kg^{-1} soil respectively.

Table 1: Physico-chemical soil properties of the study area

Soil properties	Values
pH	5.45
%Sand	43.38
%Clay	33.44
%Silt	23.18
%Organic carbon	1.10
Ca (Cmol(+)/Kg soil)	15.23
Mg (Cmol(+)/Kg soil)	8.90
Na (Cmol(+)/Kg soil)	0.53
K (Cmol(+)/Kg soil)	1.05
P (mg/kg)	4.60
%N	0.13
CEC	17.70

Regular soil testing is an important element in nutrient management. The results of particle size distribution indicate that the soils belong to sandy clay loam textural class. Soil texture is one of the most important soil physical properties because it influences the ability of a soil to provide water, nutrients, and aeration necessary for plant growth (Brady and Weil, 1996). The soil reaction was observed to be of medium acid class, many agricultural soils are in the pH range of 5.5 - 8.0 (FAO, 2005). The percentage organic carbon content was moderate in the two sites, even though values were lower than the range of 1.37-1. 1.97 reported by Jamala *et al*. 2012 of some selected Fadama soils in Adamawa State. According to Yan *et al*. (2007), soil organic carbon plays an important role in nutrient availability and soil aggregate formation and also improves retention of soil nutrients so that they will eventually be available for plant growth and also serves as a tremendous reservoir or pool of terrestrial carbon that would otherwise be released to the atmosphere. It is well established that nitrogen (N) is the macronutrient often limiting the growth of plants on soil (Vitousek and Farrington, 1997; Michopoulos *et al.*, 2008). The percentage soil nitrogen of the study sites was low, below 0.15% critical level recommended by Sobulo and Osiname (1981), Agboola *et al*. (1982). Available phosphorus was found to be below recommended a critical level of 8.1 $mgkg^{-1}$ soils (Agboola *et al*., 1982). A range of 3 to 30 $mgkg^{-1}$ soil has also been reported (Mamza, 1997). The exchangeable potassium value was moderate, based on the findings of Sobulo and Osiname (1981), whereas Boul *et al*. (1975) suggested a critical minimum of 0.2 Cmol (+) kg-1 soil. The values of exchangeable Calcium obtained indicate the Calcium content was moderate. Sodium is not a plant nutrient and therefore is not necessary for plant growth. High levels of sodium are detrimental to soil tilth and plant growth. Sodium levels are evaluated based on Exchangeable Sodium Percentage (ESP). The ESP is the percent of the cation exchange capacity (CEC) occupied by Na. ESP values above 10 percent are of concern. Table 2 presents the result of response of plant height, leave length, number of leave and girth width to applied animal manure from different sources of plant materials. The response of plant height to applied animal manure shows that there was no significant difference (P>0.05) among the treatments, even though the application of T_1 produced the highest plant height (159.85cm) followed by T_2, T_4, T_3 and T_5 respectively. The response of leaf length to the applied treatments indicates that the application of T_2 gave the highest leaf length (96.54cm) followed by T_3, T_4, T_1, and T_5 respectively. Also the response of treatments on number of leaves showed that there was a significant difference, the application of T_1 gave the highest number of leaves, followed by T_2>T_3>T_2>T_5 in that pattern. The treatments effect on girth width indicated that there was a significant difference (P<0.05), the application of T_2 gave the highest girth width followed by T_1= T_3= T_4. T_5 had the lowest value of girth width. This results agrees with the finding of Anon (2002) who found out that organic manure is an good fertilizer material because of its high nitrogen, phosphorous and potassium contact and it is readily available than the mineral fertilizer and its effect on the soil is stable, slow in releasing nutrition to crop and also improving the soil physical and chemical properties.

Table 2: Effects of Applied Manure from Different Sources of Plant Material on Growth Parameters of Maize

Treatment	Plant Height (cm)	Leaf Length (cm)	No. of leaves	Girth width (cm)
T1	159.85a±37.14	70.69b ± 5.35	33.147a±15.08	6.84ab ± 0.34
T2	146.29a±31.59	96.54a± 18.58	18.86b ± 4.21	7.25a ± 1.23
T3	126.28a±14.54	73.90b ± 4.03	11.33b ± 0.48	6.83ab ± 0.43
T4	134.25a±11.70	71.05b ± 2.95	11.56b ± 0.48	6.83ab ± 0.34
T5	119.06b±32.01	63.44b ± 7.34	9.11b ± 0.44	5.28b ± 0.37

The means followed by the same letter(s) along the same column are not significantly different (Duncan's Multiple Range Test at P< 0.05). T_1 = is a manure obtained by feeding West African dwarf goat with brewer's dried grain + cowpea husk, T_2 = brewer's dried grain + *Ficus sycomorous*, T_3= brewer's dried grain + *Vitellaria paradoxa*, T_4 = brewer's dried grain + *Anogessus leiocarpus,* while T_5 was the control with no manure applied.

Table 3 shows the effect of applied animal manure on yield parameters of maize. The result of the analysis of variance indicated that there was significant difference (P<0.05) among the treatments applied. The applications of T_1, T_2, T_3, and T_4 yield the highest values of maize cob length, cob girth, 1000 grain weight and maize yield tons/hectare. The control gave the lowest values with regards to these yield parameters. The number of grains/cob of maize obtained from plants that received T_1, T_2, T_3, and T_4 treatments was higher than the number of grains obtained from plants that received the control treatment, possibly because more nutrients were released which mineralized rapidly for plant uptake and utilization. It could also be attributed to increased microbial activities which increases nutrient release in soil as observed by Gopinath *et al*.,(2008), Olanikan(2006) and Enujeke *et al.*,(2013). These reports are generally in harmony with the work and recommendations of Brady and Weils, (1999), DIPA, (2006).

Table 3: Effects applied animal manure from different sources of plant material on yield parameters of Maize

Treatment	Cob Length (cm)	Cob width (cm)	1000 grain weight (g)	Tones/Hectare
T1	15.74a ± 0.52	10.15a ± 0.11	222.28a ±18.01	4.40a ± 0.00
T2	13.52a ± 0.50	9.73a ± 0.05	209.71a±12.17	4.58a ± 0.33

The means followed by the same letter(s) along the same column are not significantly different (Duncan's Multiple Range Test at P< 0.05).

Conclusion

This study shows that the use of animal manure derived from brewer's dried grain + cowpea husk, *Ficus sycomorous*, *Vitellaria paradoxa*, and *Anogessus leiocarpus* leaves and fed to West African dwarf goat as fodder, can be used to improve both the chemical and physical properties of the soil, thereby increasing the growth and yield of maize. The application of these manure highly increase plant height, number of maize leaves, stem girth, and other yield attributes of maize at harvest

Abstract

Field experiment was conducted at Institute for Agricultural Research, Samaru (11°11´N; 07°38'E) in the Northern Guinea Savanna ecological zone of Nigeria between July-October, 2014 rainy season to evaluate the performance of white maize inbred lines based on agronomic and kernel quality traits. White kernel inbred lines of maize totaling 6, were obtained from International Institute of Tropical Agriculture (IITA) for the study which were crossed using half diallel mating design. The 15 hybrids, 6 parents and 4 checks were generated and evaluated at Institute for Agricultural Research Farm, Samaru (11^{0}11´N; 07^{0}38'E) in the Northern Guinea Savanna ecological zone of Nigeria in a 5 × 5 partially balanced lattice design with three replications between July to October, 2014 rainy season. Each plot consists of two rows 4 m long, with inter and intra row spacing of 0.75 m x 0.25 m and 1m alleys respectively. All agronomic practices were kept uniform in all plots. Data were taken on five centered plants for observations and measurements leaving the plants on either end of the plot to avoid the border effect The result indicated significant differences ($p \leq 0.05$) among the genotypes for the following traits plant height, days to maturity, ear height, ear length, field weight, milling test and yield indicating presence of genetic variability in the genotypes. Percent whole kernel, percent kernel without pericarp damage, moisture content at harvest, grain weight, volume and density were not significant., P1 x P2 recorded the highest mean For grain yield per hectare (10650kgha^{-1}) and mean weight (4.19kg) while For per cent kernel without pericarp damage P1 x P5 had had the highest mean value which ranged from 58.00 % to 74.67 % with a CV 11.82 %. Genotype P3 x P4 had the highest mean for milling test (7.06 kg). For moisture content at harvest P4 x P6 had the highest mean (15.87%). For 100-grain weight P2 x P5 had the highest grain weight (11830.00g). Genotype P1 x P4 had the highest mean for volume (24.33m^{3}). P1 x P6 had the highest mean for density (705.50kgm^{-3}).Variations were obtained for most of the studied traits, indicating the presence of appreciable variability in the studied genotypes, which is a key requirement in a crop enhancement programme. The result of this study also showed that hybrid crosses could be developed for specific environment as indicated by significant difference in the performance of genotypes for most of the traits measured.

Keywords: Maize, Inbred Lines, Kernel, Agronomic and Traits

Introduction

Maize (*Zea mays* L.), the third most important cereal crop after wheat and rice in the world (FAO,2002) provides food and feeds, employment and income generation for small-holder families and raw materials for industries in Africa and the humid tropics. The crop is widely cultivated in tropical Africa, and no other crop is more widely distributed in Nigeria. Despite the volume of improvement research and extensive heterosis exploitation in maize (Kim, 1996); (Ogunbodede,2001); (Badu *et al*, 2010) ; (Badu *et al*, 2011), the yield of maize in the tropics is lower than that realizable in the temperate countries. This has made consistent and continuous selection for higher grain yield imperative. Genetic improvement of a crop is pivoted on the strength of genetic diversity within the crop species. Adequate variability provides options from which selections are made for improvement and possible hybridization. The objective of this study is to evaluate the agronomic performance and kernel quality traits in white maize inbred lines.

Materials and Methods

White kernel inbred lines of maize totaling 6, were obtained from International Institute of Tropical Agriculture (IITA) for the study which were crossed using half diallel mating design. The 15 hybrids, 6 parents and 4 checks were generated at Institute for Agricultural Research Farm, Samaru (11⁰11′N; 07⁰38'E) in the Northern Guinea Savanna and evaluated at National Horticultural Research Institute, Bagauda Research Farm (11°33′N; 8°23′E) in the Sudan Savannah ecological zone of Nigeria in a 5 × 5 partially balanced lattice design with three replications between July to October, 2014 rainy season. Each plot consists of two rows 4 m long, with inter and intra row spacing of 0.75 m x 0.25 m and 1m alleys respectively. All agronomic practices were kept uniform in all plots. Data were taken on five centered plants for observations and measurements leaving the plants on either end of the plot to avoid the border effect. Data were recorded for agronomic and kernel quality traits (Days to 50% tasselling , Days to 50% silking, Anthesis silking interval, plant height, days to maturity, ear height, % whole kernel, % kernel without pericarp damage, density, milling test, moisture content at harvest and grain yield). Statistical Analysis was computed using Statistical Analysis System (SAS, 2004) for individual location. The ANOVA was computed on plot mean values for all characters across the two locations. The following model (Bohren *et al.*, 1963) was used for one location in one year.

Table 1: Origin and Descriptions of the Genotypes

Results and Discussion

The result of the genotypes for agronomic and kernel quality traits at Samaru is presented in Table 3. Significant differences (p≤ 0.05) were observed among the genotypes for the following traits plant height, days to maturity, ear height, ear length, field weight, milling test and yield indicating presence of genetic variability in the genotypes This result agrees with the findings of Baqa *et al.* (2014) who reported that plant height and physiological maturity were significantly affected by the variety. According to Bello and Olaoye, (2009) the variation in cob length, number of kernel per cob, cob weight and grain yield was to be expected, as genetic composition of these materials were probably different. Percent whole kernel, percent kernel without pericarp damage, moisture content at harvest, volume and density were not significant indicating that they may be conditioned by the same genes and are genetically related for these traits. The resemblance of the genotypes for these traits is not unexpected because the source parents which mainly came from IITA, Ibadan it might be possible that the inbred are related through some of their ancestors Ibrahim (2012). The mean performance for the agronomic and kernel quality traits studied at Samaru is presented in Table 4. The genotype P5 x P6 produced the tallest plants (196.60cm) while the shortest plant height (144.40cm) was recorded in the cross P4 x P5. For days to maturity, the mean ranged from 87.0 to 92.0, P2 x P6 had the highest mean, while P1 x P2, P2 x P3 and P4 x P5 recorded the least value, and with a CV of 3.08%. The findings on days to maturity corroborates with the work of Ibrahim, (2012) who reported that days to maturity lower values of hybrids for days to maturity indicated parents were different in their genetic background, combine well to produce promising crosses for earliness. Genotype P2 x P3 produced the tallest ear (95.80cm) while the shortest ear height (70.07cm) was recorded in the cross P3 x P4. For ear length, the mean ranged from 15.43cm to 19.33cm, P1 x P2 had the highest mean while P1 x P5 recorded the least value with a CV 11.17%. For ear diameter, the mean ranged from 13.90cm to 22.30cm, P4 x P6 had the highest while P4 x P5 recorded the least value with a CV 99.99%. For field weight, P1 x P2 had the highest mean weight (4.19kg), while P5 x P6 had the lowest mean weight (2.47kg) with a CV of 20.64%. For per cent whole kernel P1 x P3 had the highest mean (69.67%) while P2 x P4 had the least mean (41.00%). For per cent kernel without pericarp damage, the mean ranged from 58.00 % to 74.67 %, P1 x P5 had the highest while P4 x P6 recorded the least value with a CV 11.82 %.. Genotype P3 x P4 had the highest mean for milling test (7.06 kg) while P3 x P6 had the least mean value (2.49 kg). For moisture content at harvest P4 x P6 had the highest mean (15.87%) while P1 x P5 had the least mean (10.73%). Genotype P1 x P4 had the highest mean for volume (24.33m^3) while P1 x P3 had the least mean value (17.33m^3). For density P1 x P6 had the highest mean (705.50kgm^{-3}) while P1 x P4 had the least mean (473.10kgm^{-3}). The findings on kernel quality traits corroborates with the work of Malvar, (2008) who reported that kernel density, per cent whole kernel, per cent kernel without pericarp damage and milling test have higher means indicating that parents were different in their genetic background, combine well to produce promising crosses for better kernel quality in maize.. For grain yield per hectare, P1 x P2 recorded the highest mean (10650kgha^{-1}) while P5 x P6 recorded the lowest mean (6265.00kgha^{-1}). The mean performance of the hybrids for grain yield per hectare recorded higher means for P1 x P2 indicating that parents were different in their genetic background and combine well to produce promising crosses for higher yield in maize . The findings on grain yield corroborates with the work (Jalal, 2003) who found that different inbred lines of maize could be combine to produce better hybrid with superior performance than their parents. This notion is in agreement with the results of the present study. This showed that this crosses received favourable gene combinations from their parents for better grain yield.

Conclusion

Variations were obtained for most of the studied traits, indicating the presence of appreciable variability in the studied genotypes, which is a key requirement in a crop enhancement programme. The result of this study also showed that hybrid crosses could be developed for specific environment as indicated by significance difference in the performance of genotype for most traits measured except ear diameter, percent whole kernel, percent kernel without pericarp damage, grain weight and volume. The overall mean performance of the genotypes signifies that there is substantial variability within the germplasm which could be used in both high yield and better quality maize breeding programs to develop suitable hybrids and varieties

Molecular Identification of Viruses Associated with Cassava Mosaic Disease (CMD) in Bayelsa State, South-South Nigeria

C. K. Nkere, O. C. Ogbe, A. Iroburachi, and T. J. Onyeka
National Root Crops Research Institute (NRCRI) Umudike, PMB 7006 Umuahia Abia State
nkerechukwuemeka@yahoo.com

Abstract
We report the current cassava virus status in five Local Government Areas (LGAs) in Bayelsa State. African cassava mosaic virus (ACMV) and East African cassava mosaic Cameroon virus (EACMCV) were responsible for Cassava mosaic disease (CMD) in the state. There was 100% prevalence of virus infection in all 23 fields sampled. The mean disease symptom incidence was 44.06% while the mean symptom severity was 3.23 on a 5-piont scale. The findings reveal that infection is predominantly through planting stakes (stem). This calls for the adoption of stringent control measures in exchange of planting materials amongst farmers.

Introduction
Cassava mosaic disease (CMD) is the most economically important viral disease of cassava in Sub-Saharan Africa (Legg *et al*., 2006). It is caused by cassava begomoviruses (CMBs), transmitted by whitefly, *Bemisia tabaci* from plant-to-plant. The spread of CMD occurs mostly by the distribution of infected stem cuttings. Cassava mosaic disease and Cassava Brown Streak Disease (CBSD) are virus diseases that affect cassava productivity. Although CMD is prevalent in all cassava farms in the country and causes substantial yield reduction, total loss is extremely difficult to estimate. However, CBSD can wipe out the entire cassava field resulting in 100% yield loss. This disease is presently in most parts of East and Central Africa. Therefore, for effective control and management there is the need for routine surveillance and screening for cassava viruses across the country.

Materials and Methods
A total of 960 plants in 23 fields were assessed for virus incidence in Bayelsa state in the south-south Nigeria. Of this number, 93 cassava leaf samples (70 symptomatic and 23 asymptomatic) were collected for virus indexing. The whitefly population count was based on the number on the top five expanded leaves.

Nucleic acid extraction

Total nucleic acids were extracted from 100 mg of cassava leaf by a modified Cetyl Trimethyl Ammonium Bromide (CTAB) protocol described by Abarshi *et al*. (2010).

Virus Index

Samples were indexed for viruses - *African Cassava Mosaic Virus* (ACMV), *East African Cassava Mosaic Cameroon Virus* (EACMCV), *East African Cassava Mosaic Virus Uganda* (EACMV-UG) and *Cassava Brown Streak Virus* (CBSV) with specific oligonucleotide primers previously described (Alabi *et al.,* 2008) by both PCR and RT-PCR using a thermocycler. RT-PCR products were analyzed by electrophoresis in 1% (w/v) TAE agarose gel containing ethidium bromide 0.003% (v/v). Gel was visualized under UV light.

Results and Discussion
A total of 304(44.06%) of the 960 plants accessed were affected with varying degree of virus infection. The mean CMD symptom severity and incidence of disease symptoms were 3.23 and 44.06%, respectively, while the mean whitefly population was 41.74 (Fig. 1). The implication of this is that, out of every ten samples, at least four are infected with varying degree of virus symptom. The whitefly population was generally low (Fig. 1). In fact, a location with 50% virus

symptom incidence had zero whitefly count. Thus, propagation of the virus disease is mainly through stem cuttings. The virus index result showed that ACMV and EACMCV were detected in the samples either as a single or as a mixed infection (Table 1). Of the 93 samples tested, 67 (72.04%) were infected. Of this number, 10 (14.93%) came from asymptomatic leaf samples. Symptomatic expression on cassava leaves alone may not be adequate for the selection of infected samples for diagnosis. Therefore, molecular techniques as well as selection of both symptomatic/asymptomatic leaves from various portions of the plant are necessary for adequate diagnosis and detection of cassava viruses. No EACMV-UG or CBSV was detected in all the samples.

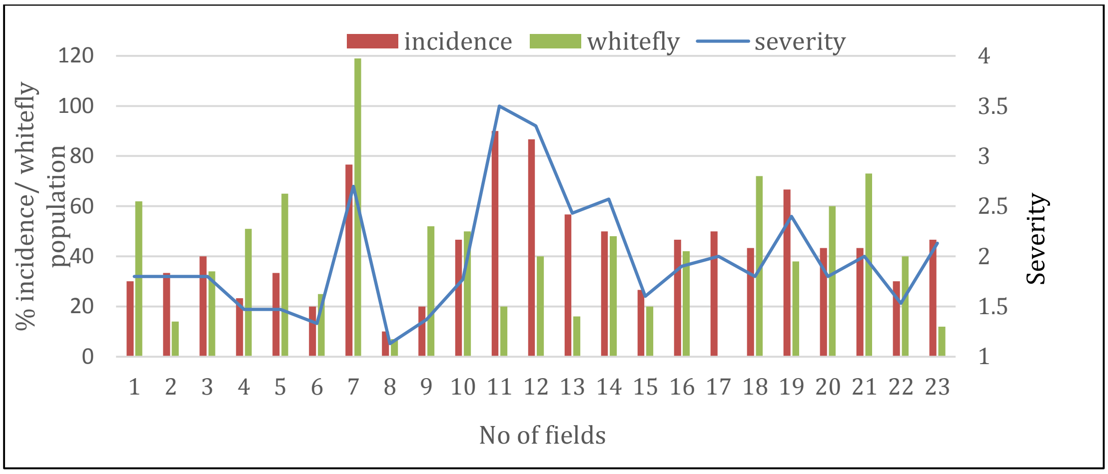

Fig. :. Virus incidence and whitefly population in fields sampled in Bayelsa State

Table 1. Virus infection in relation to the severity score

	Severity score					
Infection	1	2	3	4	5	Total
ACMV only	7	6	17	13	3	46 (49.46%)
EACMV only	2	0	0	0	1	3 (3.22%)
Mixed infection (ACMV+EACMCV)	1	2	5	7	3	18 (19.35%)
No Tested	23	21	22	20	7	67/93 (72.04%)

Conclusion

African Cassava Mosaic Virus (ACMV), *East African Cassava Mosaic Cameroon Virus* (EACMCV) are the two viruses responsible for CMD in Bayelsa state. This disease is predominantly propagated through infected plant materials (stems) and calls for a more stringent control measure. Establishment of certified Village Seed Entrepreneurs (VSEs) would serve as source of clean planting materials for farmers.

Discrimination of Viruses Associated with Cassava Mosaic Disease (CMD) in Delta State, South-South Nigeria

C.K. Nkere, O.C., Ogbe and T. J. Onyeka
National Root Crops Research Institute (NRCRI) Umudike, PMB 7006 Umuahia Abia State
nkerechukwuemeka@yahoo.com

Abstract
Our study has shown that *African cassava mosaic virus* (ACMV) and *East African cassava mosaic Cameroon virus* (EACMCV) were responsible for Cassava mosaic disease (CMD) in 41fields in 12 Local Government Areas (LGAs) in Delta state. The mean disease symptom incidence was 11.14%, the mean symptom severity was 2.83 and high whitefly mean count 104.64. Although whitefly count was high, findings reveal that infection is predominantly through stem cutting. Thus, a more stringent control measures in exchange of planting materials amongst farmers shown be adopted.

Introduction
Cassava mosaic disease (CMD) is the most economically important viral disease of cassava in Sub-Saharan Africa (Legg *et al*., 2006). Over US$1.5 billion per annum has been the estimated lost due to CMD (Thresh et al., 1997). The disease is caused by cassava begomoviruses (CMBs) transmitted from plant to plant by a whitefly vector, *Bemisia tabaci*. However, the disease spread is predominantly by exchange of infected cuttings. Cassava mosaic disease and Cassava Brown Streak Disease (CBSD) are virus diseases that affect cassava productivity. While total yield loss in CMD may be difficult to estimate, CBSD can wipe out the entire cassava field resulting in 100% yield loss. This disease is presently in most parts of East and Central Africa. Thus, for effective management and control, there is the need for routine surveillance/ screening, and establishment of certified local seed entrepreneurs across the country.

Materials and Methods
A total of 1230 plants in 41 fields were assessed for virus incidence in Delta state in the south-south Nigeria. Of this number, 99 cassava leaf samples (42 asymptomatic and 57 symptomatic) were collected for virus indexing. The whitefly population count was based on the number on the top five expanded leaves.

Nucleic acid extraction
Total nucleic acids were extracted from 100 mg of cassava leaf by a modified Cetyl Trimethyl Ammonium Bromide (CTAB) protocol described by Abarshi *et al*. (2010).

Virus indexing
Samples were indexed for viruses *African Cassava Mosaic Virus* (ACMV), *East African Cassava Mosaic Cameroon Virus* (EACMCV), *East African Cassava Mosaic Virus Uganda* (EACMV-UG) and Cassava Brown Streak Virus (CBSV) with specific oligonucleotide primers previously described (Alabi *et al.,* 2008) by both PCR and RT-PCR using a thermocycler. RT-PCR products were analyzed by electrophoresis in 1% (w/v) TAE agarose gel containing ethidium bromide 0.003% (v/v). Gel was visualized under UV light.

Results and Discussion
Of the 1230 plants accessed, 139(11.3%) were affected with varying degree of virus infection. The mean virus disease symptom incidence and severity were 11.14% and 2.83 on a 5-piont scale respectively, while the mean whitefly population was 104.64 (Fig. 1). The implication of this is that, out of every ten samples, at least four are infected with varying degree of virus symptom. The whitefly population was generally high (Fig. 1). In fact, all the fields, 13 (31.71%) with no

virus disease incidence had whitefly counts. Thus, there appears to be no relationship between whitefly population and virus incidence, rather susceptibility to virus infection is on varietal basis. The virus index result showed that ACMV and EACMCV were detected in the samples either as a single or as a mixed infection (Table 1). These two viruses have been reported in CMD infected cassava plants in West Africa. Of the 99 samples tested,40 (40.4%) were infected. Of this number, 2 (5%) came from asymptomatic leaf samples. No CBSV or EACMV-UG was detected in all the samples. Therefore, for effective discrimination of viruses, a combination of molecular techniques and selection of both symptomatic/asymptomatic leaves from various portions of the plant is necessary.

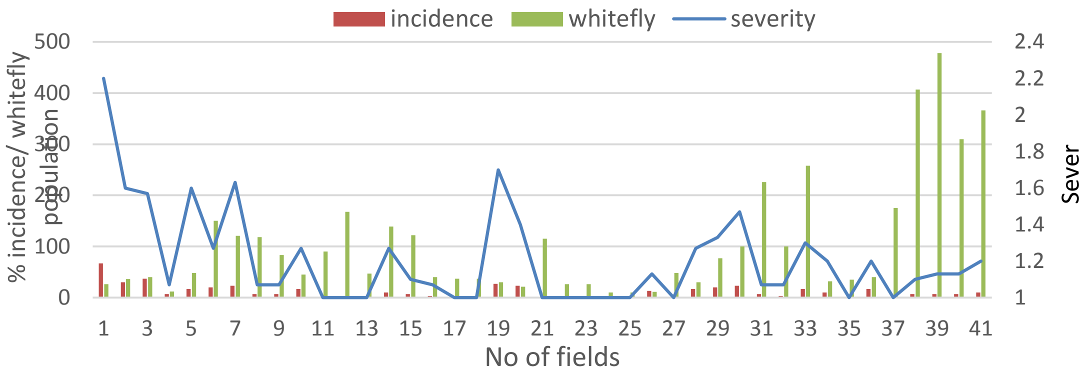

Fig. 1: Virus incidence and whitefly population in fields sampled in Delta state

Table 1: Virus infection in relation to the severity score

Infection	Severity score					Total
	1	2	3	4	5	
ACMV only	2	2	20	3	0	27 (27.27%)
EACMV only	0	0	2	1	0	3 (3.03%)
Mixed infection (ACMV+EACMCV)	0	1	3	3	3	10 (10.1%)
No Tested	42	22	25	7	3	40/99 (40.4%)

Conclusion

Virus index analysis has implicated *ACMV* and *EACMCV* as the viruses associated with CMD in Delta state. These two viruses are the cause of CMD in Nigeria. Results have also shown that there is no EACMV-UG and CBSD in Delta, however, there is the need for establishment of proper seed certification system for clean seed production for farmers.

Microbes Revolution: A Biological Approach towards Profitable And Sustainable Agriculture

A.O. Ubalua, and D.O. Onyegbula
National Root Crops Research Institute (NRCRI) Umudike, Umuahia, Abia State, Nigeria

Abstract
As the world population growth is predicted to swell-up to about 9.3 billion by 2050, the need to significantly increase agricultural food production without increasing much pressure on the environment throws up a challenge to researchers especially in the field of soil and microbial ecology. Microbial solutions could enhance farmer's agricultural yield and productivity in a sustainable way. To accomplish this objective researchers are looking beyond the conventional methods but are now tapping into the beneficial effects of microbes on plant growth which includes nitrogen fixation, nutrient acquisition and uptake, enhancement of shoot and root growth, disease suppression and improved soil structure for a profitable sustainable crop production.

Introduction
In the beginning agriculture was based on incorporating nitrogen fixing legumes and pulse crops into management practices by our primitive but foresighted farmers. Recently economic cost and environmental impacts of synthetic nitrogen fertilizers and pesticides are increasingly making these previously abandoned biological approaches more attractive to farmers. The year 2000, marked a new beginning towards doubling food production in a more sustainable fashion with reduced pressure on available resources. But one major challenge that is facing the entire world is on how to feed the ever-increasing human population of about 9.3 billion by 2050. (www.unfpa.org). Naturally, plants depend on microbes in the soil for the maintenance of their health and vigour. Like plants, we depend on a large number of microbes to digest our food, regulate our systems and to suppress some deadly pathogens. To achieve this goal, scientists are now looking beyond the conventional methods of crop production. They are now refocusing their thoughts and energies on microbial activities in the soil for inspiration on sustainable agricultural future. The authors now narrows down on the three major groups of microbes that are considered to be the architects of soil fertility, plant health, soil structure and disease suppression. Among them is nitrogen fixing rhizobia that are principally involved in biological nitrogen management that provides crops with nitrogen at the right time as well as avoiding nitrogen depletion and pollution. Beside nitrogen fixation, arbuscular mycorrhizal fungi (AMF) is one of the most ancient and pervasive microorganism that has evolved for over a period of 460 million years with the majority of land plants. This AMF forms extensive hyphal networks in soil and provide the plant with nutrients in exchange for photosynthates (Smith and Read, 1997). Also of importance are **s**ome of the frequently useful beneficial microbes in agriculture globally. One such alternative is the biocontrol of pests and diseases by some microbes including *Bacillus*, *Trichoderma*, *Pseudomonas*, *Streptomyces*, and many other species. These microbes due to their eco-friendliness and specificity are preferred over chemical pest and disease management practices. This new approach is to take advantage of what nature has already provided – the ubiquitous and amazing world of microbial community (Ubalua *et al.*, 2017). In addition, recent breakthroughs in low-cost DNA sequencing and other technologies have opened up the secret world of these microbes. This development has provided the possibility of identifying almost every member of the microbial community that makes up the plant microbiome, leading to an emerging understanding of how various microbes behave in different seasons and soil environments with the possibilities of tweaking them to help plants grow better (How microbes can help feed the world, 2012).

N_2-fixing Rhizobia

Legumes such as soybeans, beans, peanuts etc are already enjoying comfortable symbiotic relationship with N_2-fixing root microbes including *Rhizobium*, *Azospirillium*, *Mesorhizobium, Azotobacter* etc. In nature, nitrogen-fixing rhizobia that live within the roots of legumes can utilize the enormous amount of atmospheric nitrogen by converting them to an organic form that plants can use. According to Amaranthus and Simpson, 2011), a legume cover crop can add and store as much as 200 pounds of nitrogen in an acre of soil. To initiate the process, the leguminous plant attracts nitrogen-fixing bacteria to invade the cells in the root and provides them with carbohydrates as a food source while the bacteria reduce nitrous compounds in the soil that are then used by the plant (Morrissey *et al*., 2004). Figure 1A to D shows nodules on beans roots and nodules cut open to show reddish-pink colour indicating that the nodules are active and healthy after 12 weeks of planting. Apart from nitrogen fixing rhizobia, *Azotobater* is another available alternative to chemical fertilizer. This bacterium is a free-living nitrogen-fixer that has multiple beneficial effects on crop growth and yield by synthesizing growth regulating substances like auxins, cytokinin and Giberellic Acid (GA). It also stimulates rhizospheric microbes, protects the plants from phyto-pathogens, improves nutrient uptake and ultimately boost up biological nitrogen fixation (Jnawali *et al*., 2015). The attraction in exploiting the potentials of *Azotobacter spp*. in agriculture lies in their ability to utilize atmospheric nitrogen gas for the cell protein synthesis which is mineralized in soil after death, thereby contributing towards nitrogen availability of crops. It therefore implies that *Azotobacter* can be an important alternative to synthetic fertilizer and is capable of fixing an average of 20 kg N/ha per year (Jnawali *et al*., 2015). Additionally, *Azotobacter* inoculants has been associated with enhanced effect on growth parameters like root, shoot length and dry mass of maize seedlings *in vitro* and in pot experiments (Salhia, 2013). Thus, biofertilizers are economical, safer, self-replicating, and target specific, while chemical fertilizers are expensive and also induces adverse effect on soil health and microbial population.

Fig. 1A, B & C: Nodules on bean roots. 1D: Nodules from bean roots cut open to show the reddish-pink colour that indicates active healthy nodules.
Photo by Dr. Alfred O. Ubalua, NRCRI Umudike, Umuahia, Nigeria.

Biological control

The rhizosphere is the interface between plant roots and the soil and accounts for multiples of microbial activities compared to those in the bulk soil. Among the micro-organisms interacting with plant roots in the rhizosphere, are the beneficial microorganisms such as *Bacillus*, *Pseudomonas*, *Trichoderma* and arbuscular mycorrhizal fungi (AMF). The inherent two-way traffic pathway that exists between plant roots and microbial population in the rhizosphere has important ecological implications for soil function, including biogeochemical cycles, plant health and productivity. One unique and discernible benefit for the plant is a better supply of and access to nutrients. Services provided by these soil microbes are critical for plants health and survival. In their natural environment, plants depend on microbes for optimization of their growth and survival. They live in and on their roots, stems, leaves, and other plants parts (How microbes can help feed the world, 2012). These microbes support plant health by increasing the availability of nutrients, enhancing plant root growth, neutralizing toxic compounds in the soil, making plants more resistant to diseases, heat, flooding, and drought and deterring pathogens and predators (How microbes can help feed the world, 2012). Soil beneficial microbes also play significant roles in the conservation, mobilization and transportation of nutrients from soil into plants. In addition to enhancing the nutrient supply of plants, they also confer a degree of protection against plant diseases (Ubalua *et al*., 2017). A unique phenomenon where microbes protect against phytopathogens is biological control. Typical example includes various bacteria and fungi, especially of the genera *Pseudomonas*, and *Trichoderma* that produces a range of metabolites against other phytopathogenic fungi and can actively antagonize or destroy other pathogens in our agricultural crops (Bloemberg and Lugtenberg, 2001, Raijaamkers *et al*., 2002). Others are the soil bacterium *Bacillus thuringiensis* (Bt) that produces insect killing toxins (How microbes can help feed the world, 2012). For example, Table 1 shows some beneficial organisms that are commonly used globally in crop production.

Table 1: Some beneficial organisms with demonstrable functions in disease suppression

Organisms	Functions
Bacillus spp.	Competition, parasitism and predation
Pseudomonas brassicacearum	Parasitism
Pseudomonas fluorescens	General antibiosis
Streptomyces spp.	Prevent access to infection sites
Trichoderma spp.	Metabolites/disrupt plant-microbe signaling
Penicillium griseofulvum	General antibiosis

Condensed from: Vadakattu, V.S.R.G, Microbiology Australia, 2012

Arbuscular mycorrhizal fungi (AMF)

Mycorrhizae are not new. This 'symbiotic' association between the fungus and plant roots dates back since over 460 million years. In an undisturbed natural habitat, mycorrhizae proliferate on plants roots and spread into the surrounding soil as a network of tiny absorptive hyphae. Through this union, plants use their photosynthetic leaves to meet mycorrhizae carbon needs in exchange for nutrients especially phosphorus and water from the mycorrhizae (Amaranthus & Simpson, 2010). Mycorrhizal fungi are the major reason why our natural habitats are healthy and productive without artificial inputs of synthetic fertilizers and irrigation. Hence, cropping systems could be more sustainable by managing mycorrhizal fungi for increased yields and enhanced efficiencies (Amaranthus & Simpson, 2012, Ubalua *et al*., 2017). Another significant contribution of mycorrhizae to soil and agricultural practice is carbon sequestration through their hyphae. Carbon is composed of up to 30-40 percent of the glomalin molecule. Apart from the generous contribution of carbon to the soil by glomalin, it also functions as a kind of "soil superglue" helping to bind soil particles together into tiny aggregates. These aggregates hold moisture and improve tilt, making soil more loamy, nutrient-rich and less subject to erosion. But beyond nutrient and mineral acquisition, mycorrhizal fungi are also implicated in plant natural defense against fungal root diseases such as *Phytophthora*, *Fusarium, Pythium* and *Rhizoctonia*. They produce and release suppressive exudates such as antibiotics that prevent infection by these organisms and other fungal root pathogens. Their further defenses also include formation of a physical barrier made of chitin to deter invasion by soil pathogens (Amaranthus & Simpson, 2010).

Conclusion

Optimizations of plant-microbiome interactions can substantially reduce the need for synthetic fertilizers and pesticides. Application of microbial techniques in crop production has been predicted to increase crop yield by 20% while reducing fertilizer and pesticide requirements by 20% within the next 20 years. This approach in combination with some new technologies could produce dramatic benefits and may precipitate the 2nd Green Revolution.

Abstract
Field experiment was conducted during the rainy seasons of 2016 and 2017 at the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University, Keffi, Lafia Shabu Campus to determine the effects of varying planting spacing (50x50cm, 50x100cm and 100x100cm) and mulching materials (control, rice husk and dry grass) on the growth, yield and yield characters of watermelon. The nine treatment combinations were laid out in a randomized complete block design (RCBD) with four replications. The results of the study indicated that all the growth and some yield characters measured (vine length, number of branches and number of leaves per plant, number of marketable fruits, fruit length and fruit diameter) were significantly increased by a planting spacing of 100 x 100cm compared to other planting spacing (50x50cm and 50x100cm). The number of fruits per hectare and fruit yield (t/ha) were significantly increased by a planting spacing of 50x50cm compared to other spacing. All the growth yield and yield characters of watermelon measured (vine length, number of branches, number of leaves, number of marketable fruits per hectare number of fruit per plant, fruit length, fruits diameter, number of fruits per plant, and fruit yield per hectare) were significantly increased by using rice husk as mulching material compared to using dry grasses and no mulch (control). For effective production of watermelon that will translate to higher marketable yield, a spacing of100x100cm and rice husk as mulching material should be adopted.

Introduction
Watermelon; (C*itrulluslanatus*(Thum.) Matsum and Nakai) belongs to the family of *Cucurbitaceae* (Schippers, 2000).). It is an annual plant with long weak vine-like (trailing) stems of 3m (10 ft.) long. Watermelon is thought to have originated in the Kalahari Desert of Africa. The first recorded watermelon harvest occurred nearly 5,000 years ago in Egypt and is depicted in Egyptian hieroglyphics on walls of their ancient buildings. It is known for its highly nutritious edible fruit, which is one of the world most important vegetable crops, grown extensively in more than 96 countries worldwide. In 2016, global production of watermelons was 117 million tonnes, with China alone accounting for 68% of the total (FAOSTAT, 2017). Secondary producers with more than 1% of world production included Turkey, Iran, Brazil, Uzbekistan, Algeria, the United States, Russia, Egypt, Mexico, and Kazakhstan. Watermelon is not only made up of water and sugar but it is also a nutrient based food as it contains high amount of vitamins, minerals and antioxidants. It also contains niacin, thiamin, vitamin B-6, zinc, magnesium and many more nutrients that are good for one's health. There are many health benefits of Watermelon as it is low in calories so it promotes phyto-nutrients and anti-oxidants essential for the optimization of health. It also helps in the prevention of Asthma as it possess high amount of nutrients. Because of its healthy fiber and water content, it helps in prevention of constipation and there are many more benefits of the fruit (Linnewiel *et al.,* 2009). Manipulation of agronomic factors such as row and plant spacing may provide a non- chemical means of reducing the impact of weeds interference on crop yields (Buhler, 2002), a key component of alternative approaches to weed management is the enhancement of crop competitiveness against weeds (Watson and Weise, 1991). Closer rows and high plant population reduced the evaporation, increased efficiency of

water higher growth and yield by increasing the energy available to crop (Walker and Buchanan, 1981). Mulching in general is a beneficial practice for crops to increase vegetable production technique that involved placement of organic or inorganic materials on the soil surface to provide favorable environment for plant growth and development. Mulch alter soil temperature and moisture condition, which in turn may affect plant growth yield and fruit quality (Korir, 2006). Marketable yield from the mulched treatments were higher than those produced on bare soil, Farios-Larios & Orozco-Santos, 1997). Mulching vegetables can increase yields promote early harvest and reduce fruit defects. Moreover, mulches can reduce evaporation from the soil surface, prevent weed growth, modify soil temperature, reduce costs, protection of soil structure, and reduce insect number (Ekinci and Dursun, 2014). In this agro ecology, farmers produce watermelon, but unfortunately not all the fruits produced are of marketable value, due to non-adherence to correct planting spacing and the high heat emanating from the soil that destroyed the fruits before ripening. Adoption of correct planting spacing and mulching will help produce fruits that are of marketable quality, optimum plant population will be realized and the effect of high temperature that destroy the fruits before ripening will be avoided. There is paucity of information on the effects of spacing and mulching on the growth and yield of watermelon particularly in this agro ecology. This work, therefore, seeks to evaluate the effects of planting spacing and mulching on the growth and yield of watermelon.

Materials and Methods

Field experiment was conducted for two years during the dry seasons of 2016 and 2017 at the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University, Keffi, Shabu –Lafia Campus (8^0 34′ N and 80 33′E) to determine the effects of planting spacings ($50\times 50cm, 50\times 100cm, 100\times 100cm$) and different mulching materials (rice husk, dry grasses and the control) on the growth and yield of watermelon. The nine treatment combinations were laid out in Randomized Complete Block Design (RCBD) with four replications. The gross plot size was $16m^2$ (4m x 4m) while the net plot size was $9m^2$ (3mx 3m). The experimental area was harrowed followed by construction of seed beds. Between each plot was an unplanted border of 1m while between each replication, there was an unplanted border of 2m. Poultry manure (5 tons ha^{-1}) was incorporated into all the seed beds and left for 2 weeks before planting to reduce the scotching effect of the poultry manure on the seeds. Sowing was done on seed bed at 50cmx50cm, 50cmx100cm and 100cmx100cm planting spacing according to field plan and treatment combinations. Different mulching materials were applied to the experimental beds according to treatment plan at two weeks after sowing (2WAS). All other good cultural practices required for higher yield were strictly followed. Growth parameters such as vine length, number of branches per plant, number of leaves per plant were assessed at 4, 6, 8 and 10 weeks after sowing on 5 randomly selected tagged plants in each plot. Vine length was measured by using a flexible measuring tape. Number of leaves was assessed by visual count of the functional leaves on the randomly selected tagged plants and the mean recorded. Number of branches was taken by visual count of the branches on the randomly selected tagged plants and the mean recorded. At every harvest, fruit diameter was assessed by using a Vernier calliper; the fruit length was measured by using a flexible tape before the fruits were weighed using a Salter scale. Number of fruits per plant was assessed by counting the number of fruits from the randomly selected tagged plants and the mean recorded. Numbers of marketable tubers from each net plot were selected, counted and value obtained converted to per hectare basis. The fruits from each net plot were weighed and the value obtained was converted to per hectare basis to give fruit yield per hectare. The data collected were subjected to analysis of variance (ANOVA) as described by Snedecor and Cochran (1990) and significant differences among the treatment means were evaluated using Duncan's Multiple Range Test as described by Duncan (1955).

Results and Discussion

Results of the physic-chemical properties of the experimental soil before and after the experiment revealed that before the experiment, the soil was sandy, low in organic matter, organic carbon, Magnesium and moderately acidic. After the experiment, plots to which rice husk and grass hays were added as mulching materials had slight increase in organic matter, organic carbon, Magnesium and slight increase in pH (Table 1). Plots to which watermelon were planted at 100 x 100cm and mulched with rice husk produced significantly longer vines at all sampling periods compared to other planting spacing and mulching material used (Table 2). Significant interaction occurred between spacing and mulching on the vine length of watermelon at 10 WAS. The result of the interaction showed that holding the spacing constant and varying the mulching materials from the control, dry grass to rice husk significantly increased vine length. Similarly holding mulching material constant and varying the spacing significantly increased the vine length of watermelon. The longest vine was produced at 100x100cm spacing with rice husk as mulching material (Table 3). Planting of watermelon at a spacing of 100x100cm produced significantly higher number of branches compared to other planting spacing (50x50cm and 50x100cm) at all sampling periods. Plots that were mulched with rice husk had plants with significantly higher number of branches compared to those mulched with dry grass and the control at all sampling periods (Table 4). Significant interaction occurred between spacing and mulching on the number of branches at 10 WAS. The result of the interaction showed that holding the spacing constant and varying the mulching materials from the control, dry grass to rice husk significantly increase branch number. Similarly holding mulching material constant and varying the spacing significantly increases the number of branches (Table 5). Table 6 shows the effects of spacing and mulching on the number of leaves per plant at 4, 6, 8, and 10 WAS. The results obtained indicated that at 4 WAS, neither spacing nor mulching had any significant effect on the number of leaves. At 6, 8 and 10 WAS, spacing of 100x100cm produced plants with significantly higher number of leaves compared to other spacing used. Mulching of watermelon with rice husk produced significantly higher number of leaves compared to plots that were mulched with dry grasses and control at all sampling periods. Planting watermelon at 100x100cm spacing significantly produced higher numbers of marketable fruits per hectare, longer, wider, and higher number of fruits per plant compared to those plots planted at 50x50cm and 50x100cm spacing. Fruit yield per hectare was significantly increased by planting at 50x50cm followed by 50x100cm and 100x100cm spacing respectively (Table 7). Using Rice husk as mulching materials significantly produced fruits that were longer, wider, higher number of fruits per plant and fruit yield (t/ha) compared to plots that were mulched with dry grass and control. Significant interactions occurred between spacing and mulching on number of marketable fruits per hectare and fruit yield per hectare. The results of the interaction between spacing and mulching on the number of marketable fruits per hectare showed that the highest numbers of marketable fruits were obtained by planting watermelon at 100 x 100cm and applying rice husk as mulching material (Table 8). Results of the interaction between spacing and mulching on the fruit yield tons per hectare showed that planting watermelon at a spacing of 50 x 50cm and using rice husk as mulching material, produced significantly the highest fruit yield tons per hectare (Table 8).

The results of this study showed that the growth characters of watermelon were significantly improved at virtually all sampling period by planting at a spacing of 100x100cm could be attributed to less competition for water, nutrient and light between crops which allow the plant to efficiently utilize the available soil nutrient and water compared to other spacing used for effective growth and development. Though fruit yield (t/ha) and number of fruits per plant were significantly increased by planting spacing of 50x50cm compared to other spacing, significantly wider, longer and number of marketable fruits were produced under 100 x 100cm planting spacing. This could be attributed to the fact that at a spacing of 50 x 50cm, more fruits were produced due to increased plant population that translated to higher yield tons per hectare but at 100 x 100 the fruits were bigger thereby making them to have more marketable value compared to those produced at 50 x 50cm. The significant increase in all the growth and yield character of watermelon considered in this study (number of branches, fruits number, fruit diameter, number of leaves, vine length, fruit length, and fruit yield per hectare) due to application of rice husk as mulching material followed by dry grass mulch compared to control plot could be attributed to the fact that mulching improves the ecological environment of the soil, increases soil water contents, reduces infiltration rate, decomposes and add nutrients to the soil, control erosion and weeds problems, thereby translating to higher growth and yield. This is in line with the findings of Khurshid *et al.,(*2006). The significant interaction between spacing and mulching on most of the growth and yield characters measured is an affirmation of the fact that both are necessary for crop growth and yield.

Abstract
A study was conducted to assess the ecological impact of glyphosate herbicide in the FADAMA rice plain of Amaeze Ishiagu, Ebonyi State using some indicator species as termite termitereau count, earthworm abundance, fungi microbial load and plant species. Data generated on insect: termite, earthworm, and microbial load counts were subjected to statistical analysis using students T- test, while vegetation analysis was evaluated using index of similarity analysis. Results revealed significant difference (P<0.05) between unsprayed and sprayed plots and indicated that earthworms, termite number and fungal load were more in unsprayed fields than sprayed plots. Similarly, index of similarity showed disparity exist between unsprayed and sprayed plots, and revealing that unsprayed plots with less species recorded more total plant abundance than sprayed areas. This is therefore an indication than sustained glyphosate used in the study area has impacted negatively in biodiversity depletion. To ameliorate the situation and enhance biodiversity conservation interest needs to be stimulated by stakeholders on alternative methods of vegetation management involving integrated weed control that will incorporate cultural, biological, organic herbicides, mechanical vegetation control and other non-chemical control measures.

Introduction
Pesticides are chemical substances widely used in agricultural production to prevent or control pests, diseases, weeds and other plant pathogens in an effort to reduce or eliminate yield losses and maintain high product quality. They are also used for “commercial products” applied in the control of pests, diseases and/or weeds (Hayes, and Laws, 1991). Pesticides have been used for many years in the control of organisms that interfere with human interests. From this point of view, pesticides can be considered as an economic, labor-saving, and efficient too of pest management with great popularity in most sectors of the agricultural production. Most common pesticides include insecticides, fungicides, herbicides et cetera. The use of herbicides to control the spread of obnoxious weeds is an example of a pest control method. Herbicides also commonly known as weed killers, are pesticides used to kill unwanted plants (Kellog *et al;* 2000). Herbicides are widely used in agriculture and landscape turf management in the United State, they account for about 70% of all agricultural pesticide use (Kellog *et al*; 2000). Selective herbicides kill specific targets, while leaving the desired crop relatively unharmed. Some of these act by interfering with the growth of the weed and are often synthetic mimics of natural plant hormones. Herbicides used to clear waste ground, industrial sites, railways and railway embankments are not selective and kill all plant materials with which they come into contact. Smaller qualities are used in forest, pasture system, and management of areas set aside as wildlife habitat. Glyphosate is a non-selective systemic herbicide that is applied directly to plant foliage (Tomlin, 2006). As reported by RED facts (1993) when used in smaller qualities, glyphosate can act as a plant growth regulator. Glyphosate is a glycine derivative (Tomlin, 2006). The International Union of Pure and Applied Chemistry (IUPAC) name for glyphosate is N-(*Phosphonomethyl*) glycine. Glyphosate’s potential as an herbicides was first reported in 1971 (Herbicides Handbook, 2002). Roundup herbicide Bulletin (1980) reported that glyphosate was

first registered for use by the United States Environmental Protection Agency (USEPA) in 1974. Glyphosate is one of the most widely used herbicides with applications in agriculture, forestry, industrial weed control, lawn, garden and aquatic environments (RED, 1993; RED facts, 1993). Glyphosate is absorbed across the leaves and stems of plants and is trans-located throughout the plant. It concentrates in the meristem tissue. Williams et al; (2000) equally established that glyphosate is assimilated by leaves and other green plant tissues and is then rapidly trans-located within the phloem throughout the entire plant including its roots. Giesey *et al*; (2000) stated that glyphosate based herbicides are among the most widely used broad-spectrum herbicides in the world because they are highly efficacious, cost effective and readily degradable in the environment. They maintain that the most popular formulation, roundup is a combination of the active ingredient (glyphosate) and surfactant (*polyethoylated tallowamine*) that help the herbicide penetrate plant tissues. Their uses have adverse effect on ecosystem and have the potential to cause dramatic changes in the natural communities. Ecosystem we know is the interaction between and within the living (biotic) and non-living (abiotic) components of the environment in any given habitat. All components help in the maintenance of stability and balance of the system. For this, there is no component that is importance can easily be overlooked. Removal and abnormal increase of any component will affect the stability of others and the entire ecosystem because all natural resources are interdependent and interrelated. Despite these adverse effects of the use of herbicides in agricultural production, farmers all over the world still use them as major control practice (Briggs, 2002); which farmers in Amaeze Ishiagu, Ebonyi State are not exceptions. The Amaeze Ishiagu community is noted for rice production, and it is established that most farmers in this location make use of glyphosate based herbicides to clear the vegetation of their rice fields for cultivation and other weed control practices. They apply these chemicals year after year despite variations observed in production (yields), their satisfaction being reduced cost of labour associated with the use of this herbicide to clear farm vegetation. The incessant use of the glyphosate herbicide may be as a result of non-existence of more efficient, effective and readily available alternatives.
