Their wide spread use and regular application, however has caused lots of negative effects, which ranges from contamination of air, soil, water to its effects on living organisms-plants and animals (Brady,1996). It is believed that agro-chemicals affect soil micro-organisms hence the fertility of the soil, quality of water and air. Schroll *et al*; (1994) stated that concentrations of herbicides (glyphosate) on plant tissues can eliminate plant species or reduce their abundance. Furthermore, Steven and Randal (2004) reported that repeat treatment using glyphosate strongly reduced vegetation to zero at 0.14kg/hectare. Relyes (2004) revealed that widespread mortality of earthworms and other soil micro-organisms were as a result of the herbicide glyphosate. Henry *et al*; (1994) stated that glyphosate exposure caused a decrease in survival of soil termites and other soil inhabiting organisms. Herbicides reduced floral and faunal diversity and bring about instability in the ecosystem. The conservation of biological diversity (biodiversity) is becoming an integral part of the sustainable management of forest and agro-ecosystem. In this regard, vegetation management which includes chemical weed control is vital because of its widespread use and contribution to environmental degradation. Therefore, the result of this negative effect of the misuse of herbicides on our crop and environment have resulted in research into ways of reducing pesticide use and the need to properly evaluated the level of damage to the ecosystem. It is believed that chemical industries in-spite of being aware of the implications of pesticides are not giving due regard to the promotion of ecological sound practices and environmentally compatible product. In-spite of the upsurge in the use of pesticides in developing countries, there has been little or no awareness among the users of the hazards to the ecosystem. For many decades, there has been misused of herbicides without adequate information on their impact on the tropical environment. This research was envisaged to investigate the ecological impacts of glyphosate based herbicides in the FADAMA rice plain of Amaeze Ishiagu, Ebonyi State Nigeria using some indicator species.

Materials and Methods

Experimental Site

The experiment was conducted in the FADAMA rice plain consisting of strips of rice fields in Amaeze Ishiagu, Ivo Local Government Area of Ebonyi State, and South-East Nigeria. In this location, rice over the years has been intensively cultivated and glyphosate based herbicides used by most farmers in the clearing of vegetation and/or control of weeds. Ishiagu is in a derived savannah belt of South-East agro- ecological zone of Nigeria. It lies between latitude 5^0 56' longitude 7^0 31'E and has an altitude of 150m with an annual rainfall ranging from 1200mm-2000mm. The layout of the experiment consisted of ten (10) marked plots of glyphosate herbicide sprayed areas and ten (10) plots of adjacent unsprayed fields, thus giving a total of twenty (20) experimental units used for the investigation. The number of indicator species of organisms that were reduced, depleted or became extinct as a result of sustained herbicides (glyphosate) use were assessed in ten (10) marked plots of glyphosate sprayed areas and ten (10) plots of adjacent unsprayed fields the layout. Thus, consisting of a total of twenty (20) experimental units used for the investigation. In each of the sprayed and unsprayed plots of similar ecology, three (3) sample points were made, in which a quadrant was repeated thrown into the field three (3) times from the corner of the field. All plant species within the quadrant were enumerated, pressed, properly tagged and taken to the Department of forestry and environmental management Herbarium, Michael Okpara University of Agriculture, Umudike, Nigeria for identification and/or authentication. The vegetation data collected were analyzed using Mueller Dombis and Ellenberg (1974) index of similarity formula as:

$$\text{Index of similarity} = \frac{2C}{A \times B} \times \frac{100}{1}$$

Where;

C. = smallest sum of the two values common in samples A and B; A= sum of all values as % total stands for all types from sample B. The similarity index ranges from 0 (no similarity) to 100 (complete similarity). For values greater than 75, the two samples are generally considered replicates, they equally stated. A physical count of surviving termite hills (*termitereum*) in each of the plots was observed and recorded. Using a soil auger, soil samples were collected at a depth of 15cm from three (3) samples sites in each of the sprayed and unsprayed field plots. At the Pest Management Technology laboratory of Federal College of Agriculture, Ishiagu, soil samples from the three (3) samples points in each plots was pooled together, 5 litres of water poured into it in a 10 litres elastic container and sieved with 200mm mesh sieve. Therefore, the number of earthworms were counted and recorded. The data collected from both termite and earthworm counts were analyzed using students t- test as previously defined by Rogers (1999). Similarly, soil samples were collected from the plots at three (3) locations at a depth of 15cm using a soil auger. The soil samples were then taken to the soil biology laboratory of the National Root Crops Research Institute, Umudike for microbial (fungi) load/count. Serial dilutions were made using 10g of soils from each sample suspended in 90mls of sterile water, followed by inoculation of 1ml from dilutions factor 10^3 (least visible dilution factor) using four plate method as reported by Shree and Avlis (2003). The plates were incubated at 26^{0C} for 3-4 days with daily monitoring and/or observation of mycelia growth. After 4 days, the plates were observed for colony growth and counted using a counting meter (a *Gallenkamp* colony count). The number of colonies on the plates multiplied by the dilution factor gave plate count per milliliter (ml) of the soil sample solution incubated in the plates (Fawole and Qso; 1998).

Results and Discussion

Results of vegetation analysis showed that a total of 530 and 495 plants were enumerated in unsprayed and sprayed plots respectively. A subsequent community index of similarity assessment revealed a low similarity index (12.24) between sprayed and unsprayed field plots. The results showed that the mean number of termite hills (used as an indicator) were greater in unsprayed plots than sprayed ones. It also revealed significant differences ($P<0.05$) between sprayed and unsprayed fields on termite abundance. Table 3 showed the effect of glyphosate on earthworm abundance in the study area. The result revealed that there were significant differences ($P<0.05$) in the mean Standard Error (SE) of the two areas tested, such that the unsprayed plots recorded higher standard error (9.89) compared to 4.50 observed in sprayed plots. In Table 4 is shown (fungi) load of soil in the study area. The results of microbial count revealed that a higher mean fungi load of 31.1 X 10^3 fungi per millitre (ml) of soil sample solution was observed in unsprayed plots while sprayed fields recorded lower mean fungi load of 15.45 per ml of soil sample solution.

Results of vegetable enumeration and subsequent similarity index analysis revealed great disparity between sprayed and unsprayed plots in species occurrence and population abundance. There were more number of species in sprayed plots (due to nature flare back phenomenon) but depleted in total plant population abundance compared to unsprayed fields. This could be supported by Steve and Randal (2004) who stated that glyphosate application led to increased frequency of some native species but also a decrease in other native species. The decline of plant abundance on sprayed areas could be attributed to long time application of glyphosate herbicide in the study area. These tallies with Schroll *et al,* (1994) who reported that concentrations of herbicides on plant tissue can eliminate plant species or reduce their abundance. Furthermore, Steve and Randal (2004) stated that repeated treatment using glyphosate strongly reduce vegetative cover to near zero at 0.14kg/hectare. On farm continued application of glyphosate containing herbicide can significantly affect the numbers and diversity of plant species around field edges (Zobiole *et al*; 2011). The higher number of earthworm count recorded in unsprayed plots and the depleted number in sprayed areas could be ascribed to prolonged application of glyphosate herbicide in the area. This findings is in line with the result of Relyes (2004) who revealed that wide sprayed mortality of earthworms and other soil micro-organisms were as a result of the herbicide glyphosate. Glyphosate-containing could be toxic to earthworms, while the growth rate of some species are reduced by its application (Casabe *et al;* 2007). The significant decline in the population of termites in herbicide sprayed fields is directly the effect of sustained glyphosate application. However, indirect effect may be due to depleted vegetation rash, which provide regular food for termites. Henry et al (1994) had reported that glyphosate exposure caused a decrease in survival of soil termites and other soil inhabiting organism. It is apparent that the result of reduced microbial load observed on sprayed plots could be attributed to continual glyphosate application and in conformity with Haney et al (2000) who observed that the population of micro-organisms that suppresses disease causing fungi have been found to decrease in soils treated with glyphosate.

Conclusion

Findings revealed that sustained glyphosate treatment negatively impacted on plant species abundance, earthworm count, termite hill and microbial fungal load by reducing their frequency. The conservation of biological diversity is becoming an integral part of sustainable management of forest and agro-ecosystems. The result of this negative effect of prolonged glyphosate herbicide application on our crop and environment has engendered the need for a research into ways of reducing herbicide use and to properly evaluate the level of damage to the ecosystem. We therefore, have to strike a balance between increased crop productivity by the use of herbicides and maintenance (sustenance) of sound environmental quality.

Response of *Caryedon serratus* (Olivier) to *Moringa oleifera* (Lam) and *Garcina kola* (Heckel) on Stored Groundnut

O.I. Mbah, O. Chukwu and U.J. Usanga
Department of Pest Management Technology, Federal College of Agriculture, P.M.B7008
Ishiagu, Ebonyi State, Nigeria

Abstract
Plant derived powders of Moringa oleifera Lam (drum stick) and Garcina Kola Heckel (bitter kola) have been found effective as protectants of stored grain against sitophilus zeamais Motch, but limited evidence suggest that they may be useful in the control of the groundnut bruchid Caryedon serratus (Olivier).the present experiment was targeted to test this proposition. Leaf powder of M.oleifera and seed powder of G. kola were used to surface treat groundnut kernels in storage with a view to offering protection against the beetle C. serratus. Results showed that all powder concentrations of the two plants were significantly (p<0.05) more toxic to the insect relative to untreated control. However, powders of G. kola were more potent than the powders of M. oleifera, which were not too efficacious with the highest test concentration (4g) of G. kola recording the highest mean percentage mortality of 81.25% compared to the synthetic check pirimiphos methyl. Seeds treated with the two doses of G. kola powder significantly retarded post-embryonic development by the insect. Similarly, plant powders of G. kola effectively offered protection against weight loss and feeding damage by the beetle, while the powders of M. oleifera were moderately protective. The potential practical application of plant derived powders of G. kola as seed protectants and alternative synthetic pesticide available to the resource-limited farmers in West Africa is discussed.

Introduction
Groundnuts are stored both as unshelled pods and as kernels for different uses. They can be eaten raw, used in recipes, made into solvent and oil, and used in making-up medicines, textile materials, peanut butter and many other products. Both forms are vulnerable to attack by a plethora of insect pests after harvest. However, groundnut kernels are more susceptible to insect pest attack than pods in storage (Dudley and Rodney, 2003). All stored products are attacked by a wide range of insects and the most predominant among the insects are the beetles and moths. More than 100 insect pest species are known to live and feed on stored groundnuts (Cunningham and Walsh, 2002), some of which are of economic importance. The *bruchid* beetle *Caryedon serratus* (Olivier) is a major insect pest causing severe damage to oil seeds, especially groundnut. According to Duley and Rodney, (2003) reports of groundnut kernel damage by *C. setrratus* from different parts of the world have been well documented, leading to post-harvest losses of about 10-25% of the population. Insect infestation in groundnut is well known for causing direct loss, but indirect loss in terms of quality of the produce also impacts on its trade and uses. Therefore, arose the need to control the pest in storage since it reduces the economic value and viability of the crop. The use of synthetic chemicals seem to be the most effective, but most hazardous. Control of this insect pest often relies heavily on the use of synthetic insecticide, but increasing cost of application and erratic supply in developing countries due to foreign exchange constrains have stimulated interest in the development of alternative control strategies. The problems of many synthetic insecticides include high persistence, poor knowledge of application, increasing costs of application, pest resurgence, and genetic resistance by the insect and lethal effects on non-target organism in addition to direct toxicity to users (Okonkwo and Okoye, 1996). With a view to arresting/militating the apparent pollution problems in the environment and avoiding toxic effects of synthetic chemicals on non-target organism, studies on exploiting pesticides of plant origin are becoming increasingly popular in

the field of stored products entomology. Much of the plant kingdom remains unexplored for possible exploitation against insect pests. Currently, attention is being given to the use of edible plant materials as grain protectants (Ivbijaro and Agbaje, 1986; Mbah *et al*, 2011), and the tropics is well endowed with these plant species some of which are also used for medicinal purposes. Protection of stored products generally involves mixing grains with protectants made up of plant materials. The use of these traditional materials has recently induced active research to establish the scientific basis for their continued use regarding their efficacy, active constituents and effective application technology (Poswal and Akpa, 1999; Bekele, 1994). The focus of the present investigation was conceived to increase the data bank of natural products used in control of stored product insects and to test the potency of powders of drumstick (*Moringa oleifera* Lam) and bitter kola (*Garcina kola* Heckel) and their phytochemicals against the groundnut *bruchid C. serratus*.

Materials and Methods

Insect Culture

The groundnut *bruchid (C. serratus Olivier*) was reared for eight (8) weeks in the laboratory maintained at $28^{0c} {}^{+}{}_{-} 3^{0c}$, 65-70% relative humidity and 12h light dark regime. The food medium used was whole groundnut kernel. Fifty pairs of the insect species sexed following the report of Sembene *et al,* (2010) were placed in a 2-litre kilner jar containing 500g kernels of peanut. The jar was covered with a nylon mesh held with a rubber band. The groundnut grains for the investigation were disinfested by deep-freezing at -2^{0c} for 2 weeks. The seeds were thereafter, air-dried in the laboratory for 24hours prior to use. The air-dried plant materials used for the study were collected from Nigeria. They were the leaves of *M. oleifera* (drum stick) and seeds of *G. kola* (bitter kola). These plant materials were thoroughly washed with sterile water, and later dried in a well-ventilated laboratory room for 8-10 days depending on weather conditions. They were pulverized into very fine powder using an electric blender, passed through a 2-mm mesh micro sieve. The powders were later sealed in cellophane bags and stored in a refrigerator at 5 0c before used to prevent loss of active principle (Sherman, 1982).

Insect Bioassay

The plant powders of *M. oleifera* and G. kola both at the dosage levels of 2g and 4g and 0.04g of a synthetic check *pirimiphos methyl* were each weighed into 50g of clean undamaged and uninfected groundnut seeds (kernel) in kilner jars. The kernels in the control jars contained no chemical treatment or powders. The contents of the jars were gently shaken to ensure thorough admixture of the groundnut kernels with the insecticidal treatment powders. Twenty (20) (ten pairs) of 2-3 days old adult beetles *C. serratus* were inoculated into each of the jars covered with muslin white cloth held with a rubber band. Four replicates of both the treated and untreated control jars were laid out in a laboratory bench in completely Randomized design (CRD). At 1 and 7 days after inoculation, adult mortality/longevity was assessed by counting the dead and living insects carefully. Adults were considered dead when probed with sharp objects and there were no responses. On day 8, all insects, dead and alive were removed from each jar and the kernels returned to their respective jars. F1 progeny development was subsequently assessed at 8 weeks (56 days). The contents of the kilner jars were sieved out and newly emerged adult beetles were counted as F1 progeny. After 9 weeks, the groundnut grains were re-weighed using a melter balanced and percentage weight loss was evaluated as:

$$\%\text{ weight loss} = \frac{\text{initial weight-final weight}}{\text{Initial weight}} \times \frac{100}{1}$$

After 3 months of storage, damage assessment was carried out on treated and untreated seeds. Random samples of 100 seeds were taken from each jar and the number of damaged (seeds with characteristic emergent holes) and undamaged (wholesome) kernels were counted. Thereafter, percentage seed damage was determined following the methods:

$$\%\text{ seed damage} = \frac{\text{Number of seeds perforated}}{\text{Total number of seeds sampled counted}} \times \frac{100}{1}$$

Phytochemical composition of the plant materials used for the study was assessed according to the method of Oberlease (1973). Data collected were analyzed using the analysis of variance

(ANOVA). Differences in treatment means were separated using the least significant difference (LSD) test at 5 % probability according to Steele and Torrie (1980).

Results and Discussion

The toxic effect of the plant derived powders of *M. oleifera* and *G. kola* to *C. serratus* on groundnut kernels in storage is presented in Table 1. The result revealed that the synthetic insecticide *pirimiphos* methyl (which was used as a check) significant offered the most effective control of the insect and achieved 100% mortality. All the candidate plant powders significantly ($p<0.05$) reduced the longevity of the beetle on treated seeds with *bruchid* mortality ranging from 32.50% to 81.25%. Among the plant derived powders, the highest concentration of G. kola (4g) was the most potent against *C. serratus* with mean percentage mortality of 81.25% after 7 days of exposure, followed by *G. kola* at 2g dosage level (62.50%). *M. oleifera* treatments were not as efficacious with the lower dose of 2g evoking the least mean percentage mortality of 32.50% 7 days after treatment storage, which was better than the untreated control. Table 2 show the F1 progeny produced by groundnut seeds treated with different levels of plant derived powders. The different plant powders significantly ($p<0.05$) reduced the progeny of *C. serratus*. The G. kola treatments were found most effective in regarding progeny emergence of *C. serratus* on stored groundnut kernels compared to *M. oleifera* powder. The synthetic insecticide (*pirimiphos* methyl) completely suppressed post-embryonic development of the *bruchid.* The highest mean number of adults (14.50) equivalent to 72.50% emerged from the control seeds.

Groundnut kernel treated with plant powders of *M. oleifera* and G. kola showed significant differences (<0.05) in the reduction of weight caused by *C. serratus* (Table 3). The highest mean percentage weight loss of 46.00% was observed on groundnut seeds treated with the lower concentration (2g) of *M. oleifera,* which was followed by the highest level of 4g with 40% loss. However, the two dosage rates of G. kola 2 and 4g were significantly more effective in inhibiting weight reduction than the control with 70% weight loss. Seeds treated with the two concentrations (4g and 2g) of G. kola powder were significantly ($p<0.05$) the least damaged with mean percentage damage of 5.25% and 7.00% respectively (Table 4). The result indicates that these treatment powders were the most effective in protecting groundnut seeds against damage by the beetle. The most damaged kernels were found in jars treated with the two levels of *M. oleifera* 4 and 2g, which were statistically the same but significantly different ($p<0.05$) from the other treatments. Over all, the level of damage (59%) was highest in untreated control jars. The results of the phytochemical analysis of the plant powders shown in Table 5 revealed that the two plant materials contained typical plant constituents such as phenols, tannins, alkaloids, flavonoids saponins and oxalates at varying degrees.

Table 1: Effect of plant powders on adult mortality of *C. serratus* 1 and 7 days after treatment

Table 5: phytochemical composition (%) of the plant materials assayed

Plant materials	Phenols	Tannins	Alkaloids	Phytochemicals	Saponins	Oxalates	Favonoids
M. oleifera	0.15	0.88	0.40	0.86	2.48	1.06	
G. kola	0.70	1.20	4.52	1.31	1.45	0.75	

The potency of *G. kola* was high against *C. serratus* while *M. oleifera* powders was not that potent.

Results show that the mortality of the insect caused by the plant derived powders was Concentration dependent, and similarly related to the time of exposure. The resultant high mortalities of adult *C. serratus* observed on groundnut kernels treated with *G. kola* powder could be due to high toxic effect of the product on the groundnut *bruchid*. This result corroborates the findings of IIeke and Oni (2011) who reported that *G. kola* powder caused 89.70% weevil mortality after 72 hours of exposure and reduced adult emergence of *S. zeamais* Mbailao *et al; (2006) reported the effect of M. oleifera* oil on longevity of *callosobruchus maculatus* on cowpea grains. The efficacy of *G. kola* could be due to the crude toxic oil content. The phytochemical study showed that the more toxic plant powder of G. kola had a high content of the bioactive phytochemicals like alkaloids, phenols, tannins and comparatively lower proportion of oxalates and saponins. The bioactivity of different *Ocimum kenyense* plant materials against the insects may depend on several factors including chemical composition, species susceptibility and ariation in insect behavior (Cassida, 1990). Mbah (2010) had stated that the active constituents in the plant materials appear to be responsible for their inhibition effect against *Oryzaephilus mercator* onstored *Irvingia* and suggested that the high alkaloid content of *Jatropha curcas* might have contributed to the high toxic effects of the plant. Thus, these alkaloids might likely be the undesirable poisonous chemical element in the seeds, which render the oil toxic and not appropriate for human consumption (Lele, 2008). The high percentage mortality and low adult emergence at higher concentration caused by the powder of *G. kola*
can be attributed to the bitter compound in the seed (Trease and Evans, 1989). The present result seem to have validated the previous report of Okwu *et al,* (2007) who stated that the inhibition property of the extracts reside mainly in the phytochemicals contained in the plants. The plant powders also caused significant reduction in feeding damage, weight loss and the numbers of F1 progeny produced by the insect, which indicate the higher protectant potential of those powders against insect damage. The significantly lowered level of F1 emergence, kernel weight loss and damage of groundnut seeds stored with these plant powders points to the fact that the development of *C. serratus* was greatly inhibited by these powders. Mbailao et al, (2006) reported the effect of G. kola powder on reduced progeny emergence
of *Sitophilus zeamais* at the dosage rate of 12.5 and 25.0g *w/w. M.oleifera* at high concentration also reduced adult emergence of *S.zeamais. Ivbijaro* (1990) revealed that pure *neem* and the mixtures of *neem-Moringa* seed oil at 1.5ml/200g was more potent in protecting *stored* cowpea

grains against infestation and damage by *C. maculatus.* The result of this study indicate good potential for the use of *G. kola* as protectant and toxicant agents in storage pest management systems. They also demonstrate a possible scientific rationale for the incorporation of seeds of *Garcina* species into grain protection practices in Nigeria and indeed throughout the region. Botanical toxicants are broad-spectrum pesticides, and many are safe to apply, eco-friendly and can be produced by farmers and small-scale industries and therefore potentially less expensive. The chemical identity of the components from the plant powders is therefore of

Special interest. We believe that the identification of the active principles' and their mode of action currently in practice is expected to generate interest for their use in store products entomology. The use of plant materials in pest control could become important supplement to imported synthetic pesticides.

Number of Tubers and Tuber Size indices for Selection of Hybrid White Yam Genotypes for Multilocational Trial

I.I.M. Nwankwo and A.I. Ikoro
National Root Crops Research Institute, Umudike, PMB 7006, Umuahia, Abia State, Nigeria.
E-mail: nwankwomaxwell@yahoo.com.

Abstract
Eleven hybrid white yam genotypes plus three landraces of white yam were tested in the Western experimental field of N R C R I, Umudike in 2016 and 2017 with the objectives to identify and nominate superior high yielding candidate varieties in terms of number of tubers and tuber size with desirable tuber characteristics for release to farmers across the agro ecological zones for possible commercial yam production. The experiment was laid out in a randomized complete block design with three replications in an area of land that was mechanically ploughed, harrowed, ridged and spaced at 1m apart. Yam setts weighing 40g were sown 45 cm apart on the crest of the ridges and 10 cm below the soil surface and 100cm between ridges in a plot size of 20m². Data were collected on: mean total number of tubers tuber yield, number of ware tuber yield, number of seed tuber yam, number of mini-tubers and number of micro-tubers. Data on tuber yield related components such as tuber size and tuber shape were collected. Result indicated that Five hybrid yam genotypes 99/Amo/003 (37.5/1000plants/ha), 99/Amo/109 (54.4/1000plants/ha), 99/Amo/95A (41.8/1000plants/ha), 99/Amo/17 (36.6/1000plants/ha), and 99/Amo/060(43.6/1000plants/ha) are hereby recommended for its high number of tuber yield. They yielded more than Adaka (second Check variety) but lower than Ame (first Check variety) in their mean total number of tuber yield in number per plant per hectare. They have high bulking rate an indication of accumulation of usable fresh carbohydrate and cylindrical shape (TSI = >1 and <4) that is acceptable to consumers and command high market value. These genotypes are therefore nominated for multi-locational agro-ecological trial and release to farmers.
Keywords: Yam genotypes, number of tubers, high yield, agroeccologies and nomination

Introduction
In Nigeria, yam is cultivated by subsistence farmers in densely populated high potential zones. In these areas, yields realized from the farmer's fields are very low between 3.5 to 5.0t/ha (Ezulike et al., 2006). This has been as a result of low yield from adapted varieties and poor agronomic practices. To increase productivity in such zones, there is need for the utilization of higher yielding varieties that are widely adaptable across all the agro-ecological zones of the country and by use of application of appropriate agronomic practices (Daisy 2000). In most of yam growing zones, the yield of yam crop is measured not by weight of fresh tubers but by counting the number of harvested tubers per plant and per plot. The objective of this sturdy was to identify and nominate superior high yielding number of tuber candidate varieties with desirable tuber sizes attributes for tuber marketability and for release to farmers across the agro ecological zones for possible commercial yam production.

Materials and Method
Eleven hybrid white yam genotypes plus three landraces of white yam were tested in the Western experimental field of N R C R I, Umudike in 2016 and 2017. The experiment was laid out in a randomized complete block design with three replications in an area of land that was mechanically ploughed, harrowed and ridged at 1m apart. Yam setts weighing 40g were sown 45 cm apart on the crest of the ridges and 10 cm below the soil surface and 100cm between ridges in a plot size of 20m². The plots were kept weed-free manually. There was no Fertilizer application. Pre-emergence herbicide (Diuron) was used immediately after planting and complemented with

manual weeding at 12 weeks after planting (WAP). Data on yield related components were collected such as: number of total tubers produced per plant per hectare, number of ware tubers (>1000g) per plant per hectare and number of seed tubers (>500g<1000g) produced per plant per hectare, number of mini-tubers (>25g<500g) and number of micro-tubers (<25g). Data on other tuber yield related components such as tuber size and tuber shape were collected. Numbers of tuber yields were analyzed using Analysis of variance and means separation was done using standard error of difference means. Tuber Shape was scored after determining the tuber shape index (Orkwor *et al*., 2000). TSI = _ L/W. InTuber Shape Index Less than 1.0 = fair shape, 1.0 = very good shape, 2.0 = good shape, 3.0 = moderately good shape, 4.0 = poor shape, 5.0 = very poor shape. (IBPGR, 1997).

Results and Discussion

Number of tubers: The number of tubers contributes to the yield of the yam crop and is a function of yield. The result of mean total number of tubers, number of ware tubers, number of seed tuber yams, number of mini-tubers, and number of micro-tubers are presented in Table 1.

Table 1: Mean number of Tuber yield characteristics of the hybrid white yam genotypes as characteristics for marketability and agronomic traits for two years combined

Clone name	Mean Total number of tubers	Mean Number of ware tubers (1kg and above)	Mean Number of seed yams (>500<1000g)	Mean Number of mini-tubers (>25<500g)	Mean Number of micro-tubers (1g <200g)	% number of micro-tubers
99/Amo/064	28.2	12.0	13.2	3.0	0.0	0.0

Adaka	31.5	2.3	18.2	9.0	2.0	6.45
Mean	**34.79**	**7.25**	**13.39**	**9.29**	**5.15**	
Std error	19.92	0.82	19.11	8.66	5.14	
Sig. level	P<0.01	P<0.01	P<0.05	P<0.05	P<0.05	

There was high significant (P<0.01) variation in the total number of tubers, number of ware tubers, number of mini-tubers and number of micro-tubers evaluated in the two years combined (Table 1). The mean of total number of tubers varies from 18.0 to as high as 54.4 tubers (99/Amo/ 109) produced by the genotypes. However, the genotype 99/Amo/064 with 54.4 number of tubers produced more number of tubers than three of the check varieties (Ame with 47.9 tubers followed by Nwopoko with 36.7 tubers and Adaka with 31.50). The number of tubers across the genotypes for the two years combined indicated that there was high mean number of seed tubers (13.39 tubers) produced than number of ware tubers (7.25), number of mini-tubers (9.29) and number of micro-tubers (5.15). High number of seed tubers and mini-tubers are indication that the hybrid white yam genotypes could be used in the production of seed tubers for commercial ware tuber yam production and for seed tuber for marketability, and could be produced using the 40g seed weight. However, high percentage of micro-tubers produced by the genotype 99/Amo/17 and no ware yam tubers was an indication of early warning for genetic erosion. Such genotypes if not rescued, will be genetically eroded. Factors that could contribute to high percentage of micro-tuber poduction by yam genotypes include: multiple vines, continuous depletion of soil nutrient without replenishment, non adaptability of the genotypes to the local environment and as such the genotype could be endangered. However, to save the genotype was to embark on genetic rescue to save it from the environment. The genotypes 99/Amo/17 had 100.0% Micro-tubers and if not rescued will be genetically eroded. It is equally an indication that the yam genotype is not well adapted to the local environmental conditions and as a result could be endangered. Endangered genotypes should be planted only in an environment where they perform well. However, number of tubers is a function of yield. It is one of the yield factors. It is the first visual factors on which a farmer uses to assess the yield performance of his crop. Numbers of tubers per plant and per plot indicate the yield performance of a crop. That is what the farmers use to assess a high yielding crop. Most farmers (especially rural farmers) do not use fresh weight yield of a crop to assess the yield performance of crops. The number of tubers per plant gives the eye assessment of the yam crop yield and could be calculated per hectare by multiplying the number of tubers per yam plant per every 1000 yam plants per hectare. Yam genotypes with high number of ware yam tubers or seed tuber yams depending on the objectives could be selected as high yielding variety. The following genotypes should be selected for marketable seed yam production: 99/Amo/109, (25.1) and 99/Amo/060 (25.2). The three hybrid white yam genotypes produced more number of seed tuber yams than the check varieties - Nwopoko with 21.5t/ha, Adaka with, 18.2% and Ame with 15.3t/ha (Table 1).

Tuber size: The results of the size of the yam tuber in length, tuber width and tuber shape index are presented in Table 2.

Table 2: Mean tuber length, tuber width and tuber shape index

Clone name	Mean Maximum tuber length (cm)	Mean Maximum tuber width (cm)	Tuber shape index
99/Amo/064	28.50	7.45	3.80
99/Amo/109	29.00	7.98	3.63
99/Amo/060	28.10	8.20	3.43
99/Amo/080	31.53	10.0	3.16

99/Amo/X5	26.13	6.83	3.80
Ame	29.38	8.31	3.50
Nwopoko	29.34	7.6	3.86
Adaka	29.38	8.31	3.50
Std error	5.6	2.9	3.54
Range	22.93-30.0	6.83-10.0	3.16-3.97
Mean	28.81	8.06	3.84
Sig. level	P<0.05	P<0.05	P>0.05

Tuber Shape Index = Less than 1.0 = fair shape, 1.0 = very good shape, 2.0 = good shape, 3.0 = moderately good shape, 4.0 = poor shape, 5.0 = very poor shape. Tuber surface Texture

The results indicated the mean tuber size of the 14 yam genotypes in terms of bulkiness. There was significant (P<0.05) variation in the length and width of the hybrid yam genotypes. The significant (P<0.05) genotypic mean tuber size variation among the hybrid white yam genotypes which ranges from 22.93cm to 30.0cm in length and 3.16 to 8.97cm in width which indicated the extent of fresh carbohydrate accumulation and the rate of photosynthetic efficiency among the genotypes. The length and width of the tubers measures the tuber size which is the dimension, extent or how large the yam tubers were. The yam genotype with the longest tuber length was 99/Amo/056 with 34.30cm and tuber thickness of 9.19cm more than the two landraces (Table 2) which indicated high fresh carbohydrate accumulation and more photosynthetic efficiency more than the three landraces. Other genotypes with long tubers and larger width more than the landraces were 99/Amo/080 with length 31.53cm and width 10.0cm. This indicated high bulking rate of the hybrid yam genotypes. Consumers who need yam tubers for consumption buy ware yam tubers that are large. However, the farmers uses the size of yam tubers to assess the yield performance of the yam crop especially since yam plants are generally known to produce one tuber per plant. Yam genotypes that produces large tubers (ware tubers) when compare with the planted seed weight is regarded as high or low yielding genotypes. For example in commercial ware tuber (1000 and above kg) production, seed sizes weighing 150 to 250g are used. However, yam genotypes that produces ware tubers from seed tuber size weighing 40g could be regarded as high yielding genotypes if the tuber produced weighed 1000g and above. Nevertheless, there are some factors that can affect the size of yam tubers to be small. These factors includes: low fertility of the soil, nutrient in balance such as high nitrogen fertilizer, none staking of the yam plot, unweeded plots, pests and diseases infestation and general neglect of the yam field (Onwueme, and Sinha, 1991).

Tuber shape: The hybrid yam genotypes and the landraces have straight sides with almost circular ends of equal size and a constant circular cross section that can go for as cylindrical shape. This type of shape is not prone to damage during yam harvest and easy for tying on stakes during storage. Branched yam tubers are liable for damage during harvesting. All the yam genotypes including the landraces have cylindrical shapes. Hence the tuber shape index is within region of general acceptance (TSI = >1 and < 4). The mean tuber shape of all the hybrid clones was 3.84 which is an indication of cylindrical shape. This shape lends itself for ease of peeling during processing for food than round or flat shape. Yam tubers with cylindrical shape command high market prices. However, yam tubers with cylindrical shape grow deeper into the soil and less prone to breakage during harvesting. Tuber shape has indirect effect on the tuber size. When a tuber is large, the shape will manifest, it will be clearly seen if it is a round tuber, cylindrical or flat. Yam tubers with cylindrical shape are easy to harvest and command high market price. .

Conclusion

Five hybrid yam genotypes 99/Amo/003 (37.5/1000plants/ha), 99/Amo/109 (54.4/1000plants/ha), 99/Amo/95A (41.8/1000plants/ha), 99/Amo/17 (36.6/1000plants/ha), and 99/Amo/060 (43.6/1000plants/ha) are hereby recommended for its high number of tuber yield. They yielded more than Adaka (second Check variety) but lower than Ame (first Check variety) in their mean total number of tuber yield in number per yam plant per hectare. They have high bulking rate (size) an indication of accumulation of usable fresh carbohydrate and cylindrical shape (TSI = >1 and <4) that is acceptable to consumers and command high market value. These genotypes are therefore nominated for multi-location agro-ecological trial and release to farmers.

Abstract
Nigeria is considered to be the largest producer of Dioscorea spp, a crop that provides an affordable source of carbohydrates to more than 80% of the country. Due to the ease of propagation and better agronomic flexibility Dioscorea alata or water yam is one of the most widely cultivated by small holder farmers. The aim of this study was to determine the genetic relatedness between three improved accessions and samples collected from farmers in certain yam cultivating regions; using simple sequence repeats (microsatellite). The loci used in this study showed, on average, 69.81% polymorphism and were discriminatory enough for this specie. This preliminary study, showed relatedness between released TDa 98/01168 and TDa 98/01176 and two accessions sampled from two different farmers' fields in Benue state while TDa 98/01168 was closely linked to four different farmers in Oyo, Kogi and Benue as well. This study provides baseline information for further adoption studies of released D. alata varieties.

Introduction
Yam (*Dioscorea* spp) is considered a major source of food and income (Sartie and Asiedu, 2011). One of the major cultivated specie, is the edible *Dioscorea alata* (also known as 'water yam', 'winged yam' and 'greater yam'). On a commercial scale, it is second only to the guinea yam complex (*Dioscorea cayenensis-rotundata*); and its commercial success is as a result of several factors, including high nutritional qualities, low glycemic index, easy of management, high yield and resistance to yam mosaic virus (Siqueira et. al., 2012, Siqueira et al., 2014, Egesi et al., 2002). Over the years, several breeding programs have sought to produce improved yam varieties acceptable to farmers and consumers alike. The yam breeding programs, managed by the National Root Crop Research Institute and the International Institute for Tropical Agriculture have developed and released *D.alata* varieties with improved traits.. In 2016, a preliminary survey was conducted to determine the adoption status of three improved *D.alata* varieties (Table 1), released to farmers in Nigeria It is well documented that farmers change the varietal names of theses released varieties to suit their local preferred names for yam. This introduces a level of confusion as to the true status of officially released varieties in farmers' fields. We describe in this paper, the use of simple sequence repeats (SSR) or microsatellites to identify those three released varieties from some pilot sites.

Table 1: IITA released *D. alata* varieties, used in this study, with year of release and improved qualities. Leaf samples were collected from IITA multiplication trials

Released varieties	Outstanding characteristics	Year of release
TDa 98/01168	High yielding, pests and diseases tolerant, good for pounded yam, frying and boiling. (24-28t/ha)	2008
TDa 00/00194	High yielding, pests and diseases tolerant, very good for yam, fufu, frying and boiling. (37.5t/ha)	2009
TDa 98/01176	High yielding, pests and diseases tolerant, very good for pounded yam, frying and boiling, suitable for both rainy and dry seasons yam production (26-30t/ha)	2008

Materials and Methods

Sample site and Plant materials

The 4 pilot states used for this study, were chosen based on the active role of the National Coordinated Research Program trials and on-farm verification trials prior to the official release of these *D. alata* varieties. The states targeted included; Oyo, Nassarawa, Kogi and Benue states and farmers' fields were randomly selected. Different *D. alata* varieties cultivated amongst these farmers were sampled. A total of Fourteen *D. alata* were sampled from the randomly selected fields (Table 2). Three officially released *D. alata* varieties as shown in Table 1 was sampled from the breeding field of National Root Crops Research Institute Umudike, Nigeria. All samples were stored at room temperature in silica gels and dried.

DNA extraction

Silica gel dried leaf samples were transported to the Bioscience Laboratory, International Institute for Tropical Agriculture (IITA), Ibadan Nigeria. DNA was isolated from the dried leaf (100mg) yam samples using a modified CTAB extraction method as described by Sharma *et al* 2008. The DNA extracts were eluted in 100µl sterile TE buffer and the quality and concentration were assessed by gel electrophoresis using 1% agarose with known concentrations of undigested lambda DNA (Sigma, St Louis, MO, USA) The extracts were further quantified using a Nanodrop spectrophotometer and stored at -20°C for genotyping. Prior to PCR analysis the samples were standardized to 25ng/µl.

PCR Genotyping

Twenty-three SSR primer pairs developed from various yam species were selected to analyse the samples (Tamiru et al., 2015, Tostain et al., 2006). The primer pairs were tested on the released varieties and seven (Table 3) were chosen based on the capacity to reveal polymorphism. PCR reactions were conducted on a thermocycler (Applied Biosytems Veriti 96 well plates) in 10µl volumes containing 1µl of template DNA, 100 µM each of dNTP, 2.5 mM MgCl2, 0.5 µM, 10X reaction buffer and 2 units of Taq DNA polymerase. Depending on the loci used, different touch down PCR cycle program was used as seen in table 1. The PCR amplicons were electrophoresed on 2% agarose gel in 0.5 TBE buffer along with a DNA molecular size marker. Gels were photographed using a gel documentation system.

Gel Scoring and fragment analysis

2µL of PCR amplicons were mixed with loading dye and subjected to further elecrophoresis in 6% polyacrylamide gels at 100V for 30mins. The resolved and unambiguous DNA bands generated from the separation of the PCR products were counted by starting from the top to the bottom of the lanes and were also scored as presence (1) and absence (0) of bands. The binary data generated was analysed using the Gstudio package (Rodney, 2016) of the R software to determine number of alleles, observed heterozygosity, genetic distance and to conduct a clustal analysis.

Results and Discussion

DNA quality and molecular concentration

All 17 samples produced high molecular weight DNA with very good quality. The average concentration of DNA extracted was 2707.4ng/µl, ranging from 1277.8ng/µl to 4317.3ng/µl. The average A260/280 (representing the purity of the DNA extract) for the obtained DNA was 1.88 ranging from 1.78 to 1.95.

SSR pattern of polymorphism

To provide evidence that some of the officially released *D. alata* varieties are being utilized by farmers, SSRs were used in this study to determine the genetic diversity between the released maintained in NRCRI yam breeding program and fourteen sampled genotypes from , from farmers' fields. The high variability and multi allelic nature of SSRs make them low cost informative markers for determining genetic relationships in polyploid plants like *Dioscorea alata* (Girma et al., 2015, Obidiegwu et al., 2009a&b). A total 37 alleles were detected when all 17 accessions were analysed with the 7 highly polymorphic SSR loci. An average of 5.29 alleles were observed per locus (Table 3). The observed heterozygosity of 0.63 on average, varied from 0.47 (Dab2D06) to 0.82 (SSR34). All seven primer pairs produced amplicons with varying levels of polymorphism revealing, on average 69.81% polymorphism. The polymorphic information content ranged from 0.42 (Dab20C5) to 0.69 (Dab2E07) with an average of 0.66.

Table 3: Characteristics of 7 SSR markers used in this study

Primers	5' to 3' Primer sequence	*A*	Ho	Ae	PIC
Dab20C5	CCCATGCTTGTAGTTGT -F TGCTCACCTCTTTACTTG -R	3	0.53	1.74	0.42

Number of alleles per locus (A), observed heterozygosity (Ho), effective alleles (Ae) and polymorphic information content (PIC)

Genetic distance

Similarity matrix was generated with the Nei similarity coefficient method. An unweighted pair group method and arithmetic mean similarity coefficient method was used to generate a dendrogram (Figure 1). The average Nei's coefficient was 0.59, representing a high genetic diversity also seen in previous studies on *Dioscorea* spp in Nigeria (Obidegwu et al., 2009). The dendogram generated in this study from the cluster analysis classified the 17 accessions into 4 clusters. Two of the released materials sampled from the NRCRI germplasm (TDa 00/00194 and TDa 98/01176) were closely related as shown in cluster 3. This implies they might have similar pedigree history in the breeding program. Two accessions, local-3 and Tokula-2, sampled in Benue from two different farmers also seem closely related to both released varieties as seen in cluster 3. Released variety TDa98/01168 as shown in cluster 4 was closely linked to accessions sampled from Oyo (Agric-2 and Agric -1), Benue (Tokula-1) and Kogi (Local-2). This represents the closest link to possible released materials grown in farmers' fields. Samples that did form clusters and interrelatedness may be clones with close genetic identity.

Conclusion

This preliminary study shows that these markers were highly polymorphic and informative; demonstrating the role SSRs can play in yam breeding programs to determine adoption of released varieties by farmers. The findings indicate that out of the 14 fields sampled, the three released varieties were closely linked to 6 farmers in 3 out of the 4 states. The results from this preliminary study provide the needed baseline to support further investigation on the subject of yam variety adoption status in yam cultivating regions in Nigeria.

Abstract
Eleven hybrid white yam genotypes plus three landraces of white yam were tested in the Western experimental field of N R C R I, Umudike in 2016 and 2017 with the objectives to identify and select superior high tuber fresh weight with desirable tuber characteristics for marketability and for possible commercial yam production. The experiment was laid out in a randomized complete block design with three replications in an area of land that was mechanically ploughed, harrowed and ridged at 1m apart. Yam setts weighing 40g were sown 45 cm apart on the crest of the ridges and 10 cm below the soil surface and 100cm between ridges in a plot size of 20m^2. Data were collected on: mean total fresh tuber weight, ware fresh tuber weight and weight of seed yams.. Data on tuber yield related market attributes such as tuber size, flesh tuber colour and tuber surface texture were collected. Result indicated that five hybrid yam genotypes 99/Amo/ 064, 99/Amo/109, 99/Amo/060, 99/Amo/080, and 99/Amo/144 were recommended for its high fresh tuber yield. They significantly (P<0.01) yielded more than Adaka (second Check variety) but lower than Ame (first Check variety) in their mean fresh tuber weight and mean fresh ware tuber yield in t/ha. They have high bulking rate an indication of fresh matter accumulation of usable carbohydrate. These genotypes have white flesh to cream colour, smooth skin and cylindrical shape (TSI = >1 and <4) marketability attributes that are acceptable to consumers. These genotypes are therefore selected for NCRP multi-location agro-ecological trial for yield stability trial.

Key words: Yam genotypes, fresh weight, high yield, tuber and consumer acceptability

Introduction
The white yam (*Dioscorea rotundata* Poir) is one of the most popular tuber crops in Nigeria and abroad because of its yield potential and high calorific value. It is mainly cultivated almost in all the tropical and subtropical countries. It is heterozygous cross-pollinated, polyploid (2n=90) and vegetatively propagated tuber (modified stem) crop in which many of the traits show continuous variation (Jones et al 1986). In addition to protein and starch some of the yam varieties provide micronutrients such as iron *making* the tuber more nutritious. Increasing total tuber yield would be made easier by selecting for components because the components are more simply inherited than the total tuber yield itself. Correlation studies enable the plant breeder to know the mutual relationship between various characters contributions and determine the component characters on which selection can be used for genetic tuber improvement. Although correlation coefficients assessment are helpful in determining the various component of complex traits like tuber yield although they do not provide an exact picture of relative importance of direct and indirect influence of each component character. The ultimate storage tuber yield depends upon a large number of factors such as environments and genetic constitution of the organism that influence the final expression of the tuber yield and tuber traits. Such a complex scheme of relationship could be partitioned by path coefficients analysis as suggested by Wright (1921) and adopted by Dewey DR and Lu (1981). Path analysis can be used to assist plant breeders to identify traits that are useful as selection criteria to improve crop yield. In Nigeria, yam is cultivated by subsistence farmers in densely populated high potential zones. In these areas, yields realized from the farmer's fields are very low between 3.5 to 5.0t/ha (Ezulike et al., 2006). This has been as a result of low yield from adapted varieties and poor agronomic practices. To increase productivity in such zones, there is need for the utilization of higher yielding varieties that are widely adaptable

across all the agro-ecological zones of the country and by use of application of appropriate agronomic practices (Daisy 2000). However, the aim of this study was to select high tuber yielding genotypes with tuber for marketability attributes for Nationally Coordinated Crop Release Project (NCRP) multlocational trial across the agro ecological zones for possible commercial yam production.

Material and Methods

The present study was conducted at the Western experimental field of N R C R I, Umudike in 2016 and 2017. The material used in the present study was developed through ontrolled pollinated breeding method. The true controlled pollinated seeds of Ten hybrid white yam genotypes plus two landraces of white yam were tested in the experiment which was laid out in a randomized complete block design with three replications in an area of land that was mechanically ploughed, harrowed and ridged at 1m apart. Yam setts weighing 40g were sown 45 cm apart on the crest of the ridges and 10 cm below the soil surface and 100cm between ridges in a plot size of 20m^2. The plots were kept weed-free manually. There was no Fertilizer application. Pre-emergence herbicide (Diuron) was used immediately after planting and complemented with manual weeding at 12 weeks after planting (WAP). Data on yield related components were collected such as: mean total tuber weight per tonne per hectare, ware tuber weight per tonne per hectare and weight of seed yams per tonne per hectare were collected. Data on other tuber yield related components such as tuber size, flesh colour and tuber surface texture were collected. Tuber yield was analyzed using Analysis of variance and means separation was done using standard error of difference means. Tuber surface Texture (TST). Visually scored. 1.0= smooth surface (skin) tuber, 2.0= rough surface (skin) tuber (IBPGR, 1997).

Results and Discussion

Mean Fresh weight of tubers per plant: Tuber fresh weight is the accumulation of fresh matter content in the tubers of the hybrid yam genotypes. The result on mean total weight of fresh tubers, mean weight of ware fresh tubers, mean weight of fresh seed tubers and other tuber yield attributes for fresh tuber marketability are presented on Table 1.

Table 1: Mean total fresh tuber weight (t/ha), mean Fresh weight of ware yam (t/ha), mean fresh weight of seed yam (t/ha) and other related attributes for tuber marketability and agronomic traits of the yam genotypes for the two seasons combined

Clonal name	Mean Total fresh tuber weight t/ha	Mean Fresh weight of ware yam (t/ha)	Mean Fresh weight of seed tubers (t/ha)	Tuber flesh colour	Rate of oxidation < 5minutess	Type of ooze on cut surface	Tuber skin thickness

Adaka	28.2	13.0	5.2	White	Low	Gummy	>1mm
Std error	17.6	7.3	6.4				
Range	7.0-47.8	2.6-21.8	0.0-29.3				
Mean weight	32.9	15.1	17.2				
Sig. level	P<0.01	P<0.01	P<0.01				

Note: Seed yam =Yam tubers weighing less than 1000g Ware yam= tubers weighing above 1000g

Total mean tuber fresh weight of the yam genotypes significantly (P<0.01) varied among the hybrid yam genotypes. The mean total tuber fresh tuber weight varied from 7.0 (99/Amo/x5) to as high a 39.0t/ha with grand mean of 32.9t/ha. However, six yam genotypes had fresh tuber weight above the grand mean. Nevertheless, five genotypes namely; 99/Amo/064 (36.6t/ha), 99/Amo/144 (39.0t/ha), 99/Amo/109 (47.8t/ha), 99/Amo/060 (35.2t/ha), 99/Amo/056 (34.6t/ha) had more tuber fresh weights higher than the highest yielding check variety Ame with 35.0t/ha. The fresh weight of ware yam tubers significantly (P<0.01) varied among the yam genotypes evaluated in the range of 2.6t/ha (99/Amo/x5) to as high as 29.3t/ha (99/Amo/109).Ware yam tubers are tubers for commercial yam production and for consumption. It is further differentiated into Table tubers (>1.0 < 3.0kg) and ceremonial tubers (>3.0kg). Yam genotypes that produces more fresh ware yam tubers than the check varieties should be selected for evaluation across the yam growing agro-ecologies of the country for yield stability trial. Based on this result, the following yam genotypes that produced ware yam tubers with fresh weight higher than the check varieties should be selected; 99/Amo/ (21.8t/ha), 99/Amo/144 (20.4t/ha), 99/Amo/060 (19.2t/ha), 99 Amo/109 (18.4t/ha), and 99/Amo/064 (16.6). The seed tubers are for planting commercial ware yam production. The result on Table 2 indicated high significant (P<0.01) variability in the fresh weight of seed yam tubers produced by the yam genotypes. The fresh weights of the seed tubers varied from 0.0 (99/Amo/017) to as high as 29.3t/ha (99/Amo/109) with grand mean of 17.2t/ha. Yam genotypes with seed tubers whose fresh weights were above the grand mean should be selected for commercial seed tuber production (Table 2). However, the following yam genotypes 99/Amo/144, 99/Amo/060, 99/Amo/109 and 99/Amo/064 had tubers with more total fresh tuber weight, weight of ware tubers and weight of seed tubers.

Marketability attributes

Tuber size: The results on Fresh tuber length, Tuber width and other tuber related market attributes of the yam genotypes are presented in Table 2.

Table 2: Fresh tuber length, Tuber width and other tuber related market attributes of the yam genotypes

Clone name	Maximum tuber length	Maximum tuber width	Tuber shape index	Tuber skin texture	Tuber hairiness	Tuber spineness
99/Amo/064	28.50	7.45	3.80	1	1	1
99/Amo/109	29.00	7.98	3.63	1	1	1
99/Amo/060	28.10	8.20	3.43	1	1	1
99/Amo/080	31.53	10.0	3.16	1	1	1
99/Amo/114	28.91	8.21	3.52	1	1	1
99/Amo/040	27.60	7.33	3.87	1	1	1
99/Amo/17	30.00	7.55	3.97	1	1	1
99/Amo/056	34.30	9.19	3.73	1	1	1
99/Amo/95A	22.93	7.98	2.90	1	1	1
99/Amo/003	28.20	7.87	3.60	1	1	1
99/Amo/X5	26.13	6.83	3.80	1	1	1
Ame	29.38	8.31	3.50	1	1	1
Nwopoko	29.34	7.6	3.86	1	1	1
Adaka	29.38	8.31	3.50	1	1	1
Std error	5.6	2.9	3.54			
Range	22.93-30.0	6.83-10.0	3.16-3.97			
Mean	28.81	8.06	3.84			
Sig. level	P<0.05	P<0.05	P>0.05			

Note: Tuber surface Texture (TST): 1.0= smooth surface (skin) tuber, 2.0= rough surface (skin) tuber

The results indicated the mean tuber size of the 14 yam genotypes in terms of bulkiness. There was significant (P<0.05) variation in the length and width of the hybrid yam genotypes. The significant (P<0.05) genotypic mean tuber size variation among the hybrid yam genotypes which ranges from 22.93cm to 30.0cm in length and 3.16 to 8.97cm in width indicated the extent of fresh carbohydrate accumulation and the rate of photosynthetic efficiency among the genotypes. The length and width of the tubers measures the tuber size which is the dimension, extent or how large the yam tubers were. The yam genotype with the longest tuber length was 99/Amo/056 with 34.30cm and tuber thickness of 9.19cm more than the two landraces (Table 2) which indicated high fresh carbohydrate accumulation and more photosynthetic efficiency more than the three landraces. Other genotypes with long tubers and larger width more than the landraces were 99/Amo/080 with length 31.53cm and width 10.0cm. This indicated high bulking rate of the hybrid yam genotypes. Consumers who need yam for consumption buy ware yam tubers that are large.

Tuber shape: The hybrid yam genotypes and the landraces have straight sides with almost circular ends of equal size and a constant circular cross section that can go for as cylindrical shape. This type of shape is not prone to damage during yam harvest and easy for tying on stakes during storage. Branched yam tubers are liable for damage during harvesting. All the yam genotypes including the landraces have cylindrical shapes. Hence the tuber shape index is within region of general acceptance (TSI = >1 and < 4). The mean tuber shape of all the hybrid clones was 3.84 which is an indication of cylindrical shape. This shape lends itself for ease of peeling during processing for food than round or flat shape. Yam tuber with cylindrical shape command high market prices. However, yam tubers with cylindrical shape grow deeper into the soil and less prone to breakage during harvesting (Orkwor et al, 2000).

Tuber surface texture: The tuber surface texture indicates the tubers surface appeal to the eye which could influence their marketability. The result in Table 2 indicated that the tubers surface texture indices were fine. The score rating of 1.0 for hairiness, spines and surface skin texture indicated that they were all good and appealing and could enhance their marketability. .

Tuber flesh colour: The tuber flesh colour ranges from cream to white (Table 2) with very low oxidation rate after being exposed to the air for 5 minutes. Two genotypes Amo99/040 and Amo99/095A slightly turned brown after being exposed to the air for 5 minutes. Colours are good index for the acceptability or rejection of yam genotypes especially if the yam genotypes are for food preparation such as pounding of *fufu.* All the yam genotypes evaluated have white flesh colour which could be good for *fufu* food. Yam tubers with white flesh colour attract and appeal to the eyes and therefore contribute to the marketability of the tubers than yam tubers that are brownish in colour. The tuber flesh colour of the hybrid yam genotypes including the landraces were all white in colour and would be good in yam flour or in the preparation of pounded yam a prestigious carbohydrate to welcome visitors especially in South eastern Nigeria. The exudates of the genotypes are gummy and non-irritant when it comes in contact with the human skin except Amo99/003 and Amo99/X5 (Table 2) which have watery exudates. Yam tubers that are irritating to the skin does not appeal to consumers except if it has special attributes.

Tuber skin thickness: Tubers that are liable to bruises as a result of light skin does not store well. The bruise is an entrance to pathogenic organisms. Yam genotypes with skin tuber surface above 1.0mm does not bruise easily during harvest and while carting for storage or other minor handlings.

Conclusion

Five hybrid yam genotypes 99/Amo/064, 99/Amo/109, 99/Amo/060, 99/Amo/080, and 99/Amo/144 are hereby recommended for its high tuber yield. They yielded more than Adaka (second Check variety) but lower than Ame (first Check variety) in their mean total fresh tuber yield and mean fresh ware tuber yield in t/ha. They have high bulking rate an indication of accumulation of usable fresh carbohydrate. These genotypes have white flesh to cream colour, smooth skin and cylindrical shape (TSI = >1 and <4) that is acceptable to consumers and command high market value as a result of tuber surface skin texture.

bigjoyjosh@gmail.com

Abstract
Effective soybean rhizobia are seldom found in sufficient or large numbers in the soils that have no history of soybean cultivation. There may be a need for soybean grown in such soils to be supplied with inoculant rhizobia to ensure optimal inputs from biological nitrogen fixation. A trial was set up to diagnose the underlying factors responsible for variation in yield among soybean treatments at four sites in Shiroro Local Government Area of Niger State. The trial consisted of six (6) treatments and four (4) replications arranged in randomized complete block design (RCBD). The treatments were (I) Control, (II) Inoculant only, (III) Inoculant + phosphorus (30kg P_2O_5/ha), (IV) Inoculant + phosphorus + potassium (20kg K_2O/ha), (V) Inoculant + phosphorus + potassium + micronutrients (3.3kg/ha) and (VI) Inoculant + phosphorus + potassium + micronutrients + organic manure (4tons/ha). Response to bio-fertilizer varied across sites. Treatments with organic matter were significantly greater than the control in terms of plant height, nodule number and shoot dry weight but marginally greater than the control in pod number and pod dry weight. The treatments with inoculant only had similar yield parameters as the mineral fertilizer treatments as well as the organic matter treatments. The results indicate the benefit of using bio-fertilizers and organic matter in improving the productivity of soybean.

Introduction
Soybean is an introduced crop in Nigeria. Its production in Benue State, which is the largest producer of the crop in Nigeria, is about 175, 000 metric tonnes (MT) out of the estimated national production of about 437,000 MT in 2007 (FMAWR,2007; NFRA, 2008). Average yields in Nigeria are estimated at less than 500 kg/ha (NPAFS, 2009) although up to 3–4t/ha are obtained in some other countries (DAFF, 2010). Low soil fertility, especially deficiencies of N, P, K and some micro nutrients such as zinc and boron have been reported as a major factor hindering soybean productivity. Soybean like other N_2 fixing legumes, can meet part of its N requirement through biological nitrogen fixation (BNF). The TGx soybean varieties commonly grown in Nigeria were developed by the International Institute of Tropical Agriculture (IITA) Ibadan to form nodules freely with indigenous rhizobium in tropical soils (Kueneman *et al*., 1984; Pulver *et al.,* 1985). However these crops do not form effective symbiosis with indigenous rhizobia populations in all cases and do often benefit from inoculation using highly effective rhizobia strain (Pulver, *et al.*, 1985). Organic manure provides a good substrate for the growth of microorganisms and maintains a favorable nutritional balance and soil physical properties. The uses of organic matter for enhanced fertility and crop productivity is generally recognized providing most of the nutrient requirement by crops (Asei, *et al.,* 2015). However, given the limitations in its availability and ease of handling, one strategy to maintain soil fertility for sustainable production of soybean is through the judicious use of mineral fertilizers coupled with organic resources (Bobde *et al.,* 1998). There is a dearth of knowledge on the use of organic matter in soybean production within the Nigerian guinea savanna. The objective of this study, therefore, was to study the additive effect of phosphorus, Potassium, Micronutrients, Organic manure and Inoculant on the productivity of soybean.

Materials and Methods

Sites

The trial was conducted on farmers' fields located at four different sites, Kuta, (latitude N 9° 53′ 8″& Longitude E 6° 42′ 18″) Gupe, (Latitude N 9° 48′ 13″ & longitude E 6° 41′ 15″) Webwo, (Latitude N 9° 49′ 36″ & Longitude E 6° 45′ 49″) and Kukulu (Latitude N 9° 40′ 47″& Longitude E 6° 44′ 30″) in Shiroro Local Government Area of Niger State, Nigeria.

Land Preparation

The fields used for this trial were sprayed with herbicide (Paraquat). Then the field was marked, and the plots measured 10m x 10m. Each plot contained 14 ridges spaced at 0.75m interval with plots separated by 0.5 m alleys.

Source of Seeds, Inoculant and Fertilizers

Seeds, inoculant and fertilizers were all obtained from International Institute for Tropical Agriculture (IITA) Ibadan. Promiscuous soybean variety TGx 1951-3F was used for the trial. The inoculant was Legumefix, a peat based inoculant containing *Bradyrhizobium* Sp. Strain 532c. Phosphate fertilizers was Single super phosphate (SSP) while Potassium was supplied using Muriate of Potash (MOP).

Experimental Design and Treatment

The experiment was laid out in a Randomized complete block design, consisting of six (6) treatments and four (4) replications. The treatments were

(i) Control, (No Input)
(ii) Inoculant only,
(iii) Inoculant + phosphorus (30kg P_2O_5/ha),
(iv) Inoculant + phosphorus + potassium (20kg K_2O/ha),
(v) Inoculant + phosphorus + potassium + micronutrients (3.3kg/ha) and
(vi) Inoculant + phosphorus + potassium + micronutrients + organic manure (4tons/ha).

Sowing and Fertilizer Application

Soybean seeds were directly sown by dibbling two seeds per hole into the soil at 10cm intra row spacing. Fertilizer application was carried out at planting and the organic manure application was done two weeks before planting.

Data Collection

Plant height was measured at 6 weeks after sowing (WAS). Plant shoot was sampled at mid-podding, oven – dried at 70°C for 2days to get the shoot dry weight. Pods were sampled at physiological maturity and oven dried at 70°C for 2days. 100 seed weight and total grain weight was taken at harvest.

Statistical Analysis

Data were subjected to analysis of variance (ANOVA) and the means separated using the New Duncan Multiple Range Test (DMRT).

Results and Discussion

Plant Height

Inoculation and progressive addition of mineral fertilizers only led to marginal increase in height above that of the Control (fig 1). Only a combination of these amendments and organic matter led to a significant increase in height above the control. The organic matter treated plants were only marginally taller than plants treated with other fertilizers.

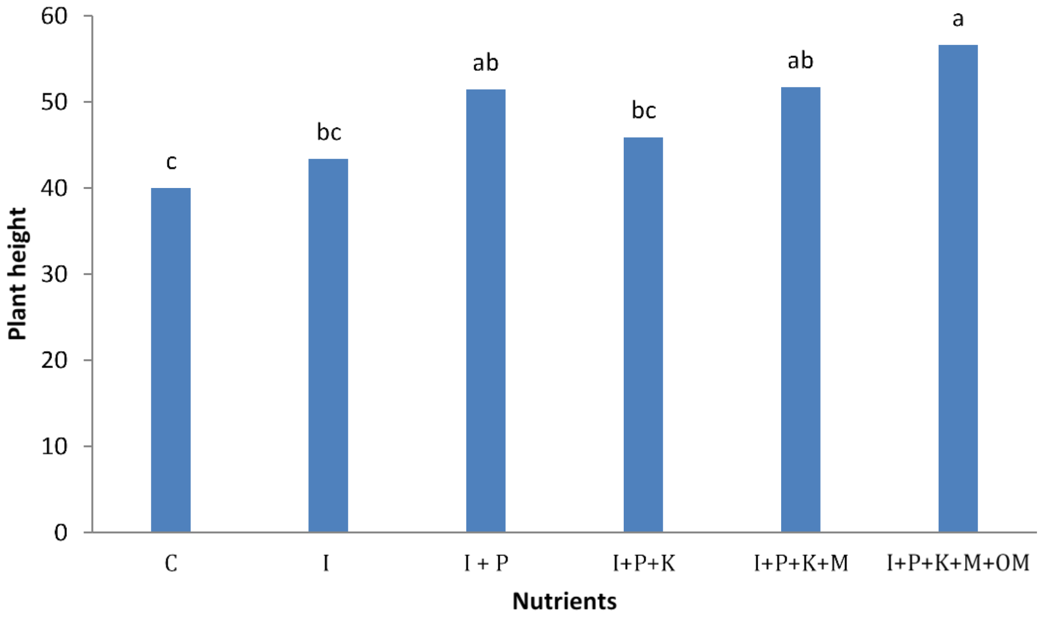

Fig. 1. Effect of nutrient combination on plant height of soybean
C- control, I – inoculant, P – phosphorus, K – potassium, M – micronutrient, O – organic manure

Number of Branches
Branch numbers of treatment with organic manure was marginally greater than the control but was not statistically different from treatments with inoculant only, Inoculant + P, and I+P+K+M, treatment with I+P+K saw statistically the same as I+P+K+M+OM.

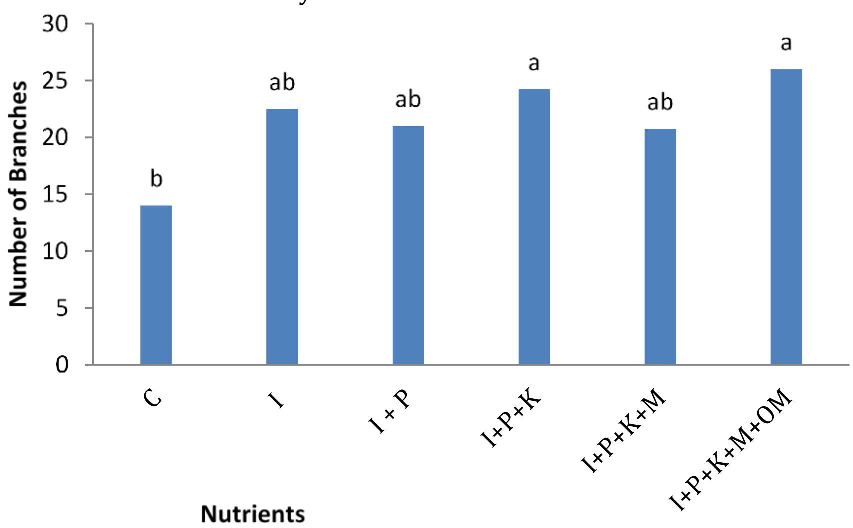

Fig. 2. Effect of nutrient combination on Number of Branches per plant of soybean
C- control, I – inoculant, P – phosphorus, K – potassium, M – micronutrient, O – organic manure

Shoot Dry Weight
Shoot dry weight of plants treated with inoculant only was marginally greater than the Control plants and similar to other treatments (fig 2). The only treatment that resulted in significantly

larger biomass than the Control was the treatment that was supplied with inoculant and all the mineral fertilizers.

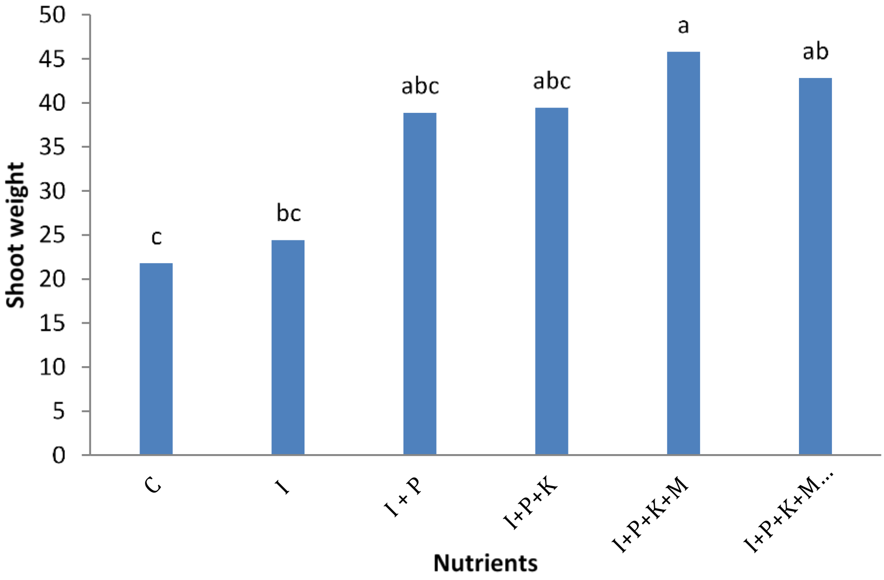

Fig. 3. Effect of nutrient combination on Shoot weight per plant of soybean
C- control, I – inoculant, P – phosphorus, K – potassium, M – micronutrient, O – organic manure

Nodule number

Treatment containing Inoculant and Phosphorus gave the highest number of nodules compared to Control which had no nutrient application. Abdul and Saud,(2012) reported that the number of bacterial nodules increased significantly in plants inoculated with UPMR020, compared with non-inoculated plants.

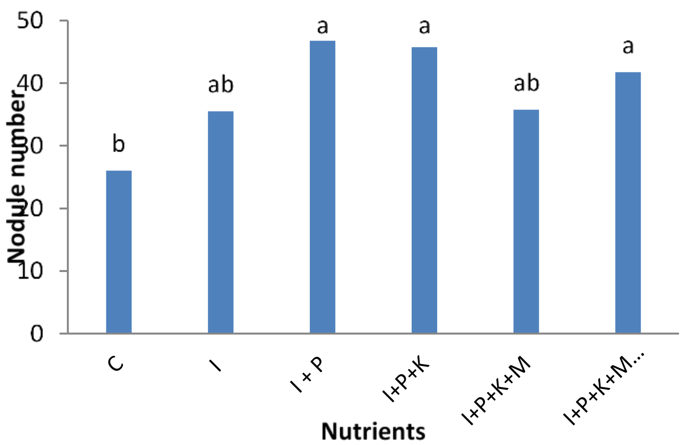

Fig. 4. Effect of nutrient combination on Nodule number per plant of soybean
C- control, I – inoculant, P – phosphorus, K – potassium, M – micronutrient, O – organic manure

Pod number

Number of pod increased as inputs were added. Treatment with inoculant, phosphorus, potassium, micronutrient and organic matter had the highest number of pods per plant compared to the control. Abdul and Saud,(2012) reported that the effect of bacterial inoculation increased the number of pods under inoculation treatments. This can be compared with non-inoculation at (P ≤0.01), which gave 27.50 pods /plant for inoculation and 6 pods /plant for control.

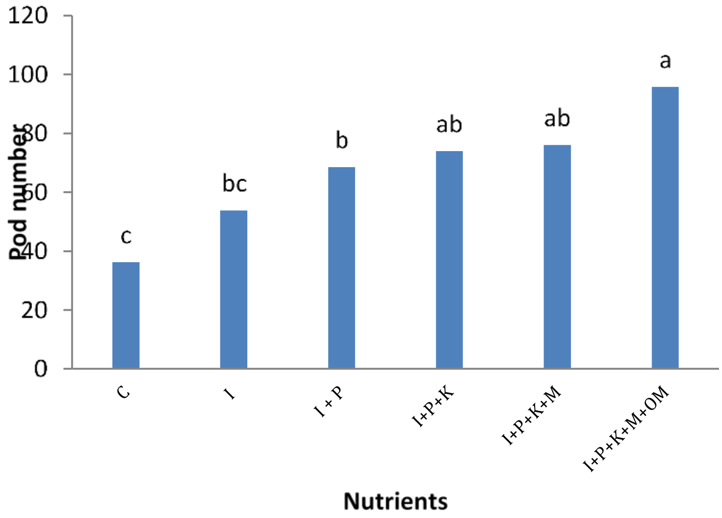

Fig.5. Effect of nutrient combination on pod number per plant of soybean
C- control, I – inoculant, P – phosphorus, K – potassium, M – micronutrient, O – organic manure

Weight of dry pod/plant

The treatment with organic matter had the highest weight of dry pod per plant compared to the control. Abdul *et al*, (2012) said the lowest amount of pod weight was shown by control treatment. The results suggested the importance of inoculation with Rhizobium to increase pod weight (P≤0.01).

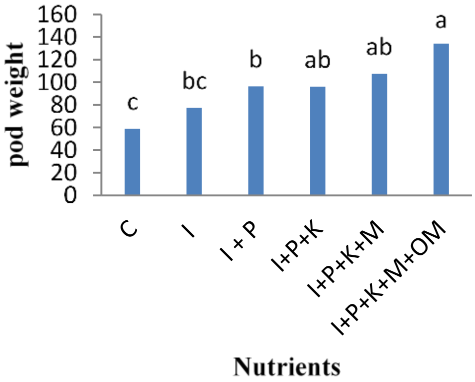

Fig.6. Effect of nutrient combination on pod weight per plant of soybean
C- control, I – inoculant, P – phosphorus, K – potassium, M – micronutrient, O – organic manure

Grain Yield
Inoculation and progressive addition of mineral fertilizer marginally increased grain yield. The addition of organic manure gave the highest grain yield, greater than the control.

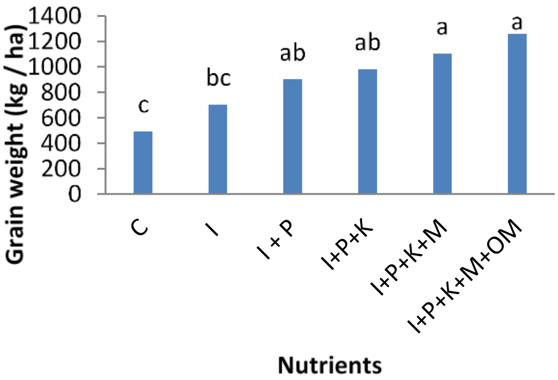

Fig.8. Effect of nutrient combination on grain weight of soybean
C- control, I – inoculant, P – phosphorus, K – potassium, M – micronutrient, O – organic manure

Nodulation, yield and other yield parameters of soybean plants that were treated with bio-fertilizer only were not significantly different from those of the control plants, suggesting that application of bio-fertilizer alone in low fertility soils may only result in marginal benefit to the soybean plant. Application of P or P and /K only led to marginal increases except in the case of nodule number. This is contrary to results of previous studies that reported significant increase in yield due to the inoculation and P addition. Legumes have a high requirement for O as a result of the pronounced effect of the element. crop quality and yields of crops (Taiwo et al, 1999; Asia et al., (2005) Abdul and Saud (2012) observed a significant increase in number of nodules and pod number and pod weight as a result of inoculation with bio-fertilizer. Rhizobial inoculation has also been shown to result in significant increase in yield and yield parameters of promiscuous soybean in some soils of the Nigerian savanna. (Osunde et al., 2003) although not in all cases. (Okereke and Eaglesham, 1993). The lack of any significant increase in yield /parameters as a result of the addition of micronutrient blend suggest that the micronutrient content in soils at the site where the trial were carried out was adequate. However, studies have indicated the occurrence of micronutrient deficiency in some soils of the Nigerian savanna, especially zimc, copper and boron (Oluwadare et al., 2013; Oyinlola, 2007). Addition of organic matter led to most yield and yield parameters being significantly greater than those of the control, suggesting its beneficial effect in nutrient supply. The fact that organic matter was necessary for significant increase in yield parameters to be achieved is an indication that either one of P,K or micronutrient fertilizers or their combination were not sufficient for the crop at the rates applied or some other nutrients were limiting, which were supplied by the organic matter. Agrolyzer the micronutrient blend used to supply micronutrients in the current experiment, does not contain boron. Given that boron is one of the elements commonly cited to be deficient in savanna soils (Oyinlola, 2007). It is probable that the significant increase in yield parameters due to the application of organic matter maybe because of the boron supplied by the organic matter.

Conclusion

Use of organic manure and bio fertilizer could improve the productivity of soybeans. Given the status of organic matter as contributor of fertility, the use of the other mineral fertilizer may not be necessary however the quality of the organic manure may need to be confirmed or accessed.

Evaluation of some Agronomic and Seed Traits in Bambara Groundnut (*Vigna subterranea*[L.]Verdc.) Accessions

***M.S. Mohammed[1] and M.I. Adebola[2]**

Abstract
Bambara groundnut (Vigna subterranea[L.]Verdc.) is an indigenous neglected and underutilized legume adapted to a wide range of conditions. It is a major source of protein grown commonly by resource poor farmers at subsistence level in Nigeria. However, few studies have been conducted to investigate the variability present in the bulk of available landraces. The study was aimed to characterize 20 accessions of bambara groundnut using some quantitative traits useful for selection. Data on days to first and 50% flowering, plant height (cm), number of pods per plant, dry weight of pods, seed weight, 100-seed weight and shelling percantage were collected and subjected to analysis of variance using SAS version 9.1. Highly significant (P<0.01) differences were observed among these landraces for all the traits. This result suggests that effective selection among these landraces can be made for both production and genetic improvement purposes.
Key words: Accessions, Bambara groundnut, Genetic improvement, Quantitative traits, Shelling percentage

Introduction
Bambara groundnut, also known as 'Okpa' (Igbo), 'gurjiya' or 'kwaruru' (Hausa) and 'Eparoro' (Yoruba), is an annual legume which belongs to the family *Fabaceae* with 2n = 22 chromosome number. The crop has an African species which is mostly grown in West Africa, but occasionally grown in Asia. Bambara groundnut is often called complete food because the seeds contain sufficient quantities of protein, carbohydrate and fat (NRC, 2006). Thus, it compares well with more commonly consumed and commercialized grain legumes such as cowpea and groundnut. Bambara groundnut as a legume crop is a cheap source of protein and minerals in many African countries where animal protein is very expensive. It fixes atmospheric nitrogen into the soil through symbiotic relationship with *Rhizobium* bacteria. The crop is mainly cultivated using landraces (Akpalu *et al*., 2013). Great variability exists in the growth and developmental characteristics of individual plant within a landrace collection (provenance) (Squire *et al*., 1996; Massawe, 2000). The landraces comprise of mixtures of different morpho-types which are distinct in physical appearances (coat color and pattern and helium) and performance, as well as product value (Akpalu *et al.*, 2013).

In spite of the importance of Bambara groundnut, it has not received the desired attentions by research community both at National and International levels. It is a common knowledge that the determination of genetic diversity among new collections is a pre-requisite for its effective utilization for crop improvement purposes This is necessary to provide information on traits useful for effective utilization by end-users (IPGRI, 2009).Therefore, this study was conducted to identify superior genotypes from the collected Bambara groundnut accessions.

Materials and Method
The research was conducted at the Institute for Agricultural Research (IAR), Samaru Research Farm, Ahmadu Bello University, Zaria, (Lat 11° 11' N; Long 7°N 38 'Altitude 660 m above sea level) in the northern guinea savanna of Nigeria with a mean annual rainfall of about 1200 mm annua,l which was essentially between March and April. The mean daily temperature during the

growing period was 27°C. Seeds of 20 homogenous accessions of Bambara groundnut landraces obtained from Gargai and Kura in Kano State were used for the study (Table 1). The 20 Bambara groundnut accessions were planted out in a randomized complete block design with three replications. In each replication, two rows of 5m represent a plot for each accessions, and each of the accessions was assigned randomly to the plots. Seeds were sown at 40 cm × 75 cm intra and inter row spacing, respectively making a total of 12 stands on each row. Sowing was done on the 15 July, 2016. Field management practices were employed to keep a healthy crop, including weeding and general field sanitation. Data were collected on: days to first flowering, days to 50% flowering, plant height (cm), number of branches per plant, number of pods per plants, pod weight (g) per plant, seed weight per plants (g), 100S=100 seed weight (g) and shelling percentage (%). Collected data were subjected to analysis of variance using statistical analysis system software (SAS 9.1 version) to determine if variation existed among the landraces. The means of each trait for the landraces were separated using LSD $_{0.05}$.

Results and Discussion

There were highly significant ($P<0.01$) differences among all the accessions for all the traits under study (Table 3). The estimate of coefficient of variation (CV) was used to compare the extent of variability within each trait. Out of the 20 accessions, number of pods exhibited the highest variation with the CV of 17.97%, followed by total weight of seeds/plant (CV=10.92%). The lowest variation was recorded in days to first flowering (2.71%). For days to first flowering, Accession 7 flowered earliest at 36 days after sowing (DAS), while Accession 20 (40.50 days) was the latest to flower. Accession 7 was also the first to attain 50% flowering (38.83 DAS), whereas, Accession 20 (45 days) was the latest to attain 50% flowering. Ouedraogo*et al*. (2008) reported a range of 30-33 DAS for first flowering among Bambara groundnut accession evaluated in Burkina Faso. This study was in agreement with the work of Molosiwa (2012) who observed significant differences for similar traits studied among accessions grown in the UK, with the exception of days to maturity. This result indicated the usefulness of genotype characterization for purposeful selection of desirable genotypes especially for breeding. Investigations in the present study showed high variations in the number branches than those reported by Molosiwa (2012) (33), Amadou *et al*. (2015) (38) and Mwangwela *et al*. (2009) (53) among Bambara groundnut accession. Accession 20 had the highest plant height of 31.44cm and number of branches of 217. Variations in heights were observed in works of Amadou *et al*. (2015), Ouedraogo *et al*. (2008) and Shegro *et al*. (2013). Highest weight of pods (288.33g) and number of pods per plant (138.72) were recorded in Accession 20. The highest mean values for seed weight per plant (74.12g) and 100 seed weight (142.67g) were recorded in Accession 20 and 14, respectively. Accession 13 had the least seed weight per plant (24.93g), while Accession 19 gave the least weight of 100 seeds (41.6g) (Table 3). Molosiwa (2012), Amadou *et al*. (2015) and Ouedraogo *et al*. (2008) recorded similar variations in their Bambara groundnut characterization studies for 100 seed weight. Shelling significantly varied in this study. It is the measure of the proportion of seeds in relations to the pod as percentage. The ranges in values of shelling percentage of the accession were in agreement with those reported by Ouedraogo *et al*. (2008). Squire *et al*. (1996) and Massawe (2000) reported wide variability in the growth and yield traits of individual plants of Bambara groundnut landraces.

Conclusion

There was wide variability among the 20 accessions of the Bambara groundnut studied as explained by their mean performance. Accession 20 performed best in almost all the traits except for 100-seed weight and could be a good candidate for farmers if its culinary attributes are accepteable. However, further field trials in more locations need to be conducted to determine which genotypes could best fit which environment, and to assess the effect of environment on the expression of the traits.

Abstract
The purpose of this study was to investigate the phenotypic and, genotypic variances, nature and magnitude of gene effects for seed cotton yield and fibre quality traits in four inter-varietal hybrids of cotton. All the hybrids demonstrated significant mid parent and better parent heterosis. Most recessive alleles for seed cotton yield per plant accumulated in KC2 x TCB26 which expressed maximum negative degree of dominance. The highest heterotic expression for seed cotton yield over standard check was 9.03% exhibited by TCH1705-101 x TCB209. The highest values for genetic advance were by TCH1716 x TCB37, TCH1705-101 x TCB209 and TSH0250 x DB3 for number of sympodial branches per plant. Hybridization and effective selection for all the characters would be of great benefit in a breeding program.

Introduction
Cotton is an important natural fibre crop of global importance grown commercially in about 111countries with a global area of 30.29 million hectares accounting for 105.06 million bales (217.724 kgs) of production with a productivity of 755 kg/ha (Magadum _et al_., 2012). In Nigeria, cotton plays a key role in the national economy by its contributions in trade, industry, employment and foreign exchange. Several breeding efforts to improve yield per hectare and fibre quality properties have proved successful. Hybrid breeding has also proved successful as many hybrids have been released by breeders and cultivated by farmers. Hybrid vigour has manifested and have been harnessed in many crops including cotton (Kalhoro _et al_ 2015). This manifestation according to Baloch et al (1993), is predicated on the genetic diversity of parental lines. However, early generation hybrids are known to express greater level of heterosis over later generations of a cross. Thus, selection at F_1 has proved not to be beneficial. As selection changes the genetic structure of a population (Budak _et al_., 2004), positive cotton improvement by selection at F_1 will largely depend on available genetic variability and superior genotypes resulting from the recombination of superior alleles at different loci. Data information on genotypic and phenotypic variability is of great importance in making effective selection and in further breeding programs (Isong and Balu, 2017). Genetic analysis of quantitative traits further helps to elucidate the nature and magnitude of genetic variation present in the F_1 population. In later generations, a considerable depression as a consequence of inbreeding is predicted. The extent of this depression in the same crop varies from character to character, generation to generation and also upon the types of hybrids. This decrease in fitness and vigour is due to fixation of unfavouable recessive genes in segregating generations. Magadum _et al_. (2012) opined that the relative amount of heritable variation could be assessed by heritability. This is vital as it also provides the basis for effective selection. Genetic variability along with heritability of a character will indicate the possibility and extent to which improvement is feasible through selection on phenotypic basis. Combination of heritability with genetic advance is more effective and reliable in predicting the resultant effect of selection (Ramanjinappa _et al_., 2011; Patil _et al_., 1996). Genetic Advance according to Hamdi _et al_. (2003) will likely show the magnitude of the expected genetic gain from one cycle of selection. This investigation sought to analyse the genetic

and phenotypic variability existing in the four selected inter-varietal hybrids, assess the heterotic components over parents and inbreeding depression on the F_2 generation.

Materials and Methods

The experiment was conducted on the research field of the Department of Cotton, Centre for Plant Breeding and Genetics, Tamil Nadu Agricultural University, Coimbatore during summer 2017. Four selected promising inter-varietal hybrids (TCH1716 x TCB37, TCH1705-101 x TCB209, KC2 x TCB26 and TSH0250 x DB3) from a line-tester cross, evaluated along with their F_2 generation, the eight parents and a standard hybrid check ((DCH32). The genetic materials were planted out in a Randomized Block Design (RCB) with three replications. Two rows each for parents and hybrids were planted at a spacing of 90 cm between rows and 60cm between plants. Basic agronomic procedures were observed. Observations from five randomly selected plants in each entry and in each replication for the traits *viz*., seed cotton yield (SCYPP) (g), plant height (PH) (cm), number of bolls per plant (NBPP), number of sympodial branches per plant (NSPP), number of monopodia branches per plant (NMPP), boll weight (BW) (g), number of seeds per boll (NSPB), ginning percentage (GP), lint index (LI) and seed index (SI) were recorded. Samples of seed cotton obtained were pooled, ginned and the lint obtained was evaluated for fibre quality characters *viz*; 2.5% span length (2.5%SL) (mm), fibre fineness (FF), bundle strength (BS), elongation percentage (EP) and uniformity ratio (UR) using High Volume Instrument 900 classic. Days to flowering (DF), days to 50 per cent flowering (DFF) and days to first bursting (DFB) were also observed for each entry per replication.AGRISTAT statistical analyses software was employed to analyze for various properties. Heterosis was estimated over mid parent (Relative), better parent (Heteobeltiosis) and the standard hybrid check (Standard heterosis). Test of significance was according to Turner (1953). Percentage of inbreeding depression according to Rao and Murthy (1970) was obtained. Heritability in the broad and narrow sense, genetic advance, phenotypic and genotypic coefficient of variation were all worked out

Results and Discussion

One of the characteristics of heterosis is that the increased vigour is confined only to F_1 generation. All the crosses exhibited significant mid parent and better parent heterosis for number of bolls per plant and seed cotton yield. The highest heterotic expression for seed cotton yield over standard check was 9.03% exhibited by TCH1705-101 x TCB209 (Cross II). The results of heterosis is in agreement with the report of Baloch *et al* .(1993). Their report indicated that exploitation of heterosis for number of bolls per plant and seed cotton yield per plant will be higher than for other traits. KC2 x TCB26 exhibited least (18.06%) inbreeding depression for seed cotton yield. Most recessive alleles for seed cotton yield per plant accumulated in KC2 x TCB26 which expressed maximum negative degree of dominance. This infers that heterosis breeding can be exploited for seed cotton yield per plant in F_1 generation in crosses TCH1716 x TCB37, TCH1705-101 x TCB209 and TSH0250 x DB3. Heterosis breeding procedures are effective in harnessing dominance gene action to the full extent (Mahalingam *et al.,* 2011).To express higher yield in KC2 x TCB26, further backcross to parent 1 (KC2) and subsequent selection in later generation would be of advantage. All the yield parameters recorded moderate to high PCV and GCV indicating an inherent and sufficient variability. However, earlier work by Ganesan and Raveendran (2007) also showed a higher PCV and GCV values for seed cotton yield. The PCV values were found to be higher than GCV in all the characters studied indicating a consistent environmental influence on these traits. This result is in agreement with the findings of Sakthi *et al*. (2007) and Tomar *et al*. (1992). This heritability range also confirms the report of Liu, *et al*., (2010) in interspecific hybrids. The implication for these on the characters is that the additive genetic variance has been fixed during breeding. The highest values for genetic advance were by TCH1716 x TCB37, TCH1705-101 x TCB209 and TSH0250 x DB3 for number of sympodial branches per plant. Genetic advance values are of minimal use in guiding the selection process in an early generation population like the interspecific F_1 hybrids. This is because most of the alleles for quantitative characters are heterozygous. More so, the phenotype expression is subject to influence of additive and dominant gene effects, and epistasis is assumed to be absent.

Conclusion

In conclusion, hybridization and effective selection for all the characters in these populations will be effective because of the availability of high variability in the characters. The hybrids can further be evaluated for their stability and be released for commercial cultivation in view of their heterotic and inbreeding performance.

Corresponding author: mkabaraini@gmail.com

Abstract
Evaluation of castor germplasm of the National Cereals Research Institute, Baddegi for resistant genotypes to Cercospora leaf spot was carried out under natural field conditions. The genotypes were grown on a resolvable incomplete block design with three replications. The results obtained revealed high variability of host resistance among the genotypes. Percentage disease incidence ranged between 16.67% and 100%. A range between 1.43 score and 4.17 score with average score of 2.89 were recorded for disease severity among the genotypes. Highest (95.92%) and lowest (13.03%) damage index were observed in the genotypes Acc. 059 and Acc.022, respectively. The results reported here could serve as a basis for further screening of the potential genotypes under controlled condition to develop resistant lines.
Keywords: Disease, castor, incidence, cercospora, and Badeggi

Introduction
Castor (*Ricinus communis* L.) is a non-edible oil crop with many industrial applications. It is widely cultivated in the tropics, subtropics and warm regions for its seed from which oil is extracted (Purseglove, 1968; Weiss, 1971). Castor plant suffers from many diseases caused by fungi and bacteria. There are many causal pathogens known to cause infections in castor. Some of these pathogens are seed-borne. Fungal diseases cause a lot of economic damage in castor, and in some areas, it is a limiting factor to commercial castor cultivation (Anjani *et al*., 2004). The fungal disease incidence often appears in castor farms and if not managed, can cause severe economic loss to the farmers. Some fungal diseases commonly found in castor include leaf spot caused by *Cercospora ricinella,* wilt caused by *Fusarium oxysporum* f *spricini*, root rot caused by *Macrophomina phaseolina*, gray rot caused by *Botrytis ricini*, Alternaria and leaf spot caused by *Alternaria ricini* (Anjani*et al*., 2004; Duke, 1983). In the present study, on-field observation of fungal infection caused by *Cercospora ricinella* in castor was carried out in an effort to identify potential resistant genotypes in the castor germplasm evaluated.

Methodology
On-field observations on fungal leaf spot disease caused by *Cercospora ricinella* were made on 86 castor genotypes at the National Cereals Research Institute (NCRI), Badeggi. The genotypes were grown on a resolvable incomplete block design with three replications. The plot size was 3m by 1.5m with inter-row and intra-row spacing of 75 cm. Two seeds per hole were planted and later thinned to one seedling per hole at three to four weeks after planting. NPK 15:15:15 fertilizers were applied at one month after planting and weeding was done three times during the experiment as at when due. Disease incidence was determined by counting diseased leaves and expressed as percentage of total leaves. Disease severity was carried out by scoring diseased plants using a 1 – 5 scales as described by Mamza (2008). Damage index (DI) was determined according to Manandhar *et al.* (2016). Data were taken on individual plants in each plot at first spike flowering and maturity. The scoring and estimation of damage index was done as follows;
Score scale for the leaf spot:

1	=	All leaves without symptom
2	=	1 – 25% of total leaf number with symptoms
3	=	26 – 50% of total leaf number with symptoms

4 = 51 – 75% of total leaf number with symptoms
5 = 76% and above of total leaf number with symptoms

Damage index (DI) = (Incidence X Severity) / Highest severity

Results and Discussion

Average mean values for disease incidence, disease severity and damage index are presented in Table 1. Disease incidence varied between 16.67% (Acc. 017) and 100% (Acc. 059), with average of 65.91%. A range between 1.43 score (Acc. 022) and 4.17 score (Acc.056 and Acc. 094), and average of 2.89 score were recorded for disease severity among the genotypes. Highest (95.92%) and lowest (13.03%) damage index was observed in Acc. 059 and Acc.022, respectively. The results obtained revealed high variability of host resistance among the genotypes. This may be an indication of presence of different gene recombinants for the leaf spot resistance among the genotypes from which resistant lines could be developed. In this sense, genotypes with low damage index will be good sources of resistance genes. The values obtained here are similar to the result of Mamza *et al.* (2008) who reported fungal leaf blight incidence and severity on castor seedling at different stages. Yield loss of 80% to 100% has been attributed to fungal disease in India (Mamza *et al.*, 2008). Lakshmi *et al.* (2010) reported that damage to castor leaves caused reduction in seed yield and any 1m^2 loss of leaf area resulted in 37.83g and 24.4g seed yield and seed oil yield respectively per hectare.

Conclusion

Identifying sources of fungal disease resistance genes is an important breeding objective in any castor improvement programme. Severe yield reduction in castor has been attributed to fungal leaf blight. The results reported here could serve as basis for further screening of the potential genotypes under controlled condition to develop resistant lines for breeding programme.

Variability Studies among Some Okra (*Abelmoschus esculentus* L. Moench.) Accessions from Niger State, Nigeria

A. K. Mohammed [1], J.A. Oladiran[2], A.S. Gana.[2] and M.N. Ishaq[1]
[1]National Cereals Research Institute Badeggi, Niger State, Nigeria
[2]Federal University of Technology, Minna, Niger State, Nigeria
E-mail: abu_sadeeq92@yahoo.com

Abstract
Field experiment was carried out at Canchaga, Badeggi, Niger State, to reveal the variability among some okra accessions. Thirty one accessions of okra were collected from farmers field and two (LD-88 and Nhae-47) collected from the Department of Crop Production of the Federal University of Technology Minna. The accessions were planted on Randomized Complete Block Design (RCBD) and replicated three times. Each accession was planted on 2m x 1.5m plot. The experiment was carried out during dry and raining (2014/2015) season. Data were collected on twenty morpho-agronomic traits. Results of the principal component analysis of the combined seasons for the traits studied showed that the first five principal components accounted for 77.2 % and 89.0 % of the total variations in the population. Single Linkage Cluster Analysis (SLCA) clustered the accessions in accordance to their similarity level through the aid of dendrogram. SLCA of the combined season showed two major cluster groups that were linked at 65.7% level of similarity. Accessions that showed variability and clustered in different group may be useful for improvement of okra.

Introduction
Okra is a member of the family *Malvaceae* and genus *Abelmoschus*. Okra has a prominent position among fruit vegetables due to its multiple virtues like high nutritive and medicinal value, ease of cultivation, wide adaptability, year round cultivation, good portability, export potential and bountiful returns (Reddy *et al.,* 2012). It is a multipurpose crop due to the numerous uses of the fresh leaves, buds, flowers, pods and stems, dry stems, pods and seeds (Schippers, 2000; Siemonsma and Kouame, 2004). Nigeria is the second largest producer of okra in the world (1,978,286 tonnes) followed by Sudan and Mali (FAOSTAT, 2016). However, yield in Nigeria is 2.86 tha^{-1} compared with 24.70, 20.60, 13.20, 9.98, and 3.58 tha^{-1} in Senegal, Ghana, Egypt, Kenya and Benin Republic respectively (FAOSTAT, 2013). A total of 2,283 okra accessions had been reported world-wide (Anonymous, 2010). A total of 77.49% of the okra accessions are currently found in West Africa (Oppong-Sekyere *et al*., 2012). Udoh *et al.* (2005) reported that Okra varieties vary in plant height, size of fruit, colour, early or late maturing, long pod, lady finger, dwarf green pods. Abdelmageed *et al.* (2012) also reported variability in characters such as yield, plant height, pod length, pod diameter, pod colour and number of days to flowering of okra. Measuring of genetic diversity and determining the variation between accessions help ensure germplasm is efficiently collected and managed. The success of a breeding programme depends on the measure of the degree of genetic divergence and genetic diversity which is a key factor for crop improvement (Reddy *et al*., 2012). Plant breeders can use genetic similarity information to complement phenotypic information in the development of breeding populations (Yuzbasıoglu *et al.,*2006). Variation is an important attribute in breeding programmes (Omonhinmin and Osawaru 2005). Gana *et al.* (2013) reported that the success of a crop improvement programmes are highly reliant on the efficient manipulation of genetic variability. The yield of okra obtained per unit area in Nigeria is very low which need to be improved upon and revealing the variability among the diverse accessions will aid the breeders evolve new genotypes that will be high yielding, disease and pest resistant. Therefore this study was conducted to collect, evaluate and reveal the variation that exists among some okra accessions.

Materials and Methods

Fruits of 31 accessions of okra were collected from Bosso, Paiko, Shiroro, Bida, Lavun, Mashegu, Katchia and Mokwa Local Government Areas of Niger state, Nigeria. NHe-47-1 and LD-88-1 Okra varieties were obtained from the Department of Crop Production, Federal University of Technology Minna, Nigeria. Field evaluation study was conducted in two growing seasons: under irrigation in 2014 dry season and 2015 raining season respectively at Chanchaga village (N 09^0 04' 14.0, E 006^0 05' 26.9, Elevation: 103 m), Badeggi, Niger State Nigeria. The 33 accessions were grown in a randomized complete block design (RCBD). Each accession was grown on a 2 m x 1.5 m plot and replicated three times. Each row was 2 m long with inter row distance of 75 cm. The spacing between plants along a row was 50 cm (i.e 75 cm x 50 cm spacing) giving five stands per row. The plants were thinned to two per stand at two weeks after seed sowing.NPK 15:15:15 fertilizer was applied at the rate of 200 kg per hectare after three weeks of planting. The experimental field was weeded manually (using hoe) twice at 3 and 8 weeks after sowing (WAS). Five plants were selected from each row for data collection on leaf colour, leave shape, fruit shape, position of fruits on main stem, fruit hairiness and petiole colour. A standard crop descriptor for okra (IBPGR, 1991) was used to characterise the various parameters. The data collected were used for Principal Component Analysis (PCA) and Cluster analysis to determine genetic variation and percentage similarities using Statistical Tool for Agricultural Research (STAR, 2013).

Results and Discussion

Combined Seasons Principal Component Analysis of Quantitative traits

The result of the combined analysis presented in Table 1 revealed that PC1 accounted for 25.7% while PC 2 contributed 18.2% of the total variation. The only character that made negative contribution to variation in PC1 was 100-SW (-0.07). The characters that contributed most to the observed 25.7% variation in PC 1 included fruit girth (0.444), stem diameter (0.402), number of nodes (0.328) and number of seeds per fruit (0.329). The 18.2% variation observed in PC 2 was largely influenced by days to first flower appearance (-0.474), days to 50% flowering, fruits per plant (0.351) and fruit weight per plant (0.428). PC 3 with 14.2% contribution was largely influenced by fruits per plant (0.558) and moderately influenced by fruit weight per plant (0.374) and petiole length (-0.358).

Table 1: Eigen value, vector scores and contribution of the first five axes to variation in okra accessions of the combined seasons

Parameter	PC1	PC2	PC3	PC4	PC5
Plant height	0.226	0.107	-0.279	0.379	-0.254

Principal Component Analysis of Qualitative Traits of Studied Okra Accession

The first five principal components accounted for 89.0% of the total variations in this population. However, only PC 1 and PC 2 with eigen values $\geq$1 had significant contribution to the observed variation. Both PC 1 and PC 2 have cumulative variation of 55.0 with PC 1 contributing 33.9% and PC 2 contributing 21.1%. Leaf colour (0.50) and petiole colour (0.52) had the most effects on the 55.0% variation. All other traits measured had moderate effects except fruit shape (0.18) and fruit position (0.28). Only fruit shape (0.61) and leaf shape (-0.41) had major effect on the contribution from PC 2 to total variation.

Table 2: Eigen value, vector scores and contribution of the first five axes to variation in okra accessions of the combined seasons for qualitative characters

Cluster Analysis of Qualitative traits of Okra Accessions Studied

Cluster analysis of the results of qualitative traits studied using complete linkage method revealed two major cluster groups (Figure 1). All accessions fell into three groups. Accessions 16 and 31 belonged to one group, Accessions 6 and 30 belonged to the second group, while the rest of the Accessions belonged to the third group. The three groups were linked at 65.7% level of similarity. The largest group was further divided into different sub groups depending on their level of similarities. Accessions 1 and 28, 13 and 27, 14 and 19, 12 and 13 showed close similarity levels.

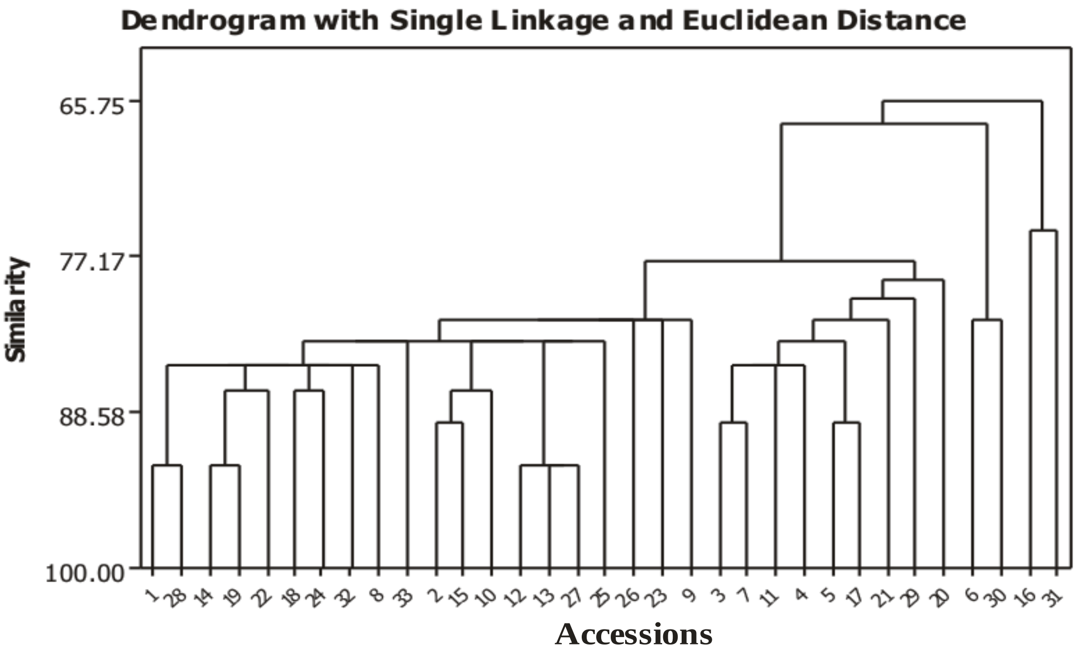

Figure 1: Dendrogram of the 33 Okra accessions based on qualitative traits

Note that: Bata-01= 1, Bata-02= 02, Dama-01= 03, Dama= 04, Egwa-01= 05, Egwa-02= 06, Esungi= 07, Gbadebo-01= 08, Gbadebo-02= 09, Gbadebo-03= 10, Gbadebo-04= 11, G-mayi= 12, Jazu= 13, K-Gar-01=14, K-Gar-02=15, K-Gar-03=16, Kwati= 17, LD-88= 18, NHae-47= 19, Pati-01= 20, Pati-02= 21, Pati-03= 22, Pati-04= 23, Pati-05= 24, Pati-06= 25, Shaba-01= 26, Shaba-02= 27, S-Lambu= 28, S-Rami= 29, Tafita= 30, Tafita sss= 31, T-Daga-01= 32, T-Daga-02= 33.

The Qualitative parameters in this study had revealed variations among the accessions. Variability was noted in all the traits among the accessions studied. This result is in conformity with the result of a study conducted in Ghana by Amoatcy *et al*. (2015) which showed significant difference in vegetative and reproductive traits of some okra cultivars which the authors stated that the phenotypic variation observed within the qualitative traits corresponded to the diverse collection sites. Oppong-Sekyere *et al.* (2011) also noted that the genetic affinity between accessions from different regions could be attributed to selection and exchange of germplasm between farmers and ethnic groups. The principal component analysis revealed the percentage contribution made by each character studied to the total variation in the population. Result of this work has revealed that different traits contributed differently to the total variation in the population which conform with the result obtained from the study carried out by Nwanburuka *et al.* (2011), using PCA to study variation among 29 okra accessions at Abeokuta, Nigeria. Characters that had high variability are expected to provide high level of gene transfer during breeding programmes as stated by Gana (2006). Maga *et al*. (2014), reported that traits which associated with PC1 and PC2 are implicated for being responsible for the phenotypic divergence observed in the studied cultivars and can be used for cultivar discrimination. The dendrogram obtained from Single Linkage Cluster Analysis (SLCA) of this study showed the accessions in accordance to their similarity percentage levels which revealed that the accessions differed. Nwanburuka *et al.* (2011) reported that dendrogram drawn from SLCA showed the relationship accessions and stated that SLCA provided information on the minimum percentage similarity among accessions and also provided an overall pattern of variations as well as degree of relatedness among accessions. However the accessions used in this study might have originated from parents with diverse genetic background since their genetic similarity index is lower than 95%, because it has been documented that for any two or more accessions to be taken as genetically identical, their genetic similarity index (GSI) should be equal to or greater than 95% (Anderson, 2007).

Conclusion

Variations existed among the okra accessions used in this studied. PCA and SLCA revealed contributions and distinctiveness of traits among the accessions. Existence of variations in the population revealed that the genotypes had different genetic make-up which can be utilize for okra improvement. The dendrogram showed distinctiveness and relatedness among the accessions depending on their characteristics. Accessions that cluster in different groups with higher variability (lower similarity percentage) should be used for okra improvements.

Abstract
The productivity of sweet sorghum (Sorghum bicolor L. Moench), a raw material for ethanol production, is mainly determined by stalk yield and sugar content. To understand inherent differences and relationship between stalk yield related traits and sugar concentration of stalk juice, a population derived from a grain sorghum × sweet sorghum was screened to select parental materials which were crossed and the F_1 hybrids evaluated in Institute for Agricultural Research (IAR) Samaru, Ahmadu Bello University Zaria irrigation field during the 2017 dry season. The experiment was laid out in a randomized, 4 x 8 alpha lattice design with two replications. Seven stalk yields and sugar related traits including days to flowering, plant height, number of internodes, 1000-grain weight, panicle length, brix content and sugar concentration of stalk juice were evaluated. Significant differences among genotypes were observed for all measured traits. Both the magnitude and direction of correlation coefficients among the traits measured were varied in different trials. Direct selection for brix content was shown to be more important than indirect selection, while selection for stem biomass had no effect on stem brix. Information obtained from this study will be very helpful to further understand the genetic mechanism of stalk yield related traits and sugar concentration of stalk juice in this population.
Keywords: Correlation, Genetic variability, Sorghum bicolor L. Moench, Stalk yield related traits, Sugar concentration and Sweet sorghum

Introduction
Sweet sorghum, a specific type of *Sorghum bicolor*, has been considered a potentially valuable source for biofuel production because of its high energy convertion efficiency (Reddy *et al.*, 2005). Many characteristics such as green stalk yield, stalk sugar content, stalk juice extractability and grain yield have been proved as major contributors to its economic superiority (Almodares *et al*., 2008). However, these traits are quantitatively and polygenically inherited in nature and very difficult to be manipulated directly in breeding procedure. Therefore, to successfully improve these complex traits, they need to be dissected into smaller morphological, physiological and genetical components, which are easily analyzed and evaluated. Cultivar development is, however, firstly based on the exploitation of genetic variability of the genotypes with the traits of interest (Makanda *et al.,* 2009). Therefore, establishing the genotypic variability available for stalk yield associated traits and sugar concentration of stalk juice in a sorghum population is very important in determining the feasibility of developing elite sweet sorghum varieties. The consequences of the phenotypic variation depend largely on the environment. This variation is further complicated by the fact that all genotypes do not respond to environmental changes in similar ways, and no two environments are exactly the same. Furthermore, correlations between the traits are of great importance for success in selections to be conducted in breeding programs. Significantly positive correlations indicate that the changes in two variables are in the same direction, while negative correlations indicate their inverse relationships with each other. For example, stalk yield has significantly positive correlations with plant height, stem diameter and juiciness (Audilakshmi *et al.*, 2010). Therefore, the improvement

of stalk yield should focus on both plant height and stem diameter. Total sugar content could be calculated from the Brix because of a significant linear correlation between Brix and total sugar content of the juice (Ma *et al*., 1992). The genetic variability and correlation of bio-fuel related traits have been studied in several different populations (Srinivas *et al.,* 2009; Shiringani *et al.*, 2010). In order to study the genetic mechanisms of stalk yield related traits and sugar concentration of stalk juice, a specific population has been developed from a cross between grain and sweet sorghum lines in our breeding nursery. The objectives of this study, therefore, were: (1) to evaluate the variability of the population for stalk yield related traits and sugar concentration of stalk juice; (2) to assess the strength of associations between stalk yield related traits and sugar concentration of stalk juice.

Materials and Methods

The experiment was conducted at the Institute for Agricultural Research (IAR) farm, Ahmadu Bello University, (ABU) Zaria (Latitude $11^0$11'N and $7^0$38'E), situated in the Northern Guinea Savannah Zone in Nigeria. The research was carried out in 2017/2018 under irrigation. Genetic materials consisted 32 genotypes (10 parents that comprised of grain and sweet sorghum, 21 F_1s and 1 check) which were laid out in a randomized, 4 x 8 alpha lattice design with two replications and evaluated at IAR research field, Samaru for agronomic traits and sugar contents. Each experimental unit consisted of two- rows plot of 3 m with inter – and intra row spacing of 30 cm x 75 cm. The data collected was subjected to analysis of variance using General Linear Model procedure of Statistical Analysis System (SAS) package (SAS, 2002), while significant difference between treatments means were determined using the Least Significant difference (LSD) test. The correlation coefficients were estimated using the formula described by Singh and Chaudhary (1985).

Results and Discussion

The mean squares from the analysis of variance (Table 1) showed highly significant ($P \le 0.01$) differences among the genotypes for all the characters studied. The presence of variability in measured traits suggests improvement can be made through selection. The plant height ranged from 135.70 cm for F5.3ssm10-14/2-1 to 244.9 cm for Samsorg 14 with a mean height of 185.1 cm among the parents (Table 2). Hybrids Samsorg 44 x F5.3ssm10-31/2-3 (269.8 cm), Samsorg 44 x F5.3ssm10-1/3-3 (269.1 cm) and Samsorg 44 x F5.3ssm10-1/1-8 (267.2 cm) were among the tallest. The hybrid Samsorg 14 x F5.3ssm10-31/5-1 (42.8 cm) recorded the highest panicle length followed by Samsorg 14 (36.3 cm). High brix greater than the mean was observed in Samsorg 40 x F5.3ssm10-1/1-8 (8.4 %), Samsorg 40 x F5.3ssm10-31/2-3 (8.2 %) and Samsorg 14 x IESV92028DL (8.2 %) genotypes. Genotype Samsorg 44 x F5.3ssm10-31/2-3 (15.04 g/l) gave the highest sugar yield followed by Samsorg 40 x F5.3ssm10-1/3-3 (13.8 g/l), Samsorg 14 x F5.3ssm10-31/5-1 (13.2 g/l) and Samsorg 40 x F5.3ssm10-31/5-1 (13.2 g/l), while genotype Samsorg 14 x F5.3ssm10-1/1-8 (5.6 g/l) had the lowest sugar yield followed by F5.3ssm10-31/2-3 (1.5 g/l) and F5.3ssm10-1/1-8 (2.4 g/l). Plants with greater plant height, brix content and juice yield also produced greater sugar yields. Higher mean values for time to flowering and plant height indicated that good options exist for selecting the genotypes with different maturity levels that can be suitable for cultivation in the dry savannah ecologies with marginal rainfall. Days to flowering exhibited significant and positive correlation among the hybrids for plant height (0.78) and number of internodes (0.80). Among the parents, days to flowering showed significant and positive correlation with plant height (0.68) and number of internodes (0.95). The positive correlation coefficients between plant height and days to flowering suggests that plant height increases as days to flowering increases, which is consistent with earlier reports in sorghum by Alam *et al*. (2001). Among the hybrids, number of internodes exhibited significant and positive correlation with days to flowering (0.80) and plant height (0.73) while among the parents number of internodes showed significant and positive correlation for days to flowering (0.95) and plant height (0.81). Brix content showed significant positive correlation with 1000- grain weight (0.99) but showed negative significant correlation with days to flowering (-0.48), plant height (-0.44), number of internodes (-0.61) and panicle length (-0.71). The correlation study has demonstrated important relationships between brix content and other agronomic traits association in sweet sorghum.

Conclusion

With the results of the present research work, there is a good scope for selection for days to 50% flowering, plant height, panicle length and brix content to improve these characters. Also, with the observed strong associations between days to flowering, plant height, number of internodes and sugar related traits, these characters could be used as the most reliable selection criteria to improve brix content in sorghum.

Abstract

The additive main effects and multiplicative interaction (AMMI) model was used to analyse the fresh root yield and root dry matter content of twenty cassava genotypes grown in three locations in 2015 and 2016 cropping season (a total of six environments) in Nigeria. Main effects due to environments (E) and genotypes (G) were found to be significant (P<0.05) for root dry matter content (RDMC) and highly significant (P<0.01) for fresh root yield (FRY). Genotype by environment interaction and IPCA1 were highly significant (P<0.001) for FRY and RDMC. This study has identified Igbariam location to be most stable for high root yield and dry matter content. The study has identified stable high yielding genotypes with high dry matter content such as IBA131825, IBA131746, IBA131872, IBA131767 and IBA131770, suggesting it is possible to combine these traits in cassava as desired by farmers. However, these genotypes can be tested further in more environments to ascertain their specific adaptability for release to farmers for cultivation to boost cassava production and ensure food security.

Introduction

Cassava is a starchy root crop which is widely grown in many parts of sub – sahara Africa, with Nigeria being the highest producer (FAO, 2014). More than 50% of Nigeria's population eats cassava at least once in a day (Njoku *et al.*, 2014) and it serves as famine reserve crop in the country. Root yield losses in unfavourable environments can be as high as 80% when compared to root yield in optimum environments. This is because genotypes exhibit different levels of phenotypic expression under different environmental conditions. Genotype by environment interaction results from differences in the sensitivities of genotypes to the conditions in the target environment (Farshadar, 2013), leading to inconsistent performances of genotypes across environments. This limits the efficiency of selection of superior genotypes. The efficiency and success of genotypic selection depend on the consistency of performances of genotypes in varying environments (Yan *et al*., 2000). For this reason, genotypes are tested in diverse environments to assess their adaptability and stability on the yield performance. It is often difficult to determine the stability pattern of genotypic responses across environments without the use of appropriate multivariate analytical and statistical tools such as additive main effects and multiplicative interactions (AMMI). The AMMI model integrates analysis of variance (ANOVA) and principal component analysis (PCA) into a unified approach that can be used to analyze multi-locational trials (Crossa *et al*., 1990; Gauch and Zobel, 1996). The study was carried out to determine the stability of root yield traits of selected advanced cassava genotypes evaluated across many environments.

Materials and Methods

The study was conducted in 2015 and 2016 at three sites: Umudike (annual rainfall of 2200 mm; altitude 120 m; mean annual temperature of 22 to 31^{o}C; coordinates 7^{o}24'E, 5^{o}29' N; DystricLuvisol soils; humid forest); Igbariam (annual rainfall of 1800 mm; altitude 150 m; mean annual temperature of 24 to 32^{o}C; coordinates 7^{o}31' E, 5^{o}56' N; DystricLuvisol soils; forest–savanna transition); and Otobi (annual rainfall of 1500 mm; altitude 319 m; mean annual temperature of 24 to 35°C; coordinates 7°20' E, 8°41' N; Ferric Luvisol soils; southern Guinea savanna) in Nigeria. These sites represent the major cassava-growing agro-ecological zones in the country. Twenty cassava genotypes tolerant to cassava green mite were used in the study. The trial was laid out in a randomized complete block design with three replications. Each plot consisted of 10 plants per row on ridges. Spacing between ridges was 1m and also between plants within the row providing a total population of 10 000 plants ha^{-1}. NPK 15:15:15 fertilizer was applied at the rate of 600kg/ha. Fertilizer was applied at eight weeks after planting using the ring method. Weeding was done by hoe. Data were collected on fresh root yield (FRY) and root dry matter content (RDMC) at harvest. Eight innermost plants per clone were uprooted and used for phenotypic assessments. Estimation of RDMC (measured as a percentage) in the root samples were determined by the specific gravity method as suggested by Kawano *et al*., (1987).

$$Specific\ gravity = \frac{Weight\ in\ water\ (g)}{Weight\ in\ air\ (g) - Weight\ in\ water\ (g)}$$

$DMC\ = 158.3\ specific\ gravity - \ 142.0$ (IITA, 1990)

Data analysis

Data were analyzed using Genstat version 12.1 and R statistical software package. The additive main effect and multiplicative interaction (AMMI) analysis was performed using the model suggested by Farshadfar *et al*. (2011) as follows:

$$Y_{ij} = \mu + G_i + E_j + \sum_{k=1}^{n} \lambda_k \alpha_{ik} \gamma_{jk} + e_{ij}$$

where Yij is the yield of the ith genotype in the jth environment, μ is the grand mean, Gi is the ith genotypic effect, Ej is the jth environment effect, λk is the square root of the eigenvalue of the PCA axis k, αik and γjk are the principal component scores for PCA axis k of the ith genotype and the jth environment, respectively, and eij is the residual.

The AMMI stability value (ASV) as described by Purchase *et al*. (2000) was calculated as follows:

$$ASV = \sqrt{\left[\frac{IPCA1_{Sum\ of\ squares}}{IPCA2_{Sum\ of\ squares}}(IPCA1_{score})\right]^2 + (IPCA2_{score})^2}$$

where IPCA1Sum of squares/IPCA2Sum of squares is the weight given to the IPCA1-value by dividing the IPCA1 sum of squares (from the AMMI analysis of variance table) by the IPCA2 sum of squares. The larger the IPCA score is, either negative or positive, the more adapted a genotype is to a certain environment.

Results and Discussion

The combined AMMI analysis of variance revealed that there were significant genotypic variations for all the traits indicating opportunity for selection and prospects for the improvement of cassava for the traits. The AMMI ANOVA indicated significant ($P < 0.05$) effects of environment and genotype for RDMC. Genotype by environment interaction and IPCA1 were highly significant ($P < 0.001$) for RDMC (Table 1). The influence of genotype by environment interaction (80.00%) on RDMC was greater than both genotype (18.16%) and environment effects (1.84%). The first two IPCAs (IPCA1 and IPCA2) contributed 33.59% and 27.15% of the interaction sum of squares respectively (Table1). Genotype by environment interaction, genotype effect and IPCA1 were very highly significant ($P < 0.001$) for FRY. Effect of environment for FRY was highly significant ($P < 0.01$) for FRY (Table 1).Genotype by environment interaction effect (76.45%) contributed a greater proportion of the treatment sum of squares compared with genotype effect (18.09%) and environment effect (5.46%). The first two principal component axes (IPCA1 and IPCA2) accounted for 30.79% and 21.79% of the interaction sum of squares respectively (Table 1). The impact of environment was highly significant for FRY and RDMC, justifying the need for multilocational testing to identify good performers for specific locations. IPCA1 was significant for all the traits studied and it explained the interaction pattern better than

IPCA2. The percentage of the treatment sum of squares (SS) captured by an AMMI ANOVA in this study is useful for assessing the overall goodness of fit. There were significant responses of genotype by interaction for all the traits. This implies different adaptation by the different genotypes suggesting the need to identify and select location specific genotypes for different environments. Stability analysis methods are often used by breeders to identify genotypes that have stable performance and respond positively to improvements in environmental conditions (Farshadfar *et al*., 2012). For RDMC, AMMI stability analysis identifies these genotypes IBA131753, IBA131743, IBA131729, IBA131738 and IBA131849 as the superior genotypes (Table 2). Genotype IBA131743 showed a wide adaptability since it was found in the six of the tested environments (Table 2). The superior genotypes IBA131825, IBA131746, IBA131872, IBA131741 and IBA131770 were selected as combining high FRY with stability (Table 3). Two genotypes IBA131870 and IBA131767 were widely adapted to three environments for FRY; the former was found in the high and moderately high yielding environments, and the latter was seen in high, moderately high and low yielding environments. This suggests that IBA131767 was insensitive to seasonal effects and can be recommended for production in the environments. IBA131825 and IBA131865 were adapted to the two most stable environment (Igbariam2015 and Igbariam2016). This indicates that the genotypes were better able to exploit their full potential yield in the good environments.

Conclusion

The study has identified stable high yielding genotypes such as IBA131825, IBA131746, IBA131872, IBA131767 and IBA131770, suggesting it is possible to combine these traits in cassava as desired by farmers. These genotypes can be evaluated in more environments to assess their adaptability and possible recommendation for release to farmers for cultivation.

National Root Crops Research Institute Umudike, PMB 7006, Umuahia Abia State Nigeria
okeyamadi2003@yahoo.com

Abstract
Polynesian Arrowroot (Tacca leontopetaloides (L.) Kuntze) is a wild growing acaulescent herb whose tubers are consumed by some ethnic nationalities in the north central Nigeria. The starch from the tubers has been found to be of industrial quality. This paper describes the morphological features of this plant based on a collection grown at Umudike (latitude 05° 29' N, longitude 07°33' E) from tubers collected from Zaki-biam LGA of Benue State. The features of the plant and variation in its characters based on visual observations were documented. Implications of the observed variations on domestication Polynesian arrowroot in Nigeria are discussed.
Keywords: Leaves, Stolon, Rhizome, Fruits, Floral structures, and Domestication

Introduction
Polynesian Arrowroot (*Tacca leontopetaloides* (L.) Kuntze) is popularly known as Amora, or Gbache by some ethnic nationalities in Nigeria. It belongs to the genus Tacca and family Taccaceae (IPNI, 2005). However some taxonomists group it with the yam family Dioscoreaceae (Caddick *et al*. 2002). It is distributed throughout Asia to Australia and Africa (Drenth, 1972). It is an annual monocot. The above ground parts die down every year and re-grow the next season from underground tubers when they break dormancy. Polynesian Arrowroot is an autonomous self-pollinating species (Zhang *et al*, 2007, 2011) with diploid (2n = 30) number of chromosomes (Darlington and Wylie, 1955). Tubers contain b-sitosterol, ceryl ethanol, and a bitter substance taccalin (Caddick *et al*., 2002; Scheuer *et al*, 1963). The rhizome of has medicinal virtues of detoxification, diminishes inflammation and acesodyne, can cure abscesses of the stomach and duodenum, high blood pressure, hepatitis, gastralgia, scalds, burns, tumefaction, and ulcers (Zhang *et al*., 2007). Abdel *et al*, 1991 found extracts from Polynesian arrowroot to have very good anticancer properties
In Nigeria, these plants grow in the wild as in other parts of Africa but are virtually unutilized with an annual production estimated at over 20 million MT (Omolaja, 2013). Polynesian Arrowroot is found naturally growing in the tropical rainforest and guinea savannah agroecologies of Nigeria. The plant is wider spread in the middle belt (Manek *et al*, 2005) and in the south western states (Borokini *et al*., 2014). Specifically, Pate *et al*, 2014 reports that it is found widely in Plateau and Nassarawa states. They have also been collected from the wild in Anyamelu LGA of Anambra State, The indigenous people of middle belt of Nigeria who consume the starch from the tubers of Polynesian arrowroot see this plant as a gift from God as it is always there in the wild for them to gather. They have therefore seen no need to domesticate it. In recent years, the population of the plant in the wild is dwindling probably due to increasing use of herbicides and urbanization. This coupled with the increasing recognition of the industrial quality of its starch (Kunle *et al*., 2003; Ukpabi, *et al*., 2009; Vu *et al*, 2017) have brought to the fore the need to domesticate the plant. National Root Crops Research Institute (NRCRI) Umudike and Raw Material Research and Development Council (RMRDC) Abuja are collaborating in the pilot effort to cultivate Polynesian arrowroot. An understanding of the morphology and morphological variations of this plant is needed for its domestication. This paper describes the morphological variation in Polynesian arrowroot with a view to highlighting its features the knowledge of which in necessary in order to harness its potentials and encourage its domestication

Materials and Methods

Ten thousand tubers of Polynesian arrowroot of various sizes were collected from Zaki-biam LGA of Benue State in October 2017 were used to plant a hectare at Umudike in 2018 in a collaborative project between NRCRI Umudike and RMRDC, Abuja (Fig 1D). The variation in the morphology of the Polynesian arrowroot plants grown on this one hectare plot based on visual observation is presented. Striking features were captured in Camera.

Results and Discussion

Morphology and Variation

Stem

Polynesian arrowroot is acaulescent. The stem is an underground tuber with apical and auxiliary buds

Leaves

Leaves extend from the apex of the underground tuber. 2-7 leaves per plant were observed. The leaves have longitudinally ribbed long hollow petioles of variable lengths which extend from the underground apex of the tuber and bear large trifid leaflets at their apex. The leaflets are pinnately lobed. The base of the petioles are sheathed while the lamina of leaflets are reticulately veined (Fig 1B).

Floral structures

Hollow Peduncles (0-2 per plant) of varying length with sheathing base arise from the underground tubers. There is usually one peduncle per plant but plants having no peduncles and a few with two peduncles were observed. Based on their length three type of peduncles were observed. Short Type: Peduncles at or shorter than the foliage usually with drooping tip; Medium type: Peduncles erect, slightly above the foliage; and Long type: Peduncles erect, very much longer than the foliage. Peduncles subtend at their apex an umbellate inflorescence bearing many flowers (10-50) subtended by several green to purple whiskers-like filiform bracteoles (almost as many as the flowers) about 10-14 cm long and greenish two whorled bracts. The bracts of the outer whorl are larger than the inner bracts (Fig 1A). Anthers are attached to a hood-like structure which brings them very close to the stigma. This floral structure is in tandem with their autonomous self pollination habit. The Stigma is 3-lobed with each lobe divided into two.

Fruits

Fruits are many (1-20), ovoid, ribbed, with persistent tepals at the apex (Fig 1C). They are subtended by short pedicels 3-5cm in length. The fruit - a berry develops from an inferior unilocular ovary with parietal placentation. They are green when immature but turn yellow when matured.

Seeds

Each fruit contains numerous striated brownish seeds with various shapes such as spherical, ovate, obovate, and elliptical (Fig 1E). Seeds are dormant at harvest.

Stolon

Stolons develop from the base of the apex of the mother tuber and grow vertically downwards swelling at the tip to form the tuber (Fig 2G-H). The stolon is cylindrical, stout, 5-15cm in length and takes the tubers deeper into the soil below the mother tuber and probably away from pests. 1-4 stolons were observed per plant but only one often ends up in fully formed tubers.

Tubers

The tubers are shperical and somewhat flattened at the apex (Fig 2 F-K). They have cream coloured skin and white flesh colour. Most plants produced only one tuber but a few produced two to four tubers. A plant with 9 tubers (1 big, 2 small, and 6 tiny tubers) was observed (Fig 2J). Tubers weighed mostly between 200-600g each but a few weighed up to 900g. Tubers are dormant at harvest.

Roots

The main roots are adventitious ranging from 20-50 depending on the size of the mother tubers. They arise from the base of the apex of the tuber and grow to lengths ranging from 10-25cm. There are roots on the surface of developing tubers (Fig 2K).

Implications of the morphology for Domestication

The floral structures become established before the foliage suggesting that plant places a premium on the production of sexual seeds over the production of tubers. Since most of the early resources mobilized from the mother tuber goes to establish the floral structures at the detriment of the foliage, removing the floral structures as soon as they emerge above ground may lead to more robust foliage that will result in production of more assimilate which if channelled to tubers will result in higher yield.

Most plants produce only one tuber per plant. Considering that tuber is the economic part of the plant and at the same time the main means of propagation, 1:1 multiplication ratio poses a major limitation to domestication. However few plants were found to produce multiple tubers suggesting the existence of variability upon which selection can be imposed to improve on the number of tubers. In addition, multiple stolon produced by a good number of plants indicate that the plant has the potential to produce more than one tuber under favourable condition

Abstract
A field experiment was conducted in 2016 at the National Root Crops Research Institute Farm, Umudike, Southeastern Nigeria, to investigate the morphological and nutritional differences between male and female individuals of fluted pumpkin (Telfairia occidentalis Hook. f.). Female plants had significantly higher (p<0.05) stem diameter, petiole length, petiole diameter, tendril diameter, harvestable vegetable weight, edible vegetable weight, and 10 leaf weight, than male plants. They also had leaves with significantly higher moisture and iron content (p<0.05) than male plants. Crude fibre content was higher (p<0.05) in leaves of male plants than in leaves of female plants. There was no significant difference between males and females in the fat, crude protein, ash and carbohydrate contents of their leaves.
Keywords: Fluted pumpkin, dioecious, male plants and female plants

Introduction
Fluted pumpkin (*Telfairia occidentalis* Hook. f.), a herbaceous perennial climber usually cultivated as an annual, belongs to the Cucurbitaceae family of dicotyledonous plants and originated from tropical West Africa (Schippers, 2000). Although a perennial by nature, it is usually grown as an annual (Ogbonna, 2009). It is prized for its leaves and seeds, which constitute an important component of the diet in many Nigerian homes (Ayanwale and Abiola, 2007; Odiaka *et al*, 2008). Fluted pumpkin is a dioecious species, and the sex of any given individual plant cannot be ascertained until flower appearance, which takes about 13 weeks for the male, and 16 for the female. The inability to determine the sex of an individual plant before flowering is a challenge to farmers who would handle the two sexes differently, to maximize profits. The objectives of the present study were to: i) study the morphological differences between male and female individuals in *T. occidentalis* with respect to stem diameter, petiole length, petiole diameter, tendril diameter, harvestable vegetable weight, edible vegetable weight and 10 leaf weight, and ii) investigate differences in the nutritional contents of the leaves of male and female *T. occidentalis.*

Materials and Methods
The field experiment was conducted at the National Root Crops Research Institute, Umudike Research Farm. Umudike is located at latitude 05^{0}29'N and longitude 07^{0}32'E on an elevation of 100 meters above sea level. After the land had been ploughed and harrowed by use of a tractor, planting was done in 21 beds, each measuring 3m x 2m. The distance between beds was 1m. In each of the 21 beds, six (6) seeds were planted at a spacing of 1m inter-row and 1m intra-row, giving a total population of 126 (one hundred and twenty-six) plants, equivalent to 100,000 plants per hectare. Beds that had both male and female individuals were randomly sampled for a study of morphological and nutritional differences between the sexes. The experiment covered a total area of 270m^2. The fluted pumpkin seeds used were sourced from a local market at Ndoro in Ikwuano L.G.A of Abia State. The field was kept weed-free, through manual weeding, throughout the duration of the work. Data were collected on morphological and nutritional characters at flowering. The morphological characters were stem diameter, petiole length, petiole diameter,

tendril diameter, harvestable vegetable weight, edible vegetable weight, and weight of 10 leaves, while the nutritional characters included moisture, fat, crude protein, crude fibre, ash, carbohydrate and iron content of leaves. Stem diameter (mm) was obtained as the thickness of the stem taken above the tenth leaf from the base of the crop. The measurement was done using a pair of vernier sliding calipers. Petiole length (mm) was obtained as the length of the leaf stalk, from the leaf axis to the point where it is attached to the blade, using a ruler. Petiole diameter (mm) was obtained as the diameter of the petiole at the mid-point between the leaf axil and the base of the leaf, using a pair of vernier sliding callipers. Tendril diameter (mm) was obtained as the diameter of the tendril at the mid-point between the point where the tendril arises on the stem and the point where it develops the first branch, using a pair of vernier sliding calipers. Harvestable vegetable weight (g) was obtained as the weight of the vegetable harvest of each plant including the leaves and shoot, using a weighing scale. Edible vegetable weight (g) was obtained as the weight of edible portion of the harvestable vegetable weight, using a weighing scale. 10 leaf weight (g) was obtained as the weight of 10 leaves of each plant, using a sensitive balance. Moisture content was determined by the gravimetric method described by Bradley Jnr (2003). Fat content was determined by the continuous solvent extraction method using a soxhlex apparatus, as described by Min and Bott (2003). Protein content was determined by the Kjeldahl digestion method described by Chang (2003). Crude fibre content was determined by the method of Bemiller (2003). Ash content (%) was determined using the incineration method (AOAC, 2000). Carbohydrate content was calculated using the formula below as described by James (1995).

% Carbohydrate = 100 - % (protein + fat + fibre + ash + moisture content).
For any given parameter, sample means of the two sexes - males and females - were obtained and compared with each other by use of independent student's t- test.

Results and Discussion

Table 1 presents the mean values and t-test comparison in respect of the morphological and nutritional characters studied. Female plants had significantly higher stem diameter ($p<0.01$), petiole length ($p<0.05$), petiole diameter ($p<0.05$), tendril diameter ($p<0.01$), harvestable vegetable weight ($p<0.05$), edible vegetable weight ($p<0.01$), and 10 leaf weight ($p<0.01$) than male plants.

Table 1: Means and t-test comparison for some morphological and nutritional parameters in male and female individuals of fluted pumpkin

Parameter	Male	Female	t-test comparison
Stem diameter (mm)	5.6800	8.2000	0.001**
Petiole length (mm)	111.8200	130.5100	0.025*
Petiole diameter (mm)	4.2500	5.4460	0.001**
Tendril diameter (mm)	1.5380	2.0160	0.000**
Harvestable vegetable weight (g)	209.8800	522.8000	0.019*
Edible vegetable weight (g)	79.3500	239.0100	0.017*
10 leaf weight (g)	18.9800	39.5600	0.000**
Moisture content of leaves	8.0250	8.3280	0.011*
Fat content of leaves	0.6700	0.6880	0.746^{ns}
Crude protein content of leaves	10.0220	10.1470	0.866^{ns}
Crude fibre content of leaves	17.8940	15.5790	0.025*
Ash content of leaves	4.6120	4.5940	0.948^{ns}
Carbohydrate content of leaves	57.9990	60.3450	0.111^{ns}
Iron content of leaves	0.21670	0.33580	0.001**

Nb: ns – non-significant; * - significant at $p<0.05$; ** - significant at $p<0.01$

The leaves of female plants had significantly higher moisture ($p<0.05$) and iron ($p<0.01$) content than those of male plants. Crude fibre content was higher ($p<0.05$) in leaves of male plants than in leaves of female plants. There was no significant difference between the leaves of male plants and those of female plants with respect to their fat, crude protein, ash and carbohydrate contents.

The observation that female plantls had significantly higher stem diameter, petiole length, petiole diameter, tendril diameter, harvestable vegetable weight, edible vegetable weight, 10 leaf weight, and moisture content of roots than males, is in agreement with the finding of (Asiegbu, 1985) who reported that female plants are more vigorous than male plants and produce higher vegetative yields. It is also in line with the observations of local farmers, who are traditionally more protective of young plants (in the vegetative phase of development) that appear to be more vigorous than others, in the belief that the more vigorous plants have a higher probability of turning out to be females than those that are less vigorous. These local farmers are usually right. Larger morphological features, especially in respect of leaves and green stems, are expected to be associated with greater photosynthetic ability, which the female plants need in order to sustain their usually longer lifespan and reproductive functions, including fruiting. Also, thicker stems and tendrils offer additional strength to vines of female plants which need to be strong in order to carry the weight of pods that usually hang down on a climbing stem. In male plants, signs of senescence, including a drop in leaf yield, appear soon after anthesis.

Conclusion

The male and female plants of fluted pumpkin studied exhibited differences as well as similarities in respect of morphological and nutritional parameters. Male plants had significantly lower ($p<0.05$) stem diameter, petiole length, petiole diameter, tendril diameter, harvestable vegetable weight, edible vegetable weight, and 10 leaf weight, than female plants. The leaves of female plants had significantly higher ($p<0.05$) moisture content than those of male plants, but the sexes did not differ from each other with respect to the fat, crude protein, ash and carbohydrate composition of their leaves. Female plants had higher iron content in their leaves ($p<0.05$) than male plants.

Morphological And Genetic Variation Of *Tilapia Guineensis* Populations From Nigerian Coastal Waters

E.A. Ukenye*, I.A. Taiwo and P.E. Anyanwu
Biotechnology Department Nigerian Institute for Oceanography and Marine Research, Victoria Island P.M.B 1279 Victoria Island, Lagos Nigeria. eekwelem@yahoo.com

Abstract
Morphometric and molecular techniques were used to characterize and investigate genetic diversity of T. guineensis populations from some Nigerian coastal waters for breeding and conservation purposes. Results of morphometric analysis showed that T. guineensis populations can be differentiated into only two distinct groups. The results implied low variability among the populations of T. guineensis from the coastal locations studied. This implied that T. guineensis populations from Nigerian coastal waters are morphologically different. Iwoama and Brass (Bayelsa state) populations were the most varied among all the studied populations. Furthermore, When compared to other locations, fish in Iwoama and Brass had the highest mean weight of 0.29±0.006 kg and 0.27±0.004 kg with mean total length of 0.24±0.002 m and 0.23±0.001 m. Molecular studies showed that Buguma in Rivers state, Badagry in Lagos state and Brass in Bayelsa state populations had the highest genetic diversity as was revealed by heterozygosity and shannon indices. Clustering using SSR data gave four major clusters reflecting some level of genetic variability. Rivers, Lagos and Bayelsa states show greater genetic and morphological divergence and are therefore considered suitable areas for sourcing T. guineensis for fish improvement.
Key words: *Tilapia guineensis, morphometric, meristic, population variation, genetic diversity,*

Introduction
Tilapia guineensis (Bleeker, 1862), one of the dominant Tilapia species in Nigeria and other West African countries is a euryhaline species usually found in creeks, lagoons, and other coastal waters of West Africa (Philippart and Ruwet, 1982). It is one of the Cichlid species and an important source of animal protein and income throughout the world especially in developing countries like Nigeria with many rural populations relying on subsistent farming (Sosa *et al*., 2005). It has continued to contribute immensely to the nutritional needs, economic growth, and development of many nations including Nigeria.
The Nigerian coastal zone comprises of Lagos, Ondo, Delta, Rivers, Bayelsa, Akwa Ibom and Cross River states and parts of Edo state, and the majority of these populations depend on catch from the wild. This includes *T. guineensis* as a source of animal protein. Therefore, efforts to determine the current level of diversity and genetic structure of *T. guineensis* populations in Nigeria and many other parts of the world are useful for fishery management, aquaculture, stock conservation, and fish improvement through breeding.
The analysis of phenotypic variation in morphometric characters or meristic counts is the method most commonly used to delineate stocks of fish (Hockaday *et al*., 2000). The population genetic analysis of species in nature is of primary importance in developing an optimal strategy for their breeding, conservation and effective management. Proper investigation has revealed dearth of information on the knowledge of *Tilapia guineensis* in terms of genetic diversity of its natural populations using microsatellite markers. In view of the importance of genetic variability in selective breeding, there is therefore need to assess the genetic diversity of *T. guineensis* for its improvement.

Materials and Methods
Sample collection was carried out after a pre-survey study in twelve locations from six Nigerian coastal states (two locations per state) for *T. guineensis* species. The locations and the

coordinates of sampling stations are listed in Table 1. Specimen were obtained from fishermen at the landing site of every station and identified by a fish taxonomist from Marine Biology Department of Nigerian Institute for Oceanography and Marine research Lagos, Nigeria. Fifty (50) fish samples were randomly selected for morphometric analysis and ten specimen for molecular study from each location. During the field trip, collected samples (tissue) for molecular analysis were preserved in 90% ethanol inside eppendorff tubes to prevent genetic and molecular deterioration while fish samples for morphometric analysis were stored in ice chase in order to prevent morphological deformation (Allendorf, 1987).
A total of 13 morphometric variables were directly measured to the nearest 0.1 cm using a thread and measuring board. Measurements of body parts were made with the head of fish pointing left. However, to avoid possible biases produced by size effects on the morphometric variables, all morphometric characters were standardized by dividing the measurement by the standard length of each fish to minimize the effect of fish size (Allendorf *et al.*, 1987).

For molecular study, genomic DNA was extracted from the caudal fin tissue (1 cm^2) using phenol-chloroform method according to Sambrook and Russell (2001) protocol. The quality of extracted DNA was checked using a Nano-drop spectrophotometer. Nine microsatellite primers were utilized to characterize and investigate genetic variation. Polyacrylamide gel electrophoresis was used for the separation of the amplified DNA.

Statistical Analysis

Paleontological Statistics (PAST; Version 18) software package was used for the analysis of morphological data. In order to reduce variables to principal component that can explain most of the variation, principal component analysis (PCA) was carried out while Population genetic data generated was analyzed using PopGen version 3.6 software.

Table 1. Geographical location of Sampling Stations

Results and Discussions

Morphometric Analysis

Analysis of morphometric data showed that the first principal component (PC-I) accounted for 85.73% while the second (PC-II) accounted for 4.54% giving a total 90.27% of the variations in morphometric measurements data and were used to explain the variations (Table 2). The highest mean weight and total length (0.29±0.006kg and 0.24±0.002m, 0.27±0.004 kg and 0.23±0.001 m) respectively with the lowest coefficient of variation (15.8% and 11.9%) in terms of weight were found in Iwoama and Brass. The values were significantly different ($P<0.05$) from other locations (Table 3). Principal component analysis showed that samples from Brass and Iwoama (Bayelsa) formed a separate cluster from samples of other locations. While Ishaka forms an out-group suggesting that Iwoama and Brass populations are morphologically different from other populations (Figure 1). Cluster analysis illustrated by the dendrogram also revealed two major clusters which indicate that the ten populations clustered into two distinct groups revealing low variability among the populations of *T. guineensis* from the coastal locations studied (Figure not shown). This is in agreement with the report of Sun *et al*, (2012) who pointed out that populations of east coast of Indian Ocean and Pacific Ocean of *P. monodon* are morphologically similar. A similar observation was made by Thirumaraiselvi *et al.* (2013) in a morphometric study of three populations of Indian Salmon. This relatedness could be attributed to gene flow that might have existed among the populations.

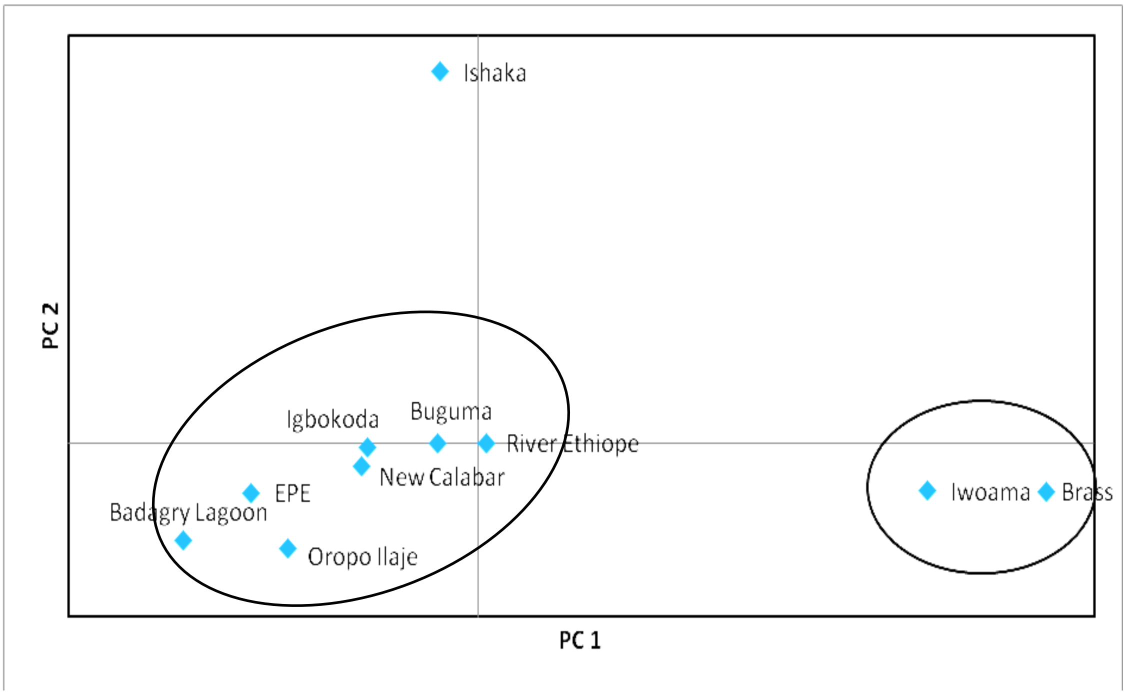

Figure 1: Principal component analysis of morphometric data based on location distribution of samples

Microsatellite Based differences in Populations

Morphological method has some limitations in studying variability among species populations. Microsatellites are among the most widely used DNA markers for many purposes such as diversity, species identification, genome mapping, etc. (Teixeira da Silva, 2005). The use of these markers to investigate genotypic variations among different populations has been previously reported by some researchers (Dang *et al*., 2014; Abdel-Kader *et al*., 2013). Nine microsatellite markers were utilized to characterize and investigate genetic variation in some coastal populations of *T. guineensis* with a view to stimulating interest and giving insights into possibilities of improving nutritional and economic qualities of *T. guineensis* through breeding and conservation programmes.

In the present study, Badagry in Lagos state population had the highest mean number of alleles (2.67), followed by Buguma in Rivers state (2.56) and Brass in Bayelsa state (2.44) while the lowest was found in Igbokoda in Ondo state (1.44). Generally, a total of 28 alleles were revealed, this is similar to the study of Abdul *et al*. (2012) who got a total 27 alleles in rice. This may imply that observation of 27- 28 alleles is sufficient for animal and plant diversity studies. In contrast, the study of Hassanien and Gilbey (2005) revealed 80 alleles in 6 loci from 5 populations of *Oreochromis niloticus* indicating higher genetic diversity than *T. gineensis*. This result suggests that *T. guineensis* had lower genetic diversity than *O. niloticus.* Urgent steps are therefore necessary to arrest further reduction in diversity of *T. guineensis* through various breeding and conservation programmes.

The mean effective alleles varied from 1.29 to 2.11. In all populations, the mean effective number of allele was lower than the mean number of alleles. Shannon information index was observed higher in Buguma population (0.77), Badagry (0.76) and Brass (0.64) reflecting high genetic diversity while other populations had low index. All populations showed low average observed heterozygosity. Badagry was the most variable (Ho = 0.467) followed by Buguma (Ho = 0.402) and Brass (Ho = 0.456) while Oron had the least observed heterozygosity (Ho = 0.211). The average expected heterozygosity was high in Buguma (0.503), Badagry (0.484) and Brass (0.411) and low in Oron (0.178) and Igbokoda (0.180) populations as shown in Table 4. Three populations (Buguma, Badagry and Brass) were identified as having the highest biodiversity in this study based on mean number of alleles, Shannon's information index and heterozygosity (observed and expected) when compared to others and are therefore considered as suitable areas for sourcing *T. guineensis* for improvement through breeding.

Moreover, clustering based on genetic distance revealed four clusters indicating some level of genetic variability between the studied populations (Figure 2).

Table 4. Summary of the Genetic Diversity Level in the Twelve Studied Populations

Population	Na	Ne	I	Ho	He
Buguma	2.7	2.11	0.77	0.402	0.503
New Calabar	1.7	1.53	0.36	0.400	0.247

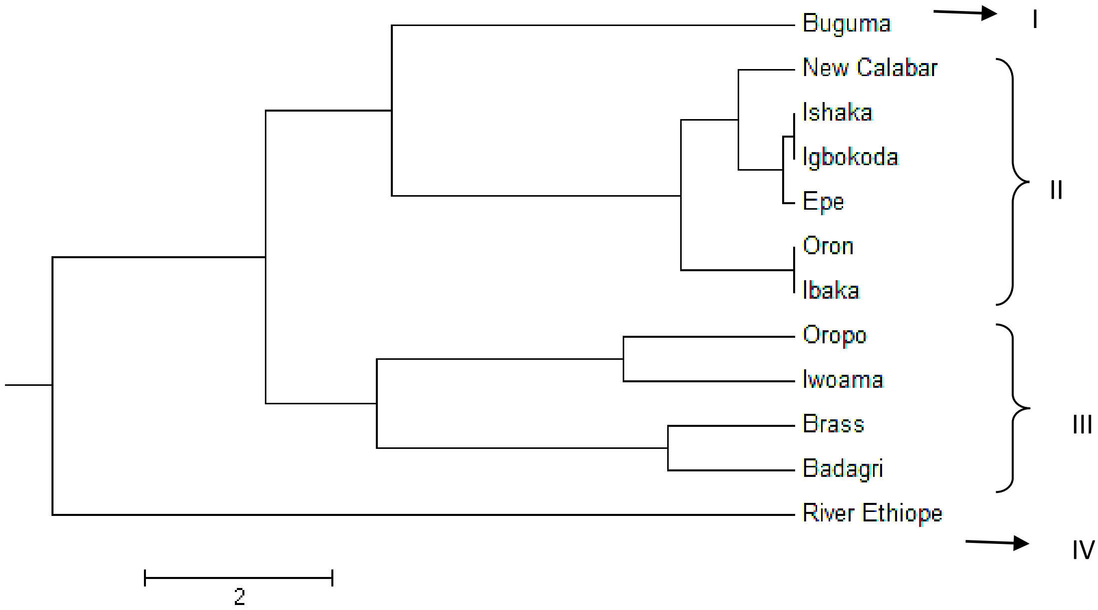

Figure 2. UPGMA Dendrogram Showing the Genetic Relationships among 12 Populations Based on Nei's Genetic Distance.

Morphology and Genetic Diversity of the Studied Populations

Using morphological and molecular data to quantify differentiation between populations of *T. guineensis* from coastal locations, some level of variation was observed morphologically and genetically between and among these populations. This study has provided significant knowledge on *T. guineensis* population differentiation. Rivers, Lagos and Bayelsa states show greater genetic and morphological divergence. Although it could be that the variation observed in morphology were significantly correlated with some genetic factors more than environmental factors. However, genetic data collected from the populations slightly support the morphological results.

Furthermore, it can be deduced that genetic differences may not always be represented by phenotypic variation. This may be due to phenotypic plasticity of fish that allows them to respond adaptively to environmental change (Lefébure *et al.*, 2006). Therefore, it has been highlighted the importance of utility of genetic information in stock differentiation and conservation studies for wild population of *T. guineensis*.

Conclusion

The present study revealed some level of morphological and genetic variation between and among the *T. guineensis* populations. *Tilapia guineensis* populations in Buguma (Rivers State), Badagry (Lagos State) and Brass (Bayelsa State) are the most morphologically and genetically diverse and are therefore recommended as starting populations for fish improvement through selective breeding in Nigeria.

Assessment Of Open Pollinated Exotic Sweetpotato Seedlings for Variation in Flesh Root Colour and Response to Pests and Diseases in Umudike Southeastern, Nigeria

Nwaigwe, G.O and Nwankwo, I.I.M.
National Root Crops Research Institute, Umudike, Umuahia. Abia state, Nigeria.
Corresponding E-mail address: nwankwomaxwell@yahoo.com. Phone:+2348063668433

Abstract

One thousand three hundred and two (1302) sweetpotato seedlings from 12 families were evaluated using a single plant seedling evaluation trial in an unreplicated block design at National Root Crops Research Institute Umudike experimental field with the following objectives: to determine the percentage survivability of the transplanted seedlings, the storage root fleshed colour of individual seedlings developed from open pollination and the response of the sweetpotato seedlings to pests and diseases attacking the crop in the field. Data collected were on: percentage survivability, the response of the seedlings to diseases attacking sweetpotato crops in the field, root colour variation of the respective seedlings using sweetpotato colour chart. Result obtained indicated that nine different colours were observed from the sweetpotato seedlings evaluated. Out of the number that survived in the field, 231 was deep orange root flesh colour and the highest, followed by 220 seedlings with orange roots flesh colour while the least colour was one seedling with white fleshed root mixed with purple. No symptom of the major diseases attacking sweetpotato crop in the field was observed on the seedlings. Since the deeper the orange colour of the roots, the higher the Beta-carotenoid content which is the precursor for vitamin A, These seedlings will be further evaluated for other characteristics for possible release for commercial sweetpotato cultivation.

Keywords: sweetpotato, seedlings, flesh colour, diseases and families.

Introduction

Sweetpotao (Ipomoea batatas L Lam) are commonly grown in every part of Nigeria and one of the major crops, used for animal feed and human foods as well as means of economic empowerment to many poor resource farmers. More than 60% of the farmers engage in sweetpotato farming and it remains a prominent food crop to many rural dwellers especially in Northern parts of the country (Edebiri, et al., 2001). There are many varieties of sweetpotato with variation in root skin and root flesh colour such as white, cream, yellow, orange and purple. Sweetpotato is a cheap source of beta carotene, carbohydrate, vitamins and other nutrients. Some of the sweetpotao varieties such as purple and orange are very important in fighting cancers; reduce incidence of blindness and incidence of malnutrition which is in high rate among children and pregnant woman. The purple sweetpotato root flesh colour is packed with some antioxidant that provided anthocyanine which boost immunity. These medicinal factor of sweetpotato led to the selection of flesh root colour as priority for selection. Martin and Jones (1986) emphasized that the root yield traits was not the highest priority for selection. Also, worldwide, the greatest disease and pest of sweetpotato is SPVD. Resistance sweetpotao genotypes to SPVD are needed by the breeding programmes for introgression of resistant genes to new progenies (Mwanga et al., 2002.).

Breeding involves the selection of new varieties from true botanical seeds which in the process will lead to identification of genotypes with desirable traits to create new and better population for future selection. Therefore the aim of this study was to determine the percentage survivability of the transplanted seedlings, the storage root fleshed colour of individual seedlings developed from open pollination and the response of the sweetpotato seedlings to pests and diseases attacking the crop in the field.

Materials and Methods

True seeds were raised in the screen house and transplanted as seedlings to the field two months after planting in the screen house. A total of 1302 sweetpotato seedling from 12 families were planted in an unreplicated block. The seedlings were evaluated using a single plant seedling evaluation trial. Each seedling was carefully removed from the polybag after loosening the soil around them, the single plants were planted at the crest of the ridge at a spacing of 1.0m x1.0m intra and inter row spacing. Agronomy practices such as weeding and fertilizer application at 4 weeks after planting were carried out. Data were collected on percentage survivability, the response of the seedlings to diseases attacking sweetpotato crops while growing in the field. At harvest, data were collected on root colour variation of the respective seedlings using sweetpotato colour chart (Burgos et al., 2009). The percentage survivability of the seedlings was calculated using the formula

$$\text{Percentage survivability:} \quad \frac{\text{Total number of seedlings survived}}{\text{Total number of seedlings transplanted}} \text{X } 100$$

Diseases were visual scored using 5 point severity rating scale where 1= no symptom, 2= mild symptom, 3= moderate symptom, 4=severe symptom and 5= very severe symptom.

Results and Discussions

The result indicated that total number of 1302 sweetpotato seedling from 12 families was transplanted to the experimental field. Number of seedlings survived was 981 which represented 75.5% survivability. The result showed that there is genetic variance among the population, since most seedling show fitness of adaptation to our harsh environment. The result is in line with the finding of (Nwankwo et al., 2015) that high percentage field establishment showed high adaptability of the seedling to the harsh field conditions (Table 1).

The result in Table 2 show various sweetpotato root flesh colour of the seedlings from 12 families. Two hundred and thirty-one seedlings (231) have deep orange root flesh colour, 220 seedlings have roots flesh colour that is orange, 114 were seedlings with yellow roots flesh colour while root flesh colour of 13 seedlings were white. The root flesh colour of 84 seedlings was light orange while the root flesh colour of 54 seedlings was cream. The root flesh colour of some seedlings was mixed. For example 43 seedlings have root flesh colour yellow mixed with orange, 9 seedlings had their root flesh colour orange mixed with purple while one seedling had its root flesh colour which is white mixed with purple.

The sweetpotato seedlings with orange deep orange and purple colour indicated presence of βeta carotene and anthocynine contents which are rich in boosting the immunity of children under five years against blindness and have cancer fighting properties.

The table 3 shows the response of the sweetpotato seedlings to major sweetpotato folia diseases attacking the crop in the field. Sweetpotato virus diseases, Sweetpotato bacteria blight and sweetpotato leaf spot showed 100% no visible symptom at rating scale of 1 severity. This indicated complete absence of these diseases attacking the seedlings in the field. This an indication of good characteristics which farmers want in any new variety.

Conclusion

Nine different colours were observed from the sweetpotato seedlings evaluated. Deep orange root flesh colour from 231 seedlings was the highest, followed by 220 seedlings with orange roots flesh colour while the least colour was one seedling with white fleshed root mixed with purple. No symptom of the major diseases attacking sweetpotato crop in the field was observed on the seedlings. Since the deeper the orange colour of the roots, the higher the Beta-carotenoid content which is the precursor for vitamin A, These seedlings will be further evaluated for other characteristics for possible release for commercial cultivation.

Abstract
The extent of genetic variability among 19 accessions of tomato (Solanum spp) was studied using genetic variability parameters as a basis for harnessing of the crop. Four-week old seedlings were transplanted in a well levelled field with 0.6 x 0.6 spacing and replicated three times in randomized complete block design. High significant differences among the accessions for all attributes studied. Cluster analysis based on 37 agro-morphological attributes separated accessions into two distinct groups according to the fruit types i.e. cherry and classic fruit types. Values for genotypic and phenotypic coefficients of variation showed variability among the accessions. Correlation analysis showed fruit per plant is positively and significantly correlated to plant height, number of branches per plant and leaf length. Very high genetic advance and heritability estimates for leaf length, leaf width, days to flower, days to 50% flowering, number of fruits per plant, fruit length, fruit diameter, fruit weight and 1000 seed weight suggest simple inheritance system and thus amenability for these attributes to selection in tomato improvement.
Keywords: *Tomato, attributes, variance, heritability, genetic advance, inheritance.*

Introduction
Tomato (*Solanum lycopersicon* L.) is one of the most important vegetable crops grown over the world because of its wider adaptability, high yielding potential and suitability for variety of uses in fresh as well as processed food industries. It is one of the most important vegetable crops grown in Nigeria and utilized in almost every household for preparation of several dishes. Tomato plays an important role in human nutrition by providing essential amino acids, vitamins and minerals (Sainju *et al.,* 2003). Its vitamin C content is particularly high (Kanyomeka and Shivute, 2005). It also contains lycopene, a very potent antioxidant that may be an important contributor to prevention of cancers (Agarwal and Rao, 2000). With production of over 150 million tons of fresh fruit on 3.7 million hectares tomato exceeds the production of all other crops, with the exception of the potato and sweet potato (FAOSTAT, 2014). Production in Nigeria has more than doubled in the last 10 years with the production in 2001, amounting to about 879,000 tonnes (Akanbi and Oludemi, 2003). However, commercial tomato production in Nigeria relies mostly on exotic introductions. The production of which is essentially restricted to the Northern Guinea Savanna and the Sudan ecologies due to favourable climatic conditions, particularly high insolation and low relative humidity. In nearly three decades, up to 2013, no tomato variety has been released in Nigeria (NACGRAB and NASC, 2013). The need therefore, to explore the production capabilities and potentials of long forgotten indigenous land races and other ecotypes has never been more urgent.

The concept of heritability combined with genetic advance are good parameters for determining gene action involved in the inheritance of any trait and by extension help in deciding the best breeding method to apply for improving such trait. High heritability indicates less environmental influence in the observed variation (Songsri *et al*., 2008; Eid, 2009), while high heritability accompanied by high genetic advance is an indication of additive gene action for such trait, making it most amenable to selection (Tazeen, *et al*., 2009). This study was carried out to determine the extent of genetic variation among available tomato accessions with the specific objective to use suitable genetic parameters as basis for future breeding work in tomato.

Materials and Method

Nineteen (19) accessions of tomato held in National Genebank at the National Centre for Genetic Resources and Biotechnology (NACGRAB) were used in this experiment. The accessions were seeded in nursery trays filled with top soil. Seedlings were transplanted at four weeks after planting (WAP) to NACGRAB research field, Moor Plantation (224m, 7°23`, 3°50`), Ibadan, Nigeria in 2013 rainy season. Seedlings were transplanted unto a well ploughed, harrowed and levelled field. Inter and intra-row spacing was 0.6 x 0.6m. Each treatment accession was in single 6 meter row plot replicated thrice in a completely randomized block design. Recommended cultural practices were followed. Data were recorded from five pre-tagged plants of each treatment. Attributes measured and recorded using descriptors for Tomato (*Solanum* spp.) (IBPGR, 1997). Data analysis of variance was done and significant means were separated using Duncan multiple range test (DMRT) SAS 9 (SAS, 2002). Mean values were used to estimate Genotypic and Phenotypic coefficients of variation as by Singh and Chaudhury (1985). The broad sense heritability and genetic advance were calculated as proposed by Johnson *et al*. (1955) and UPGMA cluster analysis was used to construct a dendogram to ascertain the genetic relationships among the tomato accessions.

Results and Discussions

Significant differences were shown among the accessions for all morphological characteristics measured, with genetic distance ranging from 0.30 to 0.49 (Fig. 1). In this study, the cluster analysis based on 37 agro-morphological attributes that separated accessions into two distinct groups at 0.32 coefficient, which were according to fruit types – into cherry and classic fruit groups corresponding to varietal types (Fig 1). This is similar to the results of Kwon *et al*. (2009) who characterized 63 tomato varieties of Korea using SSR markers and morphological descriptors. The 20 qualitative attributes had two to nine numbers of observable types. Eight attributes (40%) had more than two types, of which fruit shape had the largest variation with six types (slightly flattened, flattened, cylindrical, rounded, ellipsoid and high rounded). Hu *et al.* (2012) reported that fruit shape had the most variable types (seven). There were no obvious differences for five attributes (leaf type, division of leaf blade, stem pigmentation, abscission layer and flower colour) among the accessions studied.

Highly significant differences among the accessions for most attributes studied (Table 1) suggests enough genetic variability of the accessions hence the scope for improvement of this crop. Similar observations have been reported on 14 characters (Singh and Raj, 2004; Hidayatullah, *et al*., 2008) and all characters studied by Mohammed *et al*. (2012). Values of genotypic and phenotypic variances were lowest in peduncle length and highest in fruit yield per plant. Higher values of genotypic and phenotypic variances observed for most attributes suggest the existence of high magnitude of variability among the accessions with respect these attributes. Smallest differences observed between PCV and GCV values of attributes such as leaf length, leaf width, days to flower, days to 50% flower, days to fruit ripening, fruit length, fruit per inflorescence, fruit diameter, fruit weight, days to maturity and 1000 seed weight (Table 1) suggest lesser influence of environmental factors on their expression. Selection for improvement of tomato for these attributes is likely to be most effective. Relatively higher differences between PCV and GCV values recorded for plant height, number of branches, number of leaflets, fruit per plant, peduncle length and fruit yield indicate more influences of environmental factors than other attributes studied.

Very high heritability estimates for leaf length, leaf width, days to flower, days to 50% flowering, fruit per plant, fruit length, fruit diameter, fruit weight and 1000 seed weight (Table 3) indicate possibility of their improvement through selection. Similar results have been reported by Tasisa *et al*. (2011) and Ulla *et al*. (2012). However, Parnse (1957) stated that greater usefulness of considering estimate of genetic advance as an effective selection tool lies in accompanied heritability estimates. Hence, very high genetic advance accompanied by high heritability estimates for leaf length, leaf width, days to flower, days to 50% flowering, fruit per plant, fruit length, fruit diameter, fruit weight and 1000 seed weight suggest simple inheritance system for these traits. Fehmida and Ahmed (2007) reported similar results for plant height, number of fruits per plant, fruit size and weight of 10 tomatoes.

Fruit yield per plant (g)	1269.64	0.001	775796.1	1049841.9	274045.5	74	63.37	80.70	122.9

σ^2g = genotypic variance, σ^2g = phenotypic variance, GCV = genotypic coefficient of variation, PCV = phenotypic coefficient of variation, GA= Genetic advance, H^2b = heritability in broad sense

Conclusion

The genetic parameters discussed here are functions of environmental variability, so estimates may differ in other environments. However, based on the high genetic advance accompanied by high heritability estimates for different attributes studied, especially, days to 50% flowering, fruit per plant, fruit length, fruit diameter, fruit weight and 1000 seed weight we could conclude that the determinant genetic effects of the phenotypic expression of these characters are fundamentally of the additive type. Hence, a high response should be achievable after several selection cycles.

Abstract
The experiment was conducted at the Horticultural Nursery of Federal University of Technology Minna, Nigeria, to determine effect of maize crop residue biochar on pepper performance in Minna. The treatments were five rates of maize crop residue biochar application (0, 5, 10, 15 and 20 tons ha^{-1}), laid down in a Completely Randomized Design (CRD) with four replications. Data collected were plant height, number of leaves, number of days to flowering, fresh and dry biomass and fruit yield. The results showed that the textural class of the soil was sandy loam, soil reaction was slightly acidic (pH 6.7), low in organic carbon (3.60 g kg^{-1}), medium in total nitrogen (0.14 g kg^{-1}) and relatively high in available P (20.72 mg kg^{-1}). Application of 10 ton ha^{-1} of maize crop residue biochar produced the highest number of leaves, fresh and dry biomass weight, fruit yield and organic content of the soil. 10 ton ha^{-1} of maize crop residue biochar can be considered useful for the cultivation of pepper in a pot experiment.
Keywords: Biochar, maize crop residue, and Minna

Introduction
Pepper (*Capsicum frutescence*) is an important fruit vegetable which belongs to the night shade family Solanaceae, and is related to eggplant, potato and tobacco. It is the second most important vegetable after tomatoes, it now commonly cultivated in all parts of the world. The bulk production of pepper is found in the Savanna zone and derived Savanna areas of the south western Nigeria. Nigeria produced 0.63 million metric tonnes (MT) pepper fruits in 1980 (FAO, 1980) which increased to 1.793 million MT in 2009 (FMARD, 2010). Nevertheless, pepper yield is still low, at average of 3.85 MT.ha-1, and with much lower values obtained in the southern states due to many constraints. Pepper has increased in popularity, value and importance over a long period, thus making it an indispensable part of the daily diet of millions of Nigerian. It is an important source of vitamin A and C, which protects the body against disease attack. These vitamins in pepper help in maintenances of bones, tissues and blood and in the efficient utilization of iron. Pepper is normally used as a spice in the preparation of soup and stew when cooked with tomatoes and onions. It can also be used as a condiment and extensively in flavouring of processed meat, colouring certain food preparation and also used for medicinal purposes (Chauhan, 1972). Biochar therefore can possibly help alleviate environmental change by means of carbon sequestration. Freely, biochar can expand soil ripeness of acidic soils (low pH soils), increment rural efficiency, and give security against some foliar and soil-borne maladies. Recently, it has been observed that inadequacy in soil fertility and deficiency in important mineral nutrient has possessed serious constraints to high yield of pepper production (Fagwalawa and Yahaya, 2016). This is because fertilizer has become a scarce commodity, even when available; it is beyond the reach of the poor resource farmers due to its high cost (Fagwalawa and Yahaya, 2016). In moist tropical environment, sustainable agriculture faces large constraints due to low nutrient content and accelerated mineralization of soil organic matter (Yeboah *et.al*., 2013). The natural issue is typically mineralized quickly and just a little

extent of the connected natural issue is settled in the dirt in the long haul, however progressively discharged to the climate as CO2 (Yeboah *et.al.,* 2013). The way that various feedstuff, for example, plant deposits, maize crop residues etc. are accessible and are considered as contaminations, these waste materials can be burned and used valuably in farming. Consolidation of biochar to the dirt is advantageous in catching water to build soil dampness maintenance and accessible nitrogen hence the objectives of the study is to determine the effect of maize crop residue biochar on pepper performance and some soil chemical parameters like soil organic carbon, total nitrogen and available phosphorus.

Materials and Methods

This experiment was conducted at Horticultural Nursery, Federal University of Technology, Gidan Kwano Minna. In the Southern Guinea Savanna of Nigeria. The pots were filled 10 kg soil. There were 5 treatment which are; 0 t ha^{-1}, 5 t ha $^{-1}$,10 t ha^{-1}, 15tha^{-1-}, 20 t ha^{-1}. The experiment was laid on a completely design (CRD) with four replications. The maize crop residue biochar was mixed thoroughly two week before sowing. Pepper seed was sown by broadcasting method on nursery bed; three seedlings were transplanted into the pot at two week after emergence. The seedling was later thinned to one seedling per pot. Water was applied on daily basis. Weeding was done on regular basis by hand pulling. Soil samples were collected randomly from the Teaching and Research Farm. The soil samples were collected from each pot at the end of the experiment to determined soil chemical analysis. Sampling was done within depth of 0 – 15cm using shovel. The samples was bulked together to form a composite sample which was air-dried and analysed for particle size and some chemical properties using the standard procedures. Soil particle size distribution was determined by the hydrometer method . Soil pH was determined in a 1:2.5 soil to water with a pH meter, while the soil organic carbon was determined using the Walkley and Black wet oxidation method , total nitrogen by the micro- Kjeldhal method. Exchangeable bases were extracted with neutral 1 N NH_4OAC extraction. Na and K in the extract was determined using Flame photometry while the Ca and Mg was determined by Na-EDTA titration. Exchangeable acidity was extracted and then determined by titrimetric method and phosphorus was extracted and phosphorus was extracted using Bray P-1 method and the concentration was determined colorimetrically using atomic absorption spectrophotometer. The height of pepper was measured from the base of the plant to the tip of the plant using meter rule at 2, 4, 6, 8 10, 12 week after transplanting (WAT). The number of leaves was determined by counting of leaves on the plant at 2,4 6,8, 10,12 WAT. The days to flowering was done by visual assessment on the pepper. The number of days was calculated from the day of sowing to the date when first flower appear on each treatment pot. The number of flower was determined by counting the number of flower on each treatment pot. All the fruit harvested from the pot of each of the treatment pot was weight and recorded as fruit yield and the biomass was harvested and weighted as fresh biomass and weighed after drying as dry biomass. Data collected was subjected to analysis of variance (ANOVA) treatment means was compared using the Duncan Multiple Range Test (DMRT) at 5% level of probability.

Results and Discussion

Some Soil Physical and Chemical Properties

The soil physical and chemical properties before sowing are shown in Table 1. The textural class of the soil was sandy loam. The soil was slightly acidic in water (pH 6.7) and the organic carbon (3.62 g kg^{-1}) was low, medium in total nitrogen (0.14 g kg^{-1}) with relatively high available phosphorus (20.72 mg kg^{-1}) (Esu, 1991)

Effect of maize crop residue biochar on growth and yield of pepper

The effect of maize crop residue biochar on plant height of pepper at different growth stage is shown in Table 2. At 2 WAT, 20 ton ha^{-1} were significantly taller ($p<0.05$) than other treatments. At 6 WAT, 20 ton ha^{-1} were significantly taller ($p<0.05$) than 0, 5 and 10 ton ha^{-1} but similar to 15 ton ha^{-1}. At 8 WAT, 20 ton ha^{-1} were significantly taller ($p<0.05$) than 0, and 5 ton ha^{-1} but similar to 10 and 15 ton ha^{-1}. Similar trends were observed at 10 and 12 WAT. There was however no significantly difference among the treatment at 4 WAT. The effect of maize crop residue biochar on number of leaves of pepper at different growth stage is shown in Table 3. At 2 WAT, 15 and 20 ton ha^{-1} had the higher number of leaves which was significantly higher ($p<0.05$) than 5 ton ha^{-1}. There was no significantly difference among the treatment at 4 WAT. At 10 WAT 15 and 20 ton ha^{-1} had the higher number of leaves which was significantly different ($p<0.05$) from 5 ton ha^{-1} and control, similar trends was observed at 12 WAT.

The control flower earlier which was significantly different from 20 ton ha^{-1} that flower at the later days (Table 4). 10 and 20 ton ha^{-1} had the highest fruit yield which was significantly different ($p<0.05$) from other treatments (Table 4). Effect of maize crop residue biochar on fresh and dry biomass of pepper was shown in Figure 1. The treatment 15 ton ha^{-1} recorded the highest fresh biomass and the lowest was observed in control. Similar results were observed on dry biomass of pepper. The application of organic fertilizer like biochar have shown to enhance crop and soil quality (OIowokere 2004). Remain of organic based fertilizer have shown to increase the growth of crop such as pepper (Berova *et al.,* 2010). The application of biochar to soil improves the physical and chemical environment in soil providing microbes with a more favourable habitat. This consequence aid the transformation of nitrogen held in organic form to form available for uptake by plant roots potentially improving its availability to plant (Sandip and Harsha 2013).). Biochar provide a suitable habitat for many micro-organisms by shielding them from predation and desiccation and also provide diverse carbon energy mineral nutrient needed to plant (Warnock *et al.,* 2007). The effect of maize crop residue biochar on total nitrogen, organic carbon and available phosphorous is shown in Table 5. Treatment 10 ton ha^{-1} significantly increased organic carbon content while 15 ton ha^{-1} increased the available phosphorous but there was no significantly different from total nitrogen of the soil (Table 5). Positive change in soil chemical properties been recorded for different soil as result of application of biochar. These include increase in cation exchange capacity and pH of the soil (Liang *et al*; 2006; Cheng *et al*; 2008). Biochar also show as an increase in the availability of major cation phosphorus as well as total nitrogen concentration (Glaser *et al*., 2002; Lehmann *et al*., (2003). The volatilization of crop residue to biochar and introduction into small holder vegetable cropping system is suggested for restoring soil nitrogen in the vegetable farm as well as modifying the environmental for bioavailability and efficiency of nutrient in soil (Tagoe *et al; 2008*).

Conclusion

From the results of this study, 10 ton ha^{-1} of maize crop residue biochar improved the growth, fresh biomass weight, dry biomass weight, fruit yield of pepper and organic content of the soil and therefore it can be considered useful for the cultivation of pepper in a pot experiment.

Abstract
Sudden death of cacao plants in the field and failure of seedlings to establish in rehabilitated fields have been associated with plant-parasitic nematodes. With the aim to ameliorate their adverse effects, this research was conceived to determine the effect of soil amendments with poultry litter on cacao, parasitic nematodes, soil bacteria and fungal population densities. The field experiment was set as a randomized complete block design of a 4x3 factorial arrangement with four rates of poultry litter (0, 0.2, 0.3, 0.4t/ha) and three rates of carbofuran (0, 1.25, 2.50kg a.i/ha). The growth of cacao was significantly improved by the amendments compared to the un-amended plots. Nematode population densities were negatively correlated with plant height, stem girth, leaf area and number of leaves. Bacteria species of Arthrobacter, Bacillus and Pseudomonas were the most numerous species identified from the litter amended soil, while the fungi identified included Arthrobotrys dactyloides, Aspergillus niger, A. flavus, Trichoderma harzianum, T. viride, Paecilomyces lilacinus and Verticillium chlamydosporium. Fungal and bacterial densities increased at 3, 6, 9 and 12 months after transplanting of cacao in the field in all the treatments, reaching a peak at 9 months. However, poultry litter amended plots had the greatest number of bacterial and fungal counts, while carbofuran treatments had the least. The observed significant increase in soil borne microbial populations has an essential role in nematode suppressive mechanisms.
Keywords: Theobroma cacao, poultry litter, plant-parasitic nematode, fungi and bacteria

Introduction
Cacao (*Theobroma cacao* Linnaeus) play important roles in the agricultural sector of the Nigerian economy contributing significantly to gross national product, food security, employment, diversification of income sources in rural and urban areas (Folayan *et al*., 2006). However, plant-parasitic nematodes constitute a rapid decline in adult cacao productivity and establishment of seedlings in fresh and rehabilitated fields. While chemical control can reduce the impact of nematode infestations (Afolami, 1993), effective nematicides are too expensive for resource-poor farmers and often results in a noticeable decrease of many soil biological processes, notably by suppressing predators and parasites of these nematodes, contamination of aquifers and negative shifts such as health hazards, environmental pollution and potential atmospheric ozone depletion. However, soils, especially those with a low microbial population, are more vulnerable to reinvasion of pathogens even after fumigation (Gamliel *et al*., 2000). Nematode populations might become sensitized or resistant to repeated applications of nematicides. Hence the more urgent need to develop new management tools that are environmentally and toxicologically safe. Organic soil amendment is one of those new technologies. Organic amendments primarily used for increasing agricultural productivity have been shown to have a suppressive effect on plant-parasitic nematodes (Walker, 2004). This research was conceived to determine the effect of soil

amendments with poultry litter on cacao, parasitic nematodes, soil bacteria and fungal population densities in the field. The hope is that the current level of frustration being faced by farmers through poor cacao seedlings establishment caused by plant-parasitic nematodes can be ameliorated.

Materials and Methods

Curing of Poultry Litter and Proximate Analysis

Poultry litter (poultry droppings and wood shavings) was collected from coops with good farm sanitation and air-dried. Composite samples were obtained and analysed according to standard methods.

Experimental design

The field experiment was set as a randomized complete block design of a 4x3 factorial arrangement with four rates of poultry litter (0, 0.2, 0.3, 0.4t/ha) and three rates of carbofuran (0, 1.25, 2.50kg a.i/ha). Each treatment had 3 replications. The poultry litter in the relevant treatments were incorporated into the soil by mixing the litter with the soil at planting time and again at 3, 6 and 9 months after planting, while the carbofuran treatments were applied by mixing it with soil at planting and repeated after three months around the plants. Cacao seedlings were planted at the spacing of 3x3m. The unit plot size was 31.5m^2 accommodating 8 plant stands of cacao. Normal agronomic practices were observed. Aerial growth data measured on each plant included plant height, stem girth, leaf area, number of branches and leaves.

Soil assay for nematodes

The soil was assayed to confirm the presence and population density of the nematodes. A 100g sub-sample soil was assayed for nematodes using the tray modification of Baermann technique. Identification using taxonomic keys and counting was repeated three times and mean population of nematodes per sample calculated following the various procedures for soil assayed as outlined by Coyne *et al*. (2007).

Extraction of bacteria and fungi from soil

Counts of bacteria and fungi were determined by serially plating the soil-litter suspensions and controls onto selective media in 9-cm-diameter petri dishes with a Spiral Plater. Soil (2 g) was weighed and placed into a whirlpac blender bag with 18 ml of deionized sterile water for the first dilution. Each sample then was placed in a Stomacher blender and agitated for 30 seconds. Further dilutions were made in a laminar flow hood and the suspensions were plated onto selective media for microbial enumeration. For fungal isolation, potato dextrose agar (PDA) amended with streptomycin (0.1g/liter) and tetracycline (0.01 g/liter), and PDA amended with streptomycin (0.1g/liter) and chloramphenicol (0.01 g/liter), were used. Nutrient agar with nystatin (0.05 g/liter) was used for isolating bacteria. Serial dilutions were made to 10^{-3} for fungi and 10^{-5} for bacteria. Bacterial colony forming units were counted after 3 days and fungal colony forming units were counted 4 to 5 days after incubation at 25°C in the dark. Bacteria selected for identification based on colony morphological differences were transferred to 5% trypticase soy for purification and fatty acid methyl-esters identification – FAME (Kloepper, *et al*., 1992).

Statistical analysis

Nematode population densities were $\log_{10}(x + 1)$ transformed and percentage data were square-root-transformed prior to analysis to stabilize variances (Gomez & Gomez, 1984), while the other data collected were not transformed. Only the predominant nematode species were included in the data analysis. Analyses of variance (ANOVA) were carried out to test for main effects and interactions.

Results and Discussion

The compost used in the experiments had the following composition: total nitrogen 3.24%, carbon 27.9%, C:N ratio 9.1, phosphorus 1.86%, potassium 0.05%, calcium 1.40% and magnesium 0.64%. The growth of cacao was consistently improved by the amendments compared to the un-amended plots in the field naturally infested with plant-parasitic nematodes. The poultry litter alone or combined with carbofuran-treated plots led to a significant increase in the vegetative of cacao compared to carbofuran-treated and un-amended plots (Table 1). This is in agreement with earlier reports that the addition of organic amendments to soil provides supplementary nutrients which in turn may have a positive effect on vegetative growth and yield, consequence of which the nematode damage might have markedly reduced (Van Den Boogert *et al.,* 1994, Rodriguez-Kabana *et al*., 1987).

In contrast, plant-parasitic nematodes reduced the plant height, stem girth, number of branches and leaves, and leaf area of cacao in un-amended plots. The increase in growth parameters in nematicide treated plots attested to this fact. In the same vein, relationships between nematode population densities and vegetative growth of cacao revealed various statistically significant interactions (Table 2). *Meloidogyne incognita* population density was negatively correlated with plant height ($r = -0.63$, $P \leq 0.001$), stem girth ($r = -0.51$, $P \leq 0.001$), leaf area ($r = -0.86$, $P \leq 0.001$) and number of leaves ($r = -0.81$, $P \leq 0.001$). Similar relationships were observed for the other major nematodes associate with cacao (Table 2).

Bacteria identified from the litter amended soil included *Arthrobacter globiformis, A. ilicis, A. pascens, Bacillus macerans, B. thuringiensis, Cellulomonas fimi*, *Pasteuria penetrans*, *Pseudomonas fluorescens, P. corrugata and P. vesicularis*. Species of *Arthrobacter, Bacillus* and *Pseudomonas* were the most numerous species identified. Fungi identified included *Arthrobotrys dactyloides, Aspergillus niger, A. flavus, Trichoderma harzianum, T. viride*, *Paecilomyces lilacinus* and *Verticillium chlamydosporium*. Fungal and bacterial densities increased at 3, 6, 9 and 12 months after transplanting of cacao in the field in all the treatments, reaching a peak at 9 months (Table 3). However, poultry litter amended plots had the greatest number of bacterial and fungal counts, while carbofuran treatments had the least. This result was consistent with earlier reports that amending the soil with a low C:N ratio (less than 20:1) substrate resulted in abundance of enrichment-opportunist antagonistic microbes (Ferris & Matute, 2003; Wang *et al*., 2004, 2006) and rapid mineralization of N in the form of NH4+ or NO3- for absorption and uptake by plant roots. The poultry litter used in this experiment has a low C:N ratio (9:1) and this resulted in the suppression of nematode population on cacao. With increase in microbial diversity and numbers, it becomes more likely that bacteria and fungi capable of parasitizing specific nematode life stages or producing substances toxic to nematodes may be involved in the resulting nematode control (Sikora *et al*., 2007; Uambano & Kerry, 2007; Siddiqui & Akhtar, 2009). Bacteria and fungi identified from the litter amended plots were species that have commonly been found in soil. Bacteria are quite diverse in nutritional requirements, and several species identified in the genera *Arthrobacter, Bacillus and Cellulomonas* have the ability to use ammonium salts or nitrates as their sole source of nitrogen. Poultry litter has high levels of nitrogen in the organic and inorganic forms (Edwards & Daniel, 1992; Sims & Wolf, 1994) that would be readily available to these organisms. Bacteria, such as *B. macerans*, use ammonia to fix N2 under anaerobic conditions (Edwards & Daniel, 1992). In addition, the genus *Cellulomonas* has been isolated from substrates high in cellulose and has the ability to reduce nitrate to nitrite (Edwards & Daniel, 1992). Chicken litter is composed of poultry droppings and saw dust (Gullino *et al*., 2003), which would provide both cellulose and nitrogen to *Cellulomonas* spp.

Conclusion

Relationships between plant-parasitic nematodes, the soil environment, organic amendments and plant host health are obviously complex and make it difficult to assess the activities occurring in soil. However, use of poultry litter as soil amendment has been shown in this experiment to reduce plant-parasitic nematode infection on cacao. The observed increase in soil borne microbial populations have an essential role in nematode suppressive mechanisms. More detailed studies of microbial population dynamics in litter-amended soils are needed to identify the specific roles that fungi and bacteria may have in nematode control.

Abstract
The aim of this study was to determine the effect of dietary inclusion of Acacia tannin extract, ATE on the haematology and serum biochemical parameters of growing Merino lambs. Twenty four lambs were allocated in randomised complete block design into 4 dietary treatments and fed a TMR diet containing with T1, urea-based diet, T2, urea-TMR+46 g/kg tannin extract, T3, calcium nitrate-based TMR, T4, calcium nitrate-based TMR+46 g/kg tannin extract. Feeding lasted for 81 d, consisting of 21 d for gradual adaptation of the sheep and 60 d growth period. At the experiment, 5 mL of blood was collected from each animal via jugular vein to determine haematological profile and serum biochemical variables. Data obtained was analysed using the GLM procedure of SAS and treatment means separated with Tukey's test. No clinical or sub-clinical signs of morbidity and tannin intoxication symptoms were observed across the treatments. Animals on nitrate-based TMR had higher haematocrit, RBC count and haemoglobin concentration than animals on urea-based TMR. Similarly, ATE reduced plasma LDH and cholesterol concentration. Although there was slightly elevated BUN levels across the treatments, levels of creatinine, total protein, ALT, AST and LDH levels were within normal reference range. The result suggests that Acacia tannin extract could be added at current dose (46 g/ kg DM) to diets of animals without any serous negative consequences.

Introduction
The restriction on the use of antibiotics as dietary supplement across the EU has elicited wide interest in the use of plant secondary metabolites in sustainable animal production activities (Akanmu and Hassan, 2017; Patra and Yu (2014). These plant secondary metabolites (Phytochemicals) have wide biological activity and hence wide application in ruminant production. As a dietary additive, their utilisation continue to generate much interest especially in their ability to help increase bypass protein flow to the small intestine, control of bloat and intestinal nematode, as well as methane mitigation (Patra and Saxena, 2010). Urea is widely included in the diets of ruminants to serve as a cheap source of non-protein nitrogen (NPN) utilisable by rumen microbes for microbial protein synthesis through which ruminants can derive nutrient (Adejoro and Hassen, 2017). However, there is a growing interest in the use of nitrate salts due to its potential in mitigating enteric methane, apart from also being an NPN source (Adejoro and Hassen, 2018). Condensed tannins, though not digestible by the animals, may have significant effect on the physiological state of the animals (Makkar and Singh, 1995). Most of the studies on tannin and nitrogen interaction in ruminants have focused on protein digestibility and growth performance, while their impact on the physiology and health status of animals have not been widely reported while opportunities for nitrate use in ruminant needs to be explored further (Adejoro, ibid). Not only can high blood ammonia concentration alter hepatic

metabolism, by increasing ureagenesis and glucose metabolism in the liver and other tissues (Taylor et al., 2009), it can elicit serious effects on growth, as well as on the quality of animal products such as milk, and meat. On the other hand, high dietary tannin inclusion may have significant effect on the immune status of growing lambs and meat quality (Priolo et al., 2000). Haematological parameters as well as serum indices are reliable tools to evaluate the immune status and systemic toxicity in animals, especially serum enzymes which are known to be sensitive indicators of liver or kidney damage (Silanikore et al., 1996). Therefore, this study was designed, to evaluate the haematology and serum biochemical parameters of growing lambs receiving tannin extract supplementation.

Materials and Methods

The experiment was conducted at the small stock unit of the University of Pretoria, Pretoria, South Africa. The experiment was designed as a randomised complete block design. Forty weaner sheep (24 ram-lambs and 16 ewe-lambs) were blocked based on sex and body weight and then allocated to four dietary treatment Six male and four female animals were therefore allocated to each dietary treatment, comprising a total mix ration containing urea or calcium nitrate with or without tannin extract. Tannin extract was included at 46 g/kg feed DM. Animals were fed the respective diets for a total period of 81days comprising of an initial 21days of gradual adaptation of the sheep to the experimental diets, and 60days of continuous feeding and monitoring of growth performance. At the end of the 81 d, 5 ml blood samples were drawn from the jugular vein of each animal into separate serum bottles, for the analysis of serum biochemical and haematological parameters.

Statistical analysis

Data was analysed using the GLM procedure of SAS (SAS Inst. Inc.; Cary, NC, USA). Treatment means were compared using Tukey's test and reported as least significant means and standard error of means. Significant differences were declared when $P < 0.05$.

Table 1: Ingredients and composition of experimental diet

Ingredient	**Urea only**	**Urea + tannin**	**Nitrate only**	**Nitrate+ tannin**
Sunflower meal	16.8	16.1	17.1	16.4
Fine milled maize	27.6	26.4	28.2	27.0

ADF, g/kg DM	196.1	218.9	215.3	195.4

Results and Discussion

Tannin inclusion did not seem to have a significant effect on most of the haematological parameters. Only slight reduction in MCV, coupled with slight increase in RBC distribution width and monocyte count could be associated with tannin inclusion compared to animals without tannin (P=0.08). The result of the serum biochemistry analysis on experimental animals is shown in Table 3. The interaction effect of nitrogen source and tannin inclusion was significant (P=0.05) in blood urea nitrogen (BUN). Tannin inclusion did not have any significant effect on total serum protein, albumin and globulin concentrations in the plasma of the experimental animals. Tannin inclusion significantly affected plasma cholesterol concentrations in the experimental animals (P=0.03). Tannin inclusion did not show any significant effect on BUN or creatinine concentration of experimental animals. Neither nitrogen source, nor tannin inclusion had any significant effect on total serum protein, albumin and globulin concentrations in the plasma of the experimental animals. Tannin inclusion significantly affected plasma cholesterol concentrations in the experimental animals (P=0.03). Lambs on urea+tannin and nitrate+tannin diets had lower cholesterol concentration than animals on urea only and nitrate only diets. Nitrogen source and tannin inclusion did not show any significant effect on Aspartate amino-transferase and Alkaline phosphatase concentrations in the blood of the experimental animals. However, nitrogen source significantly affected Alanine amino-transferase, with elevated concentrations in animals feeding on nitrate diets as compared to animals feeding on urea diet. Similarly, tannin inclusion significantly reduced lactate dehydrogenase concentration in the animals feeding on urea+tannin and nitrate+tannin as compared to the urea only and nitrate only diets.

There was no obvious sign of disease condition in the experimental animals such as scouring, diarrhoea, anorexia, bloat or anaemia. Most of the haematological parameters were within the normal reference range for ovine species. Significant elevation of Hb, and RBC count associated with nitrate supplementation reported in this study is consistent with the report of El-Zaiat et al, (2014) on nitrate supplementation. Increased Hb and RBC count in animals consuming nitrate diets can be associated with a physiological response to mitigate the effect of nitrite on the oxygen-carrying capacity of the blood by increasing the cell numbers to meet reduced capacity. It is widely believed that condensed tannins are not absorbed into portal circulation (Terrol et al., 1994). However, the presence of other phenolics in the plant extract may instigate symptoms other than those associated with CT. Haemogblobin (Hb) is the iron-containing conjugated protein that transport oxygen and carbon dioxide across cells and tissues in the body. The high BUN in this study correlates with high plasma glucose concentration across the treatments although tannin inclusion led to a reduction in glucose concentration. This result agrees with the observation of Taylor-Edwards et al., (2009) who noted that high BUN is usually associated with high serum glucose concentration and occurs as a result of either a reduction in glucose utilization rate, increased net hepatic glucose production or overall increase in hepatic glycogenolysis. BUN have a linear relationship with total N-excretion rate and therefore lack of differences in BUN is an indication that hepatic activity may not impaired (Kohn et al., 2005). BUN and creatinine are indicators of kidney functionality in animals (Olafadehen, 2011). Total serum protein, albumin and globulin, though not significantly different across the treatments, are indicators of the protein status of the animals (Kaneko, 1989). It is unclear what factors could lead to the generally slightly higher ALP levels in the experimental animals compared to the reference values but age of animals have been observed to significantly affect ALP concentrations (Lepherd, 2009), with younger animals usually having higher ALP concentration in their blood. While higher LDH concentration was reported in cattle fed the leaves of tannin-containing oak (Garg et al., 1992), lower LDH concentration in animals feeding on tannin was observed in the current study as compared to the animals without tannin. This may be due to the nature of tannins-hydrolysable tannin versus condensed tannin. The stepwise introduction of the diets and gradual adaptation allows the rumen microbes to stimulate adequate production of nitrate and nitrite reducing bacteria thus reducing the animal's susceptibility to any clinical or sub clinical intoxication (Leng, 2000). These may have also played a significant role in ensuring that the physiological wellbeing of the animals was sustained throughout the experiment.

Conclusion

No clinical or sub-clinical signs of morbidity and tannin intoxication were observed in the parameters evaluated. Slight increase in haemoglobin, haematocrit and RBC count was associated with the use of calcium nitrate instead of urea as an NPN source. Acacia tannin extract and either of urea or calcium nitrate, at the current dose can be fed to growing lambs, without any serous negative consequences.

Abstract
Nigeria is the most populous nation in Africa, with enormous biodiversity. Nigerians relish eating bushmeat, there is practically no ecological zone in Nigeria where bush meat is not consumed. Tropical countries are blessed with several rodent species, they are highly esteemed and an essential income and food protein source for local inhabitants. Especially, cane rat is seen throughout sub-Saharan Africa; its flesh is very popular for domestic consumers. In countries like Nigeria, Ghana, Ivory Coast, Benin, and Togo including some Central African countries, its domestication has been successful. Ebola had come and go, but Nigerians are left with the after effect of the experience. Post Ebola era, an era where the afterwards effect of the disease is felt. This era is characterized by low demand for bush meat, although the trend may reduce as time goes on. Unfortunately, this is the era where grasscutter domestication is tipped to be a tool for poverty reduction and to reduce unemployment in the country. Researchers and civil society organizations have front the advantages of grasscutter domestication and multiplication, but all effort seems to produce little result since low patronage were recorded. Therefore, there is need to revisit the prospects involved and also access the various challenges hindering the success of grasscutter farming in Nigeria.
Key words: Grasscutter, Ebola, Nigeria, Multiplication and Domestication

Introduction

Thryonomys swinderianus, known as Grasscutter or greater cane rat is a Non timber forest product (NTFP) that is tropical in distribution (Unaeze, 2016). Being a non-timber forest product, its contribution to livelihood of rural communities is enormous. Cane rat is found in the tropical forest of Africa. The animal commonly lives among dense grasses mostly along river banks and swamps and are rampant among herbaceous vegetation where there is a good cover. They do not dig burrows like other rats but they hide in holes and scrape a small saucer- shaped depression among the vegetation (Aluko *et al*, 2015). Despite their large size, they run quick and they are known to be good swimmers, living most of their time in burrows and others at ground level. The climatic situation in Nigeria helps them to acclimatize into so many habitats and forests alike. In suitable habitats their presence are commonly known with the 45^{o} cut on the grass stem or by their characteristic feacal pellets scattered on the ground (Aluko *et al*, 2015).In Nigeria, Cane rats contribute to the protein source, provide income and assist poverty reduction of local inhabitants. It is not only eaten in Nigeria it is a choice meat to many households in sub- Sahara Africa. Experts reported the potential importance inherent in domesticated Grasscutter in West Africa (Asibey 1979; Baptist and Mensa 1986; Adedapo and Adekunle 2013). Reports in literatures also show some level of successes in domestication of Grasscutter in Ghana, Benin and Nigeria (Adedapo and Adekunle, 2013).Its meat is believed to look like that of a piglets and its price costs more than a kilogram of chicken, beef, pork or lamb. Its taste, toughness in skin and size also makes it easily acceptable (Adedapo and Adekunle, 2013).Cane rat in captive is reported to be human friendly and its odour is less unfriendly (Benjamin *et al,* 2006). The Ebola disease outbreak in West Africa has been the largest in the history of the disease since its first case in 1976 (Mafunda *et al,* 2016). At the height of the year 2013, Ebola crises hit Africa, and were declared in Nigeria by the Federal Ministry of Health on 24th July, 2014 which marks the inception of Ebola era in Nigeria. On September 23rd, 2014 the federal ministry of health reported a total of 19 confirmed cases, 15 were from Lagos while four cases were reported in Rivers State. A total of 7 deaths were recorded accounting for 40 percent case mortality rate .It had been reported that transmission of EVD to human occurs through contact with dead or living infected animals such as primates (UNICEF, 2014). Pigott *et al,* (2014) summarized the information on ebola virus infection on animals in scientific literature. Stating that species implicated are gorillas (*Gorilla gorilla*), chimpanzees (*Pan troglodytes*), Old World fruit bats (*Epomops franqueti, Hypsignathus monstrosus, Myonycteris torquata, Epomophorus gambianus, Eidolon helvum*) and duikers (*Cephalophus* spp.). Fruit bats were the only species in which the virus was detected (by polymerase chain reaction-PCR) in live animals, and remain the most likely, but still unconfirmed, natural reservoir host for EBV (EFSA, 2014). Despite the yet to be claimed epizootic nature of the disease, news making round was that Ebola was transmitted by bat. Subsequently the widespread of the news resulted into viral information on how the virus supposedly emanates from bushmeat. Consequently, policy and announcement were made on different media and forums that bushmeat were ban from consumption (Ndem *et al*, 2015). This mindset was stamped into the subconscious of many people and negatively affects the marketability and productivity across the bushmeat value chain. 2015 till present (post Ebola era), evidence of this effects were still felt in present times. Bush meat dealers reportedly ran out of business because consumers refuse to patronize them due to fear of contacting Ebola virus (Ese *et al*, 2015). Also, the fear of Ebola negatively affects anyone who had it in mind to start a bushmeat business. Unfortunately, this is an era where Grasscutter is perceived to be a future livestock to provide income and protein to rural and urban settlements that relish bushmeat. In spite the enormous potential in cane rat farming, its acceptance by farmers and its consumers maybe low compared to other established domesticated animals, therefore there is need to explore the prospect and challenges in an era where the fear of Ebola and other zoonotic diseases affects the marketability and meat value of wild and domesticated animals alike.

Ebola and its impact in Nigeria

Pre-Ebola Era

The inception of bushmeat consumption by man can be traced to man's history and marks the beginning of pre-Ebola era; the era ends immediately Ebola virus was announced in Nigeria. This era is characterized by high interest in bush meat consumption and wild animal utilization such as for ethno medicinal purposes. Ajayi (1971) reported that wild animal consumption among rural people in Nigeria's rainforest was 20% of their total animal protein intake compared to the 13% for the whole country. In this era there was little fear or awareness of contacting any disease by eating bush meat. This may be due to little research discoveries along that area. Adeola (1987) reported that 80% or more of the population would eat bush meat irrespective of their ecological zone, tribe or culture. There is low supply of bush meat as oppose to the demand because of the high rate of consumption. In this period, many tribal areas in Nigeria were heavily mounting pressure on wildlife resources and it was feared as at that time that the state of unorganized and uncontrolled exploitation could diminish the remaining game stock rapidly to an unsustainable level. Due to this, fear of extinction grips the mind of advocates of conservation, therefore in this era many conservation measures were established. Among these measures is livestock domestication. This is believed to ease the pressure on the animals in the wild. This era gave birth to the successful domestication of cane rats in West Africa.

Ebola Era

Ebola virus hit Nigeria on July 24th 2014 as declared by the federal government ministry of health and ended 24th September, 2014. Handling and consumption of bushmeat may thus increase a person's risk to fall ill from the disease (Isabel *et al*, 2017).The EVD outbreak has a much wider impact on food security, linked to the effects of measures taken to limit the transmission of the virus. The diseases affect food availability and accessibility (Olawale *et al*, 2016). The resultant effect shows that many households in rural communities whose livelihood depends on bushmeat could not meet up to the feeding and financial needs of their households, thereby depend on cheaper food with less quality nutrients such as cassava with little or no protein sources. This era is characterized by surplus supply but low demand for bush meat, marking the lowest point of bushmeat sales in the history of the nation. Consequently, many bushmeat business owners completely fold up. This trend continued during and immediately after the outbreak. Media played some roles in spreading the news, therefore helping in bushmeat perception shift. The assumption is that even when bushmeat is touched they can easily contact the deadly virus.

Post Ebola Era
This era began immediately Nigeria is declared free from Ebola virus. At the inception of this era, the sale of bushmeat was still affected by the just curtailed Ebola virus. A year after the outbreak, Oyediran *et al,*(2015) stated that before the EVD outbreak, 37.14% of the respondents had more than 50 customers while patronage reduced to less than 25 (50%) customers in a day after EVD outbreak. Similarly, 42% of respondents had more than ₦21,000 in a day before EVD outbreak as against less than ₦5,000 in a day after the outbreak. The implication of this is that the return gotten from bush meat businesses may have reduced due to the outbreak. Therefore, in the post-Ebola era, there are lower sales of bushmeat than the pre-Ebola era. Also the beginning of this era is saddle with lower bushmeat patronage but this trend may reduce overtime. In a survey conducted after Ebola outbreak, 85.5% of the respondents were wary of the Ebola virus irrespective of their educational, revealing that people are still conscious about the disease. World wildlife fund (WWF, 2014) reported that in spite of the pre scare of Ebola, hunting of wild animals for bushmeat business is still going on significantly in parts of Nigeria. Evidently, on March 29, 2016, an estimated 10,000 local hunters from the northeast of Nigeria gathered in Adamawa state for annual oath taking festival, the festival witness a large amount of fish killed. This era is also characterized by increase awareness by researchers and consumers of bushmeat on different zoonotic diseases.

Grasscutter multiplication and domestication in Nigeria

Grasscutter is locally known as OYA in Yoruba land, NCHI in Igbo land, the Urobo or Isokos calls it UDI, the Ijaws call it IKIRI and IZAY by the Igbirras, EVUATOR by the Benin's, EMI in Igala land and UNAM-UKOT by the Efiks/Ibibios. Animals are often domesticated for many reasons, according to Zeder (2012), over the past 11,000 years; wild animals are domesticated as livestock, working animals, household pets, and companions. The directions that different animal species followed into domestication are remarkably different, shaped by biological constraints and opportunities that the animals brought into domestication, as well as by the different cultural contexts of their human partners. Several reasons were reported by researcher for domesticating Grasscutter, some believed that the meat provide protein supplementation and income generation (Benjamin *et al,* 2006; Yeboah, 2009), others believed domesticated animals are alternative to poached animals (Zeder,2012: Ijeomah *et al,*2016). Cane rat have two species belonging to the genus *Thryonomys*. These are: *Thryonomys swinderianus* known as greater Cane rats which are found in Africa South Sahara, and *Thryonomys gregorianus* known as lesser cane rats found in Cameroon, Southern Sudan, and Zimbabwe (Okarafor *et al,* 2012).The native giant grasscutter, *Thrynonomys sinderianus*, is a bushmeat species that is a prime candidate for commercial farming given its size, habitat preferences, high market price, and current consumption rate (Menz, 2014). Nigerians consume only about a quarter of the minimum daily animal protein requirement which is on the low side (Abulude, 2007). Its domestication is being encouraged in West Africa to help address the problems of exploitation through aggressive hunting, provide alternative source of income for farmers and increase farmers' access to and utilization of animal protein for dietary needs.

Prospects of grasscutter multiplication and domestication
Meat quality
Grasscutter domestication generally has been tipped as an agent for economic development and to reduce unemployment (Aluko *et al*, 2015). But the Nigerian populace is yet to explore the benefit of Grasscutter farming. Grasscutter (*Thryonomys swinderianus*) is an important source of meat and is acknowledged to be the preferred meat virtually throughout West African Sub-Region, thereby opening doors for potential exportations if adequately processed and packaged. The meat of Grasscutter is of higher price per kilogram weight than chicken, beef, pork, mutton or chevon among many West Africans and elsewhere (Adu *et al*, 2017). The meat bone ratio of grasscutter meat is higher than that of beef. Compared to other meats such as rabbit meat, Grasscutter meat is very low in cholesterol and high in protein, evidently, it is high in mineral such as iron, calcium and phosphorous (Adu*et al*, 2017), suggesting that it can serve as protein supplement for Africans. Also The economic return on rearing is comparable to that of a cow, much higher than most livestock species, and only lower than that of the pig (Adu*et al*, 2017).Meat fat content of Grasscutter include many types of lipids, but has triglycerides as the main components, phospholipids and cholesterol, with the phospholipids component being relatively constant compared to the triglycerides and cholesterol (Hernández and Gondret, 2006). Often people claims that there are different in nutrient content and palatability between the meat of grasscutter reared in the wild compared with the domesticated, result from the research by Asuk *et al*, (2017) reveals that the meat crude protein, calcium, phosphorus, iron content were higher in the grasscutter caught in the wild. Also, wild grasscutter meat was reported to be more palatable than the captive one. Therefore, nutritional quality of the feed should be improved upon in other to balance up the meat nutrient and increase the palatability of the meat.

Ethno-medicinal uses
Grasscutter plays an important role in traditional African medicine for preparation of concoctions for fertility. The hair of the animal is used to season food just as much as its stomach and intestine contents. The pancreas of the grasscutter contains a high concentration of insulin which is used for local preparation for the treatment of diabetes (Bello *et al*, 2012; Aluko *et al*, 2015). Organs such as brains, blood, urine and others can be used to produce some medicines, intact grasscutter faeces is reportedly used has enema to prevent weight lost.

Economic Prospects
Thryonomys species are intensively hunted and domesticated as an important source of protein in Nigeria and west Africa. it has been ascertained that grasscutter contributes to both local and export earnings (Bello *et al*, 2012). Olayemi, (2012)it is estimated that 80million are harvested annually, equaling 300,000 metric tons of meat in west Africa. To increase meat availability, cane rats have been domesticated and efforts have been made by government and civil societies to increase production and marketability. An increase in number of animals from 35 to 243 before sales is about 600% increase within a period of one year (Ijeomah *et al*, 2016). Ijeomah *et al*, (2016) also revealed that good management is key to the marketability of grasscutter business. For instance, cane rats are sold in families of 5 (that is one male and four females) in Songhai (Ijeomah *et al*, 2016), One family is sold for ₦45,000 while a single male adult is sold for ₦4,500 (3kg). Synchronizing the breeding ensures that many breed in a month assists the management of Songhai farm to provide many families in a month. This is done as an attempt to satisfy buyers who will need many families of same or close age range. This enables the farm to generate revenue in bulk. For instance, selling of 40 families (at the rate of ₦ 45,000) and 16 males adult in April, 2015 generated a total of ₦1,872,000 for the farm. The high breeding rate and huge profit made from grasscutter in Songhai farms ensures that if proper management is put in place there is high prospect for grasscutter farming and marketing in Nigeria. In addition, Benjamin *et al*, (2006) conducted a break-even analysis of scale grasscutter farms in Ibadan Oyo state Nigeria; he found that with

improved management skills, a small scale farm could break even after the fourth year in business or earlier.

Conservation Prospect

Unsustainable poaching of wild animal for bushmeat and other uses is endemic in Africa. This has caused some animals to go into extinction and to others their population is greatly threatened. Some methods have shown prospect reducing this trend, among which is domestication of wildlife in captive. Although grasscutter population is categorized among the least concern status on the IUCN red list, grasscutter domestication will help to reduce pressure on the population of the animal in the wild. Other advantage of keeping this animal in the wild includes helping to reduce zoonotic disease from the wild. Continued hunting of bush animals with dogs and bush burning have environmental consequences of which continued domestication will help in reducing (Opara, 2010). In contrast as oppose to many reports in literature, a scarce presence of a particular bush meat in the market does not depict the true population in the wild. In fact when large mammals are heavily harvested and it becomes much more difficult to hunt them, there is a shift of sold animals from preferred marketable large-bodied species with low reproduction rate, to smaller-bodied species with higher rate of reproduction. Overall, this shift has been interpreted as an indication that the harvesting is unsustainable.

Challenges of domesticating wildlife

Grasscutter as being put forward as a model animal for poverty alleviation in Nigeria, despite its enormous advantages, there are some challenges that is needed to overcome. Insufficient information on basic production parameters such as the animal's biology has translated into poor productivity (Adu *et al*, 2017). Benjamin *et al,* (2006) highlighted the following as the major constraints in grasscutter domestication in Ibadan ;high initial capital, stock procurement, time constraint, inadequate medical attendant, disagreement with landlords over space to rear grass-cutter and inadequate follow-up by extension services(Benjamin *et al*, 2006). Ogunjobi and Inah, (2008) ranked the constraints from the most severe to least as follows; lack of capital, insufficient feed, disease, housing, lack of enough land, handling and lack of knowledge of rearing grass-cutter. Other challenges of grass-cutter include irregular stock supply, environmental issues, processing and marketing, feeding, producer's training and education, infrastructure development, poor information dissemination and disease/mortality. However, survival of grasscutter in captives depends on solving the following issues;

Reproductive competency

For survival there is need to produce, grasscutter often do this excellently in the wild to maintain its population in a particular ecosystem judging by the IUCN ranking, however under captivity, productivity is judged by how many offerings they hence there is tendency to want them produce more than when they are in their natural environment. Currently, mating of grasscutter is natural under captivity and may cause injury or even mortality to the females. Artificial insemination as being proposed to be an alternative, but it requires harmonization of estrous in the flock to ensure efficiency (Adu *et al*, 2015). Techniques such visual cue achieved by placing female grasscutter close to the male could increase the vaginal Capacity which is a sign of oestrus in most Rodents (Nyameasem *et al*, 2015).

Nutritional constraints

The domestication of cane rat has its own teething constrains, which include the need to provide regular supply of feeds rich and balanced in nutrients. It has been observed that grasscutter prefer grasses such as elephant grass, fresh maize husk, sugar cane, guinea grass with succulent stalk which may not be readily available (Akinola *et al*, 2014). In captivity therefore meeting this nutritional requirement may not be achieved by the farmer hence productivity will be low. Adu *et al*, (2017) stated that the poor reproductive performance of the grasscutter in captives can partially be attributed to the poor understanding of the nutritional physiology of the animal. Food availability can also be link to seasonality of the country; forage during the dry season may not be available or may have depreciated in value. Hence, attempt should be made in developing compounded feeds which will be rich in nutrients and the same time can be found all year round.

Diseases and mortality

Disease is one the key factor limiting livestock production. The profit margin and the viability of the business depend greatly on disease management. A single disease may cause total mortality in some livestock. High disease prevalent is associated with high neonatal mortality in livestock (Akinnola *et al*, 2015). Severity of disease in livestock has also being linked with poor nutritional quality (Opara and Fagbemi, 2009). Poor management practices have been linked to increase in disease, William *et al*, (2011) reported that more grasscutters died when they were housed in iron cages at the beginning of farm operation than when they were housed in block-cement pens. Diseases associated with grasscutter includes pneumonia, intestinal helminth, trypanosomes (although no clinical signs), others includes ectoparasites such as flea (*Xenopsyla* spp) and ticks (*Rhipicephalus simpsoni, Ixodes aulacodi, Ixodes sp* and *Haemaphysalis parmata*), other parasites such *Heterakis* spp and *Hymenolepis* (Akinola *et al*,2015).It is interesting to note that the grass cutter had not been traced to harbor pathogens that can affect humans. Ebola virus disease for example, had been traced to chimpanzees, gorillas and bonobos and may spread to humans when the meat is handled or consumed (Akinola *et al*, 2014).

Conclusion

Cane rat if properly managed and improve open is capable of meeting the protein requirements and reduce unemployment problem in Nigeria. Despite its numerous prospects, its domestication is not devoid of some challenges. In this era (post Ebola) effort is needed to encourage farmer who are interested in farming/ domesticating grasscutter in form of training and awareness to get the needed techniques required to be successful in the business. Grasscutter is not known to transfer any serious disease to man, but the perception that eating bush meat may transmit disease to man may affect its marketability and patronage. In other to reduce this, public enlightenment should be encouraged to tell people about the advantage of having a grasscutter farm.

Abstract
Studies were conducted to determine the response of broilers fed palm kernel meal (PKM) based diets with or without enzyme (Anazyme Forte®) supplementation. One hundred and forty four 7 day-old Anak (unsexed) broiler chicks were randomly divided into six groups of 24 birds each. The design of the experiments was in a 3 x 2 factorial in a completely randomized design (CRD). The test ingredient, PKM was at three levels (20, 30 and 40%) of the diet while the enzyme was at two levels (0 and 0.5%). Each treatment was replicated three times with 8 birds per replicate. Birds were fed feed and water ad libitum. Results showed that enzyme supplementation significantly ($p<0.05$) increased final body weight (FBW), daily body weight gain (DWG), protein efficiency ratio (PER) and decreased daily feed intake (DFI), feed conversion ratio (FCR) and daily protein intake (DPI). FBW, DWG, PER decreased and DFI, FCR, DPI increased with increase in the levels of PKM. There were no significant ($p>0.5$) mortality among the birds .Also there was no interaction between PKM and enzyme. It was concluded that PKM could be included in the diet of broilers up to 30% without enzyme supplementation and up to 40% with enzyme (Anazyme Forte®) supplementation without adverse effect on performance of broiler.

Introduction
Inadequate feeding and poor management practices are some of the major problems affecting animal production in developing countries like Nigeria. The high cost of production of cereals, which constitute the major source of energy in poultry diets has necessitated the search for alternative ingredients to replace wholly or partially these cereals. Animal nutritionists are challenged every day to assess the nutritive value of feedstuffs available in their communities and to propose the possible combinations of these feedstuffs in complete feeds that meet the nutrient requirements of livestock at a reasonable cost. ,Feed alone accounts for up to 70 - 80% of the total cost of broiler production and adequate nutrition is one of the major inputs necessary for the full expression of the genetic potentials of poultry, and the prevention of stress (Adene, 1989). Poultry production is one of the most economic routes for producing high quality animal protein within the shortest possible time for the rapidly increasing human population across the world, especially in Nigeria. This is because of their short generation interval and the intensive method of production, which allows high stocking density. Poor productivity and high mortality of poultry is largely explained by the inadequacy of feeding the right quantity and quality of feeds when diseases are eliminated. Consequent to these feeding problems, research efforts over the years had attempted to increase the use of cheap agro-industrial by-products like palm kernel meal (PKM), wheat offal (WO), rice bran (RB), brewer's dried grain (BDG), maize milling by-product, and maize offal (MO) (Onwudike, 1988). The use of non-conventional feed ingredients in broiler diets is expected to worsen the effects of anti-nutrients on broiler performance and nutrient excretion into the environment. One of the key technologies that could help address this

challenge is the use of appropriate enzymes. The enzyme technology has progressed a great deal over the past years with respect to efficacy and matching activities with their target substrates. For example, β- glucanases and xylanases for degradation of the β-glucans and arabinoxylans in barley, oats, wheat, rye and triticale have proven efficacy in enhancing the nutritive value of these grains for poultry (broilers in particular). The benefits of using enzymes in monogastric diets include not only enhanced growth performance and feed conversion, but also fewer environmental problems due to reduced output of excreta. Poultry do not have the endogenous enzymes necessary for breaking down of non-starch polysaccharides (NSPs). Enzymes have been approved for use in poultry feed because they are natural products of fermentation and therefore pose no threat to the animal or the consumer (Vukic Vranjes and Wenk, 1993). Their use in poultry feeds has been related to the hydrolysis of fiber or non-starch polysaccharide (NSP) fraction of cereal grains. These NSPs cannot be digested by the endogenous enzymes of poultry and could have anti-nutritive effects. They cause an increase in viscosity of intestinal content and entrap large amounts of digestible nutrients like starch and proteins. The use of commercial feed enzymes in livestock feeding has opened a new horizon for the use of hitherto waste feedstuff. Results of experiments (Atteh, 2000) showed that with the use of a bacterial xylanase enzyme, it was possible to replace 50% of maize with wheat offal without detrimental effect on broiler performance. The present study therefore was to determine the effect of dietary levels of palm kernel meal (PKM) and enzyme (Anazyme®) on the growth performance of broiler chicken.

Materials and Method

This study was conducted at the Poultry Unit of the Teaching and Research Farm of Michael Okpara University of Agriculture, Umudike, Abia State. The palm kernel meal and other feed ingredients used in the study were procured from Umuahia main market, Abia State .One hundred and forty four Anak breed 7 day-old chicks were randomly divided into 6 groups of 24 birds each. The groups were randomly assigned to 6 diets containing three levels of PKM (20, 30, and 40 %) and two enzyme levels (0 and 0.5 %) . The design of the study was completely randomized design in a 3x2 factorial arrangement consisting 6 treatments with or without enzyme. Each treatment was replicated three times with 8 birds per replicate. Feed and water were supplied *ad libitum* on deep litter system of management for the study period of 7 weeks. Feed intake was recorded daily and birds were weighed weekly. Data on feed conversion ratio, protein efficiency ratio and mortality were recorded. The chemical analysis of the proximate compositions of the experimental diets were determined according to the procedure of A.O.A.C.(1990). Data collected were subjected to analysis of variance (Steel and Torrie, 1980). Means with significant difference were separated using Duncans New Multiple Range Test (Duncan, 1955).

Results and Discussion

The proximate DM percentages of the diets ranged from 90.17 to 90.70 and followed no trend (Table 1). The CP (%), CF(%), EE(%) ash content varied between enzyme levels and increased with increasing levels of PKM. The NFE(%) and gross energy varied between enzyme levels but decreased with increasing levels of PKM. The proximate results for diets supplemented with enzyme were higher than those without enzyme except DM(%) which has slight deviation in diet 3. The effect of level of enzyme supplementation on the performance of broilers is presented in Table 2. The final live weight (FLW), daily weight gain (DWG) protein efficiency ratio (PER) of birds fed dietary PKM based diet with enzyme supplementation were significantly ($P<0.05$) higher than those fed diets without enzyme supplementation. The daily feed intake (DFI), feed conversion ratio (FCR) and daily protein intake (DPI) of birds fed enzyme supplemented PKM diets were relatively lower than those fed diets without enzyme supplementation. Varying levels of dietary PKM had significant ($P<0.05$) effect on the final live weight (FLW), daily weight gain (DWG), daily feed intake (DFI), feed conversion ratio (FCR), daily protein intake (DPI), and protein efficiency ratio (PER) . The FLW, DWG and PER had inverse relationship with inclusion level, thus decreasing with increasing rate of PKM level. On the other hand, average DFI, FCR and DPI were increasing with increasing rate of PKM level. There were no significant ($P>0.05$)

interaction effect between enzyme supplementation and PKM levels on all the parameters studied (Table 3). The FLW of birds fed 20% and 30% enzyme supplemented palm kernel meal diets were significantly ($p<0.05$) similar ; but birds fed 30% enzyme supplemented dietary PKM were similar to those fed 20% PKM diet without enzyme .DWG of birds fed enzyme supplemented diets (20, 30 and 40%) were similar and, in the same manner they were similar to birds fed 20% PKM diet without enzyme. Daily feed intake (DFI), feed conversion ratio (FCR), daily protein intake (DPI) and protein efficiency ratio (PER) of birds fed enzyme supplemented PKM were better than those fed PKM diet without enzyme. Generally, there was reduced ($P>0.05$) performance as the inclusion level increased. These variations in the performance traits indicate that the effect of PKM levels in the diets depended on the enzyme levels. The improved final live weight, DWG, DFI, FCR, DPI and PER in the birds fed enzyme supplemented diets relative to those on diets without enzyme supplementation, was due to enzyme effect as reported by Choct (2006), who stated that when enzymes are added to high fiber monogastric diets, they cause the degradation of β- mannan and 70% NSPs into soluble metabolizable products for monogastric. Feed intake was decreased in the enzyme supplemented diets compared to diets without enzyme. Ezieshi and Olomu (2004) reported higher feed intake in birds fed PKM. In similar study Atteh (2000) and Esuga *et al.* (2008) separately observed improvements in weight gain and FCR in birds fed enzyme supplemented diets. Our results have shown that enzyme supplementation of PKM based diet caused an enhanced performance in the birds. Similar, results have been reported by Iyayi and Tewe (1998) in layers, Iyayi and Adegboyega (2004), in broiler. The observed increase in feed intake by birds that consumed the diets without enzyme supplementation suggests that the birds wanted to meet their nutrient requirements and the observed decrease in feed intake by birds that consumed enzyme supplemented diets could be attributed to the enzyme. The observed decrease agreed with the findings of Ani and Omeje (2007), that enzyme supplementation of poultry diets results in decrease in feed intake. This could be attributed to improved energy availability and utilization for the growth of poultry (Aboosadi *et al*., 1996). The birds therefore, tend to consume less amount of feed when their nutrient requirement has been met. However, the results contradict the findings of Augelovicova and Michalik (1997) that the addition of enzyme to the diets of poultry resulted in increased feed consumption. The incremental levels of inclusion of PKM affected most of the performance indices of broiler significantly ($P<0.5$). A possible explanation for the reduced final live weight, DWG and PER as level of inclusion of PKM increased could include higher total intake of higher fiber diets. Fiber has been considered as a nutrient diluent in broiler diets that does not affect digestion and absorption of nutrients (Edwards, 1995), however, that observation is only reported for moderate levels of fiber (Hetland and Svihus, 2001). Higher fiber concentrations in chick diets can have negative effects on nutrient digestion and absorption (Krogdahl, 1986) and may subsequently affect performance as seen in FLW, DWG and PER responses of the broiler chicks in the current study. Similar observation had earlier been reported (Apata and Ojo 2000). Increasing dietary PKM to 40% level resulted in increased values for DFI, FCR and DPI. This depression in these growth indices could be due to high fiber diet and the need to obtain the necessary nutrients by consuming more feed. A possible explanation to the significant ($P<0.05$) decrease in DWG as PKM level increased for birds fed diets without enzyme supplement could be attributed to decrease in digestibility and utilization of the diets emanating from the high-fibre contents. Ajaja *et al.* (2003) has observed that high fibre content of diets decreased nutrient utilization and result in metabolic dysfunction with the attendant weight reduction in monogastric animals. The birds fed the high fibre diets could have utilized most of the available nutrients for maintenance purpose and channelled less nutrients for growth hence the observed depressed growth. On the other hand supplementation of the diets with enzyme resulted in significant ($P<0.05$) improvement in weight of the birds over the birds fed diets without enzyme supplementation. Iyayi and Tewe (1998) reported similar results in layers. Iyayi and Adeboyiga (2004) in broilers. Such enhanced weight gain could be attributed to improved digestion and utilization of NSPs in dietary fibre due to enzyme inclusion. Birds fed diets without enzyme supplementation had the highest feed intake in chickens is inversely related to dietary energy concentration. Increase in dietary fibre level is known to result in decrease in dietary energy level of the diets (Kung Macdonald *et al.,* 2002). Since birds eat to satisfy their energy requirement (Jurgens, 2007), birds fed high level dietary fibre had to consume more feed than other birds in order to meet their energy requirements.

Conclusion

The results of this study showed that PKM can be used up to 30% in broiler diet without enzyme supplementation and up to 40% with enzyme (Anazyme Fort®) without adverse effect on the growth performance.

Abstract
The study was conducted to determine the proximate composition and amino acid profile of Cassia obtusifolia seed meal as an alternative plant protein source in poultry diets. Triplicate samples from the raw, boiled, fried and autoclaved were milled into powder. Dry matter, ether extract, crude fiber and ash were determined while the carbohydrates contents were calculated. Proximate composition results showed high dry matter range value of 95.24 to 96.56 %. Crude protein values of 16.54, 17.03, 17.27 and 17.78 % obtained for boiled, fried, raw, and autoclaved cassia obtusifolia, while the crude fiber values of 18.40, 21.42, 21.52, and 22.92 % for autoclaved, fried, raw and boiled samples respectively. The Nitrogen free extract (NFE) values recorded in this study are 45.93, 50.88, 53.33 and 54.83 % for boiled, fried, autoclaved and raw Cassia obtusifolia seed respectively. The ash contents were 3.14, 4.16, 3.39 and 3.39 for autoclaved, boiled, fried and raw Cassia obtusifolia seed meal. The amino acid profile reveals that the seed subjected to autoclaving, boiling, roasting had amino acids contents lower than raw except for alanine, valine which recorded higher values when the seeds were boiled. It was generally observed that amino acid contents were slightly reduced as a result of processing methods employed. The amino acid (g/100g protein) composition of the raw and differently processed Cassia obtusifolia shows that Leucine was the most concentrated essential amino acid (6.27 g/100 g to 7.50 g/100 g crude protein, while Glutamic acid was the most concentrated amino acid (11.01 g/100 g protein) in the raw Cassia obtusifolia. The least concentrated amino acid was Methionine (0.81g/100 g protein to 1.01g/100 g protein recorded in this study. In conclusion, Senna obtusifolia seed meal contains appreciable quantities of nutrients and amino acids but is limiting in Phenylalanine, methionine, cysteine, histidine and lysine when compared to the established standard by FAO therefore, its use as plant protein with other feed ingredients rich in the limiting amino acids to feed poultry is recommended.

Introduction
Global food security is high on the development agenda; some estimates anticipate that a 50 to 70% increase in food productivity will be needed by 2050 to feed additional two billon people (Ingram *et al*., 2010). This is especially crucial for developing countries, where the problem of feeding poor people have been highlighted. With the anticipated population growth, urbanization, and income growth, especially in Nigeria, huge increase in demand for animal source food is envisaged; this demand will place enormous pressure on the global food system. To attain this goal, cheap sources of feed ingredients may be the best option as feed constitutes 70-80% cost of production in livestock industry (Ingweye *et al*., 2010). In the recent years, there has been a gradual increase of interest in the use of non-conventional plant protein sources that are considered safe and without any adverse side effects for use in poultry diets. Thus a search for new feed ingredients with better and cheaper substitutes for conventional feed ingredients is a natural choice. Evaluation of feed ingredients for quality is essential for providing information

on their composition as well as their suitability for poultry. Therefore before adoption of a given feed resource in livestock feeding, preliminary tests for its composition, nutritional value and health implications of its consumption are essential *Shivprasad et. al. (2012*). The exhaustive literature survey reveals that there is scanty information on proximate composition and amino acid profile of *Cassia obtusifolia* seed meal hence this work had been carried out.

Materials and Methods

Study Area

Proximate compositions were determined at Animal Care Laboratory, Ogere, Iperu, Remo, Ogun State Nigeria while the amino acid profile were determined at the biological Laboratory, University of Jos, Plateau State.

Source of *Cassia obtusifolia* seeds

Mature seed of *cassia obtusifolia* were harvested in the month of October around Maiduguri Metropolis Borno State, Nigeria. The pods containing the seeds were properly dried and threshed to obtain the seeds that were used for proximate analysis and feeding trials.

Processing of *Cassia obtusifolia* seed

The seed samples were thoroughly cleaned and sorted to remove extraneous materials. They were divided into five (5) batches each of 100 g. The seeds were processed as follows:

(i) **Raw seed:** cleaned seeds were sun dried for 72 hours and milled into powder using laboratory blender to pass through a 1mm sieve screen and tagged as RCOSM.
(ii) **Boiling:** seed samples were boiled in distilled water in the ratio of 1:10 w/v at a temperature of 100^0 C for 30 minutes, sun dried for 72 hours and milled using a attrition milling machine to obtain a particle size of 1mm mesh size, sample was tagged as BCOSM.
(iii) **Roasting:** seed samples were roasted using Aluminum pot for 30 minutes. The seeds were removed and left to cool and later milled using the attrition machine to obtain 1mm particle size. Sample was tagged as FCOSM
(iv) **Autoclave:** the seed samples were autoclaved at a pressure of 15 lb (125˚C) for 30 minutes after which the seeds were dried and milled to 1 mm mesh size and tagged as ACOSM.

Proximate Composition Determination

The seed meal was analyzed in triplicate for crude protein, crude fibre, ether extract and ash while nitrogen free extract was calculated. This was done according the methods of AOAC (1990).

Determination of Amino Acid Profile

Amino Acid Profile Determination.

The amino acid profile of *Cassia obtusifolia* seed meal was determined using methods described by Spackman *et al*. (1958). The sample was dried to constant weight, defatted, hydrolyzed, evaporated in a rotary evaporator and loaded into the Technicon Sequential Multi-Sample Amino Acid Analyzer (TSM) using ion-exchange chromatography (Technicon Instruments Corporation, Dublin, Ireland). The analysis was carried out at the analytical laboratory of the department of biological Science University of Jos. Amino acid values were calculated from chromatograph as described by Spackman *et al*. (1958).

Results and Discussion

Proximate composition

The proximate composition of raw and processed *cassia obtusifolia* seed are shown in Table 1. The crude protein values of 16.54, 17.03, and 17. 27 and 17.78 % obtained for boiled, fried, raw and autoclaved *cassia obtusifolia* seed, this is similar to 18. 46 and 19.4 % reported by (Fetus *et al*., 2010), (Ismaila *et al*., 2011) but lower than 21.4, 29.54, 20.3, 21.89 and 24 % obtained and reported by Ingweye *et al*, 2010; Agbo, 2004; Augustine *et al*. 2014; Vadivel and Janardhanan, 2005; Adjouji, 2005. The variation may be due to differences in geographical location, soil factors, and effect of climate changes. The least value of 16.54 % obtained in *cassia obtusifolia* seed subjected to boiling method of detoxification may be attributed to leaching of nutrient due to boiling. The decrease in crude protein value as a result of boiling is in line with observation of earlier report by Akinmutimi and Onwukwe (2002). This however, did not agree with findings of Audu and Aremu (2011) who reported an increase in crude protein value of red kidney bean subjected to boiling. The dry matter values obtained ranged from 95.24 to 96.56 %. These values were higher than values of 92.49 to 92.50, 93.2 % obtained for *Cassia obtusifolia* seed (Ingweye *et al*., 2010, Vadivel and janardharan, (2005). Similarly, these values were higher when compared to the values reported for sword bean (63.6 %), lima bean (65.8 %), African yam bean (70.33 %), pigeon pea (68.8 %), Jack bean (69.4 %), Bambara Groundnut (67.5 %) and Soya bean (67.3 %) (Festus *et al*., 2010), but similar to 96 % reported by Ismaila (2011). High dry matter content is valuable asset in storage and preservation. The crude fiber values of 18.40, 21.42, 21.52, and 22.92 % obtained in this study was not in conformity with earlier reports of Ingweye *et al*, (2010), Ismaila (2011), Festus *et al*, (2010) and Augustine *et al*, (2014) who reported crude fiber values of 10.18, 5.2, 6.80 and 12.45 % for raw *Cassia obtusifolia* seed. Though crude fiber does not contribute to the nutritive value of food, the presence of fiber in diet is necessary for digestion and for efficient elimination of waste. The crude fiber value fell within the world health organization (WHO) recommendation of 22 to 23 g/1000 kcal of diet. The high fiber level could be due to the tough seed coat. Nitrogen free extract (NFE) values recorded in this study are 45.93, 50.88, 53.33 and 54.83 % for boiled, fried, autoclaved and raw *Cassia obtusifolia* seed. These values are lower compared to 68.54 % figure reported for *Cassia obtusifolia* seed (Ismaila *et al.*, 2011) and comparable to 46.77 % reported by Ingweye *et al.* (2011). It also compares well with the values of 44.6 to 47.4 % of different varieties of sesbania seed reported by Huisian and Tolman (2001) and 43.3 to 60.3 % reported for Jack bean (Ajah and Madubuike, 1997). The values of nitrogen free extract and ether extract are indicative that *Cassia obtusifolia* can also be used as energy feed stuff for livestock especially monogastric. The ether extract value recorded in this study was lower than values of 7.4 % (Vadivel and Janardhanan, 2005), 7.0 % (Abdalbasit, 2008) obtained in similar studies for *Cassia obtusifolia* seed, but similar to values of 3.6 , 3.3 and 3.1 %, for Sword bean, Jackbean and African Yam bean (Festus *et al*. 2010). The Ash content of 3.14, 4.16, 3.39, and 3.77 % for autoclaved, boiled, fried and raw *Cassia obtusifolia* seed recorded in this study was comparable to value of 3.70 % (Ingweye *et al*., 2010). The Ash content is within 2.7 % to 5.1 % range found in literature for legumes that served as food sources of minerals.

Amino acid profile

The data on amino acid profile are presented in Table 2. The Phenylalanine content recorded in this study ranged between 3.70 g/100 g to 4.56 g/100g protein. These values are comparable to values 4.6 g/100g protein for raw kidney bean seed (Audu and Aremu, 2005) and 4.50 g/100 g protein reported by (Ingweye *et. al*., 2010) for raw *Cassia obtusifolia* seed. On the contrary it was higher than 2.8 g/16 g FAO reference value and lower than 5.6 g/16 g reported by Mubarak (2005) for Mung bean seed. Leucine was the most concentrated essential amino acid (6.27 g/100 g to 7.50 g/100 g crude protein, while Glutamic acid was the most concentrated amino acid (11.01 g/100 g protein) in the raw *Cassia obtusifolia*. This finding corroborates with earlier report of Audu and Aremu (2005) who reported Leucine and Glutamic acid values of 7.2 g/100 g to 8.2 g/100 g protein and 10.2 g/100 g protein in raw red kidney beans. The value of leucine obtained in this study agrees and compares favorably with values obtained by some workers on studies of some Nigerian legumes Lima bean (7.5 g/100 g protein, African Yam bean (7.45 g/100 g protein reported by Oshodi *et al*. (1998). to the raw seed. This slight reduction could be due the transamination and deamination reaction in processed *Cassia obtusifolia* seed. This finding agrees with earlier report of Uko and Kamadu (2008) who reported reduction in values of leucine and lysine in Neem kernel subjected to heat treatment. The reduction in amino acid values of *Cassia obtusifolia* seed subjected to different processing methods will require supplementation with essential amino acids such as Methionine, Cysteine and Lysine. The least concentrated amino acid was Methionine (0.81g/100 g protein to 1.01g/100 g protein recorded in this study. Boiling method in this study enhanced the values of Alanine and Valine from 3.94 g/100 g to 4.07 g/100 g protein and 3.71 g/100 g to 4.0 g/100 g protein respectively. All other amino acids investigated in this study were slightly reduced as a result of processing compared.

Conclusion

It was generally observed that amino acid values of the test ingredients were reduced slightly as a result of processing. The reduction in amino acid values of *Cassia obtusifolia* seed subjected to different processing methods will require supplementation with essential amino acids such as Metionine, Cystine and Lysine. Nitrogen free extract values of the test ingredients in this study, indicates its potential as energy source.

Abstract
A 65-day study was conducted on sixteen (16) rabbit bucks, aged 10–11 weeks to investigate the effect of four levels of Moringa oleifera crude leaf extract (MOCLE) on their growth performance and gut morphometry. Four (4) rabbits each were randomly assigned to 4 treatments in a completely randomized design and each rabbit served as a replicate. The treatment groups each received a basal diet and 4 levels of MOCLE per litre of drinking water designated as follows: 0 ml (T1), 250 ml (T2), 500 ml (T3) and 750 ml (T4). Feed intake (FI), water intake (WI), total weight gain (TWG), final weight (FW), and feed conversion ratio (FCR) were determined. At day 65 of the trial, the rabbits were sacrificed, eviscerated and the gastrointestinal tract (GIT) morphometry were determined to include the lengths (cm) and weights (g) of the oesophagus, stomach, small intestine, caecum and colon. FW and TWG differed significantly (P < 0.05) and T4 (750 ml MOCLE) produced the highest FW (2206.25 g) and TWG (812.50 g) values. FI and FCR were similar (P > 0.05) across the treatment and ranged from 51.88 – 60.40 g/d and 4.82 –5.57 respectively. WI decreased as the levels of MOCLE increased with T1 (595.25 ml) recording the highest value followed by T2 (392.25 ml), T3 (364.13 ml) and T4 (282.25 ml) respectively. All the GIT morphometry of the rabbits studied did not vary significantly (P > 0.05). In conclusion, the 250 – 750 ml levels of MOCLE supported better weight increments in rabbits and did not cause marked changes in gut measurements. Therefore, the inclusion of the 750 ml level of MOCLE in the drinking water of rabbit bucks is well tolerated and recommended for increased growth response.

Introduction
The advent of incorporating various plant extracts in animal feeding trials has over the years witnessed increased exploitation due to numerous health benefits which are well documented. *Moringa oleifera* Lam. is one of such plants that have received attention due to its nutritional and medicinal properties that abound in literature. The leaves of *Moringa oleifera* is rich in proteins, vitamins, minerals (Pandey *et al.*, 2012) and potent antioxidants (Yang *et al.*, 2006); the fresh leaves contains 76.53 % moisture, 27.51 % crude protein, 19.25 % crude fibre, 2.23 % ether extract, 7.13 % ash, 43.88 % carbohydrates and 1296 KJ g^{-1} ME (Oduro *et al.*, 2008). The leaves also contain essential amino acids at levels that are similar to soya beans (Ferreira *et al.*, 2008). The positive effect of *Moringa* leaves in the form of leaf meals has been previously demonstrated on the growth performance of rabbits (Kpodekon *et al.*, 2009; Nuhu, 2010; Dougnon *et al.*, 2012). *M. oleifera* leaf extract has found extensive use in pharmacological studies mainly carried out on rats, mice and rabbits as animal models. The recognized methods of obtaining these extracts (soxhlet, decoctions, alchoholic etc) often require standardized procedures which limit their ease of adoption. In spite of the abundant literature on the use of *M. oleifera* leaf extracts in animal studies, there is still not much information on its utilization on growth performance and gastrointestinal tract studies of rabbits, particularly, in the use of its crude leaf juice. Therefore,

the aim of the study was to determine the growth performance and gut morphometry of rabbit bucks fed various levels of *M. oleifera* crude leaf extract (MOCLE) in water.

Materials and Methods

The study was conducted at the rabbitry unit of the Livestock Teaching and Research Farm, Federal University of Agriculture Makurdi, Nigeria. Makurdi is located on latitude 7°45´ N and longitude 8°31´ E within the Southern guinea savannah ecological zone. It has two distinct seasons, the wet and dry seasons with annual rainfall range of 508–1016 mm. Day time temperatures may drop as low as 21.6°C in December/January and rise as high as 42.6°C in February/March. Fresh green leaves of *Moringa oleifera* trees were harvested from Wuse village, Awe local government, Nasarawa state, Nigeria based on abundance. The debris-free leaves were obtained and mashed locally without water added to form a paste. The crude leaf juice was extracted with a muslin (cheese) cloth, refrigerated and used to prepare the final mixtures. A total of 16 rabbit bucks of mixed crosses, aged 10 – 11 weeks, weighing between 1318.75 g and1437.50 g were used in a 65-d feeding trial. Four rabbits each were randomly allotted to four treatments with each rabbit serving as a replicate. The rabbits were housed singly in wooden and wire mesh hutches, dewormed and adjusted for a period of 2 weeks. The rabbits were fed a basal diet and four varying levels of *M. oleifera* crude leaf extract (MOCLE) at 0 ml, 250 ml, 500 ml and 750 ml per litre of drinking water, designated as T1 (control), T2, T3, and T4 respectively. The growth performance indices measured were feed intake (g/d), water intake (ml/d), weight gain (g/d), total gain (g), final weight (g), and feed conversion ratio. At day 65 of the study, the rabbits were starved of feed for about 12 hours but served clean water *ad libitum*, weighed and then sacrificed. The gastrointestinal tract (GIT) were excised, emptied, rinsed, cut into five anatomical parts (oesophagus, stomach, small intestine, caecum and colon) and weighed. The relative length and weight of the gastrointestinal tract cuts were expressed in percents of entire gastrointestinal tract length and live weight respectively. Data were subjected to one-way analysis of variance (ANOVA) using IBM SPSS® (2011) version 20. Significant means ($P < 0.05$) was separated using Duncan of the statistical software.

Results and Discussion

The calculated chemical composition of the basal diet is shown in table 1. The growth performance of rabbit bucks fed MOCLE is presented in table 2. The result did not reveal any significant ($P>0.05$) differences across treatments for feed intake (FI) and feed conversion ratio (FCR) but final weight (FW) and total weight gain (TWG) showed significant differences ($P<0.05$). FW and TWG increased in accordance with the extract levels as T4 (750 ml) produced the highest values. FW in this study was similar to that of Adeniji and Lawal (2012) who reported significant values (1981.1 g – 2216.2 g) when *M. oleifera* leaf meal (MOLM) replaced groundnut cake (GNC) in grower rabbit diets. In contrast, Nuhu (2010) did not observe any significant effect in the FW of rabbits which were lower (1625.31 g – 1902.51 g) when MOLM replaced soya bean meal (SBM). The variations in the FW noted by this author and that of this study could be as result of better availability of proteins from the leaf extracts. The TWG values from this study were at variance with the non-significantly higher values (983.64 g – 1260.84 g) reported by Nuhu (2010). The growth stage of the rabbits used in this study as compared to the other author (6 – 7 weeks) may have accounted for the lower TWG values. FI values was comparable to the not significantly different range (60.10 g – 63.40 g) reported by Nuhu (2010) but was lower than the statistically similar values of 64.53 g to 73.59 g reported by Onu (2012) who fed aqueous leaf extracts of *Telfairia occidentalis* to starter broilers. However, Adeniji and Lawal (2012) reported significantly higher values (64.4 g – 78.5 g) in FI of rabbits. The observed variations between the FI values of this study and those of other works may be due to differences in the growth stages of the rabbits. FCR values in this study agreed with the range of 5.13 to 4.22 reported by Nuhu (2010). Nworgu (2007) and Machebe *et al*. (2010) also reported better FCR in broiler birds fed leaf extracts of *T. occidentalis* and *Gongronema latifolia* respectively. However, Adeniji and Lawal (2012) and Onu (2012) found significant differences in FCR of rabbits and starter broilers respectively. Therefore the better FCR values observed in this present study with the corresponding higher FW among the MOCLE-fed groups suggests that body tissue accretion was not grossly impaired. The weekly water intake (WI) of rabbit bucks fed MOCLE (fig. 1) shows that T1 (0 ml) was most consumed followed by T2 (250 ml), T3 (500 ml) and T4 (750 ml) respectively. The observed pattern in WI suggests that T2 to T4 interfered with the palatability of the water-extract mixtures even though FW and TWG were markedly enhanced. Table 4 presents the result of the gut morphometry of rabbit bucks fed MOCLE. There was no significant differences (P>0.05) in the length and weight of the various gut segments across the treatments. The range of values of the relative length and weight of the small intestine were highest (59.84 – 61.00 % and 1.18 – 1.56 % respectively) while the stomach length (2.00 – 2.23 %) and oesophagus weight (0.07 – 0.08 %) had the least range of values. The stomach, small intestine and caecum weights from this study were lower than the values of 2.5 ± 0.34%, 2.1 ± 0.15 % and 4.7 ± 0.20% respectively reported by Yu and Chiou (1997) for California rabbit bucks fed a commercial diet. The observed differences between the weights of gut segments recorded by these authors and this study could be due to the effect of breed and plane of nutrition. In addition, Yu and Chiou (1979) reported an age-related decrease in relative gut segment weights of rabbits. These authors observed linear increases from early life to the maturity stage at 8 weeks of age, and thereafter declined in contrast to rapid body weight gain. Therefore the result indicates that MOCLE did not cause marked changes in the gastrointestinal tract of the rabbits.

Conclusion

It can be concluded that rabbits fed the supplementary levels of MOCLE at 250 – 750 ml per litre of drinking water recorded remarkable differences in final weight and total weight gain with the 750 ml level producing the best response. The water intake of the rabbits showed decreasing trend as the levels of MOCLE increased from 0 – 750 ml, though, this was of no serious consequence. The gastrointestinal tract morphometry of the rabbits were not prominently changed by the varying levels of MOCLE. It is therefore recommended that the supplementary feeding of rabbits with MOCLE up to 750 ml in drinking water is well tolerated without adverse effect on growth performance and gut morphometery.

Abstract
The study is a Supervised Experience Project (SEP) on the Feeding of Sprouted Sorghum Feed to Broiler Chickens among Poultry Farmers in 'Yar Magaji Community of Bindawa Local Government Area in Katsina State. Random sampling method was used to select thirty (30) small scale poultry farmers who were divided in to three groups in 'Yar-Magaji community of Bindawa LGA. A total of 60-day old chicks were used for this study. The birds were fed with starter mash for the first four weeks. After the four weeks the birds were divided into 3 groups with 20 birds per group of poultry farmers. Each group served as a treatment. Group A were fed with solely commercial feed, each member of group B was fed with 20g of sprouted sorghum in addition to commercial feed and each member of group C was fed with 30g of sprouted sorghum daily also in addition to commercial feed for four (4) weeks. Primary data on the farmers were collected using questionnaire. The results showed that 70 percent of the poultry farmers were male and 30 percent were female, 60% were within age range of 31-40 years, 70% were married. It was also observed that before the introduction none of the participants used sprouted sorghum to feed their poultry birds and all the participants used family labour for their poultry production process. It was also observed that 80% of the participants were not aware of the method of sprouting sorghum for poultry feeds. Average weight gain of 2.40kg, 2.18kg and 2.15kg was obtained for group A, B and C of the birds respectively. A sum total of ₦99938 was spent and a total revenue of ₦158,000 was obtained for the whole work while a net income of ₦58061.98 was obtained. The problems associated with sprouting sorghum feeding were identified by farmers in the study area which were lack of technical knowledge on how to sprout sorghum and lack of capital as well. The expenses reduced from the group fed with sprouted sorghum. It was hence concluded that the use of sprouted sorghum is more economical and convenient since the sorghum used were readily available in the market and within the locality. It was recommended that more poultry farmers should be trained and technically assisted on how to sprout sorghum feed; employ an experienced farm attendant for quality labour services; poultry farmers should be encouraged to form cooperatives in order to source for assistance from government and individuals.

Keywords: Sprouted sorghum, broiler chicks, poultry farmers and comparative economic analysis

Introduction
Poultry refers to all birds domesticated and managed by man for food and profit; these include chicken, duck, turkey, guineas, fowls, quails, geese, pigeon, pheasants, peacocks and ostriches. (Oluyemi and Robert, 2002). Broiler birds, one of the commonest forms of poultry production in Nigeria are one of the major sources of animal protein for human consumption in Nigeria. They

contribute about 10% of the national meat production. A major problem of poultry industry in developing countries today is the high cost of feed ingredients. This problem has reduced the rate of conversion of the poultry industry and has added to the low level of animal protein in the nutrition of the citizens (Adebayo *et al.,* 2008). Edache *et al.* (2005) reported that feed supply has remained a major constraint in animal production due to ever increase cost of conventional feed ingredients. To reduce the cost incurred in broiler production from feed, researchers in northern Nigeria revealed that using sprouted cereal especially sorghum as a partial alternative to commercial feed will serve this purpose. Cereals are the most important staple food for many people in the developed and developing Countries. Processing methods such as Soaking, Sprouting and Fermentation has been reported to improve the nutritional and functional properties of cereals (Jirapa *et al.,* 2001). Sprouting singly significantly increases protein, moisture content and decreases fiber, dry matter, fat and ash level. The ability of the farmer to be able to formulate his livestock feeds, enables him to reduce the cost of production and also his ability to source for his ingredients enables him/her to source for quality ingredients at cheaper price because the lower the cost of ingredients the more his profit margin. Based on this observation, there is need for individual farmers to have the techniques of feeding of sprouted sorghum to broiler chicken at minimum cost, since there is no immediate assistance from the government for the farmers. Feeding poultry with sprouted sorghum can serve as a way out of this problem. Only few poultry farmers are able to afford the high cost of feeds produce by commercial feed producers. If an appropriate solution cannot be provided, then protein deficiency will continue to be a big problem in this country. The purpose of this study is to highlight the need to make efficient use of available resources to produce feeds locally by the poultry farmers.

Methodology

This study was conducted in 'Yar-Magaji Community of Bindawa Local Government Area of Katsina State created in 1989 with an estimated projected population of 170,429.1484 as at 2017 at a growth rate of 2.8%. The State is located at latitude $12^0 43'$ north of the equator and longitude $7^0 50'$ east of the Greenwich meridian. It has total area of 398km^2 (154sq mi). Small scale farming is very prominent in the study area though the inhabitants have other sources of livelihood. The major crop that grows in the area are grains crops which include maize, millet, sorghum, cowpea and groundnut. Livestock in the area include cow sheep, goats, chicken and duck. The major language spoken in the area is Hausa and Fulani and majority of the population are farmers. Simple Random sampling method was used to select thirty (30) small scale poultry farmers who were divided in to three groups in 'Yar-Magaji community of Bindawa LGA. A total of 60-day old chicks were used for this study. The birds were fed with starter mash for the first four weeks. After the four weeks the birds were divided into 3 groups with 20 birds per group of poultry farmers. Each group served as a treatment. Group A were fed with solely commercial feed, each member of group B was fed with 20g of sprouted sorghum in addition to commercial feed and each member of group C was fed with 30g of sprouted sorghum daily also in addition to commercial feed for four (4) weeks. Primary data on the farmers were collected using questionnaire.

Analytical Technique

Descriptive statistics and gross margin analysis were used for analysis described below:

The gross margin analysis was employed to compare the profitability of locally sprouted sorghum feed and that of commercial. The model is expressed as

GM = GI - TC

Where

GM = Gross margin

GI = Gross income

TC = Total cost

Results and Discussion

Awareness of Respondents about Feeding Sprouted Sorghum to Broiler Chicken

Awareness is the first stage in the adoption of any innovation among the social community, after identifying the problems facing the poultry farmers in feeding their birds, awareness is created as a way of addressing the farmers' problems in the study area. Vanden Ban and Hawkins (1996) stated that it is easier to change the norms of a group as a whole through demonstration potential users gain experience of new innovation so that they can easily notice and understand it. It is shown on Table 1 that 80 percent of the participants were not aware of the method of sprouting sorghum for poultry feeds whereas only 20 percent were aware. This may be due to poor extension activities in the study area.

Table 1: Awareness of Respondents about Feeding Sprouted Sorghum to Broiler Chicken

Awareness	Frequency	Percentage
Aware	6	20
Not aware	24	80

Level of Feeding Sprouted Sorghum to Broiler Birds before the Introduction

Table 2 shows that none of the farmers in the study area are using sprouted sorghum feed, while 100 percent use commercial feed to feed their poultry. This signifies that the whole poultry farmers in the study area used commercial feed and despite the existence of this innovation. There is hope for the poultry farmers in the study area to expand their stock and production capacity as a result of adoption of the sprouted sorghum poultry feeding.

Table 2: Level of Feeding Sprouted Sorghum to Broiler Birds

Feed Type	Frequency	Percentage
Sprouted Sorghum	0	0.00
Commercial feed	30	100.00

Comparison of Sprouted Sorghum Feeding with Commercial Feed

From the result in Table 3, it could be observed that Group A had an average weight of 1.38kg, Group B had 1.36kg and Group C had 1.40kg weight at week 4. It is observed that there is no difference among the groups which may be due to the same treatment given to them. From the result in Table 3, at week five, it shows that the treatment given has effect on weight gain as broilers fed with commercial feed gain more weight than those fed with 20g and 30g Sprouted sorghum. The recorded average weight was 1.63kg for group A and 1.59kg and 1.57kg respectively for Group B and C given the difference of 0.4 between Group A and B and the difference of 0.2 between Group B and C. This could be due to the fact that the commercial feed is more nutritive and palatable than sprouted sorghum feed. From the result in Table 3 it shows that those fed with commercial feed at week six still gain more weight than those feed with 20g and 30g Sprouted sorghum. The observed differences were 0.9 and 0.1 between Group A and B and Group B and C respectively. From the result obtained at week seven (Table 3), it shows that broiler fed with commercial feed gained more weight (difference of 0.15 between Group A and B) than the broiler fed with sprouted sorghum feed, it might be due to the fact that at this week they eat a lot and feed conversion efficiency is high so that more weight would be gotten unlike those fed with 20g and 30g Sprouted sorghum that their weight gain is not as like that of those fed with commercial feed but they too are gaining good weight (difference of 0.2 between Group B and C) especially when we compare the cost of the feed used. From the result in Table 3 it was observed that the broiler fed with 20g and 30g sprouted sorghum and commercial feed had weight gain differences of 0.22 and 0.3 between Group A and B and between Group B and C respectively at the eight week. Those fed with commercial feed had average weight gain of 2.30kg and those fed with commercial and 20g sprouted sorghum had 2.25kg while those fed with commercial and 30g sprouted sorghum had 2.23kg of average weight gain. This could be due to the fact that, both reach mature stage and hence can be able to take any feed given to them.

Table 3: Weight Comparison among Birds Feed Sprouted Sorghum and Commercial Feed

Week	Group	Average weight
Four	A	1.38
	B	1.36
	C	1.40
Five	A	1.63
	B	1.59
	C	1.57
Six	A	1.89
	B	1.80
	C	1.79
Seven	A	2.15
	B	2.00
	C	1.98
Eight	A	2.40
	B	2.18
	C	2.15

Comparison of Cost and Return Analysis among Broiler Groups

The costs incurred in the broiler production are specified in Table 4. It could be seen that the 60 day-old chicks were purchased at the cost of ₦180 per one to give a total of ₦10,800. The birds were fed 0-4 weeks using the same treatment. About 156kg of starter feed at cost of ₦80 per kg fed to the birds. This gave total of ₦12480. The cost of waterers, feeders, trays, drugs and transportation incurred were ₦3,000, ₦3,000, ₦1200, ₦9,000 and ₦600 respectively. A total sum of ₦40,080 was spent during the first four (4) weeks for all the birds to give ₦13,360 per 20 birds. At the beginning of the fifth week, the birds were divided into three (3) groups (A, B and C). The three groups were each treated separately using different feed levels from week 5-8. Group A were fed with 75kg commercial broiler finisher feed, Group B were fed with 63.8 kg of finisher and 11.2 kg of sprouted sorghum while Group C were fed with 58.2 kg of commercial feed and 16.8 kg of sprouted sorghum. The cost of the finisher was ₦80 per kg while that of the sorghum was ₦100 per kg. Therefore, ₦6,000, ₦6,224 and ₦6,336 were incurred for groups A, B and C respectively between weeks 5 and 8. When this was added to cost in the first four weeks, total cost incurred by each group was ₦19,360, ₦19,584 and ₦19,696 for A, B, and C respectively. For the revenue accrued, birds fed with sprouted sorghum (Groups B and C) attracted higher selling price compared to those fed with solely commercial feed because they are more organic compared to Group A. Thus, the selling price per bird for Group A, B and C were ₦1800, ₦1,900 and ₦1,950 respectively. This gave a revenue of ₦36,000, ₦38,000 and ₦39,000, a gross margin of ₦16,640, ₦18,416 and ₦19,304 and a return per naira invested of 1.86, 1.94 and 1.98 for groups A, B and C respectively. The return implies that for every naira invested in broiler production, a return 86k, 94k and 98k will be realized. This reveals that feeding broiler spouted sorghum while reducing the quantity of commercial feed is more economical especially if the right consumers are targeted because even though they have relatively less weight than those solely fed with commercial feed, they are valued more be the right consumers. The advantage of sprouting sorghum is that sprouted sorghum is more economical and convenient since the sorghum used was readily available in the market and within the locality. It is also easy to make without the use of machine. It also doesn't require or occupies vast land for equipment and machines.

Table 4: Comparison Cost and Return Analysis among Broiler Groups

Cost and Return Components	Quantity			Unit Price (₦)	Total (₦)
0-4 Weeks	Group A	Group B	Group C		
No. of birds	20	20	20	180	10800
Starter mash (kg)	52	52	52	80	12,480
Waterer	2 pcs	2 pcs	2 pcs	500	3,000
Feeder	2 pcs	2 pcs	2 pcs	500	3,000
Tray	1 pc	1 pc	1 pc	400	1,200
Drugs	3 sachets	3 sachets	3 sachets	1000	9,000
Transportation					600
Initial cost (0-4 weeks)	₦13360	₦13360	₦13360		40080
5-8 Weeks					
Finisher (kg)	75	63.8	58.2	80	15,760
Cost of finisher (₦)	6,000	5104	4656		
Fresh sorghum (kg)	-	11.2	16.8	100	
Cost of fresh sorghum (₦)	-	1120	1680		
Finishing cost (5-8 weeks)	6,000	6224	6336		
Total cost (TC)	19,360	19,584	19,696		
Total revenue (TR)	36,000(1800/bird)	38,000(1900/bird)	39,000(1950/bird)		
Gross Income (TR-TC)	₦16,640	₦18,416	₦19,304		
Cost/Naira Invested(TR/TC)	1.86	1.94	1.98		

Conclusion

Based on the results obtained from this work, it shows that the performance of birds fed with sprouted sorghum is almost the same in term of weight gain though the cost of production was slightly higher than that of the commercial feed. The group found that sprouted sorghum feed is more economical and convenient compared to feeding solely commercial poultry feed since the sorghum used is readily available in the market and within the locality. Increased production depends to a large extent on getting the appropriate consumers to buy the birds. Based on the findings of the study, the following recommendations were made:

(i) Poultry business is a capital intensive project and as such Government should provide soft loan and subsidies on vaccine and good stock of day old chicks to the farmers.

(ii) Poultry farmers should be trained on how to sprout sorghum feed and employ an experienced farm attendant for quality labour services. This will go a long way in minimizing the cost of poultry feeds as well as increasing the income of farmers.

(iii) People should be enlightened on the importance of eating poultry that is more organic.

(iv) Poultry farmers should be encouraged to form cooperatives in order to source for assistance from government and individuals.

Abstract
A 65-day feeding trial was conducted on sixteen (16) rabbit bucks and aged 10–11 weeks to investigate the effect of four levels of Moringa oleifera crude leaf extract (MOCLE) in water on serum biochemical characteristics. Four (4) rabbits each were randomly assigned to 4 treatments in a completely randomized design and each rabbit served as a replicate. The treatment groups each received a basal diet and 4 levels of MOCLE per litre of drinking water and designated as follows: 0 ml (T1), 250 ml (T2), 500 ml (T3) and 750 ml (T4). At the end of the feeding trial, blood samples were collected from the rabbits and evaluated for serum total protein, albumin, globulin, total bilirubin, urea, sodium and potassium. There were no significant (P<0.05) differences across treatments in all the serum biochemical characteristics studied. The values obtained did not conform to the levels of the extract and generally fell within normal ranges reported for healthy rabbits. Therefore it can be concluded that administering MOCLE in drinking water up to 750 ml per litre did not adversely affect blood biochemical characteristics of rabbit bucks.

Introduction
Blood is a complex fliud containing large variety of dissolved, suspended inorganic and organic substances (Stewart, 1991). The primary function of blood is transport of oxygen from respiratory organs to body cells (Duke, 1975), nutrient and enzyme distribution to cells as well as removal of waste products (Baker and Silverton, 1982) thereby maintaining homeostasis of the internal environment (Bentrick, 1974). Blood examinations provide the opportunity to investigate the presence of several metabolites and other constituents that help detect conditions of stress which can be nutritional, environmental or physical (Aderemi, 2004). *Moringa oleifera* Lam. also known as horse raddish, drumstick or ben oil tree belongs to the family *Moringaceae* and it is widely cultivated in many parts of the world. *M. oleifera* has vast medicinal properties as every part is believed to be beneficial (Garima *et al.*, 2011) and serve as a rich repository of proteins, vitamins and minerals (Pandey *et al.*, 2012). The leaf of *M. oleifera* has been used in the form of meals for livestock feeding in the tropics with good results, although, in recent times there is a growing interest in the utilization of its leaf extract. Available literature on serum biochemical investigations involving *M. oleifera* leaf extracts are predominantly on rats with fewer works existing on rabbits. More so, the sohxlet extraction method is widely used for obtaining the various extracts of *M. oleifera* tree but there is a dearth of information on its crude leaf extracts thus prompting this research. Therefore this study sought to evaluate some serum biochemical characteristics of rabbit bucks fed *M. oleifera* crude leaf extracts in drinking water.

Materials and Methods
The experiment was conducted at the rabbitry unit of the Livestock Teaching and Research Farm, Federal University of Agriculture Makurdi, Nigeria. Makurdi is located on latitude 7°45´ N and

longitude 8°31′ E and lies within the Southern guinea savannah. It has two distinct seasons (wet and dry) with annual rainfall range of 508–1016 mm. Temperatures drop as low as 21.6°C in December/January and rise as high as 42.6°C in February/March. Fresh green leaves of *Moringa oleifera* trees was harvested from Wuse village, Azare development area, Awe local government of Nassarawa state, Nigeria based on abundance. The debris-free leaves was obtained and mashed locally without adding water to form a paste. The crude leaf juice was extracted with a muslin (cheese) cloth, refrigerated and used to prepare the final mixtures. A total of sixteen (16) rabbit bucks of mixed crosses, aged 10-11 weeks were used in a 65-day feeding trial. Four rabbits each were randomly allotted to four treatments with each rabbit serving as a replicate. The rabbits were housed singly in wooden and wire mesh hutches, dewormed and adjusted for a period of 2 weeks. The rabbits were fed a basal diet and four levels of *Moringa oleifera* crude leaf extract (MOCLE) at 0 ml, 250 ml, 500 ml and 750 ml per litre of drinking water, designated as T1 (control), T2, T3, and T4 respectively. At the end of the 65-day feeding trial, 16 rabbits (4 rabbits per treatment) were sacrificed and about 10 ml each of blood was separately collected into sterile sample tubes without an anticoagulant for the determination of serum biochemical characteristics (total protein, albumin, globulin, total bilirubin, urea, potassium, sodium, calcium and phosphorus). Total protein and albumin was determined according to Tietz (1976) and Grant *et al.* (1987) respectively while globulin was determined by difference of total protein and albumin. Total bilirubin investigation was done using the method of Sherlock (1951) while urea, sodium and potassium were determined using the Erba Mannheim® Chem5Z3 digital blood biochemistry analyzer. Data were subjected to one-way analysis of variance (ANOVA) using IBM SPSS® (2011) version 20. Significant means ($P<0.05$) was separated using Duncan of the statistical software.

Results and Discussion

The serum biochemical characteristics of rabbits in this study did not differ significantly as a result of the inclusion of levels of MOLE. Blood chemistry constituents reflect the physiological responsiveness of the animal to its internal and external environments which is inclusive of feeds and feeding (Iheukwumere and Okoli, 2002). Serum total protein is an indirect index of for measuring nutritional protein adequacy (Eggum, 1970a). Hawkey *et al.* (2000) opined that high total protein values signified better protein content of a test feed. The total protein range of 67.50 to 73.0 g/L from this study was not significant and did not conform to the levels of the extract. The total protein values occurred within normal range (28 – 100 g/L) reported by Flecknell (2000), however, the values were higher than the 51.0 – 69.0 g/L (converted) observed from the findings of Nuhu (2010) who replaced SBM with MOLM at 0, 5, 10, 15 and 20 % levels respectively in diets of rabbits. These finding indicate that MOLE supplied adequate proteins which supported growth and normal blood functions. Albumin investigations showed statistical similarities across treatments with values ranging from 47.25 to 56.25 g/L which followed the same trend as total protein. Albumin is quantitatively the most important liver protein as it serves as a useful indicator of hepatic function (Thapa and Walia, 2007), and it is a major transport protein in the blood due to its enhancement of plasma osmotic pressure (Brar *et al.*, 2011). Albumin values in this current work was higher than the 32 to 41 g/L (converted) found by Nuhu (2010). However, the values fell within the normal range (30 to 50 g/L) for rabbits reported by Flecknell (2000) with the exception of T3 (56.25 g/L) and T4 (52.00 g/L) that were slightly above normal. Orhue *et al*. (2005) stated that decrease in albumin could be due to reductions in liver protein synthesis, increased protein losses in gut and kidney, and malabsorption. Therefore, the normal albumin values of the rabbits imply that the levels of MOLE did not result to reductions in liver protein synthesis or adverse protein losses. Globulin values (16.25 to 23.75 g/L) were also statistically similar across treatments and occurred within the normal range of 15 to 27 g/L (converted) for rabbits reported by Flecknell (2000). This result was comparable to the range of 19.0 to 28.0 g/L observed by Nuhu (2010) who replaced SBM with MOLM in the diet of rabbits. Eggum (1970b) and Hawkey *et al*. (2000) stated that high serum globulin level corresponds with the ability of the body to fight diseases. This implies that the inclusion of MOLE in drinking water of rabbits did not impair normal functioning of this salt soluble protein. Bilirubin is a diagnostic marker for liver and blood disorders and elevated bilirubin formation can occur during abnormally high breakdown in peripheral haemoglobin i.e. haemolysis (Fevery, 2008). In addition total and conjugated bilirubins are indicators of protein adequacy (Ahemefule *et al*., 2008). Total bilirubin (0.25 to 0.42 mg/dL) recorded in this study did not differ significantly ($P < 0.05$) and was within the standard range (0 to 1.0 mg/dL) for healthy rabbits reported by Smith (2003). This result suggests that the administration of MOLE to rabbits did not disrupt liver function which probably enhanced the availability of sufficient nutrients needed to support basic body maintenance. The result for blood urea concentration (9.48 to 12.10 mmol/L) obtained in this current work followed the same pattern as that of total bilirubin and was within the normal range of 9.3 to 25.5 mmol/L for rabbits as reported and cited by Flecknell (2000). Urea is a product of general cellular metabolism and it is a general marker of renal function (Basten, 2010). Abnormally elevated blood levels are associated with poor protein quality (Eggum, 1970a) or excess tissue catabolism associated with protein deficiency (Oduye and Adadevoh, 1976) while abnormally low blood urea indicates hepatic dysfunction (Varga, 2013). The non-significantly ($P < 0.05$) different and normal blood urea concentrations in this study implies that the composite dietary protein supplied by MOLE and the basal diet was adequately utilized by the body of the rabbits. Sodium is the chief extracellular cation that exists in body fluids as free ions in maintaining cellular tonicity, fluid balance, pH and regulation of neural and muscular functions (Cheesbrough, 2000). The statistical similarity ($P > 0.05$) in sodium values (132.00 to 140.50 mmolL) obtained from this research were within the standard reference range of 130 to 155 mmol/L for healthy rabbits observed by Flecknell (2000). The abnormal increase in blood sodium results in body water retention and a consequent reduction in sodium concentration (Prohp and Onoagbe, 2014); blood pressure which is partly dependent on blood volume thereby rises with increased body water retention (Kruetler, 1980). Therefore, this result suggests that the supplement feeding of MOLE did not likely impair the osmotic as well as blood pressure functions of the rabbits. Serum potassium was not adversely affected ($P > 0.05$) by the levels of MOLE and values were within the normal range (3.50 to 7.00 mmol/L) indicated by Varga (2013). Potassium is the abundant cation in the intracellular fluid compartment. Prohp and Onoagbe (2014) reported that hyperkalaemia was associated with renal failure due to the inability of the kidney to excrete potassium. In addition, severe dehydration and renal dysfunction triggers elevations in blood potassium could give rise to muscle weakness, cardiac arrthmia and consequently heart failure (Abubakar and Sule, 2010). Therefore, the normality in the potassium values from this work suggests that renal functioning of the rabbits was not impaired by feeding MOCLE.

Conclusion

The serum biochemical characteristics of the rabbits investigated did not incur outstanding differences irrespective of the levels of MOCLE and the values generally fell within normal ranges for healthy rabbits. The supplemental feeding of MOLE of up to 750 ml in the drinking water of rabbits is highly tolerated without adverse effect on serum characteristics.

Table 1: Proximate composition of basal diet (calculated)

Abstract
The aim of this preliminary study was to establish reference normal ranges of biochemical parameters in different breeds of turkeys in the Teaching and Research Farm, Faculty of Agriculture, Ambrose Alli University, Ekpoma, Edo state, Nigeria. The animals were monitored during a 4 month period (16weeks). Blood samples, collected from growing turkeys for laboratory analysis. Serum-biochemical parameters evaluated in the blood samples of the birds were significant ($P<0.05$) differences between genotypes in Total protein, Albumin, Globulin, Cholesterol and Glucose. Local white genotype however, had the highest significant Total protein (5.70ml), Albumin (2.67 ml) Globulin (3.03ml) and Glucose (133.83m/dl) compared to other turkey genotypes. Results indicated that biochemical data were comparable to those described in turkeys. Results on blood chemistry of turkey genotypes could be used in the classification of turkeys into genetic groups and can be utilized in crossbreeding programmes to produce crossbreds that are highly productive and adapted to the environment.

Introduction
Publications on the serum-biochemical of turkeys have not been properly reported domestic or wild turkey from different geographical and Agricultural zone of the world (Warren, 1995 and Bonous *et al* 2000). Serum biochemical values have been established in most domestic avian species (Jain, 1986 and Adejumo *et al*., 2005). Turkeys (*Meleagris gallopavo*) are reared all over the world for their tasty and high quality meat. It originates from North America and has been introduced nearly worldwide including Nigeria. Though the turkey posses the ability to acclimatize in various types of climate, are very much sensitive to sudden climatic changes during the early life. Physiological tolerance of organisms is strong determinant of the environmental conditions in which they inhabit. Phenotypic Characterization could also be supported by genotype identification through laboratory study of gene markers or biochemical polymorphisms (LE-Gall *et al*., 1994). The reference value presented for biochemical values could significantly boost genetic improvement and base line information.

Materials and Methods
Study area
The research was carried out at the Poultry Unit of the Livestock Teaching and Research Farm of Ambrose Alli University Ekpoma, Edo State. The farm lies between Lat 6.44^{o}N and Log 6.8^{o}E in Esan West Local Government Area of Edo State, Nigeria. Ekpoma is within the South-South geo-political zone of Nigeria and has a prevailing tropical climate with a mean annual rainfall of about 1556mm. The mean ambient temperature ranges from 26^{0}C in December to 34^{0}C in February, relative humidity ranges from 61% in January to 92% in August with yearly average of about 82%. The vegetation represents an interface between the tropical rainforest and the derived savanna.

Management of the birds
A total of 60 growing Turkeys were used for this study. These consisted of 15 birds each of Genotype Exotic, Local white, Lavender and Local Black respectively. All birds were wing tagged for proper identification and subjected to the same management practice throughout the experimental period. Medication and vaccinations were carried out accordingly against stress and disease.
Feeds and Feeding
The birds were fed *adlibitum* with starter marsh containing 20% crude protein, 2996Kcal/kg Metabolizable Energy from Dayold-4weeks of age, Broilers finisher's diets containing 15.86% crude protein, 2716Kcal/kg Metabolizable Energy was fed from 4-16weeks of age. Clean water was supplied continuously *adlibitum* throughout the experimental period.
Sample Collection
Blood sample were collected from the jugular veins using sterile disposable needles (21-guage) and syringes. Before the blood collection, the birds were fasted over night for 12 hours and samples were collected the following morning to avoid excessive bleeding. Samples for biochemical indices analysis were collected into anti-coagulant free tubes and allowed to clot. Serum was obtained after the blood samples had been allowed to stand for two hours at room temperature and centrifuged for ten minutes at 2000.rpm to separate the cell from the serum.
Experimental design and statistical analyses
All data obtained were subjected to analysis of variance to investigate the effect of strain on haematological and serum biochemistry, using the General Linear Model of SAS (1999). Duncan's Multiple Range Test was used to separate the means that are significantly difference (Gomez and Gomez, 1984).

$\mathbf{Y_{ij} = \mu + T_j + \sum_{ij}}$
where Y_{ij} = Observed value of dependent variable
μ = Population mean
T_i = i^{th} fixed effect due to Genotype (= 1…4)
$\sum_{ij}$ = Random residual error.

Results and Discussion
Regarding the analyzed blood parameters of turkey the specific genetic variation was an important source of variability for Total protein, albumen, globulin glucose, cholesterol, urea and Creatinine were significantly ($p<0.05$) affected by genotypes. Local Black genotype however, had the highest significant Total protein (5.70ml), Albumin (2.67 ml) Globulin (3.03ml) and Glucose (133.83m/dl) compared to other turkey genotypes. These findings agree with those reported by Ibrahim *et al* (2012) and Isidahomen *et al* (2013). The increase in protein concentration in blood is partially contributed to raised albumin concentration but mainly due to increase in the globulin concentration during the cold stress. The increase in the albumin concentration might be due to effect of cortisol activity because increased cortisol level has catabolic action on muscles, lymphatic tissue and bone (Eiler, 2004).The comparison of the blood parameters of the analyzed local and pure breed turkeys show explicitly serum biochemical is strongly genetically determined. In this study, however, of fundamental significance is the comparison of results obtained for turkey breeds.

Table 1: Serum-Biochemical Parameters of Exotic and Indigenous Turkeys as Influence by Specific Genes

Parameters	Exotic	Local White	Lavender	Local Black
Total Protein (ml)	4.70 ± 0.10^{b}	4.33 ± 0.15^{c}	4.87 ± 0.06^{b}	5.70 ± 0.11^{a}
Albumin (ml)	2.30 ± 0.04^{b}	2.55 ± 0.07^{a}	2.60 ± 0.06^{a}	2.67 ± 0.08^{a}
Globulin (ml)	2.23 ± 0.04^{b}	1.73 ± 0.06^{c}	2.27 ± 0.08^{b}	3.03 ± 0.09^{a}
Glucose (m/dl)	127.17 ± 4.12^{ab}	123.33 ± 1.31^{bc}	118.17 ± 1.11^{c}	133.83 ± 2.01^{a}
Cholesterol (m/dl)	96.83 ± 2.55^{a}	83.67 ± 2.09^{b}	95.00 ± 3.32^{a}	94.83 ± 1.28^{a}
Urea(ml)	4.33 ± 0.21^{b}	6.17 ± 0.40^{a}	6.80 ± 0.20^{a}	6.17 ± 0.40a
Creatinine (ml)	0.72 ± 0.04^{ab}	0.63 ± 0.04^{b}	0.77 ± 0.04^{a}	0.77 ± 0.04^{a}

a,b,c; Means in the same row with different superscript are significantly different ($P<0.05$)

Conclusion

According to the results of current experiment, it was found that the four analyzed genetic groups of turkeys exhibited a response to genotype and could be considered as preliminary reference values which are particularly important for turkey diagnosis and breeding. Further it is evident from the study that birds can also thrive well in the humid environment of Nigerian.

Abstract

One hundred and twenty poults comprising sixty, each of indigenous and crossbred were used to evaluate the differences in body weight and feed efficiency between indigenous and crossbred turkey genotypes. Feed intake, body weight and feed efficiency were recorded at 2, 4, 8, 12, 16 and 20 weeks of age. The results of this study showed that body weight had significant (P<0.05) effect on genotype only at 20 weeks of age. However, the crossbred poults consistently had higher least square means value of body weight throughout the experiment. Conversely, significant sexual dimorphism was observed in all the weeks except at 2 weeks of age, with male having higher means value in all the weeks of the experiment. Furthermore, genotype had significant effect (P<0.05) on feed intake in all the weeks of the experiment except at 2 weeks of age. The crossbred consumed more feeds when compared to their indigenous counterpart. More so, the feed efficiency was significantly influenced (P<0.05) by genotype at 4, 8 and 12 with indigenous turkey had higher efficiency of feed utilization in all the weeks of the experiment. It was concluded that superiority in body weight exhibited by crossbred genotype and better feed efficiency displayed by the indigenous turkey suggested that the crossbred took the advantage of the heterosis of the indigenous and exotic parents and can be further improved upon to show superior quality in most of the productive and adaptive traits than their exotic and indigenous parents. The indigenous on the other hand effectively utilized the feed consumed indicating opportunities for improvement

Introduction

Turkey (Meleagris gallopavo) production is an aspect of poultry industry which is not popular in Nigeria until last decade. Turkey production is now carried out in all parts of the country in Nigeria but at a very low scale (Maikasuwa *et al.,* 2014). Most of the turkeys reared in Nigeria are indigenous breeds with only few exotic breeds (such as Nicholas white, Kelly and British United) and their crosses. Several researches on turkey production in the past have been directed toward improving exotic turkeys with the aim of improving percent breast meat, feed efficiency, fecundity, livability among other performance characteristics. Generally, Nigeria indigenous turkeys are very hardy, tolerant to most of the diseases of turkey in temperate region, can survive on low nutrient feed resources and best adapted to prevailing tropical climatic conditions. These birds are nondescript with multi-colored plumage and sometimes appearing as pure black or white. The productivity of indigenous turkeys can be improved by crossbreeding exotic Toms, having superior genetic make-up with indigenous hens. It was stated in Adebambo *et al.* (2006) that the controlled introduction of new and improved genetic materials into indigenous breeds of bird is expected to speed up genetic progress through the exploitation of hybrid vigour. There is need therefore to compare the productivity of indigenous and crossbred turkeys in terms of feed efficiency and reproductive performance. This will help to justify the need to improve indigenous turkeys using exotic genetic makeup. The objective of this study was therefore to evaluate genetic variation in body weight and feed efficiency of indigenous and crossbred turkeys in Nigeria.

Materials and Methods

Study area: This research work was carried out at the Turkey Breeding unit of the Teaching and Research Farm of the College of Animal Science and Livestock Production (COLANIM), Federal University of Agriculture, Alabata road, Abeokuta, Ogun state Nigeria. The studied area was described by Ilori *et al.*(2010).

The Management of experimental birds: The birds used for this experiment include; two genotypes of day old poults comprising sixty indigenous and sixty crossbred breed generated from mating exotic toms with indigenous hens. The birds were raised under intensive system of management. The toms and hens were housed separately on deep litter. Feed and water were provided *ad libitum*. They were being fed commercial feed and clean water *ad libitum*. Starter diets of 28% crude protein (CP), grower mash of 24% CP and finisher mash of 20% CP were provided for the birds from 0-6 weeks, 7-16 weeks and 17-20 weeks of age respectively. The birds were vaccinated against marek, Newcastle and fowl pox diseases and administered antibiotic and anticoccidial prophylactically. They were placed initially on grower mash and provided with breeder mash after they attained 10% egg production. The birds were wing tagged for proper identification. Body weights were taken weekly on the poults of the two genetic groups from day old to 20 weeks of age. Feed intake was recorded on daily basis while feed efficiency was computed for the two genetic groups throughout the experiment. The two genotypes were reared differently but under the same management system.

Experimental design and statistical analyses: Data obtained were analyzed using General Linear Model of SAS(1999). The model used is as follows:

$Y_{ijk} = \mu + G_i + S_j + (GS)_{ij} + e_{ijk}$

Where

Y_{ijk} = The parameter of interest, μ = overall mean for parameter of interest, G_i= effect of the i^{th}sire genotype (i= 1,2), S_j = effect of j^{th}sex (J = male, female), $(GS)_{ij}$ = effect of the interaction of the genotype and sex while e_{ijk} = random residual error.

New Duncan's Multiple Range Test (Duncan, 2005) was used to separate means which were significant.

Results and Discussion

Body Weight: The analyses of variance for body weight (BW), Sex, feed intake and feed efficiency showed that genotype had significant effect (P<0.05) as shown in table below.

Table 1: Least square means of body weight (g) as affected by genotype and sex

Age in weeks	Genotype		Sex	
	Indigenous	Crossbred	Male	Female
0	44.27 ± 0.62^a	44.32 ± 0.58^a		
2	85.68 ± 15.33^a	94.51 ± 2.33^a	96.41 ± 15.25^a	71.68 ± 1.96^a
4	299.78 ± 7.28^a	338.46 ± 9.96^a	333.23 ± 8.87^a	297.83 ± 7.99^b
8	991.54 ± 21.69^a	1007.13 ± 31.96^a	1060.58 ± 24.62^a	904.64 ± 20.69^b
12	1743.00 ± 38.50^a	1840.42 ± 36.91^a	1844.97 ± 35.91^a	1591.33 ± 29.47^b
16	2302.56 ± 45.78^a	2479.91 ± 43.42^a	2487.47 ± 40.77^a	2223.81 ± 47.57^b
20	2869.68 ± 46.08^b	3330.79 ± 34.01^a	3155.57 ± 44.25^a	2907.86 ± 60.81^b

Within variable grouping, means in the same row with different superscripts are significantly different (P<0.05)

Table 2: The least square means of the effect of genotype on feed intake (g/day)and feed efficiency

Age in weeks	Genotype			
	Feed intake		Feed efficiency	
	Indigenous	**Crossbred**	**Indigenous**	**Crossbred**
2	10.73±1.05[a]	14.13±2.02[a]	0.57±0.06[a]	0.43±0.05[b]
4	31.93±2.78[b]	65.20±10.77[a]	0.50±0.05[a]	0.26±0.05[b]
8	87.39±6.73[b]	136.53±34.82[a]	0.33±0.03[b]	0.27±0.07[b]
12	131.83±16.79[b]	212.02±28.31[a]	0.21±0.03[a]	0.13±0.02[b]
16	190.03±15.03[b]	281.40±40.02[a]	0.12±0.01[a]	0.10±0.01[a]
20	225.66±14.26[b]	343.99±40.64[a]	0.11±0.01[a]	0.11±0.01[a]

Means in the same row with different superscripts are significantly different (P<0.05)

At 20 weeks, the crossbred turkey had superior values in body weight in all the weeks of the experiment suggested that crossbred turkey had a better growth potential than its indigenous counterpart. This agreed with the findings of Ilori *et al.* (2010) who reported that exotic turkey had superior body weight than the crossbred turkey. This was due to the fact that the crossbred utilized the advantage of higher growth rate derived from exotic parent to achieve improved body weight. This further proves that the crossbred is able to transmit the gene for faster growth to its progeny (Ilori *et al.,* 2010) Though o ur indigenous poultry have gone through more of natural selection for adaptation and survival to the tropical climate rather than artificial selection for productivity. The sexual dimorphism exhibited on growth by each genotype in this study agreed with the findings of earlier documented (Hancock *et al.,* 1994 and Deeb and Cahaner, 2001). The above authors opined that males consistently had higher mean values than females and this was attributed to the differences in hormonal profile, aggressiveness and dominance of the males when feeding (Ibe and Nwosu, 1999).The results on feed intake and feed efficiency showed that genotype was affected in the experiment. This result agreed to the findings of Ilori *et al.* (2010), who reported that the crossbred consumed more feed on the average than exotic and local turkeys.This may be due to the fact that they combined the genetic make-up of both the indigenous and the exotic turkey in terms of feed intake. Ayorinde and Oke (1995) reported that the quantity of feed consumed in kilograms by different strains differed as well as the efficiency in converting the feed to flesh.

Conclusion

Differences in body weight, feed intake and feed efficiency observed between the two genotypes could be attributed to differences in their genetic makeup. This suggested that the crossbred turkeys can be further improved to a stage where it will have superior quality in most productive and adaptive traits than their indigenous and exotic parents.

Abstract
Diet is an integral aspect of animal growth and development, adequate amount of needed amino acids must be properly inculcated. This study was conducted to evaluate health status of ducks fed fermented cassava root-leaf meal blend as a replacement for maize. One hundred and fifty, day old unsexed Mallard ducklings was used for the experiment. Ducklings were randomly distributed into 5 groups of 30 ducklings per treatment. Each treatment was further subdivided into 3 replicates with 10 ducklings per replicate in complete randomized design (CRD). The study is made up of 5 dietary treatments consisting of control (Treatment 1), fermented cassava root-leaf blend used to replace maize at 25% (Treatment 2), 50% (Treatment 3), 75% (Treatment 4) and 100% (Treatment 5) levels respectively. The PCV and Hb levels increased as FCRLM inclusion increased in the diet. RBC values recorded increased with increased in dietary inclusion of FCRLM. The result of the hematological parameters revealed that The RBC, Hb, RBC and WBC all showed reference values. However, WBC values recorded were higher than reference values for the species used in this study. Increased in FCRLM led to decreased in blood cholesterol level

Keywords: Ducks, cassava root- leaf meal blend, fermentation, haematology and serum

Introduction
Diet needed for survival of animals and humans due to its basic function in nutrition to supply adequate amount of needed amino acids must be properly addressed (Owosibo and Longe 2007). Dietary components affect the blood profile of healthy birds (Iheukwumere and Herbert, 2012). It is often very difficult to assess the current health status of animals without detailed examination of blood (Amakiri et al., 2009). Examination of blood provides the opportunity to clinically investigate the presence of several metabolites and other constituents in the body and it plays a vital role in the physiological, nutritional and pathological status of the animal (Aderemi, 2004; Doyle and Williams, 2006). The haematological examination is among the methods which may contribute to the detection of some changes in health and physiological status, which not be apparent during physical examination but which affects the fitness of the animal (Bamishaiye et al., 2009).They are good indicators of the physiological status of animals (Adenkola and Durutoye, 2004; Adenkola et al., 2008) and it changes are of value in assessing the response of animals to various physiological situations and disease conditions(Schalm et al., 1975). Evaluation and interpretation of the results obtained are dependent on the reference values for each animal species, in those regions under existing environmental conditions (Otto et al., 2000) which are used as reference point for comparing and interpretation of metabolic state or condition of animals (Babatunde et al., 1992). In Nigeria, due to the scarcity and high cost of conventional ingredients, there is a renewed interest in the use of non-conventional cheap and easily available ingredients in feeding birds. Cassava products have been in use for a long time as an energy source in place of cereal grains for livestock (Eruvbetine et al., 2003) but limited by its high fibre content, low protein value and hydro-cyanic acid which is deleterious to

animal growth and development (Tewe and Iyayi, 1989; Panigrahi ,1996; Yeoh and Yruong, 1993). The inclusion of leaf meal in poultry nutrition serves as sources of proteins, vitamins, minerals and carotenoids at a relatively reduced cost (D'Mello *et al*., 1987; Opara, 1996) and fermentation has been employed to break down fibrous feedstuffs and reduce toxicity of hydrocyanide in cassava leading to nutritionally enriched product due to the increase in growth and proliferation of fungi or bacterial complex in the form of single cell proteins (Antai and Mbongo, 1994; Oboh, 2002) are approaches to alleviate major constraints to cassava utilization in poultry. Therefore, evaluating the nutritional and potential of wholesome mixtures of the three waste materials with the aim of replacing and serving as an input in animal feedstuff production was inevitable. This study was aimed at determining the level of the fermented cassava root leaf meal that ducks can tolerate when included in their diet without detrimental effect on their health status.

Materials and Methods

Experimental site: The project was carried out at the Teaching and Research farm of Yaba College of Technology Epe Lagos State. It is situated at latitude 6.58ºN, Longitude 3.98ºE. It is 42m above the sea level along the Epe- Ijebu Ode road. Epe lies in the low land rain forest, vegetation zone within the savannah agro ecological zones of south Nigeria (Google earth, 2015).
Cassava root- leaf meal processing: Fresh cassava root tubers (TMS30572) were harvested, washed and grated. The cassava leaves were harvested and chopped into smaller pieces using kitchen knife. A maize-soybean diet was formulated as control. Fresh grated cassava root and leaves was mixed at a ratio of 1kg cassava root meal with 300g cassava leaves, fermented for 5 days under an air-tight environment, air dried (for 2-3 days) and used to replace maize at varying proportions in the basal diet. Products obtained at the expiration of the fermentation were analysed for proximate composition using the standard methods of (AOAC, 2002) and gross energy (Adiabatic Bomb Calorimeter).

Experimental Birds, Management and Design

One hundred and fifty, one-day old unsexed Mallard ducklings was distributed randomly into 5 groups of 30 ducklings per treatment. Each treatment was further subdivided into 3 replicates with 10 ducklings per replicate in complete randomized design (CRD). The study is made up of 5 dietary treatments consisting of control (Treatment 1), fermented cassava root-leaf blend used to replace maize at 25% (Treatment 2), 50% (Treatment 3), 75% (Treatment 4) and 100% (Treatment 5) levels, respectively. Diets were formulated to meet the NRC (1994) requirements. The ducklings were raised on deep litter in an open sided deep litter house. Feed were offered *ad libtum.* The study was conducted for a period of 6 weeks.

Data Collection

Measurement of haematological indices
Blood samples meant for haematological indices analysis were collected from ducks at 42 days from 6 birds per treatment through wing vein using sterilized syringe. 2.5ml blood was collected from each bird into vials containing ethytlene diamine tetra-acetic acid(EDTA)as anticoagulant and used for the following hematological determinations: packed cell volume (PCV), red blood cell count (RBC), haemoglobin concentration (Hb), total white blood cell count (WBC), and percentage distribution of white blood cells (differential leukocyte count) using standard techniques (Schalms *et* al*.,* 1975; Coles, 1986).

Measurement of serum metabolites
Blood samples were collected from ducks at 42 days from 6 birds per treatment through wing vein using sterilized syringe. 2.5ml blood was collected from each bird into vials without anticoagulants were ***allowed to clot. The serum from the clotted blood samples were used to determine Total serum protein (TSP),Serum albumin (SA),Serum globulin (SG),Serum uric acid (SUA), Serum creatinine (SC),Serum glucose (SG),Serum enzyme activity (ALT and AST). The total serum protein was determined according to the method of Colowick***

and Kaplan (1955),while serum albumin and globulin were determined using bromocresol purple method of Varley **et al*****.(1980). Serum creatinine was determined using the principle of Jaffe reaction as described by Bousnes and Tauslay (1945) while the serum uric acid was determined by the kit (Quinica Clinica Spam) (Wooton, 1964). Serum glucose was determined colorimetrically using the method described by Braham and Trinder (1972). Serum cholesterol was determined by enzymatic end point method as described by Roeschlau et al. (1974) while serum enzyme activity was determined using the colorimetric method.***

Result and Discussion

The proximate composition of fermented cassava root- leaf meal as shown in Table 1. The result of haematological parameters in Table 2 revealed that RBC, Hb, and WBC were significantly different. PCV and Hb levels increased as FCRLM inclusion increased in the diet. RBC values recorded increased with increased in dietary inclusion of FCRLM but lower than the the proximate composition of fermented cassava root-leaf meal is as shown in Table 1. The result of the haematological parameters (Table 2) revealed that The RBC, Hb, RBC and WBC all showed reference values. However, WBC values recorded were higher than reference values for the species used in this study. The blood parameters are good indicators of physiological, pathological and nutritional status of an animal and changes in values have the potential of being used to elucidate the impact of nutritional factors. This is supported by previous work that RBC, Hb and other parameters vary among bird species and are affected by diet contents (Odunsi *et al*., 1999; Kurtoglu *et al*., 2005). According to Peters et al.,2011), previous reports stated that Packed Cell Volume, haemoglobin and mean corpuscular haemoglobin are major indices for evaluating circulatory erythrocytes, and are significant in the diagnosis of anaemia and also serve as useful indices of the bone marrow capacity to produce red blood cells as in mammals (Awodi et al., 2005; Chineke *et al.,* 2006). Furthermore, Chineke *et al.* (2006) posited that high Packed Cell Volume (PCV) reading indicated either an increase in number of Red Blood Cells (RBCs) or reduction in circulating plasma volume. Table 3, showed that FCRLM at 50% inclusion on serum metabolites like protein, globulin, albumin, uric acid, creatinine, triglyceride, cholesterol, AST and ALT significantly affected the values. A slight decrease was observed in protein, globulin, albumin, uric acid values with increase in the inclusion of test ingredient. The observed decrease in cholesterol level with increase in the FCRLM inclusion could be linked bio active compounds like flavonoid, tannins and saponins present in cassava leaves which prevents LDL oxidation and decreases cholesterol and triglycerides (Sallappan and Akoh, 2002). Also saponin is able to lower biosynthesis of exogenous cholesterol by tying up bile salts and cholesterol in intestine which reduces cholesterol in the blood(Oyewole and Akingbala, 2011).

Conclusion

It can be concluded based on findings of this study that cassava root when fermented with cassava leaves (at 300g/kg leaf- root) can successfully replace maize up to 50% replacement will enhance better blood circulation and health status of ducklings

Abstract
The review assessed the utilization of exogenous enzymes in boosting fibre degradation in poultry nutrition. Specifically, it explained the concept of enzymes, concept of dietary fibre, limitations of enzymes. A thorough literature approach and search was used for this study. The concept of exogenous enzymes indicates that enzymes help fundamentally to improve the efficiency of meat and egg production by changing nutritional profile of feed ingredient. Examples of enzymes includes but not limited to; Amylolytic Enzymes, β- glucanase, Xylanase, β-mannanase. For the purpose of this study, β-mannanase was the main focus due to the importance of the enzyme in poultry livestock. Previous empirical findings revealed that β-mannanase increases; feed conversion ratio, average daily gain, egg weight, overall egg production and also mitigates ileal viscosity in broilers fed at 2.5% guar hulls. One of the limitations linked with β-mannanase is, it does not ease the heat stress of aged laying hens raised under hot climatic conditions. The review concluded that the use of exogenous enzymes (β-mannanase) is important in poultry nutrition because it aids further physiological and morphological development as well as productivity of poultry animal. It was recommended that β-mannanase supplementation should be considered when low energy diets are formulated and under commercial conditions, birds require a minimum and a maximum amount of fiber in their diet for optimal performance.

Keywords: Exogenous enzymes, β-mannanase, Dietary fibre, Egg Production, and Poultry Nutrition.

Introduction
According to Amerah *et al*, (2015) feed are primarily produced to optimize the growth potential of the target animal through a defined nutritional specification. However, feed need to satisfy other criteria including feed safety, which is becoming an important priority and physical quality. Enzymes are organic catalyst that lowers the activation energy in a biological system thereby speeding the rate of reaction. Feed enzyme helps fundamentally to improve the efficiency of meat and egg production by changing the nutritional profile of the feed ingredient. Breanna *et al*, (2017) recently opined that feed constitutes the largest cost in commercial livestock production systems. As the cost of formulated rations increases, improving feed efficiency is an important step for farmers to have an economically sustainable business. Dietary fiber is a concept that is difficult to define chemically and is therefore not easy to measure in feed, Mateos *et al*, (2012). Establishing a proper definition for dietary fibre has historically been a balance between nutritional significance and the availability of adequate analytical methods, with a clear tendency to adapt the definition to the existing analytical procedures rather than to the physiological effects of the different fiber fractions on the physiology and health of the gastrointestinal tract. However, De Vries (2004) defined dietary fibre as the non-digestible fraction of plant cell walls in food and feed ingredients and typically includes oligosaccharides, pectic polysaccharides,

hemicellulose, cellulose, lignin, gums, and some minor associated plant cell wall substances. It encompasses very diverse polymers with large differences in physicochemical properties that, when included in the diet, result in differences in digestive viscosity, ion exchange capacity, fermentation capability, and bulking effect within the gastrointestinal tract. The effects of dietary fibre on voluntary feed intake, organ size, gastrointestinal tract motility, enzyme production, microbiota growth, and bird behaviour differs depending on the source of fiber. Specifically, the effects of dietary fibre on poultry physiology and productivity depend on the inclusion level and source of fiber as well as on the nature of the basal diet, the physical structure of the fiber source, the feed form, and the type and age of the birds, Mateos et al , (2012). In the last fifty years, feeding enzymes to poultry is one of the major nutritional advances. It is the culmination of something that nutritionists realized for a long time. Enzymes are one of the many types of protein in biological systems, Khattak *et al*, (2006). Their essential characteristic is to catalyze the rate of a reaction but is not themselves altered by it. They are involved in all anabolic and catabolic pathways of digestion and metabolism. Enzymes tend to be very specific catalysts that act on one or group of compounds known as substrates. Feed enzymes help break down anti-nutritional factors (e.g. fibre, phytate) that are present in many feed ingredients. Anti-nutritional factors can interfere with normal digestion, resulting in reduced meat or egg production and lower feed efficiency, and can also trigger digestive upsets. Feed enzymes are used to increase the availability of starch, protein, amino acids and minerals such as phosphorus and calcium from feed ingredients, Barlette, (2010). The largest cost of livestock production system is feed. As cost of formulated rations increases, improving feed efficiency is an important step for farmers to have an economically sustainable business. The objectives of this review are as follows; to explain the concept of enzymes, concept of dietary fibre and identify the limitations of enzymes. The paper review adopted a literature review approach in discussing utilization of exogenous enzymes in boosting fibre degradation in poultry nutrition.

Concept of Enzymes

The concept of enzymes in animal nutrition emanates century ago. Breanna *et al*, (2017) identified the enzymes supplemented to animal diets as follows; Amylolytic Enzymes, Proteolytic Enzymes, β- glucanase, Xylanase, β-mannanase and defined these enzymes as enzymes that are expected to increase the digestion and further utilize dietary starch, protein, β-glucose, arabinoxylans and β-mannan respectively. This review using poultry livestock as case study will focus more on the nutritional benefits and drawbacks of β- mannanase and β-mannan.

β – Mannanase (Beta-Mannanase)

From the American Biosystems, Beta-Mannanase (endo-1, 4-ß-mannanase) is made from a refined strain of Trichoderma reesei through liquid fermentation and extraction technology. Beta-Mannanase is a subcategory of hemi-cellulase, which can break the beta-1, 4 glycosidic bonds of mannan into mannan-oligosaccharides. The substrates are ß-mannan, galactomannan, and galactose. It improves the utilization of protein, fat, and carbohydrate by degrading plant cell wall structures.

Benefits of Exogenous Enzymes (β- Mannanase) in Poultry Livestock

In discussing the properties of β-mannanase this review considers the uses and benefits. According to Breanna, (2017) β-mannanase supplementation has proven to be highly effective in increasing feed conversion ratio, average daily gain, and carcass weight of poultry Additionally, increases in egg weight and overall egg production has been linked to β-mannanase supplementation in poultry. Lee *et al*, (2003) found that supplementation of β-mannanase not only removed growth depression and increased feed conversion efficiency, but also mitigated ileal viscosity in broilers fed a ration containing at least 2.5% guar hulls. Mok *et al*, (2013) further revealed that it increased ileal digestibility of amino acids such as leucine and phenylalanine. β-mannanase appears to reduce viscosity in the ileum and thus create an environment that promotes nutrient digestibility and gastrointestinal health. Besides production related improvement, health benefits of supplementing β-mannanase have been reported more often in non-ruminant species. From the findings of Cho and Kim, (2013) it was revealed that broilers fed β- mannanase have low density lipoprotein cholesterol. This indicates that there will be potential increase in dietary fat digestibility and availability of polyunsaturated fatty acids.

Practical Uses of Dietary Fibre

Under practical feeding conditions, gizzard function is enhanced when structural components such as whole grain, coarse particles, or fiber sources are included in the diet. According to Svihus, (2011), when moderate amounts of coarse fiber sources are fed, fiber accumulates in the gizzard and slow feed passage rate in the proximal part of the gastro intestinal tract. In respect of this, insoluble fiber sources such as oats hull or sun flower hull seem to play a more profound role on gizzard activity than soluble fiber sources such as sugar beet pulp. Fiber particles are in general, harder to grind than other dietary particles and consequently, tend to accumulate in the gizzard Hetland *et al*, (2005) where they stimulate organ development and function, especially when large insoluble, lignified fiber sources are used. Large, well developed gizzards, improves gastro intestinal tract motility, favours gastro duodenal refluxes, and stimulates the secretion of pancreatic enzymes Svihus *et al*, (2004). Under practical feeding conditions, particle size and solubility of the fiber fraction in the digestive environment and the degree of lignification are key characteristics affecting bird productivity because of their effects on rate of feed passage in the upper part of the gastrointestinal tract and fermentative ability in the distal part Saki *et al,* (2011). The effects of fiber inclusion on poultry performance depend on the physico-chemical characteristics of the fiber source as well as the species considered and the age of the bird. Probably, the response to fiber inclusion is more limited in pullets than in broilers and in fact, the effects of fiber on gastro intestinal tract development might disappear with time, once the pullets or the young hens are fed a regular laying diet. The effects of inclusion of dietary fibre on physiology and development of gastro intestinal tract, passage rate, microbial growth, nutrient digestibility and growth performance differ depending on the composition of the basal diet, feed form, type and level of dietary fibre and age of the bird, Jimenez *et al,* (2014). Under commercial conditions, birds require a minimum and a maximum amount of fiber in the diet for optimal performance. Therefore, diets for broilers should be formulated with a minimum and a maximum level of dietary fibre De Vries, (2004).

Effect of Dietary Fiber (β-Mannan Polysaccharide) in Exogenous Enzymes (β-mannanase)

According to Moreira and Filho, (2008), the polysaccharide β-mannan is a major component of the plant cell walls and can be classified into 4 groups: pure mannan, glucomannan, galactomannan, and galacto-glucomannan. The livestock industry continues to integrate plant by-products as feed to reduce feed costs. By-products commonly used in livestock diets that contain relatively greater amounts of β-mannans include palm kernel meal (32%), soybean hulls (8%), and soybean meal (3%) Breanna *et al*, (2017). β-mannans are typically known for their structures resistance to solubility that creates high viscosity in feed and therefore promotes anti-nutritive properties in animal feed specifically in poultry livestock Zaib *et al*, (2012). The viscosity of β-mannan has been proposed to be the reason for depressed digestion and absorption in the gut as well as decreased pancreatic enzyme activity within the small intestine of non-ruminants, Breanna *et al*, (2017). Additionally, β-mannans can greatly affect gastrointestinal health by initiating innate immune signalling receptors Ausubel, (2005) and by over-stimulation of immune functions of the mucosal walls in the intestine Zaib *et al*, (2012). Due to immune signalling and stimulation, β-mannan is associated with decreased nutrient utilization, thus requiring surplus nutrient intake to reach the production potential. Additionally, several studies link β-mannan to reduced gastric emptying.

Limitations of Exogenous Enzymes

According to the report by Moon *et al* (2017), the increase of β-mannanase to poultry livestock feeds has little positive impacts on performance and egg quality. Dietary β-mannanase did not ease the heat stress of aged laying hens raised under hot climatic conditions. Svihus *et al,* (2004) revealed that an excess of fiber may have opposite effects. The level of fiber required for optimal performance depends on the source of fiber considered, the age and health of the bird, and the trait studied. **(Make more research to make fleshy)**

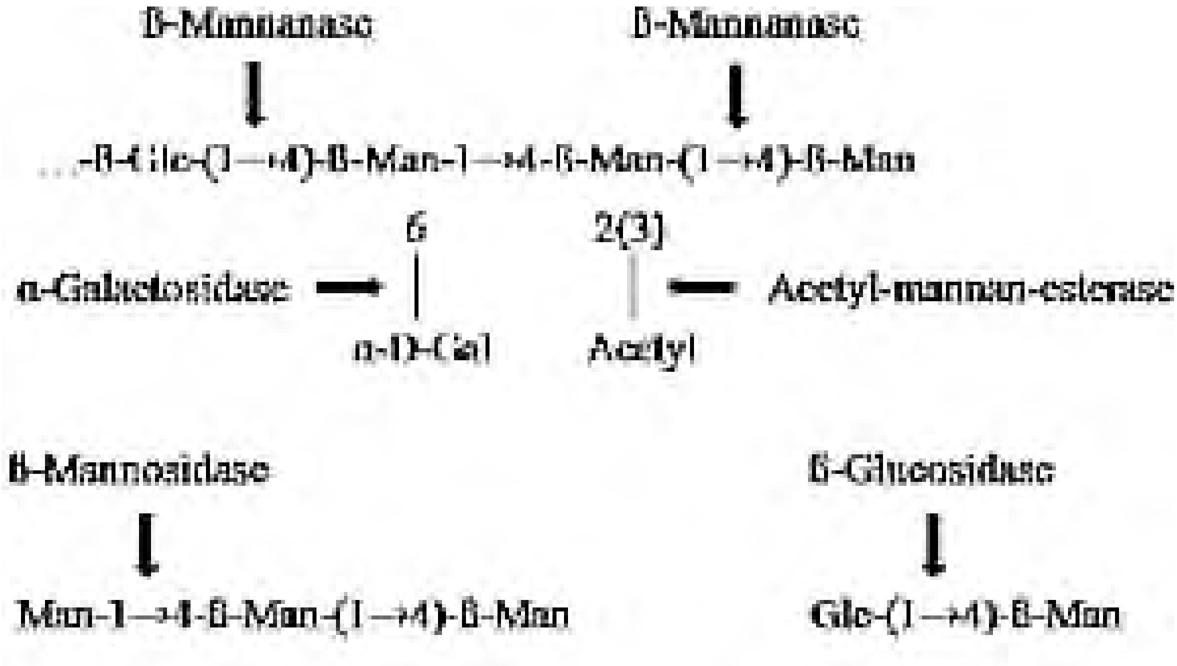

Figure 1: Structures of Enzymes and Polysaccharides
Source: Shastak *et al* , 2015
The structure shows the composition of β-mannanase in poultry nutrition

Conclusion

The review concluded that the use of exogenous enzymes (β-mannanase) aids physiological and morphological development as well as productivity of poultry animal. However, β-mannans promotes anti-nutritive properties in animal feed specifically in poultry livestock. The review recommended that β-mannanase and β-mannans should be added to poultry livestock feeds to aid productivity but the quantity of β-mannans added should be determined by the health and age of the bird so as to attain optimal performance.

Abstract
This study was carried out to evaluate the performance and economic evaluation of broiler chicken fed jackfruit leaf meal as replacement for commercial vitamin-mineral premix. One hundred and twenty birds were randomly selected and allocated to four dietary treatments. In each of the treatment the jackfruit meal was used at different level of inclusion 0.00, 0.25, 0.50, 0.75 % respectively to replace commercial premix. The chicken was fed for seven (7) weeks i.e 49 days. Feed intake was measured daily, and the birds were weighed once weekly. Feed and water were given ad-libitum. The experimental design used is Complete Randomized Design (CRD). Result showed that there was significant difference ($P<0.05$) in feed intake among broilers fed 0% (T_1), 0.25% (T_2), 0.50% (T_3) and 0.75% (T_4) levels of inclusion of jackfruit leaf meal as a replacement for vitamin mineral premix. There was no significant difference ($P>0.05$) observed in daily weight gain among T_1 (12.811±1.93), T_2 (12.417± 0.376), T_3 (12.623 ± 0.597) and T_4 (12.176 ± 1.027). The result showed no significant in the feed cost benefit analysis.

Introduction
Poultry has been identified as a means of bridging the protein intake deficiency in Nigeria. The main limitation of expansion of poultry industry is the availability of adequate supplies of needed feed ingredient at reasonable price (Ani and Okone, 2005; Babatunde and Hazat, 2005).
Feed make up for about 70% of all the cost of production (Ademola and Farinu, 2006) and high cost of feed in mainly as result of competition of most ingredient between man and livestock for grain and conventional source of plant and animal protein(Adegbola, 2007; Emenalom, 2004).The most promising way to solve the problem of competition between man animal for protein is to identify cheaper and easier available feedstuff that are of low human preference and little or no industrial uses that can meet nutritional requirement of poultry with or without processing (Fanimo *et al*; 2004, Fasina *et al*; 2004) as reported by Onunkwo, 2017.
Jackfruit leaf is therefore found to be rich in vitamin and mineral, thiamin and riboflavin which helps in turning the food into energy and keep the eyes, hair healthy; It contains compound that have antimicrobial effect which could help prevent contamination with bacterial that causes food borne illness (Smriti, 2017).

Materials and methods
This study was carried out at the Teaching and Research Poultry unit of the Department of Animal Science and Technology, Faculty of Agriculture, Nnamdi Azikiwe University, Awka,

Anambra State. The location lies between Latitude 6.24^{0}N and 6.28^{0}N and longitude 7.00^{0}E and 7.08^{0}E on the South Eastern part of Nigeria, the climate is the tropical wet and dry type with a clear season, the mean daily maximum temperature is usually 27^{0}C all over the year although it could reach 34^{0}C in March and lowest during the harmattan months of December and January (Ezenwaji *et al,* 2013).
Jackfruit leaf meal was purchased at Ifite, Awka in Anambra State, Nigeria. Some branches were cut from the tree and later was manually plucked and sun dried for three (3) days, then crushed into fine particles size.
One hundred and twenty (120) day old chicks was randomly assigned into four (4) treatment group of 30 birds per treatment and 3 replicates of 10 birds per replicate. Complete Randomized Design was used. Each group was raised on wood shavings litter and contained with feeders and drinkers to provide *ad-libitum* access to feed and water. Chicks were brooded with charcoal stove and kerosene lamp for seven days, thereafter the intensity of light was reduced gradually from 14-16 hours/day. Routine vaccination against common diseases (Newcastle and gumboro) and medication was administered to birds and this was done throughout the experiment. The experiment lasted for seven (7) weeks. Three (3) weeks for starter phase and four (4) weeks for finisher phase.
The birds were fed with commercial feed at the first week, then the chicks were divided into four treatment dietary treatment groups as T_1 (0% JFLM), T_2 (0.25% JFLM), T_3 (0.50% JFLM) and T_4 (0.75% JFLM) as presented in Table 1 and 2 for starter and finisher diet.
Data were collected on initial weight, feed intake, average weight gain and feed conversion ratio. The cost of treatment diet (naira/kg) was recorded to determine the cost of each diet. Feed intake per bird per treatment for the experimental period was used to multiply the cost per kilogram feed to obtain the cost of feed consumed per bird. The cost per weight gain was determined which involves taking the pr5oduct cost per kg feed and feed to gain ratio (FGR) of consuming the diet.
All the data were subjected to Analysis of Variance as described using SPSS package (2003) windows version 8.0. and means separated using Duncan New Multiple Range Test (Duncan, 1955)

Table 1: Gross Composition of Experimental Diet for Broiler at Starter Phase

Ingredient	Diet 1	Diet 2	Diet 3	Diet 4

Results and Discussion

The result of this study showed that there was significant ($P<0.05$) difference in average feed intake among treatment group as shown in Table 3. T_1 had the highest feed intake. This finding contradicts with Mahadevan and Pradeep, (2009) that observed that the inclusion of *Moringa Oleifera* leaf meal at 5% and 7.5% respectively enhanced better feed intake

The result of this study showed that there was no significant ($P>0.05$) difference in weight gain amongst treatments. This could be due to the relatively similar crude protein of the four diets. T_3 recorded the highest weight gain. This is probably because the minerals, vitamins as well as amino acids in the jackfruit have higher biological functions which acted as growth promoter's enhancers, antimicrobial agents and absorption enhances, antimicrobial agents and metabolic modifiers (Gill, 2009). The birds differ significantly ($p<0.05$) from other treatment groups. The study agreed with the findings of El-Husseiny, (2002) that using medicinal plants mixture improves digestibility of broiler birds.

The results of feed conversion ratio of this study showed that there was significant ($P<0.05$) difference amongst treatment, however, T_3(9.47 ± 0.19) had the best feed conversion ratio, whereas T_2 (10.31 ± 0.28) had the least conversion ratio, this could be due to the relatively higher crude fibre content of the T_3 diet compared with the T_2 diet. This agrees with the work of Iguro, (2014) that observed significant difference ($p<0.05$) in the growth parameters among the four treatment fed jackfruit leaf meal.

The results of feed cost benefit analysis of this study showed that there was significant ($P<0.05$) difference amongst treatment, however, T_2 has the least cost, whereas T_1 had the highest cost. This could be due to high cost of commercial vitamin premix in the T_1 diet. This is in agreement with some works that reported leaf meal supplementation in the diet of poultry as a means of reducing high cost of conventional protein sources and to improve profit margin (Onyimonyi *et al.,* 2009). There was no significant ($P>0.05$) difference in the gross profit margin amongst treatments, this could be due to relatively similar cost of production of the birds. T_3 showed the highest profit margin while T_1 was the least. This is in agreement with some works that states that Leaf meal supplementation has been included in the diet of poultry as a means of reducing high cost of conventional protein sources and to improve profit margin (Iheukwumere *et al.,* 2008).

The result of this study showed that there was significant ($P<0.05$) difference amongst treatment with respect to return on investment. T_2 recorded the highest value on the return on investment while T_1 recorded the least. The result of this study showed that there was significant ($P<0.05$) difference amongst treatment with respect to return on investment. T_3 recorded the highest feed cost benefit while T_4 records the least.

Conclusion And Recommendation

It can be concluded that jackfruit leaf meal can be used replace vitamin premix by 0.25%, 0.50% and 0.75% because there is no significant (P>0.05) difference on weight gain among them. Although the best level of inclusion of jackfruit leaf meal as a replacement for vitamin premix is 0.50% since the broilers achieved their highest feed intake, weight gain, highest profit and least cost of production.

In view of the high cost of conventional vitamin premix as a source of vitamins for livestock and poultry, I recommend that jackfruit leaf meal can be used as a replacement for commercial vitamin premix at 0.50% level in broiler diet. This will obviously give a better performance and minimal cost.

Abstract
This study was conducted to assess the growth performance of Archachatina marginata fed diets containing poultry dropping meal. 120 grower Archachatina marginata snail species were used for the experiment which lasted for 8 weeks. Four treatment diets were formulated with inclusion of various levels of poultry dropping meal. Diet 1 (T1) had 0%, Diet 2 (T2) had 10%, Diet 3 (T3) had 20% and Diet 4 (T4) had 30% inclusion of sundried poultry dropping meal. The snails with similar body weight were randomly allotted to four different dietary treatments and each treatment was replicated three times with 10 snails in each replicate. Proximate analysis of the sundried poultry dropping was done at the beginning of the experiment to assess the proximate composition of the poultry dropping meal. Data were obtained on weight, shell length, shell girth, shell aperture, feed intake, shell thickness, cost per feed intake and feed cost per weight gain and were analyzed using one way Analysis of Variance (ANOVA) and Duncan Post Hoc Test. The result of the experiment showed that there were no significant differences (P>0.05) in weight gain, average daily weight gain, shell length increment, shell girth increment, shell aperture increment, shell thickness increment, total feed intake and average daily feed intake. There were significant differences (P<0.05) in the feed conversion ratio, cost per feed intake and feed cost per weight. Diet 2 (10% poultry dropping meal inclusion) recorded least feed cost per weight gain and best feed conversion ratio and so is recommended to snail farmers for maximal growth at low cost of production.

Keyword: Archachatina marginata, poultry dropping meal, growth parameters

Introduction

One of the most serious nutritional problems in the developing countries of which Nigeria is not excluded is the shortage of protein from animal sources and this is because, most of us are yet to discover what nature has endowed us with (Chidulue,2015). Animal proteins are more biologically complete than vegetable protein because they contain a complete range of amino acids that are essential for maintenance of health (Hoffman *et al.*, 2014). According to Ajibefun (2000) as cited in Amumihe *et al.,* (2015); the average animal protein intake in Nigeria is low, calling for concerted effort towards alleviating these crises of protein shortage. Food and Agricultural Organization (FAO) recommended 35g of animal protein per person for normal growth and development but average Nigerians consume 8g of animal protein out of the recommended (Oayida *et al.,* 2007) which is not far from the fact that the contributions of the conventional sources of meat as protein are not enough and at the same time too costly to meet the required need of an average Nigerian. This crisis then, can be alleviated by looking into unconventional sources as suggested by (Ebenebe, 2000; Etchu *et al.,* 2008) referred to micro livestock production.

Micro livestock production refers to rearing of unconventional animals of which the production of snail is part of it. Snails have been known as a valuable source of animal protein in many countries in the world. Its meat compares favourably to other conventional sources of animal protein like beef, pork and poultry meat (Nyameasem and Borketeyla, 2014). Snail meat popularly known as Congo meat in many parts of Nigeria is known to contain high protein, low cholesterol, iron, calcium, magnesium, phosphorus, copper and zinc as well as vitamin A, vitamin B6,vitamin B12,vitamin K, folic acid, etc (Ukpong, 2009). It is also relatively cheaper when compared to conventional sources (Fagbuaro *et al.,* 2006).
However, to rear these snails in captivity requires adequate supply of feed (balanced ration) as it constitutes the major factor in livestock production, thereby making the availability of feed resources at low cost the key to the success or failure of livestock industry (Omole, 2012). Snails are herbivores and feed on many plant feed resources like pawpaw leaf, banana leaves and so on (Omole, 2012) but such vegetables and fruit peels alone cannot meet the nutrient requirement for fast growth and reproduction in snail (Ebenebe *et al*., 2014) and so production of commercial feed for snail at low cost is deemed necessary.

Fish meal as feed ingredient in the formulation of snail feed due to its high cost adds to making these commercial feeds costly. Poultry droppings on the other hand, is a waste protein source and has a high content of nitrogen, readily available in large quantity from the birds managed in battery cages and some in deep litter in the south eastern states of Nigeria. According to Durunna *et al.,* (2015); poultry droppings can be used at any level as feed ingredients in the production of African giant land snails. It will make good business tool for making profit and there is need to investigate the use of poultry dropping meal as feed material beyond 28 days. Therefore, this work is aimed at determining the growth performance of *Archachatina marginata* fed diets containing poultry dropping meal and the level at which poultry dropping meal can conveniently substitute fish meal in snail feed and also the cost effectiveness of the use of poultry dropping meal as feed material to reduce fishmeal inclusion.

Materials and Methods

This research was carried out at the Snail and Edible insect unit of the Teaching and Research section of the Department of Animal Science and Technology in Nnamdi Azikiwe University, Awka (6°11'N and 7°02'E) according to Ezezue *et al.,* (2017). The snails were reared in plastic bowls of 7.5cm height, 28cm diameter, 88 cm circumference and 7.5litres capacity, filled to one-third with treated soil The poultry droppings used for the experiment was purchased from Handmaids Girls Secondary School, poultry farm, Amansea, Awka South Local Government Area, Anambra State, sundried and milled with its proximate analysis done. 120 grower snails (*Acharchatina marginata*) with average weight range of 52.40g to 59.85g were procured from Ochanja market, Onitsha, Anambra State. The 120 snails were allotted randomly to four diets of 30 snails per treatment. Each treatment was further sub divided into three replicates groups of 10 snails each. During the experiment, four dietary treatments were formulated based on the level of inclusion of the poultry dropping meal to reduce the fishmeal portion of the diet. These treatments were designated as Treatment 1(T_1) (had 0% inclusion of the poultry dropping meal with 5% fishmeal and served as the control), Treatment 2 (T_2) (had 10% inclusion of the poultry dropping meal with 4% fishmeal), Treatment 3 (T_3) (had 20% inclusion of the poultry dropping meal with 3% fishmeal) and Treatment 4 (T_4) (had 30% inclusion of the poultry dropping meal with 2% fishmeal).The Experimental design was therefore a Completely Randomized Design (CRD), with four treatments and three replicates per treatment with the model $Yij= \mu+ Ti+ Eij$ where Yij is observation made on i^{th} treatment (growth indices of snails) arising as a result of μ (population mean),Ti(Treatment effect), Eij(Experimental error),i(Number of treatment) and j(Number of replicates).The gross composition of each of the experimental diets is presented in table 1.

Table 1: Gross composition of the Experimental Diet used for the Study.

Ingredients	T1 (0%)	T2 (10%)	T3 (20%)	T4 (30%)
Maize	21.00	17.00	20.00	13.00
Cassava flour	14.75	13.75	10.75	11.75
wheat offal	14.00	14.00	10.00	10.00
Soya bean meal	25.00	21.00	18.00	18.00
Groundnut cake	15.00	15.00	13.00	10.00
fish meal	5.00	4.00	3.00	2.00
poultry dropping meal(PDM)	0.00	10.00	20	30
Bone meal	2.50	2.50	2.50	2.50
Limestone	2.00	2.00	2.00	2.00
Lysine	0.25	0.25	0.25	0.25
Methionine	0.25	0.25	0.25	0.25
TM/Vit premix	0.25	0.25	0.25	0.25
Total	100	100	100	100
Crude protein%	24.03	23.97	24.14	24.19
Energy Kcal	2670.57	2640.60	2686.43	2646.25

The diets were presented to the snails in the flat round plastic troughs inside their respective bowls. The snails were fed once a day for 8 weeks and water sprinkled daily. Data on feed intake was collected daily while data were collected weekly on the following; body weight(measured in g using SF400 sensitive weighing scale), shell length and shell girth(measured in cm using A30018 Vernier caliper) and shell aperture (measured in cm using thread and meter rule). Data on shell thickness was collected only at the beginning and end of the experiment. Feed conversion ratio was obtained by dividing the total quantity of feed consumed by the total weight gain. The feed cost (₦/g)was calculated by dividing the total cost of ingredients (plus transport cost) by the total gram of feed produced for each group. Cost of feed intake was calculated by multiplying feed cost by total feed intake. Feed cost per weight gain (cost of production per treatment) was realized by multiplying feed cost(₦/g) by Feed conversion ratio.
Data collected were analyzed using one way analysis of variance (ANOVA), using SPSS Computer Software Package (version22) at 0.05 significant level. The sample means were separated using a Post Hoc Test (Duncan Multiple Range Test).

Result and Discussion

The chemical composition of the experimental diets is presented in Table 2.The proximate composition of the anand poultry dropping meal used is presented in Table 3 while in Table 4 is the summary of the performance of experimental snails. The result showed that there were no significant differences (P>0.05) on the weight gain as all the snails gained similar weight among treatments. Poultry dropping meal(PDM) had no significant effect on the feed intake as all the treatments compared favourably.This shows that PDM was well accepted by the snails and this agreed with the report of Ademolu(2005) who fed snails with 20% poultry dropping meal inclusion and pawpaw leaf. There were significant differences (P<0.05) on the feed conversion ratio between treatments; Treatment 4 (T4) had the highest value of 2.29 while Treatment 2(T2) had the lowest value(1.43) which implies that Treatment 2 converted less feed to more meat and so the best feed converter. No significant differences (P>0.05) were also observed on the shell characteristics of the snails (shell thickness, shell aperture, shell length and shell girth) and this means that poultry dropping meal (PDM) used as a feed ingredient to reduce quantity of fishmeal in snail feed had no negative effect on the shell characteristics. This could be as a result of relatively same ash content in the feed as shell of snail is made of calcium which is present in the ash(Hamzat 2004; Omole *et al.,* 2008). Feed cost per gram decreased as inclusion of PDM increased. Treatment 1(T1) had ₦0.315 while Treatment 2,Treatment 3(T3) and Treatment 4 had ₦0.267, ₦0.222 and ₦0.177 respectively. The lowered feed cost in Treatment 2 to Treatment 4 was as a result of cheap sourcing of alternative feedstuff which agreed with Abel *et al.,* 2014 that stated that there is lowered feed cost when an alternative feed ingredient is used in place of conventional feedstuff. Cost per feed intake(₦/g) was significantly lower($p<0.05$) for snails on T4(₦5.69) than snails on T3(₦7.53), T2(₦8.54) and lastly T1which had high value of ₦9.16. Significant difference($p<0.05$) was noted in the feed cost per gram weight gain(cost of producion), it was observed that T4(₦7.22) was similar with T3(₦6.98) and T3 being closely related to T1(₦5.67) and least in T2 (₦4.51).This pattern of increase in cost of production was influenced by feed conversion ratio.The chemical compositon of the experimental diet and proximate compositon of the poultry droppings meal are shown in table 2 and 3.

Data represents mean ± standard deviation. Row Sharing different superscripts are significantly different (P<0.05)

Conclusion

The result of the research suggest that poultry dropping meal can be included in all the proportions (10%, 20%, 30%) as feed ingredient to reduce fish meal inclusion in snail feed for the production of *Archachatina marginata* snails. The utilization of this poultry waste (faecal material) reduced waste and pollution in the environment and most importantly reduced cost associated with usage of fishmeal in snail feed.

Abstract
This study was carried out to evaluate the haematological and blood biochemical parameters of broiler chickens fed graded levels of Roselle Seed Cake (RSC) diet as replacement for groundnut cake (GNC). Proximate Composition of the test diet and experimental diets were conducted to determine their nutrient contents. Four diets were formulated for the broiler starter and finisher phases respectively; The Diet 1 served as the control diet while diets 2, 3 and 4 contained 8%, 16% and 24% with Roselle seed cake (RSC) diets respectively as replacement for groundnut cake (GNC). A total of 120 day old Ross broiler chicks were randomly allotted to four dietary treatments with four replicates and each treatment consisted of 30 birds in a completely randomized design (CRD). Feed and water were provided for the birds ad libitum. The blood parameters measured are haemoglobin, packed cell volume, red blood cell, white blood cell, heteropils, lymphocytes, monocytes, eosinophils, basophils and band cell. The results from the parameters measured for blood quality showed no significant (P<0.05) differences for haemoglobin level, packed cell volume (PCV), white blood cell (WBC), across the treatments. But the red blood cell (RBC), heterophils and lymphocytes had a significant difference across the dietary treatments and this implies that Roselle seed cake (RSC) inclusions in the diets of the birds had a positive effect on the oxygen carrying capacity, immunity level and antibodies producing capacity of the birds. The blood biochemical parameters measured are total protein, albumin, cholesterol, creatinine, triglycerides, HDL and LDL. The parameters measured showed no significant (P<0.05) differences in total protein (TP), creatinine, high density level (HDL) and low density level (LDL) across dietary treatment while albumin and cholesterol had significant differences (p>0.05) across the dietary treatments. RSC can replace GNC at 16% dietary inclusion levels.

Introduction
The poultry industry in Nigeria, in the last decade, has been greatly affected by high cost of feed (ogbuewu *et al*, 2010). The provision of feed alone has been reported to account for 60 - 80% of the total cost in most livestock production in developing countries such as Nigeria (Igboeli, 2000) and this emphasize the interest to develop local feedstuffs.
Protein is a very important nutrient that is responsible for growth and its deficiency leads to growth depression. Proteins are used in the construction of body tissues such as muscles, nerves, cartilage, skin, feathers, beak, and so on. All animals require protein for growth, reproduction and production depending on the age, productivity of the animal and their environment (Olomu, 1995)

The conventional protein feedstuffs for poultry such as soya bean meal (SBM), groundnut cake (GNC) and fish meal (FM) are scarce and expensive because they are competed for by humans as food and other industrial uses. The development of alternative protein feedstuffs in animal diets will therefore continue to be a necessity in developing countries. In view of this, there is increased interest by Nigerian livestock farmers to harness unconventional feed ingredients such as Roselle seed meal.

Roselle (*Hibiscus sabdariffa L.*) belongs to the *malvaceae* family and forms a popular vegetable in Indonesia, India and many tropical regions (Tindal, 1986). It is now widely grown in the North Eastern and middle belt regions of Nigeria (Akanya *et al*., 1997) mainly for its calyxes used for the preparation of a local drink but the leaves are also used for soup and as pot herb (Adigun, 2003). The leaves are used as vegetable and the floral parts in the preparation of "Zobo", a local drink. The stem provides fibre and the seeds are eaten by scavenging poultry(Phillips, 1997). The seed of *Hibiscus sandariff* is said to have high protein value and it is on account of its protein content that it is well priced for human consumption. They also contain high amount of minerals such as calcium, magnesium and phosphorus. The seeds from Nigeria are reported to contain about 35.90% crude protein, 10.14% ether extract, 10.09% ash and 15-17% crude fibre (Dashak and Nwanegbo 2002).

The use of blood examination as a way of assessing the health status of animals plays a vital role in physiological, nutritional and pathological status of such animal (Muhammad *et al*, 2000).

Haematology has been defined as the study of blood and an important part of clinical pathology as well as diagnostic process (Lutz and Pryluski, 2008). Haematology includes not only the examination of the cellular and fluid portions of blood, but also includes a study of the tissues that form, store and circulate blood cells. However, the serum is the component that is neither a blood cell nor a clotting factor. It is the part of blood that is like water and that contains substances (called antibodies) that fight disease.

Serum includes all proteins not used in blood clotting and all the electrolytes, antibodies, antigens, hormones and any exogenous substances (Martin, 2007). The result of haematology and serum analysis is usually used to assess the health status of an animal.

Haematological and serum parameters have been observed as good indicators of the physiological status of animal and their changes are important in assessing the response of such animal to various physiological situations (Khan and Zafar, 2005). This study was carried out to determine the effects of Roselle seed cake meal on haematological and serum biochemical profile of broiler chickens.

Materials and methods

The experiment was carried out at the Poultry Unit of Teaching and Research Farm of Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria. Umudike is located within Latitude 5º 28' North, longitude 7º 32' East and on an altitude of 122m above sea level. The area falls within the Tropical Rainforest zone. Annual rainfall averages 2177mm. The monthly ambient temperature ranges between 20^{o}C and 36^{o}C, and relative humidity between 50 and 59%, depending on season (NRCRI, 2017).

The experimental materials; maize, Roselle seeds, soya bean meal, etc were procured from a local market in umuahia, abia state. Samples of the Roselle seedcake and experimental diets were taken to the Animal Science Biochemical Laboratory of Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria for proximate analysis using the methods described by A.O.A.C (2005). The analysis was done to obtain the nutrient composition (Dry matter, Ash, ether extract, crude protein, crude fibre and nitrogen free extract) of the experimental diet. The metabolizable energy was determined using the Janssen formula (Janssen, 1989).

Four diets isonitrogenous and isocaloric diets (23.62 %CP; 2959kcal/kg ME) and (19.28 %CP; 2961kcal/kg ME) were formulated for the broiler starter and finisher phases respectively as follows: Diet 1: 0% of Roselle seedcake in the diet (control), Diet 2: 8% level of Roselle seed cake in the diet, Diet 3: 16% level of Roselle seed cake in the diet and Diet4: 24% level of Roselle seed cake in the diet. Gross composition of the experimental diets are presented in Tables 1 and 2 respectively.

One hundred and twenty (120) day old Ross broiler chicks were purchased from a reputable farm in Ibadan and were used for the starter and finisher phases. The broiler chicks on arrival were counted and were given a common ration for one day and allowed to adapt to the environment. Their initial average weight was recorded and the chicks were randomly distributed into four treatment groups of 30 chicks each with four replicates of 15 chicks per pen in a Completely Randomized Design (CRD). Each group was assigned to the four experimental diets and they were all subjected to the same management practices all through the period of the experiment.

The birds were given lasota Intra ocular (I.O) vaccine on arrival and vitalyte was added to their water to reduce stress. They were given their first dose of gumboro at 7 days old, first dose of lasota at 14 days old while second dose of gumboro and second dose of lasota were administered at 21 days and 28 days old respectively. The birds were also treated against coccidiosis orally at 3weeks of age.

In the starter phase (0-4weeks) the birds were assigned to four dietary treatments where RSC was included at 0, 8, 16 and 24% respectively. The 0% represents the control group without Roselle seed cake in their diets while others are fed diets with inclusion of Roselle seed cake in their diet. They were fed starter feed. Feed and water were provided *ad libitum* throughout the study period. In the finisher phase (5-8weeks) birds from the starter phase were used. The birds were assigned to four dietary treatments as in the starter phase but their feed was changed to broiler finisher feed. Feed and water were provided *ad libitum.*

At the end of the experiment, 1.5 millilitres of blood were collected from the wing vein of each bird with disposable 2ml syringes and needle set. Three birds per replicate making a total of nine birds per treatment were randomly selected. Blood samples were collected into labelled bottles containing Ethylene Diamine Tetra acetic Acid (EDTA) and taken to the nutrition and biochemical laboratory for determination of haematological parameters. The samples were assayed for: Packed cell volume (PCV), haemoglobin content (hb), white blood cell (WBC), red blood cell (RBC) and differential blood count (heterophils, lymphocytes, monocytes, eosinophils, basophils and band cell).

The data obtained from the study were analyzed using One-way ANOVA. The General Linear Model procedure of Statistical Analysis System (SAS, 2002) was used and the mean was separated using Dunnet because the control diet was used to compare with other treatments (Dunnet, 1964).

Results and Discussion

According to the proximate composition of Roselle seed cake presented in table 3, the dry matter content was 95.15%, crude protein 32.45%, crude fiber 4.25%, ash 6.25%, ether extract 10.05% and nitrogen free extract content was 50.05%. Ether extract value of 10.05% was lower than the value of 15.4% reported by some authors. The metabolizable energy value of 3059.64kcal/kg agreed with the range of 2880-3500kcal/kg reported by various authors. The variations in values obtained and reported by various persons could be as a result of different sources of Roselle seed cake, differences in processing methods and storage conditions.

The values obtained for haemoglobin (11.56-12.37g/dl) for broiler chickens 0% (control) diet to 24% diet group fell within the normal range values (8.00-13.00g/dl) for domestic chickens as shown in Table 4. This signifies that the birds had good aerobic capacity and were not aneamic.

The packed cell volume values obtained amongst the treatments are not significantly different ($p<0.05$) except for T_2 (8%) which is higher with value 37.27% and show a significant difference from others.

The red blood cells values obtained from T_4 (24%) and T_2 (8%) diets agrees with the average values of RBC (2.5-4.5mm^3) while that of T_3 (16%) and T_1 (0%) are a bit higher. This implies that birds under T_3 and T_1 diets had higher oxygen carrying capacity but none of the birds had depressed bone marrow.

There is no significant difference ($p<0.5$) in the white blood cell (WBC) values amongst the dietary treatments. This showed that the birds WBC produced antibodies which protected the birds from infectious agents.

The Heterophils were not significantly different ($p<0.05$) within the dietary treatments except for T_3 (16%) diet which is higher and significantly different ($p >0.05$). This implies that birds under T_3 diets had higher immunity to infections and bacteria than birds in other dietary treatments since high level of heterophil prevents infections.
The lymphocyte values obtained from T_2 (8%), T_3 (16%) and T_4 (24%) diets; 51.43-53.16% showed significantly different ($p>0.05$) from that of T_1 (control) diet; 50.02. They all agree with the average value which is around 20-55% but birds under the control diet produced lesser antibodies than birds under 8%-24% dietary treatments.
The differential counts like Eosinophil, Monocytes, Basophils and Band cells were not significantly difference ($p<0.05$) from each other across the dietary treatments.
There were no significant difference ($p<0.05$) in the total protein as shown in Table 5. The values obtained from the dietary treatments (2.75-3.01g/dl) agrees with the average total protein value (2.5-5.5g/dl) and this shows that the birds growth and body were proper.
There was significant differences ($p>0.05$) in albumin and cholesterol values of the different dietary treatments. This indicates that Roselle seed cake had an effect on the protein, cholesterol level and health status of the birds.
The creatinine values obtained (0.44-0.52mg/dl) fell within the range values (0.20-0.5mg/dl) and **t**his signifies that roselle seed cake did not have any detrimental effect on the kidney function of the birds because feeds were properly utilized by the birds.
There was significant difference ($p>0.5$) in tryglyceride value between the different dietary treatments with 24% dietary treatment being the highest amongst others.
High density lipoprotein (HDL) and low density lipoprotein (LDL) is a combination of lipids and proteins. The higher the lipoprotein value, the better because it lowers the risk of coronary artery disease.

Conclusion

Based on the findings from the study, it was concluded that Roselle seed cake (RSC) as an alternative feedstuff can replace groundnut cake (GNC) at 16% dietary roselle seed cake inclusion levels and incorporated in the diet of broiler chickens. Inclusion of RSC in the diets of broiler chickens did not have adverse effect on the haematology. Feeding RSC to broiler chickens do not have any adverse effect on their blood biochemical indices.

Table 3: Proximate composition and energy value of Roselle seed cake

Abstract
This study was conducted to evaluate the performance of broiler chicken fed raw, dehulled and boiled kidney bean seed meal on the feed intake, weight gain, feed conversion ratio and the cost implication of feeding these diets. The experiment lasted for seven weeks (excluding 1week of acclimatization). A total of One hundred and twenty (120) unsexed day old Abor acre chicks were used for the experiment. The birds were weighed and randomly distributed into four treatments using Complete Randomized Design (CRD) with 30 birds per treatment and 10 birds per replicate. The dietary treatments were replicated three times and they include T_1, T_2, T_3 and T_4 which were diets made without kidney bean, with raw kidney bean, dehulled kidney bean and boiled kidney bean respectively. The diets were fed at both starter and finisher stages. The feed intake was recorded daily while the weight gain was recorded weekly but the cost implication of feeding the diets to the birds was assessed at the end of the experiment. The data collected were subjected to analysis using SPSS and differences between means were separated using Duncan Multiple Range Test. Highest value of average daily feed intake was recorded in T_1(13.77) followed by T_4(13.63) and then T_3(13.21) while the lowest value was recorded in T_2(11.96). There was no significant difference ($p>0.05$) between birds fed T_1 and T_4 diets. There was no significant difference between birds fed T_3, T_4 and T_1 diets. There was no significant difference between birds fed T_3 and T_2 diets. There was a significant difference ($p<0.05$) between birds fed T_1 and T_2 diets as well as in birds fed T_4 and T_2 diets. There were no significant differences between the treatments ($p>0.05$) in the total weight gain of the birds. The Feed Conversion Ratio (FCR) of the different treatments were not significantly different ($p>0.05$). There was no significant difference ($p>0.05$) in the cost of feed per weight gain in T_2, T_3 and T_4 diets. It is concluded that aqueous heating is better for processing kidney beans for inclusion in the diets of broiler chickens as well as for a cheaper cost of production.

Introduction
Feed is one of the essentials in animal production. In animal feed, the protein required is supplied by both animal and plant sources of protein. The plant protein sources are cheaper compared to animal protein sources and the plant protein supplements are lower in some essential amino acids, energy and minerals such as phosphorus as compared to animal protein supplements (Yun *et al*., 2005). In recent times, there has been a wide gap between production and supply of animal protein to feed the ever increasing population of over 140 million Nigerians (National Population Commission, 2006) resulting in low per capita consumption of the product (Christopher *et al.* 1997 as cited by Oyebode, 2015). This high cost of broiler production leads to low poultry production, high cost of poultry meat and protein malnutrition in household. According to other researchers, the high cost of feed for poultry production is mainly based on the high cost of energy and protein sources of the feed. Kidney bean (*Phaseolus vulgaris)* is considered as a potential component of diets of pigs and poultry. Kidney bean contains high amounts of protein and energy, and amino acids content is similar to that of soybean except for a lower level of methionine (Laurena *et al*., 1991 as cited in Emiola, 2011). It is also a rich source of vitamin, minerals and relatively high in

crude fiber. The Seeds are also rich in calcium, phosphorus and iron. According to Audu *et al* (2011), the minerals contained in red kidney bean include the following: calcium, nickel, zinc, manganese, magnesium, copper, iron, cadmium, lead, sodium, potassium, phosphorus, chromium while the amino acids includes lysine, histidine, arginine, aspartic acid, threonine, serine, proline, glutamic acid, alanine, valine, cysteine, methionine, isoleucine, phenylalnine and tyrosine. The fresh pods and green leaves are used as vegetable. Kidney beans are also known as the chilli beans. These are dark red in colour and visually resemble the shape of a kidney (Soumya *et a1*, 2012). Kidney bean as well as other legumes has been reported to contain anti-nutritional factors particularly haemagglutinin and trypsin inhibitors (Amaefule *et al*., 2005; Teguia *et al*., 2008; Akande *et al*., 2010; Maidala *et al*., 2016) which limit their utilization in animal feeding. The objective of this study was to evaluate the growth performance, the FCR and the cost implication of feeding differently processed kidney bean seed meal based diet to broiler chickens.

Materials and methods

The study was carried out at the Poultry unit of Teaching and Research farm in the Department of Animal Science and Technology, Faculty of Agriculture, Nnamdi Azikiwe University, Awka, Anambra state. Awka town is located between latitude 6.24^{o}N and 6.28^{o}N and longitude of 7.00^{o}E and 7.06^{o}E on the South Eastern part of Nigeria, the climate is the tropical wet and dry type with a clear cycle of seasons. The mean daily maximum temperature is usually 27^{o}c all over the year although it could reach 34^{o}c in March and lowest during the harmattan months of December and January, the mean annual rainfall according to the local meteorological station which has maintained climatological records since 1978 reveal a mean rainfall of about 1600mm with a relative humidity of 80% at dawn. (Ezenwaji *et al.,* 2013).

The kidney beans used for this experiment were measured, sorted, weighed and subjected to the different processing methods. For boiled, the dry seeds were sorted, weighed and then poured into a cooking pot with water boiling at 100°c and heated for one hour after which it was spread under the sun using an empty rice bag until they were sufficiently dried. For the Dehulled, the dry seeds were soaked in cold water for between 18-24 hours then the outer seed coat removed using a grinding machine then the hand was used to separate the seed coats from the bean. The beans were then rinsed and sundried using empty rice bag until they were sufficiently dried. The raw kidney bean together with the dehullled and boiled kidney beans were then ground and used in formulating the broiler diets.

The birds were fed with four compounded experimental starter and finisher diets having crude protein content of 22% and metabolizable energy of 3000kcal/g and 20% crude protein and metabolizable energy of 3000kcal/kg respectively. The Percent composition of differently processed kidney bean meal based diet fed starter and finisher broiler chickens is shown in table 1 and table 2. Proximate analysis was carried out on the starter and finisher diets and the results are presented is table 3 and table 4.

A total of one hundred and twenty day old unsexed broiler chicks (Abor acre 308 strain) were used for this experiment. The birds were acclimatized for one week. The birds during this period were fed commercial feed (vital feed). From the second week, the birds were randomly weighed and allocated to four treatment diets using a Completely Randomized Design (CRD) with thirty (30) birds per treatment and ten (10) birds per replicate. The birds were also assigned to four treatment diets namely: T_1, T_2, T_3, and T_4. The treatments were T_1- control, T_2- birds fed raw kidney bean seed meal, T_3- birds fed de-hulled kidney bean seed meal, T_4- birds fed boiled kidney bean meal. The birds were brooded for four weeks on deep litter using kerosene lanterns and charcoal stove. The birds were offered feed and water *ad libitum*. Vaccination and other management practices were maintained. The data collected were subjected to Analysis of variance (ANOVA) using SPSS analytical package and differences between means were separated using Duncan Multiple Range test (Duncan 1955).

Results and Discussion

The result of the growth performance of broiler chicken fed differently processed kidney bean is presented in table 5. There was significant ($p<0.05$) difference in average feed intake among the treatment diets. The boiling of dietary kidney beans probably rendered their diets more palatable than other processing methods studied. The low feed intake of the chicks fed the raw kidney bean diet could be due to the presence of anti-nutritional factors, which lowered the palatability of the feed. This finding agrees with the work of Akanji *et al* (2015), who reported that feed intake was similar ($P>0.05$) between birds fed control diet and dehulled – cooked cowpea diet, but significantly ($P<0.05$) reduced in those fed raw cowpea, dehulled cowpea and dehulled – roasted cowpea respectively. It also agreed with Wafar *et al*(2016) and Damang *et al* (2017) as they reported difference among the birds fed raw diet and other diets. There was no significant ($p>0.05$) difference in the total weight gain of the birds fed the different diets. This report agrees with that of Fikru *et al*(2014) which he reported that there was no significant ($p>0.05$) differences in initial and final body weight among the treatments. This work disagreed with Wafar *et al* (2016) who reported that the result of average daily weight gain was significantly ($P<0.05$) different and it ranged from 31.46g/bird in T_1 fed diet to 35.80g/bird in T_2 diet.

There was no significant difference ($p>0.05$) in the FCR of the different treatments. This report agrees with the report of Fikru *et al* (2014) which he stated that the feed conversion efficiency did not differ ($p>0.05$) among treatments and that of Taburuwa *et al.* (2016) who reported that there was no significant difference ($P>0.05$) in feed conversion ratio of the birds fed seed meal of African locust bean (*Parkia biglobosa*). Feed cost per weight gain recorded the highest value in T_2 (77.53) followed by T_3 (74.04) and then T_4 (69.44) while T_1 recorded the lowest value with 50.84. The feed cost per weight gain in $T_1$was significantly different from other dietary treatment ($p<0.05$). There was no significant difference ($p>0.05$) in the cost of feed per weight gain in T_2, T_3 and T_4. The diets containing kidney bean were not significantly different and this could be said to be due to the cost of the kidney bean in the diet. These variations in the numeric values of the cost of feed per kg weight gain may be due to differences in the processing costs of the kidney beans, and variations in the efficiencies of feed utilization across dietary treatments.

Table 5: Growth of differently processed kidney bean.

	Dietary treatments			
Parameters	T1	T2	T3	T4
Initial live Wt.(g/bird)	92.07	85.43	87.60	86.60
Final live Wt.(g/bird)	2524.30	1549.80	1845.77	1942.70
Total Wt. gain(g)	2432.36±1280.15	1464.61±106.92	1758.12±149.34	1856.12±59.51
Avg. daily Wt. gain(g)	49.64±26.13	29.89±2.18	35.88±3.05	37.88±1.21
Avg. daily FI(g)	13.77±0.92^{a}	11.96±0.44^{b}	13.21±1.02^{ab}	13.63±0.32^{a}
Total FI(g)	674.58±45.12^{a}	586.28±21.54^{b}	647.32±49.77^{ab}	667.97±15.54^{a}
FCR	0.32±0.12	0.40±0.03	0.37±0.00	0.36±0.00
Feed cost/ Wt. gain(₦/kg)	50.84±18.44^{b}	77.53±6.12^{a}	74.04±0.99^{a}	69.44±1.05^{a}

Mean having different superscripts are significantly different at $p<0.05$, Wt. = weight, FI=Feed Intake, FCR=Feed Conversion Ratio, g = gram, Avg. = average, T1= treatment1 (control), T2= treatment2 (raw), T3=treatment3 (dehulled), T4=treatment 4(boiled).

Conclusion

The study concluded that boiling of kidney bean gives best result in growth performance; therefore, processing kidney beans for broiler chickens diet improves growth and it is cheaper to use boiling for processing kidney beans for inclusion in the diets of broiler chickens as it showed a lower value for feed cost per weight gain.

Abstract
This study was conducted to investigate the efficacy of litter amendment on broiler performance. A total number of 120 day old Ross 308 broiler chicks were randomly assigned to two equal groups. One bearing the control group and the other group was kept on deep litter treated with Aluminium sulphate [$Al_2(SO_4)_3$]. Each having 30 chicken in four replication of 15 chicken in a Complete Randomized Design (CRD). The treatment groups were T_1 control (0g of alum), T_2 (300g of alum per 4.86sqm), T_3 (400g of alum per 4.86sqm) and T4 (500g of alum per 4.86sqm). The experiment lasted for 9 weeks. Data on final body weight, average daily weight gain, average daily feed intake, total feed intake, feed conversion ratio and protein efficiency ratio were collected. At the beginning and end of the experiment the litter samples were collected and the ammonia and nitrogen gas level were determined. The data obtained from this experiment were analysed using one way Analysis of Variance (ANOVA) and Duncan Multiple Range Test. The findings of this study showed that there were significant ($P<0.05$) differences in final body weight, T4 recorded the highest in finial body weight (3.70±0.01), and in total weight gain (2.86±0.01) while T_1 (control) recorded the lowest in finial body weight (2.88±0.01), and in total weight gain (2.03±0.01). There was no significant ($P>0.05$) differences in average daily weight gain, total feed intake, average daily feed intake, feed conversion ratio, and protein efficiency ratio for all the treatment. There were significant ($P<0.05$) difference in the level of ammonia at the starter phase, T_4 had the highest. (9.52±0.00) and T_3 had the lowest (5.97±0.43) and there was no significant ($P>0.05$) difference in the level of nitrogen gas emission in all the treatment. At finisher phase, there was no significant ($P>0.05$) difference in the level of ammonia and nitrogen gas emission in all the treatment. From the results obtained it is safe and best to use 500g of alum per 4.86sqm for improved growth performance and good litter quality making sure that the level of ammonia is not up to 25ppm.

Key words: Aluminium sulphate, litter quality, broiler birds, growth performance

Introduction
The world's population is expected to reach more than 9 billion by 2050, imposing food security challenges particularly for developing countries (Yadav *et al.,* 2016). Moreover, economic growth has increased the demand for livestock products putting pressure on the livestock sector to produce more with limited resources. Nevertheless, the livestock sector is one of the fastest growing agricultural sectors, contributing about 40 percent of the global value of agriculture production (Yadav *et al.,* 2016) supporting the livelihood and food security of almost 1.3 billion people. In intensive commercial broiler production, birds are reared on floor having absorbent material which is of different types to keep the floor reasonably dry to ensure comfortable condition for birds. It also gives the birds a suitable medium on which feeding, watering and other management practices are carried out. As poultry production increases, the amount of litter required by the system also increased. Broilers spend most of their lives in contact with their litter. The rapid growth of the poultry industry has increasingly raised concern of disposal (Musa *et al*., 2012). In Nigeria, about 932.5metric tonnes of commercial poultry manure were reported to be

produced (Musa *et al*., 2012). The current record of annual poultry manure appears to be unknown but is expected to be multiples of the above figures. Consequently both litter management and disposal raise important challenges to the poultry industry. Source of litter materials usually varies according to region (Gilaneh *et al*., 2016). Sawdust, wood shaving, rice or oat hulls, sugar cane pulp or bagasse, chopped straw, paper mill by product, corn cobs and dried leaves are often used as litter sources (Gilaneh *et al.*, 2016). Litter is composed of the bedding material plus the excreta, feed, feathers and water. Poultry litter that is a mixture of bedding material and manure has high organic matter and macronutrient and micronutrient contents, leading to the formation and release of ammonia as volatile compounds (Chung *et al.*, 2015). Following defecation by birds, the breakdown of faecal matter in litter occurs leading to the production of various gaseous pollutant whose concentration and emission is influenced by the litter type, management, humidity and temperature (Arjumand *et al.,* 2017). In addition, poultry litter provides an ideal environment for microbial proliferation. It also helps the thermal insulation, moisture absorption and reduction of ammonia emissions and serves as protective barrier from the ground (Gilaneh *et al*., 2016). Litter quality may be the origin of environmental and management problem in commercial poultry industry (Gilaneh *et al*., 2016) if not properly selected or managed. In broilers production, poor growth performance, compromised immune system and increased incidence of breast burns and blisters, leg abnormalities and foot pad dermatitis have been reported in literature as partially due to poor litter condition (Gilaneh *et al*., 2016). In broilers production, poor litter management results to poor growth performance which compromised immune system and increased incidence of breast burns and blisters, leg abnormalities and foot pad dermatitis and also production and emission of harmful gas like ammonia have been reported in literatures as partially due to poor litter condition (Gilaneh *et al.,* 2016) Therefore, treatment of poultry litter materials will reduce incidence of poor health condition and improve performance of birds leading to increase in the earnings of poultry farmers.

Materials and methods

The study was carried out at the Poultry Unit of the Department of Animal Science Teaching and Research Farm, University of Nigeria, Nsukka. Nsukka lies in the derived savannah region and is located on longitude 6’25’N and latitude 7’24’E and at altitude of 430m above sea level. It has the natural day length of 13 to 14 hours; mean maximum weekly indoor and outdoor temperature of 27.9 $^{\circ}$C to of 27.9 $^{\circ}$C and 26.8 $^{\circ}$C to 30.5 $^{\circ}$C, respectively, mean maximum weekly indoor and outdoor temperature; 20.5°C to 22.3°C and 20.0 $^{\circ}$C to 23.60 $^{\circ}$C, respectively, relative humidity of 73.1% to 76.6% and mean total monthly rainfall of 781.33mm (Energy centre UNN, 2008). The study lasted for 9 weeks and was conducted in two phases (Starter and finisher).

Aluminium sulphate ($Al_2(SO_4)_3.14H_2O$ or alum was purchased in powdered form procured at Head bridge, Onitsha. It reduces ammonia volatilization and its offensive odour. The floor of each pen in the experimental unit was covered with bedding material (dry wood shaving) and alum was mixed into top ½ inch by broadcasting method. During the application of alum to the litter, protective covers like goggle, gloves, nose mask and boots were worn to prevent inhalation of the alum dust and skin irritation.

120 day old Ross 308 breed of broiler chicks were used for the study. The wood shaving was obtained from timber market in Nsukka. The treatment groups were T_1 control (0g of alum), T_2 (300g of alum per 4.86sqm), T_3 (400g of alum per 4.86sqm) and T4 (500g of alum per 4.86sqm). The chicks were vaccinated on the first day and brooded together for 4 weeks due to the cold weather that was experienced during the time of the study. The brooding was carried out using charcoal pot as heat source. Fresh water and feed were given to the chickens *ad libitum*. Drinkers were washed on daily basis with clean water and clean sponge. The chickens were given a routine vaccination. Chicks from 0-4weeks were fed with starter mash containing 22% crude protein and 3000kcalME/kg. From 5-9weeks, the chickens were fed with finisher mash of 19% crude protein and 3100 kcalME/kg. A commercial feed named “Hybrid feed” was used. Proper sanitation and bio-security measures were carried out like, washing the pens and brooding house with Izal and clean water, then fumigation using formalin before the arrival of the chicks, making sure that the water mixed with Izal in the foot dip at the doors of brooding house and experimental units were changed daily The following parameters were measured; Weekly body weight, Daily feed intake, Daily protein intake and Protein efficiency ratio. Litter samples were collected at week 5 and 9 at 5

random locations from each pens. The litter samples collected inside a plastic bag weighed 1kg and it was thoroughly mixed with droppings. The litter sample was subjected to laboratory tests using boric acid trap system/method and sulphuric acid calorimetric method. Chemical analysis was done on the litter sample to analyse ammonia (NH_3) and nitrogen gas (N_2). In determining the nitrogen level, 0.5g of poultry litter sample were weighed in a 500cm^{3}Kjeldahl flask, 1g of catalyst mixture and 20cm^3 of conc.H_2S0_4.added and digest it on the kjeldahl digestion heater until all the traces of carbon changed to white fumes. When cooled, 50cm^3 of distilled water was added and the substance was washed in another flask of 100cm^3 volume with distilled water up to 100ml volume leaving the poultry litter. 10cm^3 of the poultry litter was added and digested in 10cm of 45% NaOH then connect it immediately on kjeldahl distillation assemble, after the receiving flask (100cm^3) must have contained 20cm^3 of 2.5% boric acid with 2 drops of the mix indicator was also fixed. The electricity heater for distillation was put on to collect about 50cm^3 of the distillate. The distillate 0.05N HCL was titrated from blue distillate to pinkish end point and the titre was used to determine the nitrogen gas content in the poultry litter sample.
In determining the ammonium, 2g of the poultry litter was weighed into a 250ml shaking bottle. 100ml of distilled water was added and shook in a mechanical shaker for 30minutes. It was allowed to settle and filtered with a watman 110cm tilter paper, then the filtrate was used to determine ammonia. 50ml of the extract was pippete into a 250ml conical flask and 20ml of 20% formalin solution added and mixed thoroughly. 3 drops of phenolphthalein indicator was added and the suspension titrated with 0.1N Sodium hydroxide solution to a permanent pinkish colour end point. Then the titre value was used to calculate the ammonia content in the poultry litter sample using the formula below:

$$T \times \text{Normality} \times \text{Equivalent weight} \times \frac{1000}{\text{Weight used}}$$

NB: all in mg/kg as unit of reporting result.
The data collected were subjected to analysis of variance (ANOVA) in a Complete Randomized Design (CRD) using a Static Graphic Computer Package (SPSS, 2007) Model. Means were separated using Duncan's New Multiple Range Test (Duncan, 1955).

Results And Discussion

The performance of broiler birds reared under litter materials treated with aluminium sulphate is shown in table 1. The mean final body weight and total body weight gain were significantly ($P<0.05$) different among the treatment group. There was no significant ($P>0.05$) difference in mean average daily weight gain among the four treatment group. The differences observed in the final body weight and total body weight gain of the four treatment groups could be attributed to the differences in aluminium sulphate inclusion levels on the litter where various groups were reared. This is suggested in as much as other genetic and environmental factors such as breed, light, temperature, humidity, age and other management practices were the same in each of the treatment groups. The total body weight gain results obtained in T_4 (500g of alum per 4.86sqm) are somewhat consistent with those of Moore *et al.,* (2000) which reported that alum treatment to poultry litter resulted in increase in weight gain.
However, there was no significant ($P>0.05$) difference in average feed intake among treatment group. T_1 consumed the highest feed, followed by T_2, T_3 and T_4 respectively. Feed intake decreased progressively with age of the birds in all groups. This showed that the birds consumed less feed as they grew older. The level of nitrogen gas and ammonia affects the feed intake of birds (Moore *et al.,* 2000). The energy level of ration plays important role because birds generally consume more to satisfy their energy requirement (Hill and Dansky, 1954).
There was no significant ($P>0.05$) difference in the feed conversion ratio among the treatment groups. T_4 had the best feed conversion ratio followed by T_3, T_2 and T_1. It progressively decreased with the age of the birds in the four treatment groups. The findings from this study corroborate with those of Moore *et al.,* (2000) which reported that alum treatment to poultry litter resulted in improved feed conversion ratio.
There was no significant ($P>0.05$) difference in the protein efficiency ratio among the treatment group. Protein efficiency was equally observed to have progressively increased with the age of the

birds in the four treatment groups. This shows that due to good feed conversion ratio the birds were able to attain high protein efficiency ratio.

Table 1: Growth performance of broiler birds reared under aluminium sulphate treated litter

Parameters	Treatment 1	Treatment 2	Treatment3	Treatment 4	P-value
Initial body weight (kg)	0.85±0.00	0.85±0.00	0.85±0.00	0.84±0.00	
Final body weight (kg)	2.88^{d}±0.01	3.08^{c}±0.00	3.17^{b}±0.00	3.70^{a}±0.00	0.00
Total body weight gain (kg)	2.03^{d}±0.01	2.23^{c}±0.00	2.32^{b}±0.01	2.86^{a}±0.01	0.00
Average daily weight gain (kg)	0.40±0.32	0.08±0.00	0.08±0.00	0.10±0.00	0.512
Average daily feed intake (kg)	0.15±0.00	0.15±0.00	0.14±0.00	0.13±0.00	
Total feed intake (kg)	63.38±0.00	61.97±0.00	57.90±0.00	55.52±0.00	
Feed conversion ratio (g)	2.14±0.00	1.87±0.00	1.66±0.00	1.29±0.00	
Protein efficiency ratio	2.66±0.00	2.99±0.00	3.395±0.00	4.29±0.00	

Means bearing different superscripts in the same rows are significantly different ($P<0.05$)

The nitrogen gas values obtained in the starter phase showed no significant ($P>0.05$) difference in the nitrogen gas level but T_3 had the highest (2.87±0.) while T_4 had the lowest (2.38±0.42) as shown in table 2. Ammonia level in T_1 and T_2 (6.92±1.21 and 7.48±0.56 respectively) are statistically similar with T_4 (5.97±0.43) and that of T_1 and T_2 (6.92±1.21 and 7.48±0.56) are statistically similar to T_3 (5.97±0.43) but T_3 (5.97±0.43) and T_4 (5.97±0.43) are significantly ($P<0.05$) different from each other.

At finisher phase both the nitrogen gas and ammonia level did not show any significant difference among the treatment groups as presented in table 3. T_2 had the highest (3.01±0.21) while T_3 had the lowest (2.38±0.00). In ammonia level, T_2 (5.795±0.61) had the highest while T_3 had the lowest (3.29±0.07). The results are somewhat consistent with those of Moore *et al.,* (2000) which reported that alum treatment to poultry litter resulted in decrease in ammonia level when there is decrease in nitrogen gas and increase in ammonia level when there is increase in nitrogen gas.

Table 2 Nitrogen gas and ammonia level in the aluminium sulphate treated litter in starter phase

Parameter	Treatment 1	Treatment 2	Treatment 3	Treatment 4	P-value
Ammonia (mg/kg)	$6.92±1.21^{ab}$	$7.48±0.56^{ab}$	$5.97±0.43^{b}$	$9.52±0.00^{a}$	0.088
Nitrogen gas (mg/kg)	2.80±0.28	2.87±0.07	2.87±0.21	2.38±0.42	0.585

Means bearing different superscripts in the same rows are significantly different ($P<0.05$)

Table 3 Nitrogen gas and ammonia level in the aluminium sulphate treated litter in finisher phase

Parameter	Treatment 1	Treatment 2	Treatment 3	Treatment 4	P-value
Ammonia	4.63±1.43	5.795±0.61	3.29±0.78	4.76±0.61	0.402
Nitrogen gas	2.73±0.21	3.01±0.21	2.38±0.00	2.59±0.35	0.383

Conclusion

The present study revealed that litter amendment with alum has an important role in augmenting broiler growth performance, feed conversion and efficient utilization of protein. Alum treated litter at 400g/4.86sqm was more efficient in controlling nitrogen gas and ammonia level of the litter than alum litter at 500g/4.86sqm but alum litter at 500g/4.86sqm had the best performance in respect to weight gain. But all the litter treatment had better performance than that of control group with respect to finial body, total body weight, protein efficiency ratio and litter quality. So the use of acidifier like alum in litter is beneficial to maintain the litter quality which directly enhances the productivity in broiler production without any adverse effect.

Abstract
This study was conducted to investigate the effect of Natural clean probiotic on the carcass yield and organ weight of broiler chickens at the Poultry unit of Teaching and Research farm, Nnamdi Azikiwe University, Awka. A total of 96 Abor acre day old broiler chicks were randomly allotted to four treatment group in a Complete Randomized Design. Four levels of Natural clean probiotics were added in water as follows: T1(0g Natural clean probiotics), T2 (1.5g Natural clean probiotics), T3 (2.5g Natural clean probiotics) and T4 (3.5g Natural clean probiotics) which served as treatments for the experiment that lasted for 8 weeks. Commercial feed (Top feed) was used as the experimental diet. Each treatment had 3 replicate of 8 birds per treatment. Diet were fed in two phases, starter phase (from day 0-28days) and finisher (from day 29-56days). Carcass yield and organ weight measurements were obtained at the end of eight weeks. Statistical analysis was done using SPSS version 22. There were no significant (p>0.05) effect of the treatment on the carcass yield and relative organ weight. It was observed that T_2 had the highest dressing weight percentage (71.97%) which compared favourably with the control T_1(70.75%), T_3(69.82%), T_4 (67.85%). However the results are the same statistically, hence, the natural clean probiotics improved the carcass yield and organ weight. Therefore, natural clean Probiotics can be used in water to enhance broiler performance.
Keyword: Natural clean, Probiotics, Carcass yield, Organ weight, Broiler birds.

Introduction
The poultry farming is a means of bridging the protein deficiency gap common in many developing countries of the world (Jibir and Usman, 2003). It is an efficient means of supplying the fast growing human population with high quality protein (Gueye, 2004). The average Nigerian still consumes far less animal protein than his counterpart in the developed world because the animal production industry is still in its infancy due to hydra-headed problems and the low per capita income leading to a consumption of less than 9g of animal protein per capita per day as compared to over 50g per capita per day in North America and Europe (Grigg 1995; Boland *et al.* 2013). Broilers are important source of protein rich in essential amino acids that are required for the teeming population in terms of human growth. Also broiler has low level of cholesterol content which has also increase the demand of broilers in developing countries. However, poultry industries has always been confronted with challenges in form of various diseases such as bacteria caused diseases which includes fowl cholera, avian tuberculosis, *Escherichia coli* infections. These lead to increase use of antimicrobial growth promoters (AGP) especially antibiotics and growth hormone in order to combat these challenges and boost broiler production. Antibiotics are among the most widely used veterinary drugs in poultry industries (Simon and Baxter, 2006). Antibiotics has been used in poultry farming for several decades in combating bacterial infections (Olatoye and Ehinowo, 2009) as growth promoter (Geidam *et al*., 2009). Unfortunately, edible poultry tissues may be contaminated with harmful concentration of drug residues due to continuous and improper antibiotic usage in poultry industry (Shareef *et al*., 2009; Jarere,2015) Also the presence

of poultry diseases has reduced the production of broilers in poultry farming. As a matter of fact, the use of antibiotics in animal production has been banned in Europe since 2006. Furthermore, the use of sub therapeutic antibiotic dose in animal feeds or water to promote growth and improve feed efficiency was eliminated effectively January 1, 2017, as a new Food and Drug Administration (FDA) veterinary feed directive in the United States. Consequently, following the ban on the use of antibiotics and the urgent need to increase livestock productivity, there is then the need to find an alternative way to boost livestock production. Therefore probiotics is an alternative to antibiotics in order to increase livestock production. In other words probiotic are now replacing chemical growth promoters (Yirga, 2015). According to Food and Agriculture Organisation, FAO and World Health Organisation, Probiotics are live micro- organism which when administered in adequate amount confer a health benefit on the host (FAO, 2016). This definition was accepted and adopted by International Scientific Association for Probiotics and Prebiotics (Hill *et al.,* 2014). Many researchers have reported that probiotics have a beneficial effect on the broiler performance, modulation of micro flora and pathogen inhibition by lowering the gut pH, thereby improving sensory characteristics of dressed broiler meat. Therefore, this study was aimed at determining the effect of graded levels of Natural clean probiotics on carcass yield and organ weight of broiler chickens.

Material and Methods

The experiment was carried out at the Animal Science Teaching and Research Farm in Nnamdi Azikiwe University, Awka, Nigeria. The site is situated at 6.242889 degree North(N), 7.11829 degree East Ezenwaji, 2013). A total of 96 birds of the breed Abor acre were obtained from Fidan Chicky chicks located at Ibadan, Oyo state. 24 birds were allocated per treatment, each treatment were replicated thrice with 8 birds per replicate. The treatments involves the probiotics (Natural Clean) gotten from Lagos State Agriculture Development Authority (LASADA). Natural clean probiotic culture media comprised kelp, salt, milled corn, rice hull, calcium and hydroxide. Commercial feed (Top feed) were given *ad libitum* and the chemical composition is presented in table 1. The natural clean was given at 0g (T1), 1.5g (T2), 2.5g (T3), and 3.5g (T4) in clean drinking water for 56 days.

At 56 days, total of 12 birds were slaughtered. Prior, to slaughtering, the birds were starved of feed for 12 hours, hence live weight of the birds were taken. In the slaughtering process, modified kosher method was followed by cutting the birds jugular vein leaving the trachea and oesophagus attached to the body. After the slaughtering process the chicken was allowed to bleed for about 11/2 minutes before scalding. Scalding was done for about half minutes in an hot water which was not up to the boiling point for easy removal of feather, hence plucked weight was taken. Also eviscerated weight was taken after internal organs were removed. The shank and head were also removed in order to obtain the dressed weight.

The primal cut such as the breast, back, wings, drumstick, neck, shank were obtain from the dressed carcass. Hence, all were weighed using kitchen scale (7000g) capacity. Organ weight -Organ such as the liver, heart, spleen, proventiculus, lungs, gizzard, kidney, abdominal fat, pancreas, small and large intestine were separated and weighed.

All data were subjected to analysis of variance, and the means were separated using Duncan's Multiple Range Test (Duncan, 1955) as outlined by Daniel (1991).

Table 1: Chemical composition of the experimental diet

	Starter	Finisher
Crude protein	21.00	18.00
Fat and oil	6.00	6.00
Crude fibre	5.00	5.00
Calcium	1.00	1.00
Available phosphorus	0.45	0.40
Lysine	1.00	0.85
Methionine	0.50	0.35
Salt	0.30	0.30
Metabolisible energy kcal/kg	2900	2900
Net wet/kg	25	25

Results and Discussion

The result of the carcass yield of broiler birds offered natural clean probiotics at is shown in table 2. There was no significant difference (p>0.05) observed in the live weight, plucked weight, eviscerated weight, dressed weight of broiler chicken. These findings proved that natural clean probiotics can be used in raising of broiler chickens. However, It was observed that T_2 recorded the highest dressing weight percentage of 71.97% when compared to T1(70.75%), T3(69.82%), T4 (67.85%). This is in agreement with the report of Afsharmanesh and Sadaghi, (2014) that there is no difference in carcass yield, growth rate and feed efficiency of bird at day 42 with a treatment using commercial probiotics (galli-pro) containing *B. subtilis*. However this findings contradict the report of Addel-rahman *et al*. (2013) that the carcass yield of broiler at 42 days increased concurrently with increased growth rate and improved feed efficiency with the use of commercial probiotics (antra pro EF) *E. Faecium* in drinking water at the rate of 2g per 100 birds. Consequently, FAO (2016) reported that the effect of probiotics on carcass yield may be as a result of inconsistency in response due to difference in probiotics strain or breed of birds. Inconsistency may be due to different concentration and species of the direct fed microorganism. The mean organ weight of broiler birds offered natural clean probiotics is presented in table 3. There is no significant difference (P>0.05) on the relative organ weight. Hence, this findings is in line with the report of Zhang *et al. (*2012) that relative organ weight were unaffected by dietary inclusion of probiotics containing *Bacillus subtilis.*

The weight of proventiculus for T_1, T_2, T_3 and T_4 are the same statistically, there was no significant difference (p>0.05). among the treatment group. T_1 had the highest weight (13.67g) and T_3 had the lowest (11.00g). Similarly, T_1 which is the control group had the highest liver weight as (48.00g) compare to T_2(41.31 g), T_3(38.67 g),T_4 (37.67 g). There was no significance (p>0.05) difference in spleen weight which is in agreement with Awad *et al.* (2009) who reported no significant difference in weight of liver, spleen and caecum in broiler birds offered probiotics. The highest empty gizzard value (42.33g) was obtained in T_4 followed by T_1(41.33g), T_2(35.67g) and T_3(34.00g). Following the same trend, abdominal fat had no significance(p>0.05) difference among the treatment. This was in concurrence with the result of Franciszek *et al.,* (2010) who reported that probiotics bacteria (*Pseudoccocus specie*) have no effect on the weight of gizzard, liver, abdominal fat.

Means within the row, means with the same subscript are not significantly different (p > 0.05)

Conclusion

The findings from this study revealed that the carcass yield and organ weight were not negatively affected by the inclusion of the natural clean probiotics, hence there were no significant difference on the parameters measured . therefore, concluded that the probiotics (natural clean) resulted in an enhanced carcass yield and organ weight.

Recommendations

Based on the study, it can be recommended that:

- Probiotics (Natural clean) can be used in water up to 1.5g for effective carcass yield and organ weight.
- Probiotics can be used as an alternative for antibiotic growth promoters as pressure to eliminate antibiotics in animal production increases.
- Probiotics Natural Clean offer good alternative to improve poultry production.

Abstract
An experiment was conducted to investigate the performance and economic evaluation of Archatina fulica fed varying inclusion level of whole Jackfruit meal (WJM). A total of 120 growing Archatina fulica snails were allocated to four treatments (T_1, T_2, T_3 and T_4) replicated three times with ten snails per replicate in a Complete Randomized Design. The snails in T_1, T_2, T_3 and T_4 were fed 0%, 5%, 10% and 15% inclusion levels of the whole jackfruit meal based diets. The experiment lasted for eight weeks. The parameters measured include the weight gain, feed intake, feed conversion ratio, shell length, shell aperture, shell girth and shell thickness increase. The data obtained were analyzed using one way analysis of variance (ANOVA). The proximate analysis result of the test ingredient (Whole Jackfruit meal) showed that WJM had a crude protein content of 11.34%, crude fibre of 5.85%, and ash content of 4.75%. The result of the experiment showed that there was no significant ($P>0.05$) difference in the shell length, shell aperture and shell thickness amongst the treatment but snails fed T_2, T_3 and T_4 recorded higher values than control. There was significant ($P<0.05$) difference in the shell girth increment with T_4 having the highest value. There was no significant ($P>0.05$) difference in feed intake, weight gain and feed conversion ratio of snails across the treatments. Snails fed the T_4 diet had the least cost of production but did not maximize growth; however T_3 (10%) though it had a higher cost of production than T_2 and T_4 and lesser cost of production compared to T_1 (control) was not statistically different but numerically greater in maximizing growth than T_1, T_2 and T_4, thus is recommended to snail farmers.

Key words: Archatina fulica snails, whole jackfruit meal, Performance, Economic evaluation.

Introduction
Food which is a combination of macro and micro nutrient is a basic necessity of life. Food must contain all the necessary nutrients to make it balanced. Nutritious food are those food items that contain the required macro and micro nutrient in a normal proportion, including fruits and vegetables, which contain nutrients such as vitamins, protein, carbohydrates and minerals that are required to sustain the body and provide healthy living (Olhorst *et al.,* 2013). Eating food without the right nutrient composition could lead to malnutrition. It has been estimated that the daily minimum crude protein requirement of an adult in Nigeria varies between 65 and 85g per person. However, it is recommended that 35g of this minimum requirement should be obtained from animal products (Adetunji and Adepogu, 2011). The conventional and regular sources of animal protein in the country like beef, pork, goat meat, fish, and poultry are getting out of the reach of the common populace due to their high price as a result of the economic downturn in recent years (Akinnusi, 2004). Emphasis is presently on the micro-livestock to either complement the conventional sources of animal protein supply or as a major alternative animal protein source. A rich source of animal protein that had being under-utilized for years in West Africa and is highly prolific is snail. There is great need to make snail meat available all seasons of the year, it has therefore become necessary to initiate some organized form of domesticating/ rearing snails. This

calls for effort towards feeding snails with cheap locally available but rich feed ingredients, to minimize the effect of high cost of compounded feeds and seasonality of plant materials to ensure the continuity of snail production all year round.

Hence, there is need to search for locally available and cheap sources of feed ingredients particularly those that do not attract competition with human. This has led to the consideration of whole Jackfruit (*Artocarpus heterophyllus*) meal as feedstuffs for snails. Jack fruit can be considered as the largest fruits amongst edible fruits; it has multiple fruit (syncarp) with a green to yellow brown rind (Jahan *et al*. 2011). Several research works have been carried out on the seed meal of jack fruit on livestock but not much has being carried out on the whole jack fruit on livestock, therefore the utilization of whole jackfruit as functional feed ingredient included in snail feed seems an interesting beneficial research which merits a study.

Materials and Methods

The study was carried out at the Snailery unit of Teaching and Research farms of the Department of Animal Science and Technology, Faculty of Agriculture, Nnamdi Azikiwe University, Awka, Anambra state. The location lies between Latitude 6.24^{0}N and 6.28^{0}N and longitude 7.00^{0}E and 7.08^{0}E on the South Eastern part of Nigeria, the climate is the tropical wet and dry type with a clear season, the mean daily maximum temperature is usually 27^{0}C all over the year although it could reach 34^{0}C in March and lowest during the harmattan months of December and January (Ezenwaji *et al,* 2013).

A total of one hundred and twenty *Archatina fulica* were procured from a reliable source and transported to the study area in a well aerated polyethylene bags. The snails were fed with vegetables for the one week acclimatization period. After acclimatization, the snails were randomly assigned into different bowls according to the levels of whole jackfruit meal inclusion that is T_1, T_2, T_3 and T_4. T_1 which served as control did not contain whole jackfruit meal while T_1, T_3 and T_4 contained 5%, 10% and 15% whole jackfruit meal respectively. Each of the treatment was replicated three times in Completely Randomized Experimental Design. Ten (10) snails were randomly placed into the twelve bowls which had the dimension 15cm depth and a diameter of 56cm in a circular pattern which was filled with sterilized garden humus soil obtained from forested areas around the experimental site at the depth of 3cm and which was subsequently watered. A flat plastic container was used as feed saucer and contained their feed which was placed at the middle of the bowl. The bowl was then covered with mosquito netting material and tied with a twine to avoid intrusion of insects.

The snails were fed once a day, in the evenings due to the snail's nocturnal feeding habit. They were served with a feed saucer which was cleaned on daily basis. The snails in treatment one (T_1) were fed with diet without any inclusion of whole jackfruit meal, those in T_2 had 5% level of inclusion of WJM, T_3 had 10% level of inclusion of WJM and T_4 had 15% level inclusion of WJM as presented in table 1. The feed saucer was cleaned daily before introduction of fresh feed.

The feed intake was measured by subtracting the feed refused from feed offered on daily basis. The shell length and shell girth were measured using Vernier caliper on weekly basis. The shell thickness was measured using a micrometer screw guage at the beginning and end of the experiment. The shell aperture circumference was measured using a thread and meter rule on weekly basis. The weight gain was measured using a sensitive scale on weekly basis.

The proximate analysis to chemically evaluate the nutritional potential of the WJM and experimental diets was determined by the methods of AOAC (2002) as shown in table 1 and 2 respectively

Results and Discussion

The proximate analysis of the experimental diet is shown in table 1. Crude protein of 19.63 (T_1), 19.42 (T_2), 19.31 (T_3) and 18.94(T_4) showed that there was minimal decrease in crude protein content as the percentage inclusion of whole jackfruit increased. Crude fibre, dry matter content and metabolizable energy of the diets increased minimally as the percent inclusion of whole jackfruit meal increased. The ether extract, nitrogen free extract and ash content varied without a specific pattern. The moisture content reduced minimally as the percent inclusion of whole jackfruit meal increased. The minimal difference between the experimental diets showed that it was homogenous.

The proximate analysis carried out on whole jackfruit meal whole jackfruit meal contains a crude protein of 11.34% and metabolizable energy of 3619kcal/g which compares favourably with that of maize and sorghum, this shows that whole jackfruit meal could serve as a functional feed ingredient.

The shell growth characteristics of *Archatina fulica* fed different inclusion levels of whole jackfruit meal (WJM) is presented in table 3. There were non-significant (P>0.05) difference amongst the four treatments on the shell length, shell aperture and shell thickness increase, these showed that the T_2, T_3, and T_4, compared favourably with the control diet in terms of shell length, aperture and thickness. The result also showed significant (P<0.05) difference in the shell girth increase, with T_4 having the highest value and T_3 and T_1 having the least value, this showed that at T_4 shell girth increase is optimum

The growth performance of *Archatina fulica* fed different levels of whole jackfruit meal (wjm) is shown in table 4. There were non-significant (P>0.05) difference in the average daily feed intake, total feed intake, total weight gain, average daily weight gain and feed conversion ratio. This shows that the inclusion of whole jackfruit have no negative effect on the body growth performance of *Archatina fulica.* However, T_4 recorded a numerically lower feed intake and weight gain when compared to other treatments and T_3 had a numerically higher feed intake and weight gain, compared to other treatment and T_2 had the best feed conversion ratio, the lowered feed intake and weight gain observed in T4could be attributed to the antinutritional factors present in whole jackfruit meal. Akande *et al.,* (2010) also stated that anti-nutrients, also known as anti-nutritive compounds or physiologically active compounds or anti-nutritional factors, are substances that may produce undesirable effects when they are consumed by an animal.

The feed cost benefit analysis is presented in table 5. The cost of feed per gram of diet was least in T_4 and highest in T_1, The lowered cost of feed in T_2 to T_4 was as a result of cheap (free) sourcing of the alternative feed stuff. Abel *et al.,* (2014) also reported that there is reduced feed cost when an alternative feed ingredient is used in place of conventional feedstuffs. The cost of feed intake was highest in T_1 and least in T_4. The feed cost per weight gain which is also the cost of production was highest in T_4 and least in T_2.

Conclusion and Recommendation

The study showed that whole jackfruit meal can be used as a functional feed ingredient as it has a crude protein, energy, and fibre content that is comparable to maize and sorghum. Whole Jackfruit meal improved the shell growth characteristics (shell length, aperture, thickness and shell girth) of *Archatina fulica*. The body weight characteristics showed that whole jackfruit meal included at 10% improved weight gain and feed intake, whereas feed conversion ratio was improved at 5% inclusion. Inclusion of whole jackfruit meal reduced the cost of feed at 15% but the cost of feed per weight gain was reduced at 5%.

The findings of this result shows that it is safe to recommend that *Archatina fulica* could be fed whole jackfruit meal to help improve their shell growth characteristics, whole jackfruit powder meal should be included between the levels of 5-10% inclusion levels to achieve maximum feed intake, weight and feed conversion ratio. Although 15% inclusion saved more money for feed production, it wasn't efficient in maximizing growth. Therefore to save cost of feed production and also maximize growth of *Archatina fulica* 10% inclusion of whole Jackfruit meal should be used for feeding *Archatina fulica*

Abstract
This study was conducted to investigate the effect of breeds on the serum biochemical parameters of three different breeds of rabbits. Thirty rabbits (both sex); 10 Chinchilla, 10 New Zealand White and 10 Dutch rabbits were used. The rabbits were reared for eight weeks and were fed pelletized commercial feed and forages ad libitum and water was provided as well. On the day of blood collection, Six rabbits (both sex) were randomly selected from each breeds (B1- Chinchilla, B2- New Zealand white and B3- Dutch respectively) and 5ml blood samples were collected from direct cardiac puncture using 5ml syringe and was drawn into a sterile tubes without anticoagulant (EDTA). The following analyses were perform on serum samples-: total protein, albumin, globulin, urea, creatinine, cholesterol, alanine aminotransferase and aspartate aminotransferase. The values of these parameters were obtained and statistical comparisons between the three breeds of rabbits were performed using complete randomized design and SPSS . From the result, no statistically significant (p>0.05) differences were found between the three rabbit breeds for the parameters analyzed. Hence, breed had no significant effect on the total protein, albumin, globulin, urea, cholesterol, creatinine, alanine aminotransferase and aspartate aminotransferase. The values obtained in this stidy were within the reference range in the literatures and other studies. Therefore, the Chinchilla, New Zealand White and Dutch breeds can be used as breeding stock in rabbit production as they are resistance to diseases and other environmental conditions.
Keywords, New Zealand white, Chinchilla, Dutch, serum biochemistry.

Introduction
The rapid growth in Nigeria population has informed the need to increase livestock production in order to satisfy her animal protein requirement. Thus, about 90% of the Nigerian populace consume less than 10g as against recommended 35g animal protein per day (Ahamefule *et al.,* 2000; FAO, 2011). This wide nutritional gap has fueled the need to intensify the production of some livestock species to address the low per capita animal protein intake by Nigerians. This shortage of animal proteins can easily be met by small animals such as rabbits, poultry and pigs. Hence, among the micro livestock of interest is rabbit, a caprophagus herbivore whose production before now has been low. Shahrbabak *et al*. (2009) and Sarikhan *et al*. (2010) maintained that rabbit production has potential of bridging the supply demand gap of animal protein in the country.
Biochemical variables of blood are generally used to monitor and evaluate health, nutritional, and physiological status of animal of which rabbit is not an exception (Al-Eissa *et al*., 2012; Gupta *et al*., 2007) and reflects the responsiveness of the animal to her internal and external environments (Esonu *et al*., 2001; Iheukwumere *et al*., 2002) and as well be used to detect organ dysfunction or diseases (Schmidt *et al*., 2007). It is also useful in selection of breeding stock that are genetically resistant to certain diseases and environmental conditions that constrains rabbit's production. It has been reported that most biochemical parameters such as glucose, total cholesterol, total protein, creatinine, blood urea, conjugated and total bilirubin, globulin, albumin, calcium,

potassium, sodium, chloride, alkaline phosphate, alanine aminotransferase, and aspartate aminotransferase) may be affected by many factors including but not limited to breed, age, feeding, environmental conditions, gender, stress and disorder (Chineke *et al*., 2006; Melillo, 2007; Jeklova *et al*., 2009). Though serum biochemical values of rabbit have been established (Karen, 2012) but It is important to establish baseline indices for these parameters on the basis of these factors and to determine the effects of these factors on these indices .None of these studies, however, has evaluated the impact of the breeds to these biochemical parameters and there is dearth of literature report on the comparative evaluation of serum biochemical indices of various breeds of rabbit especially with respect to our local feed and environment, hence this study to bridge this knowledge gap.

Material and Methods

The study was carried out at the Rabbitry Unit of the Teaching and Research Farm of College of Animal Science and Animal Production, Michael Okpara University of Agriculture, Umudike, Abia State. Umudike is located within the tropical rainforest zone of Nigeria which is characterised by hot and humid climate and the environment is characterized by an annual rainfall of 2177mm with relative humidity of about 90% and temperature range of 22^0 - 36 ^{0}C depending on the season. Umudike bears the co-ordinates of 5^0 28 North and 7^0 31 East and lies on altitude of 122m above sea level (NRCRI, 2017).

Thirty (30) four months old rabbits of three different breeds (male and female) were used for the study. The three breeds used were Chinchilla (B1), New Zealand White (B2) and Dutch (B3) at equal proportion. The rabbits were purchased from a reputable farm at Umudike. The rabbits were certified healthy and were identified with tags. They were housed singly in rabbit hutches for ease of identification and management. Wood and wire mesh were used in constructing the hutches. The animals were provided with feeders and drinkers. The animals were fed commercial pelleted concentrate and mixed forages *ad libitum*. Clean water was provided as well. During acclimatization period that lasted for two weeks, anti-stress, antibiotics and anthelmintic drugs were administered. That is, prior to the commencement of the experiment, the rabbits were prophylactically treated against ecto- and endo-parasites by giving subcutaneous injection of 0.2 ml ivomectin per rabbit. They were equally given a broad spectrum antibiotic (Altracycline®, 0.4ml intramuscular injection per rabbit). The hutches, pens, waterers, feeders as well as the surroundings were regularly cleaned to maintain good hygiene. The experiment lasted for 8 weeks and the rabbits gained an average weight of 1.7kg, 1.90kg, 1.76kg for Chinchilla, New Zealand White and Dutch rabbits respectively. The experimental design used was Complete Randomized Design experiment (CRD).

At the end of the experiment (8^{th} weeks), five rabbits were randomly selected per breed and were restrained or immobilized and 5-ml blood samples were collected via direct cardiac puncture in the immobilized animals. This was done very quickly in order to limit the effect of acute stress on blood parameters. A 5ml syringes was used to collect the blood into sterile tubes without anticoagulant (EDTA). All blood samples were transported to the laboratory immediately. Serum was separated and frozen at -20°C for biochemical analyses.

All data collected from the field and laboratories were subjected to analysis of variance using SPSS (2013), IBM SPSS Statistics Version 22, Release 22.0.0.0. The Significant differences between breeds were separated using Duncan's Multiple Range Test (Duncan, 1955).

Results and Discussion

The result of the effect of breed on the serum biochemical parameters of three breeds of rabbits is presented in table 1. There was no significant ($p>0.05$) difference the serum biochemical parameters between the three breeds of rabbits. The total protein, albumin, globulin, cholesterol, urea, creatinine, alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were similar across the three breeds. However, Chinchilla (B1) breed was higher in albumin, creatinine, AST and ALT values among the three breeds whereas New Zealand White (B2) breed was maximum in total protein, globulin, creatinine and urea values.

The values ($p>0.05$) presented in Table 1 were within the range of reference values in literature and also harmonized with values reported for rabbits in previous studies (Woolf, 1991; Yazar *et al*., 2004; Silva *et al*., 2005; Elmas *et al*., 2006; Melillo, 2007). The stability of serum albumin, cholesterol, creatinine, ALT and AST concentration in rabbits across the three breeds indicates the normal physiological function of the rabbits. The New Zealand White breeds had the maximum total protein value than Chinchilla and Dutch breeds and the value is higher than the one reported by Talis *et al*. (2005) and Saad, *et al*. (2006) but lower than 5.83+-0.55 obtained by Olayemi *et al*. (2006) which could be ascribed to androgen anabolic effect. The total protein values of both Chinchilla and Dutch breeds were in accord with 4.17g/dl - 6.37g/dl observed by Okwori, (2017).

Table 1 Effect of breed on the serum biochemical parameters of breeds of rabbits

Parameters	B1(CH)	B2(NZW)	B3(DH)	SEM
Total protein (g/dl)	6.15 ± 0.31	6.22 ±0.23[a]	5.79 ±0.12	0.135 NS
Albumin (g/dl)	4.39 ± 0.15[a]	4.29 ±0.11	4.35 ± 0.14	0.715 NS
Globulin (g/dl)	1.76 ± 0.23	1.93 ± 0.21[a]	1.45 ± 0.69	0.111 NS
Urea (mg/dl)	31.56 ± 5.42	39.01± 5.23[a]	31.61± 4.61	2.891 NS
Cholesterol (mgl/dl)	20.03±1.81	24.87 ±8.75[a]	16.98 ± 4.33	3.209 NS
Creatinine (mg/dl)	1.27 ± 0.18[a]	1.26±0.17	1.24± 0.09	0.084 NS
AST (im/l)	33.80± 6.48[a]	27.54±3.33	2 t4.83±7.52	3.401 NS
ALT (im/l)	30.95± 5.04[a]	30.31±2.99	29.80±6.79	2.811 NS

NS- Not Significant, [a]: means within the row have maximum value. Where : B1- Chinchilla, B2- New Zealand White, B3-Dutch, AST- Aspartate aminotransferease, ALT- Alanine aminotransferease, SEM- Sum of error mean.

The Albumin level of 4.39± 0.15 in Chinchilla breeds (B1) was the maximum among the three breeds and there was no significant difference (p>0.05) between the three breeds. The values obtained were within the reference range for rabbit in literature even though there was an overlapping of the intervals at the upper end of the reference range indicating that the rabbits used for the study consistently outperformed those rabbits used for the reference values. This also showed that the liver, kidney and digestive system of Chinchilla, New Zealand White and Dutch rabbits were functioning well and the rabbits were not dehydrated but had an increased rate of metabolism (Azoz *et al.,* 2005). The albumin level in B1 was within the reference value for Chinchilla rabbits (Talis *et al*., 2005), but higher than the value obtained by Abdel, (2015) which could be as a result of increased metabolic rate which reflects the change in liver function.

The globulin level of Chinchilla, New Zealand White and Dutch rabbits were not significantly different (p>0.05). The values in B1, B2 and B3 were within the normal value for rabbits although there is a decrease at the lower part of the reference range obtained among the three breeds of which B3 had the lowest value 1.45±0.69, followed by B1 (1.76±0.23) and then B2 (1.928±0.209) p<0.05. The decrease could have been as a result of endocrine malfunctions (Hansen *et Al.*, 2008) and the differences indicates that New Zealand White breeds had the highest strength or ability to substitute it's feeds to fight against diseases when compared with Chinchilla breeds and Dutch breeds. The globulin value of B1, B2, and B3 were lower than the values obtained in several studies (Saad *et al*., 2016, Etim *et al*., 2011).

The serum urea nitrogen values of the three breeds were not significantly different (p>0.05). The urea value of 39.01±5.23 in New Zealand White breeds was the maximum among the three breeds, followed by B1 and then B3 (31.56±5.41 and 31.61±4.61) respectively. These urea values obtained in the three treatments were still within the normal urea reference range for rabbits even though there is an increase in the values among the three breeds of rab0.bits which may be as a result of poor kidneys functions that may result in decrease in glomerular filtration, increased catabolism of protein and persistent enzymes activities (Ajagbonna *et al.*, 1999).

The cholesterol values in B1, B2 and B3 were of no significant difference (p>0.05) among the three breeds of rabbits. The values were also within the reference range for rabbit in literature. The results also shows that rabbit breeds differ in lipid metabolism as New Zealand breeds have the maximum rate of lipid metabolism, followed by Chinchilla rabbits and then Dutch breeds. The value obtained in Chinchilla breeds were in accordance with values Obtained by Ogbuewu *et al.*

(2010) and Mohammed *et al.* (2011). B2 value was higher than the values obtained in some studies for New Zealand White rabbit (Njidda *et al*., 2010, and Burnett *et al*., 2006, Adeyeye *et al*., 2007) of which the prolonged increased could be related to the tendency to feed slightly larger slightly quantities of feed or anabolic steriods that could affect the enzymes involved in cholesterol synthesis and may result in the deposition of cholesterol in the walls of the blood vessels and subsequent heart attack as a result of blockage of important blood vessel.

The creatinine levels ($p>0.05$) observed between the three breeds were of no significant difference. The values were within the reference values for rabbits and also are in harmony with the values in literatures (Talis, 2005, Ahamefula *et al.*, 2008, Ogbuewu *et al*, 2008). Between the breeds, the creatinine values of 1.27 ± 0.18 in B1 and 1.26 ± 0.17 in B2 are the maximum while B3 (1.24 ± 0.09) was the minimum values. This results indicates that the liver where the creatinine is synthesized normal state. Hence, the rabbits where neither starved to the extent that the rabbits had to survive at the expense of their body reserve nor was there any wastage of muscle tissue among the rabbits of which B1 and B2 fully utilize their dietary protein more than B3.

The values of ALT ($p>0.05$) between the breeds showed no statistical significant difference. The values found in B1, B2 and B3 were within the normal reference range for rabbits and harmonized with values found in several studies (Simek *et al.*, 2017., Ngokere, 2014.,Talis, 2005., Ozegbe, 2005) which was an indication that the liver were not injured or damage. Between the treatments, the maximum level of ALT was obtained in B1 (30.95 ± 5.04) followed by B2 (30.31 ± 2.99) and then B3 (29.80 ± 6.79). The ALT values of the three treatments were higher than the value obtained by Ahamefula *et al.* (2008) which could be a sign of necrosis and myocardic infarctions that may be indictors of poor protein of diets fed to the rabbits. B2 value was lower than value of Olayemi *et al.* (2007).

AST values was maximum in B1 and B2 while B3 was the minimum although all the values falls within the reference range for rabbits and are similar with other studies (Ozcan, 2005., Ngokere, 2014., Talis, 2005.) which dictates that the cardiac and skeletal muscles were not damaged which could have resulted in the release of these enzymes into the blood thereby increasing their levels in the blood.

Conclusion

The findings of this study proved that the serum biochemical parameters investigated among the three pure rabbits breeds were not significantly different ($p>0.05$). The values were within the reference ranges in the literature and harmonized with several studies. Hence, the total protein, albumin, globulin, urea, creatinine, cholesterol, AST and ALT were within the normal reference range for rabbits. Therefore, the Chinchilla, New Zealand White and Dutch breeds can be used as breeding stock in rabbit production as they are resistance to diseases and other environmental conditions.

Abstract
This study was carried out to evaluate the effect of garlic rhizome powder on blood profile of broiler at different growth phases (starter and finisher phase). One hundred and twenty Abor acre broiler chicks were used for the study and the chicks were randomly distributed into four treatment groups and the treatment groups were then divided into different replicates with each replicate having 10 chicks i.e. 30 chicks in each treatment group. The garlic powder was included at different inclusion levels and the treatments were designed as T_1: basal diet with no garlic powder, T_2: basal diet supplemented with 0.5% garlic powder T_3: basal diet supplemented with 1.0% garlic powder and T_4 having 1.5% garlic powder. Starter diet was offered to the birds for the first four weeks of the feeding trial and finisher diet was also provided for the birds within 5^{th} to 8^{th} week. Daily feed intake and weekly body measurement were taken. At the end of the starter phase, blood was collected for haematological and serum biochemistry analysis also blood was collected for blood profile analysis at the seventh (7^{th}) week of the experiment. The blood samples collected were analyzed for haematological parameters which include haemoglobin, Packed cell volume, Red blood cells, White blood cells, Mean corpuscular haemoglobin, Mean corpuscular volume, Mean corpuscular haemoglobin concentration, heterophils, lymphocytes, monocytes, eosinophils and serum biochemical parameters which include Aspartate aminotransferase, Alanine aminotransferase, Alkaline Phosphate, Cholesterol, Total protein, Albumin, Globulin, Uric acid and Creatinine. Results showed that the effect of feeding graded levels of garlic rhizome powder on the haematological and serum parameters were significant ($P<0.05$). The cholesterol levels of experimental birds dropped significantly with increasing levels of garlic in the diets. Inclusion of garlic powder on broiler feed had no significant difference ($P>0.05$) on the creatinine level. Therefore 1.5% inclusion of garlic should be added to broiler feed to enhance production of broiler lean meat with lowest cholesterol

Introduction
Poultry meat has been regarded as the second largest global food commodity (Manning, 2007). High cost of feed ingredients and disease outbreak are factors limiting poultry production in the tropics, hence the need for the use of cheap feed ingredients and antibiotics (Mellon, 2000).
Additives are added in poultry feed to improve nutritive value of ingredients and enhance broiler performance by promoting growth rate and improving feed efficiency. Antibiotics growth promoters (ABGP) have been intensively used in broiler production to improve productivity. However, they are notorious for alteration of natural gut micro biota and drug resistance in bacteria and their negative impacts on the consumers' health(Sharma, 2007).
There have been negative effects of using synthetic antibiotics on humans' health and subsequent reduction in haematological and serum parameters in broilers would predispose the animals to reduced immunological responses to infection. The European union banned antibiotic growth promoters owing to its cross resistance, also to the risk of possible drug multiple resistances in

human pathogenic bacteria. Again high cost of these growth enhancers and their technicalities involved in their use for improving broiler growth reduces their usage by farmers.

Some consumers are aware of the residual effects of antibiotics in poultry meat that is the reason organic poultry products is the consumer's preference, hence the search of alternative natural growth enhancers such as plants and their extracts. Medicinal plants contain many useful substances, some of which are biologically active. These substances can be used for therapeutic purposes and have been applied for several decades to serve as precursors for the synthesis for new drugs (Evans, 2002).

Garlic has been used as a spice and a native medicine for many years. It posses antibacterial, antifungal, anti-cancerous characteristics. Garlic supplement in broiler chicken diets have been recognized for their strong stimulating effect on the immune and digestive system in birds.

The use of blood examination as a way of assessing the health status of animals has been recorded. This is because it plays a vital role in physiological, nutritional and pathological status of organisms. Hematological parameters are those parameters that are related to the blood and blood forming organisms. It has been reported that biochemical changes as a result of toxins have effect on the haematological parameters. They are thus used to determine systemic relationships and physiological adaptations in the body of animals exposed to toxicants and stresses due to environmental nutritional and pathological factors.

Materials and Methods

This study was carried out at the Poultry unit of Teaching and Research farm of the department of Animal science and Technology, Faculty of Agriculture, Nnamdi Azikiwe University, Awka, Anambra state. The location lies between latitude 6.24^0N & 6.28^0N and longitude 7.00^0E and 7.08^0E on the south eastern part of Nigeria, the climate is the tropical wet and dry type with a clear season, the mean daily maximum temperature is usually 27^0C all over the year although could reach 34^0C in March and lowest during the harmattan months of December and January. The mean annual rainfall according to the local Metrological Station which has maintained records since 1978 reveals a mean rainfall of about 1600mm with a relative humidity of 80% at dawn (Ezenwaji *et al,* 2013).

The test ingredient **(**Garlic bulbs) were purchased from Eke Awka market in Anambra State. The bulbs were chopped into tiny cuts, sundried for three weeks and then oven dried at temperature of 50^oC for 15 hours and then ground into powder. The powder obtained was further dried under sun for proper desiccation. Four experimental diets for starter and finisher broilers were formulated as T_1 (control, with no garlic powder supplementation), T_2, T_3 and T_4 which contained 0.5%, 1.0% and 1.5% of garlic powder respectively as shown in table 1 (starter diet) and 2 (finisher diet). One hundred and twenty Abor acre broiler chicks of mixed sexes from FIDAN farm Ibadan North, Oyo state were used for the experiment. The chicks were randomly assigned to four (4) treatment groups with three replicate per treatment and each replicate having a number of 10 birds.

Few days to the arrival of the chicks, the brooding pen, drinkers and feeders were disinfected. The birds were raised on a commercial starter mash for 2 (two) weeks together in one pen after which they were divided into different treatment groups with each treatment group having a total of thirty birds (30) each and the different replicates with each replicate having 10 birds each. Birds were housed under deep litter system. Kerosene stoves and lantern were used to provide heat needed to keep the temperature within the temperature range of 33-35^{o}C. Feed and water were given to the birds *ad libitium* usually in the moving and evening. The birds were weighed at the beginning of the trial to get their initial weight and thereafter, weekly weight again were taken. Daily feed intake was determined by weighing the feed offered and the leftover the following morning. The feeding trial lasted for 8 (eight) weeks. The birds were vaccinated at appropriate time and litter changed at appropriate time.

Blood samples were collected from two broiler birds per replicate at fourth week of the feeding trial and the eight (8) week i.e at the end of the feeding trial through the wing vein using 5ml sterilized syringe.

About 2.5ml of blood samples per bird were collected into sterilized bottles containing (EDTA) ethylene diamine tetra acetic acid which is the anti-coagulant which were used for determining the hematological parameters and the second set of bottle without EDTA were used for collection of

blood for biochemical analysis and about 2.5ml of blood from each bird were collected for serum biochemical analysis. Blood samples for haematology were analyzed for haematololgical parameter which include haemoglobin, packed cell volume, red blood cell, white blood cell, heterophils, lymphocytes, eosinophils, monocytes, mean corpuscular haemoglobine concentration (MCHC), mean corpuscular volume (MCV) and the blood samples for serum biochemical analysis were analyzed for total protein, Albumin, globulin, vin acid cholesterol, creatinine, glucose, Aspartate aminotransferase (AST), Alamine aminotransferase (ALT), Akaline phosphates serum was harvested from blood by centrifugation and kept inside the freezer until when needed for biochemical analysis.
Data generated were subjected to analysis of variance using the linear model procedure of the SAS (2000). A probability of (P<0.05) was considered to be statistically significant using Duncan multiple range test of the same package.

Results and Discussion

The results of the haematologial indices of starter and finisher broiler is presented in table 3 and 4 respectively. Packed cell volume, red blood cells and the haemoglobin at both the starter and finisher phase were significantly (P < 0.05) among the treatment groups. The significant variation in red blood cells, packed cell volume and haemoglobin indicates that garlic powder had an effect on normal erythropoiesis and transportation of oxygen, chemicals and nutrients essential for life. This findings opposes the report of Elaglb *et al*, (2013) who reported non-significant (P>0.05) effect of garlic powder inclusion at 3 and 5% level on PCV, RBC, Hb. Mmerole, (2004) reported that haemoglobin and packed cell volume levels are normally higher in a well-nourished than poorly

fed animal. The increase in PCV, Hb and RBC levels of birds fed the test ingredient is an indication of improved oxygen carrying capacity of the cells which translated to a better availability of nutrients to the birds consequently affecting their well-being (Elaglb *et al*., 2013). Aengwawich *et al*, (2003) reported that deviation of packed cell volume from normal is an indication of anemia in birds and packed cell volume decreases when chickens are exposed to heat stress. The decrease in haemoglobin content in broilers at the finisher phase may be due to the presence of some hemolytic bioactive constituents in garlic. This report agrees with findings of Fadlalla *et al*, (2010), Onyimonyi *et al*, (2013) and Jawad, (2007) who reported that value of haemoglobin content of broilers was found to be insignificantly lowered in garlic treated groups.
At both starter and finisher phases, there were significant difference (P < 0.05) in the white blood cells. The increase in white blood cells at both phases indicates the Immuno-stimulant properties of garlic (Oluwole, 2001).This is in contrast with findings reported by George-Gay and Parker, (2003) who established that decrease in white blood cells was as a result of decreased production in the bone marrow or destruction due to viral infections or toxic reaction.
The mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH) and mean corpuscular haemoglobin concentration (MCHC) showed significant difference (P < 0 .05) among the treatment groups. This may be due to the defense reaction against *Allium sativum* which occurs by stimulation of erythropoiesis (Sealant *et al.*, 2006). From the findings, lymphocytes, monocytes, eosinophils and heterophiles showed significant difference (P < 0.05) at both phases. Iraql, (2014) reported improvement of broiler chicken immune system and significant increase of lymphocytes, heterophiles with garlic extract supplementation due to immuno-stimulant effect of garlic. At both phases the mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH) and mean corpuscular haemoglobin concentration decreases at an increasing rate at both phases.

The results of the biochemical indices of starter and finisher broiler is presented in table 5 and 6 respectively. There was significant difference in the cholesterol percentage. The result showed that broiler chickens fed diet 1 (0% GP) were significantly higher (P < 0.05) than those fed diet supplemented with garlic at various inclusion level. This result showed that as the inclusion level of garlic increases, there was more reduction in cholesterol percentage. This result corresponds with findings reported by Mansomb, (2011) who reported reduction in total cholesterol with broilers supplemented with 1g/kg of garlic. Stanacev *et al*, (2011) reported that garlic manifested hypocholesterolemic effects on chicken through inhibition of the most important enzymes that participate in the synthesis of cholesterol and lipid. At the finisher phase there is increase in cholesterol level, there is significant different (P<0.05) among the treatment group. This is in agreement with findings of Benjamin *et al*, (1987) that carried out a research on dogs reported elevation in cholesterol level in the blood but after 4-5 months decreased. This researcher attributed this to the effect of garlic on gradual release of cholesterol from its storage places which leads to elevation of cholesterol level, then decreased when storage is exhausted. From the result it was observed that the level of Aspartate amino-transferase (AST), Alanine amino transferase and Alkaline phosphate (ALP) decreases significantly (P<0.05) except for treatment group with inclusion level of 1.5% garlic rhizome powder which shows increase in ALP. This result agrees with the finding reported by Jimoh *et al*, (2012) who observed that supplementation of garlic reduced the serum levels of aspirate amino transferase and Alanine aminotransferase indicating the supplementation has no toxic effects on the liver.

Zinkl, (1986) reported that usually low levels of Aspartate amino transferase are normally found in the blood poultry birds but when high levels are found (400-4000 unit/μ) there is likely to be cases such as viral hepatitis and carbon tetrachloride poisoning. Also this result correlates with result of Kumar et al, (2013) who observed that serum of glutamate oxaloacetate transaminase (SGOT) and serum glutamine pyruvate transaminase (SGPT) concentration decreases significantly (P <0.05) of broiler due to Allium sativum supplementation in different treatment group compared to control group at 28th and 42nd days. Reduction in AST level indicates improvement in live function. At the starter phase, the total protein showed broiler chicken fed diet 1 (0%GP) have the higher value of total protein than other groups. The result showed significant different exist in the total protein, Albumin, Globulin, uric acid across treatment groups at both phases. At the starter phase, there is a decrease in the total protein while at the finisher stage, the result showed increase in total protein. The blood protein and creatinine depends on the quality of dietary protein. Form the result, the increase in the total protein showed beneficial synergistic effect of phenolic and flavonoids on protein metabolism. The higher albumin level observed in birds fed garlic powder at the finisher phase confers a positive result as albumin is responsible for delivering important nutrients to body cell and also prevents cell damage.

From the result, there was no significant difference (P> 0.05) in creatinine at both starter and finisher phase. This indicates that supplementation of garlic powder has no effect on the muscle wastage of broiler chicken. Higher creatinine indicates poor utilization of nutrient due to muscle wastage but from the result above, there is no significant difference among treatment group.

There was significant difference in glucose and uric acid at both phases. At the starter phase, there was increase in glucose level as the level of inclusion of garlic powder increases while at the finisher phase, there was decrease order of glucose level. The glucose level of broiler chicken fed diet 1(0% GP) is higher than other groups while at the starter phase, the glucose level of broiler chicken fed diet 4(1.5%GP) is higher than other groups. The reduction in glucose level at the finisher phase agrees with the findings of Shalaby *et al*, (2006) and Daoud, (2003) who observed reduction in serum glucose concentration due to garlic supplementation and this may be due to allicin and sulphur compounds of garlic.

Conclusion

Garlic is a feed additive which can be added in the diet of broiler without any harmful effect. This study proved that 1.5% inclusion of garlic has the highest reduction effect on cholesterol, also the addition of garlic powder in broiler diet does not have any effect on the creatinine level of the broiler birds. Therefore 1.5% inclusion of garlic should be added to broiler feed to enhance production of broiler lean meat with lowest cholesterol.

Abstract
This experiment was conducted to investigate the effect of aqueous extract of cocoyam leaves (Xanthosoma sagittifolium) on the growth performance of broilers fed full-fat soya bean based diet. A total of 120 unsexed day old Abor acre chicks were used for the experiment. The chicks were randomly assigned to four treatment groups (T_1, T_2, T_3, T_4) with three replicates of ten birds per replicate and 30 birds per treatment in a Complete Randomized Design. The birds were given equal quantity of formulated feed and subjected to similar managerial and sanitary conditions so that the only source of variation was the concentration of aqueous extract of cocoyam leaves offered to the birds. T_1 which served as the control contained 0g of cocoyam leaves aqueous extract, T2 (100g cocoyam leaves aqueous extract), T3 (150g cocoyam leaves aqueous extract) and T4 (200g cocoyam leaves aqueous extract) were offered per 6 litres of water to the experimental birds for a period of 56 days. During this experimental period, feed intake, body weight and water intake were monitored. The feed intake and body weight gain were used to calculate feed conversion ratio. Data collected were analysed using Analysis of Variance (ANOVA) for Completely Randomized Design, while the means were separated using least significant difference ($P < 0.05$). The result showed that there was no significant (P>0.05) difference in the feed intake, weight gain and feed conversion ratio of broiler chicks treated with aqueous extract of cocoyam leaves. However, the daily intake of water differed significantly (P>0.05), T_1 recorded higher value followed by T_2, T_3, T_4 and T_5. From the findings of this study, broiler birds can be subjected to aqueous extract of cocoyam leaves at the inclusion levels of 100-150g of cocoyam leaves per 6 litres of drinking water without any negative effect on the weight gain.

Keywords: Xanthosoma sagittifolium, aqueous extract, cocoyam leaf, Abor acre, cocoyam leaves, performance

Introduction
Animal protein is essential for human health and development but its availability for human consumption especially in developing countries has become a mirage (Onilude and Oso, 1997 as cited by Omoikhoje, 2017). The Nigerian population and the overall demand for animal protein is growing at an alarming rate while the current animal protein production is growing at a decreasing rate much below the population growth rate and animal protein demand. This portrays a situation of hunger for animal protein and so to effectively combat this malnutrition and under-nourishment, FAO/WHO recommended a minimum of 65g of protein per person per day of which 35g (53.8%) must come from animal sources or 12.8kg per person per annum. (Lamorde, 2008). According to Adegbola (1990) as cited by Inyang *et al.* (2014), only 8.2g of animal protein is consumed per person per day by an average Nigerian which goes a long way to indicate that about 60 – 80 percent of Nigerians are malnourished. The problem of animal protein production shortage in Nigeria is attributed to the fact that the human population is growing at 2.8%per annum (NBS, 2010) while that of animal population is growing at 1.8%per annum (Ilu *et al.,* 2016). Therefore, only an optimum animal production will help to alleviate this situation. Besides, massive

production of prolific animals like swine is limited by challenges of religious and socio-cultural prohibitions. Meanwhile, poultry animals and products have been considered to be one of the options in Nigeria for reducing the incidence of this malnutrition particularly animal protein shortage in diets of populace because of its ability to provide a good supply of protein, essential vitamins, and minerals, regulating cholesterol and blood pressure. However, these poultry animals that have high generation interval are also challenged by high cost of feed ingredients and feeds, thereby causing an impediment on the increase in animal protein supply. Apart from the problems associated with production cost, poultry meat is also associated with fat deposition.
In recent times corn/soya feed mix has been the practice in most feed formulating industries (NRC, 1994), but the fat related diseases and disorders such as atherosclerosis, high blood pressure, high cholesterol, heart diseases, cancer, obesity, resulting from such meat is making a lot of people to search for meat with less fat content (lean meat). Thus, the need to access the possibility of minimizing fat deposition using readily available feed additives. Cocoyam leaves appear to have the potential to reduce the fat deposition in animals raised on corn/soya mixture.

Materials and Methods

This study was carried out at the Teaching and Research Poultry unit of the Department of Animal Science and Technology, Faculty of Agriculture, Nnamdi Azikiwe University, Awka, Anambra State. The location lies between Latitude 6.24^{0}N and 6.28^{0}N and longitude 7.00^{0}E and 7.08^{0}E on the South Eastern part of Nigeria, the climate is the tropical wet and dry type with a clear season, the mean daily maximum temperature is usually 27^{0}C all over the year although it could reach 34^{0}C in March and lowest during the harmattan months of December and January (Ezenwaji *et al,* 2013).
A total of one hundred and twenty (120) day-old broiler chicks of Abor acre breed were procured from Zartech farm, Ibadan and was transported to the Teaching and Research Farm of the Department of Animal Science and Technology, Nnamdi Azikiwe University, Awka in the early hours of the morning in order to minimize heat stress. The birds were fed with commercial broiler starter for one week. to ensure their acclimatization to the new environment before the commencement of the experiment. Prior to the arrival of the birds, the brooding pens were kept in good condition for brooding together with the feeders, drinkers and heat source. The full fat soya used for the experiment was purchased from Nnobi village market in Anambra State. The sand, debris and all unwanted components in the seeds were removed by hand picking, thereafter, the full-fat seeds was heat treated by roasting in an open pan for forty-seven (47) minutes to reduce anti-nutritional factors and enhance digestibility. The roasted full fat soya was further processed by milling using a locally fabricated milling machine model before incorporation into experimental diets. The cocoyam leaves were collected from the local farmers at Uga in Anambra State and air-dried for seven (7) days in a room using a ceiling fan. Thereafter, the dried plant materials were ground using a locally fabricated hammer milling machine and then stored in air- tight container. 100g, 150g and 200g of ground air dried plant material powder were separately macerated in drinking troughs each containing six litres of water. Aqueous extract of *Xanthosoma sagittifolium* leaves were obtained by sieving the sediments from the liquid using a sieve. The chicks were randomly assigned to four treatment groups (T1, T2, T3, T4), each treatment with three replicates such that each treatment had 30 chicks replicated three times with 10 chicks per replicate in a Complete Randomized Design. T1 which served as the control contained 0g of aqueous extract of cocoyam leaves, while birds on T2, T3, and T4 were offered aqueous extract of cocoyam leaves at 100g, 150g and 200g per 6 litres of water respectively. An experimental diet was prepared using full fat soya bean to ensure the broiler chicks were given feed that will allow fat deposition. The gross composition of the diet is shown in table 1.

Results and Discussion

The proximate composition of cocoyam leaves (*Xanthosoma sagittifolium)* and the four experimental diet are presented in Table 2 and 3 respectively. The result showed that cocoyam leaves (*Xanthosoma sagittifolium*) have crude protein content of 15.53% and gross energy of 2990.36kcal/kg. Thus, it can serve as a feed ingredient in poultry nutrition. The experimental diet has crude protein of 19.70%, crude fat of 5.60% and gross energy of 2910.76kcal/kg. The mineral composition of cocoyam leaves (*Xanthosoma sagittifolium)* is presented in Table 4. Cocoyam leaves (*Xanthosoma sagittifolium*) have high content of potassium 220.05 mg/100g, sodium 192.06

mg/100g, phosphorus 150.40 mg/100g, calcium 130.18 mg/100g. This collaborated with the findings of Chukwu, *et al.* (2008); Ekwe, *et al* 2009; Lim, 2016; Opara, 2003 who stated that cocoyam leaves have high Calcium, Phosphorus, and Magnesium content and also with the findings of Holloway, (1988) as cited by Boakye *et al.* (2018) that cocoyam leaves are high in potassium content. The phytochemical composition of cocoyam leaves (*Xanthosoma sagittifolium)* is presented in Table 5. The result showed flavonoid content of 2.90, Tannin content of 1.28, Alkaloid content of 9.60, Steroid content of 0.61, Phenol content of 230.40, Cyanide content of 0.21, Phytate content of 1.19 and Oxalate content 0.07. This collaborated with the findings of Apata and Babalola (2012). Cocoyam leaves (*Xanthosoma sagittifolium*) have high content of phenols (230.40mg/100g) which are important antioxidants in plants and thus can be explored in food and pharmaceutical industries.

The effect of aqueous extract of cocoyam leaves on growth performance of broiler birds is presented in Table 6. There is no significant (P>0.05) difference in the feed intake of broiler birds treated with aqueous extract of cocoyam leaves. The lower quantity of feed intake recorded in T_2 could be due to the lower crude protein content of the aqueous extract of cocoyam leaves (at 100g inclusion). This study collaborated with the findings of Giang, (2010) where the total dry matter intake was highest on the treatment on ducks when fed 7% of live weight of taro leaves mixed with a mineral-premix. There was no significant (P>0.05) difference amongst the treatments on the weight gained by the broiler chicks. This agrees with the findings of Giang, (2010) on his experiment conducted to evaluate the effect of taro silage (made from leaves and stem of *Coloscasia esculenta*) and rice bran on the growth performance of ducks. There is no significant (P>0.05) difference in the feed conversion ratio of broiler chicks treated with aqueous extract of cocoyam leaves. This collaborated with the findings of Giang, (2010) who reported that there was no significant effect on feed conversion ratio of including a mineral-premix when taro leaves were fed. There is no significant (P>0.05) difference in the feed efficiency of broiler birds treated with aqueous extract of cocoyam leaves. There is no significant (P>0.05) difference in the specific growth rate of broiler birds treated with aqueous extract of cocoyam leaves There is significant (P<0.05) difference amongst the treatments on the total and mean daily water intake by the broiler chicks. T_1 had the highest water intake while T_5 had the lowest water intake following a decreasing trend. This could be due to the fact that cocoyam leaves contains tannin (anti-nutrient) and thus increases with increase in cocoyam leaves inclusion in the treatments. Thus, as stated by Haslam, (1989) as cited by Ndyomugyenyi, (2016) that tannins are astringent, bitter-tasting plant polyphenols which by implication reduces the free water intake of the bird.

Conclusion

The proximate and mineral analysis of cocoyam leaves showed that cocoyam leaf possessed appreciable quantity of nutrients and minerals and can serve as a source of feedstuff in livestock nutrition. It is also safe to say that broilers could be subjected to aqueous extract of cocoyam leaves and should be included between the levels of 100-150g per 6 litres of water without any negative effect on the weight gain.

Abstract
This study was conducted to evaluate the effect of breed on the semen biochemical parameters of three breeds of adult rabbits. Three breeds (Chinchilla breed, Dutch breed and New Zealand White) were used. Ten rabbit bucks were used per treatment, and were housed individually in hutches. The experiment lasted for eight weeks. Semen samples were collected using artificial vagina (AV) for evaluation of semen biochemical parameters. Complete Randomized Design experimental design was used. Thus, the experiment was conducted using one way analysis of variance (ANOVA) and differences between treatments means were separated using Duncan New Multiple Range Test. The biochemical parameters analyzed were total protein, albumin, globulin, initial fructose, total cholesterol, total phospholipids, total calcium, total lipids, Alanine aminotransferase and alkaline phosphatase. The results obtained showed that there were significant ($p<0.05$) differences in total protein, initial fructose, total phospholipids and alanine amino transferase between the breeds. There were no significant ($p>0.05$) differences between the breeds in albumin, globulin, total cholesterol, total calcium, total lipids, aspartate amino transferase and alkaline phosphatase. From the findings of this study Chinchilla breed had the highest values in five parameters-.total protein, globulin, initial fructose, total phospholipids and total lipids. Dutch breed had the highest values in total calcium. New Zealand White had the highest values in albumin, total cholesterol, aspartate amino transferase, alanine amino transferase and alkaline phosphatase. Chinchilla and New Zealand white had the highest values in the different biochemical parameters and are therefore, recommended for the production of genetically superior rabbit with good quality semen

Introduction
Inadequate animal protein in the diets of people in developing countries has called for the integration of some micro livestock in the farming system as sources of animal protein. Increase in the rabbit production is one way of meeting the animal protein requirements of the Nigerian populace (Iyeghe-Erakpotobor *et al*, 2002). Rabbits have high efficiency in the production of meat compared to other farm animals; thus are considered good source of animal protein. Also rabbit production is amenable to all levels of production, and therefore the field of investment of rabbit production is available for everyone especially young people. Rabbit production has a lot of benefits among which are: high adaptability, easiness to handle and manage, high growth rate, high efficiency in converting forage to meat, short gestation period and very high prolificacy (Aduku and Olukosi 1990 and Onifade *et al*., 1999). It also provides high returns on investment, produces high quality meat products which contains high protein level of about 20.8%, low sodium, low fat and cholesterol levels .It is used for laboratory processes and as pets and its faeces is a good source of manure, and its consumption is without cultural and religious biases (Biobaku and Oguntona, 1997; Omole *et al*., 2005). The presence of caecal microbes enables the rabbit to digest large amounts of fibrous feed as most non ruminant species cannot (Taiwo *et al*., 1999). Costs of beef, chevon, mutton, chicken and frozen fish are high compared to rabbit meat (Aduku and Olukosi, 1990; Ajala, 1990).

Semen consists of spermatozoa suspended in a fluid medium called seminal plasma. Seminal plasma is the fluid portion of semen, secreted by both the epididymis as well as the accessory glands before and during ejaculation. Seminal plasma is a complex fluid, which serves as a vehicle for transporting ejaculated spermatozoa towards their journey from the testes to their target, the oocyte. Seminal plasma not only transports the spermatozoa but also provides protection and nutrition to the spermatozoa during their onward movement in the female reproductive tract. Seminal plasma consists of various biochemical components, such as glucose, cholesterol, proteins, metabolites, intracellular and antioxidant enzymes, mineral elements which are important for sperm function and metabolism. In rabbit, the seminal plasma exhibits some positive roles, which include activation and augmentation of the sperm motility, buffering to provide the optimal osmotic and nutrient medium, prevention of premature activation during physiological transport of spermatozoa and stabilization of the plasma membrane with capacitation inhibitors, protection of spermatozoa from phagocytosis and destruction in an inflammatory environment. Addition of seminal plasma or its components into post thawed semen increases oxygen uptake and motility of spermatozoa (White *et al*, 1987). In the tropics the most restrictive constraint to effectual rabbit production is inefficient reproductive performance and Nworgu (2007) also reported that reproductive related problems especially infertility poses threat to rabbit production. Therefore for optimal productivity and profitability, as well as successful AI good reproductive performance of the buck is necessary. This study therefore sought to evaluate the effect of breed on the semen biochemical parameters of three breeds of adult rabbit bucks.

Materials and Methods

The study was carried out at the Rabbitary unit of the Teaching and Research Farm of Michael Okpara University of Agriculture, Umudike. Umudike is situated in Ikwuano, Abia state in south eastern, Nigeria. Its geographical coordinates are 50' 28 North, 70' 33 East and at an altitude of 112m above sea level in the tropical rainforest zone Umudike has an average rainfall of about 2177mm per annum with a relative humidity of about 72% and a monthly temperature range of 22°C to 36°C (NRCRI, 2017).

Three different breeds of rabbit bucks were used for this study. A total number of thirty healthy domestic bucks (*Oryctolagus cuniculus*) were bought at 4 months old with average body weight of 1.90kg (New Zealand), 1.76kg (Dutch) and (1.75kg) Chinchilla. The animals were housed in their individual hutches. The animals were fed *ad libitum* with a commercial pelleted grower's ration alongside with forages such as *Centrosome pubescens, Calopogonium mucunoides and Panicum maximum.* Fresh and clean water was also made available for the animals.

The semen was collected from the rabbit bucks of different breeds with the aid of an improvised Artificial Vagina (AV) which was designed and constructed by Herbert and Adejumo (1995) shown in figure 1. The device was constructed using a PVC pipe reducer socket of about 4.2 cm and 5cm inner diameter and length, respectively. A round plastic valve was fitted into the center of the PVC socket to narrow down the canal. The device was equipped with two liners (inner and outer liners) both made of latex (condom) which were fitted inside the device. About 2 ml glycerol was poured inside the device (in-between the inner and outer liner), the liners were then fastened to the body of the device at the top and bottom with aid of elastic rubber bands. Before the semen collection, the device was pre-heated by immersing it in hot water about 60^{o}C for about 5 minutes. The function of the glycerol added to the device was to help retain heat (temperature) due to its anti-freezing property (cryo- protectant), thus keeping the device at the temperature that mimics the natural temperature of the female reproductive tract (vagina) so as to enhance ejaculation following intromission into the AV. A calibrated tube is attached to the device in other to measure the volume of the semen ejaculated

Semen samples were collected from different breeds of the rabbit bucks with the use of the artificial vagina were evaluated for Initial fructose (IF) (Mann 1984), total phospholipids (TPh) (Takayama *et al.* 1977), total cholesterol (TC) (Flegg 1973), total calcium (Tca) (Gindler and King 1972). Total protein (TP), albumin (Alb), total lipid (TL), the activities of aspartate aminotransferase (AST) and alanine aminotransferase (ALT), alkaline phosphatase (ALP), and globulin in semen were determined by colorimetric enzymatic methods using commercial kits purchased from bio-diagnostic company (Recycling Crusher-SBM R). (Attia *et al.,* 2009).

All data were tested for normality using Mann-Whitney's normality test, and were analyzed as a completely randomized design using One-way analysis of variance (ANOVA) coupled with appropriate post-hoc statistics. The statistical confidence was set at 95 % ($P < 0.05$). Values were expressed in terms of means ± standard error. The breed differences were investigated using multiple linear regression analysis (MLRA), in comparing the semen qualities, and the seminal biochemistry.

Results and Discussion

The result seminal plasma constituents of the three common breeds of rabbit bucks is presented in table 1. The findings from this study showed that there were significant (p<0.05) difference among the three breeds in the following biochemical parameters- total protein, initial fructose, total phospholipids, alanine amino transferase. There were no significant (p>0.05) different on the following biochemical parameters-Albumin, globulin, total cholesterol, total calcium, total lipids, Aspartate amino transferase and alkaline phosphatase. Chinchilla breeds of rabbit has the highest value in total protein (mg%), Globulin (g/DL), initial fructose (mg), total phospholipids(mg%) and total lipids (mg/DL). Dutch breed records the highest in total calcium (mg/DL) and new Zealand white breed has the highest value in albumin, total cholesterol (mg), aspartate amino transferase (AST), alanine aminotransferase(ALT), and alkaline aminotransferase (ALP). Chinchilla breed and New Zealand white breed recorded the highest value in different biochemical parameters.

The globulin level of Chinchilla, New Zealand White and Dutch rabbits were not significantly different (p>0.05). The values were within the normal value for rabbits although there is a decrease at the lower part of the reference range obtained among the three breeds. The decrease could have been as a result of endocrine malfunctions (Hansen *et al.*, 2008) and the differences indicates that New Zealand White breeds had the highest strength or ability to substitute it's feeds to fight against diseases when compared with Chinchilla breeds and Dutch breeds. The globulin value of were lower than the values obtained in several studies (Saad *et al*., 2016, Etim *et al*., 2011, The values of ALT (p>0.05) between the breeds showed no statistical significant (p>0.05) difference. The values found in the three breeds were within the normal reference range for rabbits and harmonized with values found in several studies (Simek *et al.*, 2017., Ngokere, 2014.,Talis, 2005., Ozegbe, 2005) which was an indication that the liver were not injured or damage. The ALT values of the three treatments were higher than the value obtained by Ahamefula *et al.* (2008) which could be a sign of necrosis and myocardic infarctions that may be indictors of poor protein of diets fed to the rabbits. B2 value was lower than value of Olayemi *et al.* (2007).

AST values was maximum in Dutch and Chinchilla while New Zealand white was the minimum although all the values falls within the reference range for rabbits and are similar with other studies (Ozcan, 2005., Ngokere, 2014., Talis, 2005.) which dictates that the cardiac and skeletal muscles were not damaged which could have resulted in the release of these enzymes into the blood thereby increasing their levels in the blood.

Table 1: Seminal plasma constituents of the three common breeds of Rabbit bucks

Semen biochemical Parameters	Breed		
	Dutch	**Chinchilla**	**New Zealand White**
Total protein (g/dl)	6.54 ± 0.0^{b}	6.86 ± 0.06^{a}	6.65 ± 0.10^{ab}
Albumin (g/dl)	3.38 ± 0.03	3.34 ± 0.01	3.41 ± 0.00
Globulin (g/dl)	3.29 ± 0.12	3.53 ± 0.00	3.30 ± 0.03
Initial fructose (mg %)	164.31 ± 0.50^{c}	172.03 ± 0.94^{a}	168.63 ± 0.36^{b}
Total cholesterol (mg %)	186.32 ± 1.07	187.69 ± 1.72	187.70 ± 3.41
Total phospholipids (mg %)	54.34 ± 0.60^{b}	57.16 ± 0.08^{a}	56.09 ± 0.26^{ab}
Total calcium (mg %)	6.85 ± 0.03	6.76 ± 0.09	6.72 ± 0.01
Total lipid (mg/l)	393.00 ± 2.64	395.33 ± 3.18	393.67 ± 0.88
AST (IU)	124.86 ± 0.14	120.76 ± 0.84	125.43 ± 2.39
ALT (IU)	29.10 ± 0.15^{a}	26.26 ± 0.50^{b}	29.90 ± 0.25^{a}
ALP (IU)	53.53 ± 0.74	52.30 ± 0.32	51.80 ± 0.81

Values were expressed as mean ± SEM. (n=6). 'a, b,c' indicates significant differences (p < 0.05) among the three breeds. Aminotransferase (AST), Alanine aminotransferase (ALT), Alkaline phosphatase (ALP).

Conclusion

Chinchilla breeds of rabbit has the highest value in total protein (mg%),Globulin (g/DL), initial fructose (mg), total phospholipids(mg%) and total lipids (mg/DL). Dutch breed records the highest in total calcium (mg/DL) and new Zealand white breed has the highest value in albumin, total cholesterol (mg), aspartate amino transferase (AST), alanine aminotransferase(ALT) and alkaline aminotransferase (ALP). Chinchilla breed and New Zealand white breed recorded the highest value in different biochemical parameters.

Recommendations

Based on the results of this study, it is recommended that Chinchilla breed and New Zealand white breed should be used in the production of genetically superior rabbit with good quality traits because increase in rabbit production is on a way of meeting the animal protein requirements of the Nigerian populace. Further studies should also be carried out on the semen biochemical parameters of other breeds of rabbit buck.

Abstract
This study was conducted to evaluate the growth response of quails (Coturnix coturnix japonica) fed varying levels of pro-vitamin A cassava. Ninety-six Japanese quails were randomly allotted to four dietary treatments. In each of the four diets, sun-dried cassava tuber meal (SDCTM) was used to replace maize at 0, 25, 50, and 75% inclusion levels. The experimental design that was used is Complete Randomized Design (CRD). The study lasted for a period of 49 days (7 weeks). Feed intake was measured daily, and the quails were weighed once weekly. Feed and water were given ad-libitum. The parameters determined were Total feed intake, Average daily feed intake, Average daily weight gain, Total weight gain, Feed conversion ratio (FCR). Findings from the study showed that there was no significant difference (P>0.05) in feed intake among quails fed 0% (T_1), 25% (T_2), 50% (T_3) and 75% (T_4) levels of pro-vitamin A cassava root meal based diet. No significant difference (P>0.05) was observed in weight gain among T_1 (84.657±8.73), T_2 (79.247± 7.45), T_3 (89.800 ± 10.67) and T_4 (76.857 ± 10.36). The result of feed conversion ratio showed no significance difference among treatments group. It implies that SDCTM can favorably replace maize at any inclusion level though 50% level of inclusion had the best performance.

Introduction
The protein intake level of humans in most developing countries including Nigeria is very low due to the high cost of the product (Abeke *et al*., 2003). Animal protein is essential in human nutrition because of its biological significance and the poultry sub-sector is vital to its provision to the Nigerian populace. The poultry industry in Nigeria has hitherto been dominated by rearing of domestic chickens. However, in recent times there have been new entrants into the sector. One of the poultry species slowly gaining prominence is the Japanese quail (*Cortunix coturnix japonica*) which is suited for commercial rearing, meat and egg production under intensive management (Egbeyale *et al.,* 2013). Quails have a lower feed requirement compared to the chicken, also require minimal space for rearing (Ijaiya *et al.,* 2013). They thrive well in small cages and can be reared at a cheaper cost within a relative short time (Ojo *et al.,* 2011). Hemid *et al*. (2010) reported that quails have a short generation interval, high rate of lay and much lower feed and space requirements than the domestic fowl. Quail eggs are very rich in vitamin D, antioxidants which according to Sahin *et al*. (2008) improve the quality of food from animal origin in terms of colour, oxidative stability, tenderness and storage properties. They have a highly positive effect on people with stress problems, hypertension, digestive disturbance, gastric ulcer, liver problems, bronchitis illness, depression, panic and anxiety illness. The nutritional value of quail eggs is 3–4 times greater than the nutritional value of chicken eggs (Tunsaringkarn *et al.,* 2013). Quail eggs are also known to increase sexual appetite, stimulate brain functions which improve intelligence quotient and generally rejuvenate the body (Onyewuchi *et al.,* 2013). There are also some claims that consumption of quail eggs fortifies the woman's body during pre- and postnatal periods as well as

after surgery and radiotherapy (Onyewuchi *et al.,* 2013). Quail meat is tastier than chicken and has less fat content (Igado and Aina, 2010). Generally, products from quail birds are known for their high quality protein, high biological value and low caloric content, making it a choice product for a hypertensive patient (Sahin *et al*., 2008).

The increasing competition between man and livestock for available grains and tubers for food, feed and industrial raw materials coupled with Nigeria's sole concentration on oil sector to the utter neglect of agriculture, has further led to the high cost of available food/feed resources (Udedibie and Durunna, 2000). Poultry feed producers are thus faced with the task of finding alternative feedstuffs that will not compromise quality. The search of such alternatives has occupied the attention of Animal Nutritionists in Nigeria for over a decade (Onyimonyi and Okeke, 2002; Onyimonyi and Onukwufor, 2003; Oke *et al*., 2005; Onyimonyi and Okeke, 2005; Tuleun *et al*., 2005). Cassava appears to possess the potential of serving as an alternative to maize. This study therefore assessed the growth performance of quails (*Coturnix coturnix japonica*) fed varying levels of pro-vitamin A cassava.

Materials and methods

The study was carried out at the Teaching and research poultry unit of the Department of Animal Science and Technology, Faculty of Agriculture, Nnamdi Azikiwe University, Awka, Anambra state. The location lies between latitude 6.24^0N & 6.28^0N and longitude 7.00^0E and 7.08^0E on the south eastern part of Nigeria (Ezenwaji *et al,* 2013).

Fresh pro vitamin A cassava was sourced from a reputable farm. The roots were washed and chopped into small pieces using kitchen knife, the roots were sun-dried on a tarpaulin sheet for about five (5) days with regular turning. Sun-drying is aimed at reducing the moisture content. The chopped root was milled using a hammer mill and used to compound the experimental diet.

A total of Ninety-six (96) day old unsexed Japanese quails (*Coturnix coturnix japonica*) were purchased from a reputable farm. These quails were weighed individually and randomly allocated into four (4) dietary treatment group of T_1 (0% Pro vitamin A cassava), T_2(25% Pro vitamin A cassava), T_3 (50% Pro vitamin A cassava) and T_4 (75% Pro vitamin A cassava). Each treatment was assigned twenty-four quails which has three replicate of eight quails per replicate. The experimental design that was used is Complete Randomized Design (CRD). Before the arrival of the birds, the brooder pens, feeding and drinking troughs were cleaned and properly disinfected. Litter materials (wood shavings) were spread on the floor to absorb moisture and ease the regular removal of poultry droppings from the house. The feeding and drinking troughs were put in their positions on the litter. Feed and water were given to the birds *ad libitum*. Adequate care was taken to prevent the chick from drowning in water troughs by placing stones in their drinkers. Light was provided for 24hrs during brooding to avoid cold and mortality. The gross composition of the experimental diet, proximate analysis of the test ingredient and proximate analysis of the experimental diets is shown in Table 1, 2 and 3 respectively.

The parameters determined were Total feed intake, Average daily feed intake, Average daily weight gain, Total weight gain, Feed conversion ratio (FCR). The data was subjected to ANOVA (Analysis of Variance) as described by Obi (2002) using SPSS package (2003). Means were separated using Duncan New Multiple Range Test (Duncan, 1955).

T1 (0%)	90.10	19.18	3.06	4.03	3.38	70.35
T2 (25%)	90.05	20.71	3.88	7.97	4.75	62.69
T3 (50%)	89.46	19.28	3.57	6.43	5.74	64.98
T4 (75%)	89.30	19.10	3.27	6.13	5.82	65.60

Results and Discussion

The growth performance of Japanese quail (*Cortunix coturnix japonica*) fed varying Levels of Pro Vitamin A Cassava is presented in table 4. The result of this study showed that there was no significant ($P>0.05$) difference in the feed intake amongst treatments. This is in agreement with the findings of Odo and Nnadi (2012). The no significant difference amongst treatment could be due to relatively similar chemical composition of the experimental diets. The study recorded the highest feed intake in T_3(1678±251) and the least feed intake in T_4(1560±184), this result is in agreement with Hagerman (2002) that presence of anti-nutritional factors in higher quantity in diets reduces palatability of the diet and thus feed intake of livestock.

There was no significant ($P>0.05$) difference in the weight gain amongst treatment group. This could be due to the relatively similar crude protein (isonitrogenous) of the four diets. Olubamiwa *et al*. (2009) also stated that growing quails are able to keep body growth rate over a wide range of dietary energy levels. The report of this study is also in agreement with the findings of Odo and Nnadi (2014). The highest weight gain was recorded in T_3 (89.00±10) whereas the least weight gain was recorded in T_4 (76.88±10), this could be due to presence of higher level of anti-nutritional factors present in T_4, This is in agreement with the findings of (Akande *et al.,* 2010), who opined that in poultry, negative effects such as feed intake reduction, poor nutrient utilization, and growth depression have been attributed to the presence of anti-nutritional factors in diets constituting non-conventional feedstuffs

The result of this study showed that there was no significant ($P<0.05$) difference in the feed conversion ratio amongst treatment, however, T_3(3.04±0.26) had the best feed conversion ratio, whereas T_2(3.38 ± 0.56) had the least conversion ratio, this could be due to the relatively higher crude fibre content of the T_3 diet compared with the T_2 diet. The findings of this report is in agreement with the findings of Odu and Nnadi (2014) but disagrees with the findings of Whyte *et al.* (2000) who observed that feed conversion ratio (FCR) varied significantly ($P<0.05$) among the different treatment groups. It was highest in T_4 group with 75% inclusion level of cassava tuber meal followed by T_3, then T_2 and lowest in T_1 with zero percent inclusion level of cassava tuber meal as a replacement for maize

Conclusion and Recommendation

It can be concluded that Pro vitamin A cassava can be used to replace maize by 25%, 50% and 75% because there was no significant difference among them. Although, the best level of inclusion of cassava tuber meal as a replacement for maize is 50% since the quails achieved their highest feed intake and weight gain at this level.

In view of the high cost of maize and the uncertainty about their sustainable supply as energy source for livestock and poultry, I recommend that cassava tuber meal can be used as a replacement for maize at 50% level in quail diet. This will obviously improve productivity of quails.

Table 4: Growth Performance of Japanese quail (*Cortunix coturnix japonica*) fed varying Levels of Pro Vitamin A Cassava

Parameter	T_1	T_2	T_3	T_4
Average daily feed intake per bird(g)	33.1718 ± .239	33.1071 ±2.192	34.2491± 6.366	31.8384 ± 5.1278
Total body weight gain (g)	84.657 ± 8.73	79.247± 7.45	89.800 ± 10.67	76.857 ± 10.36
Total Feed Intake(g)	1625.42 ± 11.69	1622.25 ± 107.41	1678.21 ± 251.26	1560.08 ± 182.22

Abstract

This study was carried out to determine the effect of breed on the semen quality of 3 breeds of rabbits namely New Zealand white (NZW), Dutch (DUTCH), and Chinchilla (CHINCH). A total of 30 rabbit bucks (10/breed) were assigned into 3 treatments with 10 replicates each in a Complete Randomized Design. The animals were fed ad libitum with a commercial growers pellet containing 16% crude protein alongside with forages. Fresh water was made available. The rabbit bucks were trained for semen collection for 2 weeks with artificial vagina using a female doe as a teaser. After adaptation period semen was collected using artificial vagina. Reaction time and semen characteristics were studied during the experiment. The results showed that the reaction time was fastest in CHINCH followed by NZW and DUTCH. Nevertheless, semen pH was highest in DUTCH. Sperm concentration and live sperm proportion were highest in CHINCH breed. Discrepancies were observed in semen pH, semen consistency, sperm mass motility, proportion of live sperm, total viable spermatozoa, and total abnormal Spermatozoa among different breeds. However, no significant effect of breed was recorded on semen volume, semen color, total number of ejaculate, normal spermatozoa proportion. At the end of the study it was found that the CHINCH breed had the highest semen quality going by semen motility, livability, semen concentration and morphology values of 85.25%, 93.53%, 114.05×10^6/ml and 98.17%, respectively. A further research is recommended on the effect of other factors on the semen quality of rabbit bucks.

Keywords: Chinchilla, New Zealand White, Dutch, Semen evaluation, Semen characteristics, Artificial vagina

Introduction

Rabbit (*Oryctolagus cuniculus*) is a micro livestock species and is one of the cheapest and fastest means of producing high quality animal protein and fast-growing livestock. According to Ajala and Balogun (2004) rabbits possess a number of qualities that will be of advantage in the small holder farming subsistence integrated farming in Nigeria and its production is an appropriate means of eradicating low animal protein intake in Nigeria. Onifade *et al*. (1999) as cited in Shinkut (2015) reported that rabbit meat is rated sixth in the order of meat animal production and consumption in Nigeria. Other studies have reported that rabbit is highly adaptable to the tropical environment, very easy to control and manage, high growth performance, high food conversion ratio, short gestation period and very high prolificacy and buck attains sexual maturity as early as 5 months depending on the breed. Also Omole *et al*. (2005) posited that the rabbit meat is a white meat and has high quality because it contains high level of protein, low sodium, fat and cholesterol. It's used for educational and research purposes and as pets and its faeces is a good source of manure, and there is no religious or cultural barrier against its consumption. The rabbit is a pseudoruminant and are hindgut fermenters which enables it to digest large amounts of fibrous feed as most non ruminant species cannot and they also practice coprophagy. Costs of other conventional sources of meat such as cattle, sheep ,goat, and poultry are high compared to rabbit meat .Rabbit farming in Nigeria is faced with many constraints, which has led to the massive decrease of supply of meat to meet up the demands of the growing populace. (Nworgu, 2007).

The quantity and quality of semen determines the ability of the semen to fertilize as well as its viability. Many factors have been associated with the quantity and quality of semen output and normal morphology is considered as one of the most important. The quality of semen in relation to its fertilizing capability is determined by the morphological features of spermatozoa, percentage of live spermatozoa concentration, motility of spermatozoa and the ejaculated volume also the length and breadth of sperm cell add to the quality of the sperm with respects to its fertility. (Akhter *et al*., 2013).

The evaluation of the reproductive capacity of the buck should be regarded as an advantageous practice among breeders because the semen quality characteristics represents the reproductive potential of the male and the functionality of the testicles. All the methods used for the verification of semen quality that are widely known are valued for the symptoms of the essential processes of the spermatozoa, morphological characteristics and chemical composition. According to Lavara *et al* (2005) information regarding the fertilizing ability of sperm must be revealed by evaluating the semen. In spite of the fact that the use of one feature does not provide as much as is needed exactly to prejudge the fertility of the semen ,the number of spermatozoa inseminated and their motility are the most pertinent parameters that are associated with the rate of fertility . Additionally, the intricacy of semen evaluation is such that consequential variability among laboratories can be introduced in the evaluation of sperm parameters (sperm counts, motility and morphology; WHO, 1999).

Quinteiro *et al*. (2007) produced a composite index which better prejudge the fertility and fecundity of semen samples by inserting several characteristics of rabbit semen (motility, sperm abnormalities and altered acrosomes). Nonetheless, seminal characteristics is known to be affected by many factors (genetic strain, feeding, health status, rearing condition, season, age and collection frequency), which consequently contributes to the significant variability in semen traits (El-Azim and El-Kamash, 2011).

Previous studies have found that Semen evaluation is imperative in AI programs, because the quality and concentration of spermatozoa determines the extent to which the semen will be diluted, hence the number of females which can be inseminated .The success of an AI program also depends on the assessment of the potential fertilizing capacity of the spermatozoa in the semen. In the tropics the most restrictive constraint to effectual rabbit production is inefficient reproductive performance and Nworgu (2007) also reported that reproductive related problems especially infertility poses threat to rabbit production. Therefore for optimal productivity and profitability, as well as successful AI good reproductive performance of the buck is necessary. This study therefore sought to compare the semen characteristics of New Zealand, Dutch and Chinchilla breeds of rabbits.

Materials and Methods

The experiment was carried out at the Rabbitry Unit of the Teaching and Research Farm of Michael Okpara University of Agriculture, Umudike. Umudike is situated in Ikwuano, Abia State in South Eastern Nigeria in the west of Africa. Its geographical coordinates are 50 28' North, 70 33' East and at an altitude of 112m above sea level in the tropical rainforest zone. Umudike has an average rainfall of about 2177mm per annum with relative humidity of about 72% and a monthly temperature range of 22^{o}c to 360^{o}c (Meteorological station of National Root Crop Research Institute (NRCRI), Umudike)

A total of 30 rabbit bucks (10/breed) were used. Care was taken when placing the animals into groups according to their different breeds' .The animals were about 4 months old and the experiment lasted for 8 weeks. The bucks used for the experiment had average body weight of 1.76, 1.90, 1.75 KG for Dutch, NZW, CHINCH breeds respectively. The animals were housed in their individual hutches. The animals were fed *ad libitum* with a commercial pelleted grower's ration alongside with forages such as *Centrosema pubescens, Calopogonium mucunoides* and *Panicum maximum*. During acclimitization period anti- stress, antibiotic and anthelmintic were administered which lasted for 2 weeks. The animals were prophylactically treated against ecto and endo parasites by administering 0.2ml Ivomectin per rabbit subcutaneously. They were equally

given broad spectrum antibiotic 0.4ml intramuscularly. Fresh and clean water was also made available for the animals. The feeders, water troughs and surroundings were always kept clean.
The semen was collected from the rabbit bucks of different breeds with the aid of an improvised Artificial Vagina (AV) which was designed and constructed by Herbert and Adejumo (1995). The animals were trained for two weeks with artificial vagina using a female as teaser. The semen colour and consistency was evaluated macroscopically and recorded. The consistency scale (1-4), adopted by Chibundu (2013) was used. **Consistency score 1:** Whey-watery, **2:** Watery, **3:** Thick, and **4:** Very thick

Colour score: **1:** Milky-white, and **2:** Creamy-white

Semen ejaculates were collected using an artificial vagina maintained at 45.8^{0}C to 46.8^{0}C and a teaser doe. The volume of each ejaculate was recorded after removal of the gel mass. The reaction time (RT) was the time interval from the introduction of the teaser doe into the male's cage to ejaculation; it was measured in seconds using a stopwatch and was considered as an indication of libido. Immediately after collection, semen was maintained at 35.8 in a water bath for evaluation. Fresh semen (two drops) was placed on a warm slide and covered with a cover slip to determine mass motility. Mass motility from at least three fields was examined at 37.8^{0}C under a microscope with phase-contrast optics, at × 40 magnification, and assessed from 0% to 100%. The total sperm output was calculated by multiplying semen ejaculate volume and semen concentration. Assessment of live and abnormal spermatozoa was performed using an eosin–nigrosin blue-staining mixture (El- Sherbiny, 1987 modified by Attia *et al.,* 2009). The percentage of live, dead and abnormal spermatozoa was determined using stains that penetrated cells with damaged membranes. Normal live sperm exclude the eosin stain and appear white in color, whereas dead sperm take up eosin and appear pinkish in color because of loss of membrane integrity. Normal sperm have an oval head with a long tail. The total number of motile sperm was calculated by multiplying the percentage of motile sperm and the total sperm outputs. The total viable sperm (TVS) or functional sperm fraction (TFSF) was also calculated by multiplying the total sperm output and sperm motility and normal-morphology sperm (Correa and Zavos, 1996).
The method described by El- Sherbiny (1987) was adopted. The semen samples collected via epididymal washings from each treatment group was evaluated for progressive motile sperm cells. This was done immediately after collection. A drop of the semen was smeared on a preheated glass slide and viewed under a light microscope at a lower magnification of 10 and 40 and scored subjectively in percentage. The Descriptive and numerical scales for evaluation of microscopic pattern of semen is shown in table 1.

Table 1: Descriptive and numerical scales for evaluation of microscopic pattern of semen.

Numerical scale	Descriptive scale	% sperm motility	Wave pattern
0	V. Poor	0 – 20	Immotile, no wave
1	Poor	20 – 40	Stationary and bunting. Weak movements; no waves
2	Fair	40 – 50	Oscillatory or rotary movements. Few waves and eddies
3	Good	50 – 80	Progressive rapid movement. Waves and eddies seen.
4	V. good	80 – 90	Vigorous rapid movement. Eddies seen
5	Excellent	90 - 100	Very vigorous rapid movement. Rapid waves and eddies

Source: Peter (2002).

Individual motility score (1 – 4), **Progressive rectilinear motility –** rapid straight forward movement, **Circling motility –** moves in circles because of mid and tail defects, **Reverse circling motility –** moves in circles, in backward direction; no marked progress., **Pendulation motility –** jerky, serpentine movement; no marked progress

The proportion of sperm cells that are viable (alive) was determined by staining a drop of the collected semen (epididymal washings) with Eosin-Nigrosin stain. The stained glass slides were allowed to dry for 30 seconds before fixing with ethanol. The stained slides were viewed under a light microscope at 100 magnification (oil immersion), and the proportion of the sperm cells that were viable was counted with a hand-held stopwatch manual counter. A total of 300 cells were counted and the percent viable sperm cells calculated. The sperm cells that were alive (viable) did not pick the stain while those that picked the stain were dead (El-Sherbiny, 1987).

The concentration of the sperm cells in the semen samples were evaluated using the haemocytometer, a method described by Herbert (1992). A dilution of 1: 200 was made using a red blood cell pipette. 10% buffered formalin solution was used as the semen diluting fluid to immobilize the sperm cells. The **haemocytometer** was charged with a drop of the sperm solution and allowed for 2 minutes on a wet paper (to allow the sperm cell to settle) before it was mounted on a light microscopic stage and viewed under 40 magnification. The abnormal sperm proportion was determined by the method described by El- Sherbiny (1987). A drop of the semen was stained using E/N stain and the mixture smeared on a glass slide and viewed under a lower magnification of × 40 to check for primary and secondary abnormal sperm cells, percentage of the differential abnormalities such as head abnormalities, tail abnormalities, mid-piece abnormalities etc. (El-Sherbiny, 1987).

All data were tested for normality using Mann-Whitney's normality test, and were analyzed as a randomized design using One-way analysis of variance (ANOVA) coupled with appropriate post-hoc statistics. The statistical confidence was set at 95 % ($P < 0.05$). Values were expressed in terms of means ± standard error. The breed differences were investigated using multiple linear regression analysis (MLRA), in comparing the semen qualities.

Results and Discussion

The results of the semen qualities of the three common indigenous breeds of rabbit bucks is presented in table 2. There were no significant ($p>0.05$) differences on the reaction time/sec, semen volume, semen colour, individual sperm motility, total number of spermatozoa and normal spermatozoa proportion of the different rabbits. However there were significant ($p<0.05$) differences between the breeds on semen pH, semen consistency, sperm mass motility, proportion of live sperm, sperm concentration, total viable spermatozoa and total abnormal spermatozoa.

The results indicated that there was no significant ($p>0.05$) difference between the breeds on reaction time where the value of Dutch was 2.27, NZW 2.67 and CHINCH 2.28. Although there are no standard values for reaction time in literature but previous research has found out that the shorter the reaction time, the higher the libido, while the longer the reaction time the lower the libido. The findings of the study shows that the reaction time is short and it implies high libido which in turn indicates that the animal is sexually mature.

The outcome of the study on the effect of breed on semen volume shows that they are statistically the same at $p<0.05$ where the value of Dutch was 0.55ml, NZW 0.50ml and CHINCH 0.61ml this result is agreement with that of Brackett (2004) who reported that semen volume varies from 0.4 - 0.6. The result is also close to that of IRRG (2005) who reported that semen volume varies with 0.3 - 0.9ml. According to previous research a large volume of semen does not imply that the total spermatozoa content is greater than those from large nevertheless large volume is not preferable because the larger the volume the lesser the concentration.

The semen pH of Dutch (7.56) was higher than that of NZW (7.46) and CHINCH (7.51) the measurement of semen is of great importance because any semen extender used should be approximated to the same pH as the semen. (El-Azim and El-kamash, 2011). This results is in agreement with the literature findings of Alvarino (2000) who asserted that semen pH varies between 6.8 - 7.3 and with that of El-Azim and El-kamash (2011) they reported that the semen volume to be between 7.35 - 7.50. This result is far from that of WHO (1999) whose result is 6.8 - 8.4. Semen pH should be slightly alkaline and if it is not so this indicates a bad semen quality. The result of the semen pH shows that the semen is slightly alkaline and thus its of good quality.

Semen colour was graded from milky white to creamy white. All the breeds had the same colour of semen which is milky white. The effect of breed is not significant in this regard this shows that at $P>0.05$ the results are statistically the same. The Results were close to with those of Arrebola and Fernandez (2011) who is of the view that pearly white semen is of good quality and it agrees with those of Campos *et al*. (2014), Alvarez *et al.* (2006) and Gorge *et al*. (2017) they all posited that semen of good quality should have a milky appearance as this gives an indication of high semen concentration. This result is far from that of Matavelli (2008) who opined that the best quality semen is found in creamy - white semen. The result of the semen color of the rabbit shows that it was not contaminated during collection, because yellowish semen according to Campos *et al.* (2014) is as a result of contamination with which occurs when the temperature of the artificial

vagina is too high. The semen color obtained from this study shows that semen is normal and of good quality and this could also be attributed to the healthy state of the animal too.
The effect of breed was highly significant on Semen consistency which means that values are statistically different at $p<0.05$, the values obtained were 2.00, 2.66, and 2.66 for Dutch, NZW and CHINCH breeds respectively. The consistency was graded from whey-watery, watery, thick to very thick. The result of the study found out that the consistency of Dutch breed was whey-watery while those of NZW and CHINCH were watery.

There were no significant difference in the individual sperm motility of the 3 breeds they are statistically the same at $p>0.05$. The individual sperm was graded from progressive rectilinear motility, circling motility, reverse circling motility and pendulation motility. The result of the study found out that the individual sperm motility of the 3 breeds were in a progressive rectilinear motility. The mass motility of semen was significantly different between the 3 breeds at $p > 0.05$, the CHINCH breed had the highest sperm motility of 85.25% while Dutch and NZW had 78.33% and 80.00% respectively. The findings of this result is in agreement with those of Brackett (2004), Salcedo-Baca *et al.* (2004), IRRG (2005), Ogbuewu *et al.* (2009) and Iwuji and Herbert (2012). They all posited that semen of good quality should have a motility range of 30-90%. This is important because it is believed to be the most pertinent parameter related to male fertility because of its relevance for spermatozoa migration through the genital tract and for gamete interaction at fertilization. It also portrays the viability and vigour with which the sperm cells are propelled during the process of fertilization. Low motility denotes bad semen quality and poor reproductive performance of the animal thus reducing its fertilizing capacity. The result of the study implies that the animals are reproductively sound.

Results for live sperm (%) indicated that NZW had the lowest value (84.33%) compared with Dutch (91.80%) and CHINCH (93.53%) the effect of the breed was significant in this parameter showing that the values are statistically different at $p<0.05$, with CHINCH breed having the highest result of 93.53%. This result is in agreement with those of Brun *et al.* (2002b) who graded sperm cells with more than 70-80% viability as very good and Uysal *et al.* (2010) who is of the view that rabbit semen of good quality should not possess more than 25% of dead cells. The result for total viable spermatozoa is highest in CHINCH breed (598.04) compared to those of Dutch (458.720) and NZW (392.25) and the effect of breed is highly significant in this parameter.

The result for sperm cell concentration was highest in chinch breeds ($114.05 \text{x} 10^6$ml) while that of Dutch and NZW were 107.55×10^6/ml and 102.74×10^6/ml respectively. The effect of breed was significant implying that they are statistically different at $p<0.05$ with CHINCH breed having the highest sperm cell concentration. This result does not agree with those of IRRG (2005) and El-Azim and El-Kamash (2011) they reported that the concentration of rabbit semen varies between 150-$500 \text{x} 10^6$sperm/ml but agrees with that of farrell *et al*.(1993)they asserted that the minimum sperm numbers required for fertility were 0.05million and 0.1million for normal litter size. The result is also far from that of Ogbuewu *et al*. (2009) who reported the value of 20.15×10^6/ml. This could have been caused by the feeding protocols of ogbuewu *et al*.(2009).Also the total number of spermatozoa/ejaculate is 60.04, 51.54 and 70.87 for Dutch, NZW and CHINCH breeds respectively .There is no significant difference on the effect of breed on this parameter ,they are statistically the same at $p>0.05$. The result is far from that of Ogbuewu *et al. (*2009) who reported a value of 14.75×10^6/ml for total sperm ejaculate. The reason for low concentration in this result could be due to lack of necessary sexual stimulation and age too. The bucks should be sexually stimulated before copulation because it increases the concentration semen thus enhancing the fertilizing capacity of the semen this is important because insemination with too low number of viable spermatozoa results in reduced pregnancy rate or no pregnancy at all.

The results indicated that the effect of breed on normal spermatozoa proportion was not highly significant ($p>0.05$) indicating that they are statistically the same where the value of Dutch was 98-05%, NZW 96.95% and CHINCH 98.17%. The result is close to those of Salcedo-Baca *et al.* (2004) who reported the following values for NZW and CHINCH breeds to be 94.69% and 94.18% respectively. This shows that the sperm was morphologically sound and as such has high fertilizing capacity. Also results from total abnormal spermatozoa shows that the effect of breed was highly significant at $p<0.05$, where the value of Dutch was (1.94), NZW (4.54) and CHINCH (1.82). The results are in agreement with those of Kuzminsky (1999) who is of the view that total abnormal sperm should not exceed 17-18% and that of Brackett (2004) who indicated that every ejaculate contains some abnormal spermatozoa but when it is more than 20% it leads to reduction in fertility while an expected range of 8-10% has no adverse effect on fertility. The final result of the study is in agreement with that of Oyeyemi *et al*. (2007) who is of the view that fertility capacity or semen quality is increased with the increasing percent of motility, livability, semen concentration without increasing in abnormal sperm cells. This implies that CHINCH breed has the lowest number of abnormal sperm cells this could be attributed to the genetic makeup of this breed thus showing that it is genetically sound.

Conclusion

The result of the findings shows that the effect of breed was not significant on the following parameters Reaction time, semen volume, semen colour, normal spermatozoa, Total number of spermatozoa and Individual sperm motility. The result also shows that the effect of breed was significant on the following parameters semen pH, semen consistency, sperm mass motility, sperm concentration, total viable spermatozoa, total abnormal spermatozoa, proportion of live sperm. The result of the study shows that the chinchilla breed of rabbit had the highest motility, livability, semen concentration and morphology and this implies that it has the highest semen quality. Semen motility and semen morphology are very important parameters correlated to male fertility as they are useful tools used for detection of sperm fertility and estimation of semen quality. Adequate morphological screening allows elimination of animals with low fertility potential and low semen quality.

Table 2: Semen qualities of the three common indigenous breeds of Rabbit bucks in Nigeria.

Semen Parameters	Breed		
	Dutch	**New Zealand White**	**Chinchilla**
Animal Weight (kg)	1.76 ± 0.05^{ab}	1.90 ± 0.03^{a}	1.75 ± 0.04^{b}
Reaction time/sec (libido)	2.27 ± 0.12	2.67 ± 0.15	2.28 ± 0.11
Semen volume (ml)	0.55 ± 0.06	0.50 ± 0.03	0.61 ± 0.07
Semen pH (1 – 14)	7.56 ± 0.02^{a}	7.46 ± 0.01^{b}	7.51 ± 0.01^{ab}
Semen colour (1 – 2)	1.00 ± 0.00	1.33 ± 0.21	1.00 ± 0.00
Semen consistency (1 – 4)	2.00 ± 0.00^{b}	2.66 ± 0.21^{a}	2.66 ± 0.21^{a}
Individual sperm motility (1 – 4)	1.00 ± 0.00	1.00 ± 0.00	1.00 ± 0.00
Sperm mass motility (%)	78.33 ± 2.69^{b}	80.00 ± 0.57^{ab}	85.25 ± 1.54^{a}
Spermatozoa live proportion (%)	91.80 ± 1.61^{a}	84.33 ± 1.47^{b}	93.53 ± 1.32^{a}
Sperm concentration (10^6/ml)	107.55 ± 3.24^{ab}	102.74 ± 2.19^{b}	114.05 ± 2.30^{a}
Total number of spermatozoa/ ejaculate (10^6/ml)	60.04 ± 8.53	51.54 ± 4.31	70.87 ± 9.04
Total viable spermatozoa (10^9/ml)	$458.72+ 21.04^{ab}$	392.25 ± 20.49^{b}	598.04 ± 24.12^{a}
Normal spermatozoa proportion (%)	98.05 ± 0.27	96.95 ± 0.63	98.17 ± 0.28
Total abnormal spermatozoa (%)	1.94 ± 0.27^{b}	4.54 ± 1.24^{a}	1.82 ± 0.28^{b}

Abstract
This study was carried out to investigate the growth performance and economic evaluation of Giant African Land Snail (Archachatina marginata) fed whole jackfruit based diet. A total of 120 Giant African Land Snails (Archachatina marginata) were used. The study was carried out at the Snailery unit of Teaching and Research farm of Animal Science Department, Nnamdi Azikiwe University, Awka. The snails were randomly grouped into four treatment and replicated thrice with ten snails in per replicate. The jackfruit was sourced from Igbo-Ukwu in Aguata local government area of Anambra state. The whole jackfruit was cut into pieces and then oven dried and finely ground. The jackfruit meal was incorporated into the diets at the rate of 0, 5, 10, and 15% as T_1, T_2, T_3, and T_4 dietary treatments respectively with each treatment having thirty snails. The experiment lasted for 8 weeks including the one week acclimatization period. At the end of the experiment the growth performance parameters were evaluated. There was significant difference ($P<0.05$) in weight gain between the treatment group. Snails fed T_4 gave a higher weight gain and had a highest feed intake. T_4 also gave a better feed conversion ratio. In the area of shell length increment there was no significant difference ($P>0.05$). This was also observed on the shell thickness having a higher increment value with no significant difference with the other treatments. There was no significant difference ($P>0.05$) observed for the shell girth increment but T_2 gave a higher numerical value. Likewise, no significant difference ($P>0.05$) was observed for the shell aperture. This study also showed an improved cost effectiveness on the snails under T_4 as it gave better value on the feed cost (#) per weight gain and had the best feed conversion ratio than others and there was a significant ($P<0.05$) difference between the treatment diets on the cost effectiveness. Thus it could be recommended to farmers and feed millers to incorporate whole Jackfruit meal in the diet of snails.

Keywords*: Archachatina marginata, Whole jackfruit meal, Shell girth, Shell aperture, Shell length*

Introduction
Nigeria is endowed with abundant food and had a climate that supports various species of wildlife, domestic animals and crops; yet more than 70% of the population are hungry with a mean daily protein consumption of about 30g below the recommended dose per person. Snail coupled with other small livestock species such as grasscutter, giant rat constitutes ''micro-livestock'', a new but rapidly expanding area of animal production and research. The snail forms a common component of food in the diet of people, rich in protein (88.37%) thus compares well with conventional animal protein sources, beef (92.75%), broiler (92.21%), chevron (86.63%), mutton (86.34%), pork (82.42%) and fish (91.99% and 90.81%) (Banjoko, 2010). Snail belongs to a group of invertebrate called Mollusc (Akinyemi, 2008). The *Archachatina marginata* is the most accepted and highly cherished snail specie in Nigeria. Snails having a considerable quantity of protein will help to a great dimension in giving a boost to the animal protein intake by Nigerians as reported by FAO (2007) that Nigerians consume only 5.5g per head per day far below the recommended 35g. The African giant land snails are regarded as delicacies and important source of animal protein. In many developing countries meat production from domestic livestock is not sufficient to meet the

high demands for animal protein. Revitalization of some wild animal species like snail could assist in combating this challenge (Ademola *et al*. 2004). It is highly nutritious and contains 19.53g of protein/100g of fresh meat, has low fat content of 2.44% and rich in calcium (126.4mg/100g) and iron (2.29mg/g) (Babalola *et al*., 2015). The low fat content of snail meat makes it a good antidote for fat related diseases such as hypertension, atherosclerosis, e.t.c and is readily accepted by many people.

One of the major challenges in snail production is the feeding aspect especially due to the cost of feed materials. In livestock farming, feed cost is responsible for 60-70% of the total cost of production (Omole *et al,* 2010). Against this back drop the need to utilize the whole jackfruit powder meal as a component for feed to the snail which will hopefully not only make it economical in the feeding of snail but also will help increase the weight gain of the giant African land snail (*Archachatina marginata*).

Materials and Methods

The study was carried out at the Snailery unit of Teaching and Research farms of the Department of Animal Science and Technology, Faculty of Agriculture, Nnamdi Azikiwe University, Awka, Anambra state. The location lies between Latitude 6.24^{0}N and 6.28^{0}N and longitude 7.00^{0}E and 7.08^{0}E on the South Eastern part of Nigeria, the climate is the tropical wet and dry type with a clear season, the mean daily maximum temperature is usually 27^{0}C all over the year although it could reach 34^{0}C in March and lowest during the harmattan months of December and January (Ezenwaji *et al,* 2013).

A total of one hundred and twenty *Archachatina marginata* were procured from a reliable source and transported to the study area in a well aerated polyethylene bags. The snails were fed with vegetables for the one week acclimatization period. After acclimatization, the snails were randomly assigned into different bowls according to the levels of whole jackfruit meal inclusion that is T_1, T_2, T_3 and T_4. T_1 which served as control did not contain whole jackfruit meal while T_1, T_3 and T_4 contained 5%, 10% and 15% whole jackfruit meal respectively. Each of the treatment was replicated three times in Complete Randomized Design. Ten (10) snails were randomly placed into the twelve bowls which had the dimension 15cm depth and a diameter of 56cm in a circular pattern which was filled with sterilized garden humus soil obtained from the experimental site at the depth of 3cm and which was subsequently watered. A flat plastic container was used as feed saucer and contained their feed which was placed at the middle of the bowl. The bowl was then covered with mosquito netting material and tied with a twine to avoid intrusion of insects. The proximate analysis of the test ingredient (Whole jackfruit) and the experimental diet are presented in table 2 and 3 respectively

The snails were fed once a day, in the evenings due to the snail's nocturnal feeding habit. They were served with a feed saucer which was cleaned on daily basis. The snails in treatment one (T_1) were fed with diet without any inclusion of whole jackfruit meal, those in T_2 had 5% level of inclusion of WJM, T_3 had 10% level of inclusion of WJM and T_4 had 15% level inclusion of WJM as shown in table 1. The feed saucer was cleaned daily before introduction of fresh feed. The droppings of the snails were removed on daily basis, the corners of the bowls were cleaned on daily basis while the tops of the media were scrapped off on weekly basis to prevent soil from sticking together which could arise as a result of their slime. The soil was pulverized and watered to make it moist.

The feed intake was measured by subtracting the feed refused from feed offered on daily basis. The shell length and shell girth were measured using Vernier caliper on weekly basis. The shell thickness was measured using a micrometer Screw guage at the beginning and end of the experiment. The shell aperture circumference was measured using a thread and meter rule on weekly basis. The weight gain was measured using a sensitive scale on weekly basis. The proximate analysis to chemically evaluate the nutritional potential of the whole jackfruit meal and experimental diets were determined by the methods of AOAC (2002).

Results and Discussion

The oven dried jackfruit meal used in the experiment had dry matter content of 92.5%. It contained also ash of 4.75%, crude protein of 11.34%, crude fibre of 5.85, nitrogen free extract of 65.66% and a metabolizable energy (ME) of 3619.61 Kcal. The moisture content here differs from

Reza(2014) report on moisture content of 72% and Tang (2013) of 83% and this could be traced to the oven drying to which the jackfruit was subjected to as compare to the wet basis analysis of the two authors mentioned.
The result obtained on the average daily feed intake and total feed intake of the snails showed that there was no significant difference (P<0.05) between the snails subjected to the four dietary treatments. Though there is no significant difference between the feed diets, T_4 with 15% inclusion of jack fruit meal gave higher feed intake value and this could be due to the fact that T_4 had the least Nitrogen free extract (carbohydrate) and according to Ivan (1994) livestock feed mainly to meet their energy requirement.

The results obtained on the feed conversion ratio of the snails showed that there is a significant difference amongst treatments. The study revealed that T_4 had the highest conversion ratio and this could be due to the higher fibre content in the diet. T_3 and T_2 had the least feed conversion ratio and this could be due to lower fibre content in their diet when compared with T_4. The results revealed that there were significant differences (P<0.05) between the total weight gains of *Archachatina marginata.* Snails fed T_4 (15%) inclusion level of jackfruit meal gave higher weight, followed by T_1 with inclusion level of 0%. T_2 and T_3 were least and not significantly (P>0.05) different from each other. This could be attributed to the different gross energy value of the experimental diet.

The results of the shell growth characteristics of *Archachatina marginata* fed whole jackfruit meal based diet is presented in table 4. The results obtained on shell length showed that there was no significant different (P>0.05) in the shell length increment amongst the diet. This could be due to the similar ash content of the diet. The result obtained on shell aperture increase showed no significant difference (P>0.05) between the *Archachatina marginata* fed with the four treatment diets. This agrees with work by Ejidike *et al* 2010 that there was no significant difference on the shell aperture of *Archachatina marginata* specie of snails fed on different treatments. Though there were no significant difference; snails on treatment diet with 0%(control) inclusion level had a higher increase in shell aperture and this could be traced to the protein content of the treatment (19.63%) which is in close proximity to Ejidike *et al* report of 2010. The result obtained on the increment on shell girth of *Archachatina marginata* revealed that there was no significant difference (P>0.05) between the shell girth of the snails fed on the different dietary treatments. This is in line with the work of Ejidike (2016) which states that each of the study animal in the diet treatments did not differ significantly (P>0.05) at the end of the study period. The no significant difference in the shell girth increase of snails fed the different dietary treatment could be attributed to the relatively similar ash content of the diets. The result obtained on shell thickness of *Archachatina marginata* revealed that there was no significant difference (P>0.05) between the shell thickness of the snails fed with the different treatment diets. This result is in agreement with the work of Adeniji *et al (*2014) and Ejidike (2010) which recorded no significant difference on the Increment of shell thickness. *Archachatina marginata* fed on dietary ingredient with 15% inclusion (T_4) had the least level of thickness and this could be attributed to the lower protein content compared with other treatment.

The feed cost evaluation of *Archachatina marginata* fed whole jackfruit meal based diet is shown in table 5. The study recorded a lower feed cost as the inclusion level of Jack fruit meal increased T_4 had the lowest feed cost and T_1 had the highest feed cost this could be attributed to the cheap (free) sourcing of the alternative feed ingredient. This assertion can be traced to the work of Bijaya (2016) that locally available products benefits the farmer as it reduces the feed cost which in turn can reduce the total cost of production. Result of cost of feed intake showed that T_4 had the least cost of feed intake and T_1 had the highest cost of feed intake this could be attributed to the lower feed cost of T_4. Also it was recorded that though T_2 had a higher feed cost than T_3, T_3 had a higher cost of feed intake than T_2, this also could be attributed to the higher feed intake of snails fed with T_3 diet. Feed cost per weight gain which is also the cost of production recorded T_1 with the highest cost of production and T_4 with the least; this could also be attributed to the feed cost.

Conclusion

The results of the proximate analysis carried on the WJFM (test ingredient) proved that it possessed enough quality that makes it a good source of feed stuff for livestock in Nigeria. Whole jackfruit meal incorporated into the feed of Giant African Land snails at 15% inclusion level gave a better result in the area of growth performance also on the cost effectiveness, so whole jackfruit can comfortably use as an energy feed resource to replace or substitute maize.

Table 1 Percent composition of feed ingredients of snails fed with different levels of jack fruit meal

Ingredients	T1 (0%)	T2 (5%)	T3 (10%)	T4 (15%)
Maize	49.25	44.25	39.25	34.25

Abstract
In spite of the vast natural and cultural resources which Nigeria is endowed with, the country tourism industry has not grown significantly. The study was carried out to assess the awareness of tourist centres among citizens in Ogun state. Random sampling technique was used for selecting the respondents in the study. The result showed that most of the respondents were male (52.5%) and below 40 years (61.6%), married (59.2%) and had formal education (89.2%). They were low income earners as 54.2% earned less that ₦20,000. Also, the level of awareness of the respondents about tourist centres in the state was high among the male and those between age 20 and 39 years compare to those who are 40 years and above. The level of awareness was high among those between 20 and 39 years, and the respondents who possessed tertiary education. There was a significant difference in level of awareness (p<0.05). Olumo rock (77.5%), Ake palace (61.6%), Yemoji resort centre (47.5%) were rated the most the popular tourist centres in the state. There should be more adverts on tourism in the state and the facilities around the tourist centres should be developed.
Keywords: Tourism, development, facilities and potentials

Introduction
Tourism is a term defined as the science, art and business of interacting and transporting visitors, accommodating them and graciously catering for their needs and wants (Ayodele and Falade, 1989). This implies that any activities that voluntarily and temporary takes a person away from his/her usual place of residence in order to satisfy a need either for pleasure, excitement, experience and/or relaxation can be termed as tourism. Tourism has the potentials of contributing to country's revenue, economic growth and generating foreign exchange for Nigeria, and create more jobs for people in hospitality industry (Falade-Obalade and Dubey, 2014; WTO, 2011; Ijeomah, 2007). And by developing the tourism in the state, government would tackle economic problems and solve social amenities and infrastructural development problems (Kukoyi *et al* 2016). Nigeria is endowed with abundant natural resources and a wide spectrum of cultural heritage which are great asset to the country's tourism development (Uluocha, 2014). The nation is also blessed with an excellent climate with sunshine year round, vast tracts of unspoiled nature ranging from tropical forest, magnificent parks and protected areas, waterfalls, unique wildlife, beautiful rivers and beaches. Its cultural attraction include many national museum, ancient slave site, palaces and shrines, well preserved local customs. However, Nigeria tourism industry has not grown significantly. Tourism in Ogun state was in poor condition before year 2003, when Gateway Tourism Development Corporation (GTDC) was established. This tourism organization was saddled with the responsibilities of ensuring a proper coordination of all activities of tourism that include among others the festivals, sports tourism, sites, hotels, eateries and others. The board was to also resuscitate the facilities in various tourist centres which were in deplorable situation. The study will add to existing body of knowledge by assessing the awareness level of tourism among in Ogun state. The specific objectives are to study the level of tourism awareness among the people in Ogun state, identify various tourism

sites in the State, assess the facilities and infrastructures available for use by tourist and identify the challenges faced by the tourists.

Methodology

Study Area

Ogun State is located in South-West geo-political zone of Nigeria. It lies within latitude 7°00'N and longitude 3°35'E with a total land area of 16,762 square km. The State with the appellation ''Gateway state'' is bounded in the West by Republic of Benin, in the East by Ondo in the North by Oyo and in the South by the Atlantic Ocean on one part and Lagos State on the other (Nigeria Bulletin, 2015). Ogun State comprises of twenty (20) Local Government Areas.

Data collection and analysis

Primary data was used for the study. Data was obtained through the use of structured questionnaires administered to one hundred and twenty (120) respondents randomly selected. Data was analyzed using descriptive (frequency counts and percentages) and inferential statistics (chi-square).

Results and Discussion

Socio-economic characteristics of the respondents

Table 1 revealed that most of the respondents were male (52.5%) and below 40 years (61.6%), indicating that most of the respondents were young people. Most of the respondents were married (59.2%) and 89.2% had formal education (10.0% had primary education, 34.2% had secondary and 45.0% possessed tertiary education). They were low income earners as 54.2% earned less that ₦20,000.

Table 1: Demographic information of the respondents

Variables	Frequency	Percentage
Age		
Below 20years	22	18.3
20-39	52	43.3
40-59	39	32.5
60years and above	5	4.2
No response	2	1.7
Sex		
Male	63	52.5
Female	55	45.8
No response	2	1.7
Marital Status		
Single	49	40.8
Married	71	59.2
Total	120	100.0
Educational Background		
No education	13	10.8
Primary education	12	10.0
Secondary education	41	34.2
Tertiary education	54	45.0
Estimated Monthly Income (₦)		
Below 10,000	33	27.5
11,000-20,000	32	26.7
21,000-30,000	12	10.0
Above 30,000	19	15.8
No response	24	20.0

Source: Field Survey.

In Table 2, the level of awareness about tourist centres was high among the male than female. Based on age, the level of awareness is high among those between 20 and 39 years compare to those who were 40 years and above. According to EUROPA (2018) the share of older people participating in tourism is lower than the share of general populace above 15 years (EUROPA, 2017). One the main drivers of the young people to tourist centre is curiosity. Tourists visit the centres for education, entertainment (pleasure) and religious purposes. They want more information. On the basis of education, those who possessed tertiary education were more aware of the tourist centres than others

Table 2: Level of awareness of tourist centres in the state based on sex, age, and level of education

		Aware	Not Aware
Sex	Male	60(54.05)	3(42.86)
	Female	51(45.95)	4(57.14)
Total		111(100)	7(100)
Age	Below 20years	21(18.92)	1(14.29)
	20-39 years	50(45.05)	2(28.57)
	40-59 years	35(31.53)	4(57.14)
	Above 60years	5(4.50)	-
Total		111(100)	7(100)
Level of Education	No education	13(11.50)	-
	Primary education	12(10.62)	-
	Secondary education	37(32.74)	4(57.14)
	Tertiary education	51(45.13)	3(42.86)
Total		113(100)	7(100)

Source: Field survey. Values in parentheses are percentages.

Considering the level of awareness of the respondents of tourist centres in the state, Olumo rock in Abeokuta was rated the most the popular tourist attraction (77.5%), followed by Ake palace (61.6%), Yemoji resort centre (47.5%) and the least being oronna shrine (1.7) (Table 3). Table 4 showed a significant difference in the level of awareness ($p<0.05$). On the present state of tourist centres in the State, most of the respondents remarked that tourists centres were in average condition. This supports Olatunji (2016) who reported similar findings in Osun state.

Table 3: Awareness of tourist centre in the state by respondents

Tourist site	Aware	Not aware
Olumo rock	93 (77.5)	27 (22.5)
Ake palace	74(61.6)	46(38.3)
Yemoji resort centre	57 (47.5)	63 (52.5)
Birikisu Sungbo tourist complex	18 (15.0)	102 (85.0)
Abeokuta golf resort	5 (4.2)	115 (97.8)
Suna cultural centre	3 (2.5)	117 (97.5)
Oronna shrine	2 (1.7)	118 (98.3)

Source: Field survey. Values in parentheses are percentages.

Table 4: Level of Awareness of tourist centre among the respondents in the state

	Observed N	Expected N	Df	X	P-value	Remark
Aware	113(94.2%)	60	1	936.633	0.001*	Significant
Not Aware	7(5.8%)	60				
Total	120					

*Significant at 0.05 level of significance

The available facilities observed around the tourist centres by respondents include picnic site, restaurants, children playground and hotel (Table 5).

Table 5: Facilities available in the tourist centres

Facilities available in the tourist centre	Available	Not available
Picnic site	47 (39.2)	73 (60.8)
Restaurant	34 (28.3)	86 (71.7)
Children's playground	23 (19.2)	97 (80.8)
Hotel	13 (10.8)	107 (89.2)

Values in parentheses are percentages.

Conclusion

The study was carried out to assess awareness level of tourist centres among citizens in Ogun state. It is concluded that level of awareness was high among the respondents. Although the level of awareness was high among the respondents, there are still those who are aware of some tourist centres in the state. Therefore there should be more campaigns and adverts about the potentials of tourism in the state. Also, facilities around these tourist centres should be developed to attract more tourists.

E-mail: *iamkanusamuel@gmail.com*

Abstract
This study was carried out to determine the effect of different roof catchments on the physiochemical quality of rainwater harvested for domestic consumption in Umuahia Metropolis in the month of April as such determine the roofing material most suitable for rainwater harvesting. The overall water resources were assessed by the application of water quality index (WQI). Analysis of physiochemical properties in sampled rainwater were subjected to ANOVA among the roofing materials and the mean differences were separated using Duncan Multiple Range Test. The level of pollution between the sampled rainwater was made comparing the results of the physicochemical parameters to WHO and FMEnv for portable uses. The result showed that asbestos roof catchment recorded the highest mean values except in zinc where corrugated iron sheet recorded the highest. However, all the values obtained for physiochemical properties fell within the WHO & FMEnv permissible limit except zinc from corrugated iron sheet which recorded 4.35mg/l above the WHO limit of 3.0mg/l but within FMEnv limit of 5.0mg/l. Notably, Lead was detected only in Asbestos during the month of April. From the calculation of WQI, all roof catchments in all the months exceeded the critical value of 1.0 used to judge unpolluted water and therefore should be subjected to treatment for portable purposes. SRC4 (Harvey-tiles) proved to be the most suitable roof catchment for rainwater harvesting, followed by SRC2 (Aluminum rooftop). However, it is advised to subject rainwater from roof catchments to further treatments especially if it must be used for drinking.

Introduction
Water is essential to all forms of life. It is second in ranking, next to air in the list of human daily needs. As a result, it is in high demand as it represents a unique resource in every settlement: for drinking, sanitation, washing, fishing, recreation and industrial processes. Therefore, Aderogba, (2005) has posited that access to clean and regular water supply is a basic human right as its access to unadulterated food. Irrespective of the vital nature of this resource, the World Water Council has predicted that the need for water within the next fifty years will boost due to a prediction of 40-50% population growth coupled with industrialization and urbanization (Mahmoud *et al*., 2014). It is as a result of this that estimations has been made that about two billion people will be short of access to safe drinking water by the middle of this century (Parmar, 2003). The provision of water for domestic and other uses in rural and urban centres is one of the most intractable problems in Nigeria today, with 52% of Nigerians lacking access to improved drinking water supply (Lekwot *et al*., 2012; Orebiyi *et al.,* 2010). Even though Nigeria is endowed with enormous surface and groundwater resources, the provision of potable and safe water supply is still inadequate (Nwankwoala, 2011). In tackling this problem of limited access to water, identification and utilization of additional sources of water to supplement existing or dominant sources becomes paramount, where a crucial source identified is harvested rainwater (Opare, 2012). Rainwater harvesting technology comprises of three essential stages, which includes catchment areas (rooftops and land surfaces), conveyance systems (plastic or corrugated iron gutters) and collection devices (storage tanks). Among the various catchments

for the harvesting of rainwater, roof catchment seems to be the most common. This can be attributed to the fact that households use existing roofs of their houses with no additional costs incurred but the quantity and quality of rainwater collected is dependent on the area and kind of roofing material (Olaoye and Olaniyan, 2012). Chang *et al* (2004) reported that roofs can also be a crucial source of non-point source pollution as well. Efe (2006) assessed the level of portability of rainwater samples collected from thatch, aluminum, asbestos, corrugated iron roofing sheets, and open surfaces from catchment's roofs in 6 rural communities of Delta State, Nigeria. The result revealed that most of physiochemical characteristics of rainwater samples were generally below the WHO threshold, as such the rainwater characteristics showed satisfactory concentration in these rural communities. In Abeokuta Ogun State of Nigeria, Aladenola and Adeboye (2009) addressed the potential of rainwater from roof catchments commonly used in the area and concluded that Rainwater collection systems can provide water for purposes not requiring drinking water quality. Rainwater from Aluminium roofing sheet proved to be most suitable. The work of Olaoye and Olaniyan (2012), found out that all the physical and most of the chemical parameters analyzed from rainwater harvested from different roof tops conformed to the recommended standard value apart from chloride and total hardness value. In the research of Beatrice and Onakufe, (2000), Rainwater samples collected directly from the atmosphere and through various roof catchments (aluminium, zinc, asbestos and thatch) were analysed for their physical, chemical and microbiological qualities in Rivers State. Results showed that the physical and chemical qualities of the rainwater, except for colour, were within the limits approved by the World Health Organization (WHO). Galvanized iron roofing sheet appeared to be a better material for rainwater collection than aluminum, asbestos and thatch

Several studies have looked at the effect of roofing material on harvested rainwater quality but common roofing materials and coatings will vary across the country and the world. This research will therefore focus on assessment of the effect of different rooftops on rainwater quality to ascertain their suitability for domestic consumption in Umuahia metropolis, Abia State, Nigeria.

Methodology

Study area

The study was carried out in 3 layouts in Umuahia Municipal, New town layout, Eghem layout and Uzo Avoiteyi layout of Abia state in Southeast, Nigeria. It is found in the tropical rain rainforest zone of Nigeria on latitude 5.5250^{o}N and longitude 7.4922^{o}E with a population of 147,167 (NPC, 2006). Umuahia experiences the two seasons in a year; the rainy season (March-October) and the dry season (November-February) with a break in August usually referred to as the "August break".

Sampling procedure

A random sampling technique was adopted for the study within the three layouts in the study area on the basis of the availability of the selected roof catchments. The technique was employed in selecting four buildings each with the four identified roof types, namely; asbestos roofing sheet, aluminum roofing sheet, corrugated iron sheets and Harvey-tiles rooftop. The four types of existing roof materials were designated SRC, signifying Sample Roof Catchments, in which;

(i) Asbestos Rooftop (SRC1)
(ii) Aluminum Rooftop (SRC2)
(iii) Corrugated Iron Rooftop (SRC3)
(iv) Harvey-Tiles Rooftop (SRC4)

Above all, rainwater was harvested directly from the atmosphere as control signifying atmosphere.

Stainless basins were placed on elevated- wooden stands above the ground surface for rooftops rainwater samples, while the one directly from the atmosphere involved placing basins on the rooftops to avoid splashing. The samples were then crammed and put into clean polythene bottles, corked and labeled according to the different roof catchments then placed in freezers that contains ice block. This study was conducted in the month of April, the beginning of rainfall season. All rainwater samples were packaged and taken to the laboratory for physiochemical analysis.

Data analysis

Results of data collected were subjected to descriptive statistics which illustrated the means and standard deviation from replicates of data collected. Means of the collected data was afterwards subjected to mean separation using Ducan Multiple Range Test.

Application of water quality index (WQI)

Water quality index expressed the pollution level of water bodies developed and used by Horton (1965). This is expressed mathematically:

$P_{ij} = (maxCi/Lij)^2 + (meanCi/L$……………………..(1)

Horton (1965), used multiple items of water qualities as expressed as *Ci's* and permissible levels of the respective item expressed as L_{ij}*'s*. then the pollution index, *Pij* may be expressed as a function of the relative values of Ci/L_{ij} (Horton, 1965).Here, *i* is the number of the *ith* item of the water quality and j is the number of the j-th water use. Each value of (Ci/L_{ij}) shows the relative pollution contributed by the single item. A value of 0.1 is the critical value for each (Ci/L_{ij}). Values greater than 0.1 indicates that the water requires some treatment prior to use for specific purpose. Combining the mean value of Ci/L_{ij} into a common index, values over 1.0 signify a critical condition under which a proper treatment is needed for portable water.

Horton proposed that, the pollution index of water can be computed using the multiple items of water qualities and permissible levels of the respective items for use. If Pij is the pollution index then:

$P_{ij} = F\{C_i/L_{ij}, C_2/L_2j. C_3/L_j$………………. $C_i/L_{ij}\}$ ………. (2)

This is then applied in the study of water resources to know the pollution level and the treatment expected.

Results and Discussion

From Table 1, it was observed that all parameters were below the WHO acceptable limits for portable use except in Corrugated iron sheet which recorded a zinc value higher than WHO permissible limits. This is close to the findings of Efe (2006); Beatrice and Onakufe (2000). Of interest is the rainwater sample from asbestos roofing sheet which had the highest mean value in all the parameters, in agreement with Olaoye and Olaniyan (2012). According to Achadu *et al*. (2013) higher acid value in rainwater harvested from Asbestos roof type could be attributed to its lower pH and the presence of washed off particles from the Asbestos roof type by the rain. Similar observation was reported by Eruola *et al*., (2010) on rainwater harvested from Asbestos and other roofing materials in Abeokuta, Nigeria. The variations in the conductivity values obtained could be due to the type of roofing materials which could have an impact on the chemical properties of the harvested rainwater. The comparable higher value of nitrate obtained from Asbestos roof type is an indication of the presence of some biological materials like droppings from birds that stick on the coarse surface of the Asbestos roofing material. The higher sulphate content obtained in the rainwater from the roofing materials compared to the control is an indication that the roofing materials accumulate these ions from the droppings of birds and roof climbing animals or other unknown processes. The absence of lead in other rooftops except in asbestos indicates that there is minimal concentration of Lead in the environment that could be carried to the rooftops and washed into the rainwater. The presence of iron (FE) in rainwater harvested from aluminum roof type and corrugated iron sheet roof type could be due to the fact that the rain run-offs on the roof tops washed off some iron which is part of the material used in their manufacturing. The higher zinc value found in corrugated iron sheet is not surprising as eroded particles of zinc are washed off by runoff water from the corrugated iron sheet rooftop. From the calculation of water pollution index (WPI) in Table 2, it is observed that rainwater in the study area from Asbestos (SRC1) recorded the highest pollution value (6.39) which indicated that rainwater from asbestos was heavily polluted with physicochemical tracers because the calculated value is more than critical value of 1.0 used for the judgment of unpolluted water. Worthy of note is that Harvey-tiles roof catchment (SRC4) had the lowest pollution index value (1.37) making it the most suitable followed by aluminum roof catchment (2.56). This is close to the findings of Aladenola and Adeboye (2009) who reported that aluminum rooftop was found most suitable in their work and in disagreement with Beatrice and Onakufe, (2000) who reported that corrugated iron sheet was more suitable than aluminum rooftop.

Table1: Statistical summary of the physiochemical properties of early harvested rainwater from different roof catchments

Conclusion

Rainwater Harvesting is an environmental sustainable alternative for water supply. It is the simplest way to ensure the availability of water in areas experiencing water scarcity and from this study; it has been observed that its quality varies from the type of roof catchments. This study revealed that the values of the physiochemical properties of the harvested rainwater samples fell within the WHO and FMEnv standard limits except for zinc. However, from the pollution index, rainwater from Harvey-tiles is the most suitable followed by aluminum rooftop while asbestos had the highest level of pollution followed by corrugated iron sheet. By these findings, rainwater could serve as an alternative water source for domestic uses like washing, bathing and cleaning, and should be subjected to proper treatment if it must be used for drinking purposes. Harvey-tiles should be encouraged for building rooftops and where unaffordable, aluminum should be used for the purposes of harvesting rainwater. The roof catchments should be cleaned up regularly to ensure a good water quality. The first rainfall events regarded as first flush should also be diverted away from the storage system as this is usually the most polluted rainwater because of accumulated dust particles from the dry season. Rainwater is advised to be filtered to remove debris which accumulates in the roof catchments by the use of rapid sand filter while chlorination and boiling should be used as treatment methods if rainwater must be used for portable use.

Abstract
This paper is based on ethno-medical survey of some medicinal plants used to treat different ailments including internal, external infections and parasitic diseases as well as poisons. It was discovered that some of these vital medicinal plants are going extinction due to human activities without replacing them back. The control the uncultured activities, a total awareness about the importance of tree plant for medicinal properties should be created generally by the Government and forestry Department. The importance of trees herb in curing ailment should be brought to the people through health care delivery and the Government proper documentation in research should be made.
Keywords: Ethno-medicine, health care, ailments and Forest

Introduction
Forests have been known since ages to provide certain amenities for the benefits of mankind which include environmental protection, ecotourism services, revenue and medicine. Forests have, in one way or the other, contributed and still contributing to the socio-economic, cultural and environmental development of the people all over the world. In the developing world, forest provides a basis for the daily living of the people. The world's tropical rainforest are especially rich in biodiversity both fauna and flora that are immense benefits to man whose potentials have not been fully utilized. The socio cultural and economic values of forest plants are numerous and should not be ignored. Forest provides vast number of food which includes tuber, nuts, edible leaves, barks, roots and honey (Alves and Rosa 2007).
Forests have long been recognized as major contribution to the socio-economic, cultural and environmental development of the world at large. Plants of the tropics are means of meeting the basic needs of the rural sustaining in rural and urban which provides employment and income, maintaining the environmental stability needed for continued food production and purifying the atmosphere. Plants contribute to the wellbeing of the rural people by providing forest foods which are important dietary supplements mainly during period of agricultural cycle when production tends to be low. Rural nutrition could be improved in Nigeria through forestry programmed as there are numbers of indigenous forest plants or trees known for providing edible fruits and seeds, spices, fats and oil are also obtained from Nigeria plant (FAO, 1985). Forests provide food supply for human, wild life consumption, in many parts of Nigeria and livestock (NEST, 1991).
Plants roots, barks, leaves and twinges have contributed immensely to rural health through provision of drugs for the treatment of many ailments. Huge foreign exchange should have been saved from the singular contribution of *Azadiracha indica* to the treatment of malaria. An extract obtained from *Rauwolfia* specie is generally considered to provide the best known treatment against high blood pressure (Isebemhe, 2000).

Forest as phytomedicinal and pharmaceutical source
Department of Health, Medicine Research Unit and Control of Scientific and Industrial Research (CSIR) in America (2005) reported that medically, no plant is useless, in other words, all plants have medicinal uses. If a plant is deemed medicinally useless" it is just that its use or uses not yet known. The use of traditional herbal medicine is very common in Nigeria as in other parts of the

world such as Ghana, Ethiopia, Kenya, Gambia, Cameroun, China, India, Sri Lanka, Bangladesh and Brazil. Universally, despite modern development in the treatment of the human body, herbal remedies have been continuously used. Modern medicine in the beginning depended on the herbal remedies for plants were the fundamental sources of therapeutic products for professional and non-professional healers of the earliest times. The efficacy of herbs has been confirmed in different disease condition all over the world. Herbs have succeeded where conventional or synthetic medicine has failed, especially in chronic diseases. Apart from this efficacy, it is very important to mention the little or no side effects in the treatment of diseases because they act as foods and as medicines. In the treatment of hypertension, for instance, herb is used first to lower the blood pressure; to clean the arteries, to slow and regulate the heart rate, to improve the blood circulation and to relax the mind unlike the conventional ones that will dilate the arteries or the veins until they reach their maximum elastic point which may suddenly burst and cause vascular accident, causing stroke or death. There are a few or no synthetic drugs that will do all of the above. People all over the world have used to cure and control different diseases that are peculiar to their sub-regions and Nigeria is no exception. Malaria and sickle cell are examples of diseases in this sub-region. If researchers work harder and in humility into natural remedies, we will find more than fagara Root, Almond Leaves (for sickle cell); Ewedu Root, Siam weed; Asurun Oyibo (for malaria) within this sub-region (Igoli *et al*., 2005). Preparation from leaves, roots, bark, flowers, fruits and seeds are employed for curing elements in various ways, some are coked together and taken as tea. These are commonly used for ailments such as fever, pile and dysentery. While some may be cut into pieces such as roots, stems, fruits, seeds are soaked in cold water for strong drinks. Other forms in use include and the powdered form tooth ache, *Vernonia amydalina, Garcinia Kola* etc. Roots of *Cola nitida* and *Cola acuminata* are excellent chewing sticks. They clean the teeth, disinfect the mouth and strengthen dental gums (Farombie *et al.*, 2005). Some medicinal plants are cooked as soup especially for pregnant women these plants are traditionally employed in a variety of ways sweetness anti-infection, moluscides, anti-malaria, laxative, cardiovascular nervous disease treatment in Ghana more than 800 wild plants and many other herbaceous species are known for their medicinal properties (Berhan *et al.*, 2006).

Role of African leafy vegetables in health promotion and protection

Quite a large number of Africa indigenous leafy vegetables have long been known and reported to have health protecting properties and uses. Ozumba, 2008 observed that the roots, leaves and twigs as well as the bark of the tree of *Moringa Oleifera* are used in traditional medicine. Several of the indigenous leafy vegetables continue to be used for prophylactic and therapeutic purpose by rural communities (Githens, 1949; Igoli *et al.*, 2002). Some herbs are common and others are not common. The common ones have become so well known that they are daily used as vegetables, it is well known fact that the body's requirement are more in what we get from vegetables, herbs and fruits more than in any other food. Because of this, it is easier and more natural to repair worn out organs, to cleanse the blood and to keep the body fit by the use of herbs. The history of how long herbs have been in use is as far back as man's history. The properties of herbs show clearly that they have direct relevance to the chemistry of the body and are therefore used to repair and activate the system more effectively without side effects. The body's acceptance and assimilation of herbs shows that herbs are natural needs to the body. The human body is made up of organic substances such as phosphorus, potassium, sodium, Zinc, sulphur, Magnesium, Chlorine, Calcium and others. All these are found more in fruits vegetables and herbs. Deficiency in any of these minerals in the body can results in one type of disease or the other (Ogboru *et al.*, 2017).

Species Flavouring and Thickeners

Food provides the needed strength and energy as well as preventing diseases and ill-health to the body Addis *et al*., 2005 reported that spices cannot be classified as food for they contain little of nutritive value. They however give an agreeable flavor and aroma to food and greatly to the pleasure of eating. In addition, they excite the appetite and boost the flow of gastric juice due to their roles; they are referred to as "food accessories or adjuncts". They are notable from condiments which are spices or other flavoring substances that have sharp taste and are usually added to food after it had been cooked. Medically, spices are very important as many of them are used as carminatives and antiseptics, spices from our forest are: *Monodora myristica, Xylopia* *athiopica, Tetrapleura teraptera, Pipper gnensis* leaves and seeds), *Dennetia tripetala, Aframonum melegueta, Allium cepa, Zingiber officingle, Curcumalonga cimanonum, Zeylanicum and Frangrance* among others.

Non-timber forest products and household health

It has been said that 80% of total households particularly in the rural areas depend on natural herbs for their health care delivery (Chowdhury *et al.,* 2009). Recent trends have confirmed this observation as the number of people depending on herbs for their health needs keep increasing (Wachtel-Galor & Benzie, 2011). This is due to the worsening economic situation in the country which makes orthodox medicine unaffordable to the rural people. Often times, the distances between rural communities and health care centre are quite considerable hence, rural dwellers naturally rely on traditional herbs when need arises. It is only when the situation gets out of hand that they seek modern medicines, assistance e.g. during complicated child delivery process by women, fatal accidents and prolonged illness (Burkill, 1995).

Plants used as anti-diabetic

Several plants have been identified as having great potentials and ingredients to provide curative measures to some ailment affecting rural people. For example, *Azadirachta indica* (Neem) which is known as the village doctor because of the many medicinal uses to which it is put, is still popular among patients suffering from diabetic mellitus. With the availability of formulated drugs containing 10% Neem, Insulin treated patients are gradually shifted away from dependency on exogenous supply of insulin (Gill, 1992). *A. indica* apart from being used as anti-diabetic, it is also found to be antiseptic and anti-fungi. It is known to have anti-malaria, cardiovascular, nervous and anti fertility properties. Glucolisine and diabetoline were also reported from *Tecoma stans* (Ayodele *et al.,* 2010). Carica papaya used as anti-diabetic in etho-medicine has been reported (Ajoola *et al*.,2011).

Table 1: Selected Plants and their Ethnobotanical Potentials

S/n	Name of plant	Part used	Medicinal use
1.	*Abroma augusta (*Devil cotton*)*	Root bark	emmenagogue agent
2.	*Abrus precatorius (*Jequirity, Indian liquorice*)*	Root, leave	Liquorices substitute expectorant BPC, constipation, snake bite, contraceptive.
3.	*Acacia nilotica(*Bonni)	Bark and leaf	Pile, cures keratoderma, dysentery and diarrhoea
4.	*Acalypha ciliata (*Jiwinni)	Leaf	Ulcer
5.	*Acanthospermum hispidum (*Emu*)*		Jaundice, malaria, ear ache, eye sight
6.	*Achyran these asperlinn (*aboro)	Root	Treatment of scorpion bite
7.	*Adansonia digitata* (Ose)	Leaf	Anaemia, amenorrhea
8.	*Adenia cissampeloides*	Bark	Hypertension and numbness
9.	*Aegle marmelos* Beal fruit	Unripe fruit	Astringent in diarrhea and dysentery
10.	*Aframomum melegueta* (Atare)	Seed	Cancer, cough, anaemia, dysmenorrheal
11.	*Afzelia Africana (*Apa)	Leaf and bark	Cough, hypertension, stomach ache and gonorrhea
12.	*Ageratum conyzoides (*Imi esu)	Leaves	Jaundice, dysentery, diabetes, convulsion, conjunctivitis, Eyes Inflammation, sore throat treatment and female infertility
13.	*Akhornea cordifolia (*Ewe epa)	Leaves	Eyes rheumatism, fever
14.	*Albizia zygia (*Ayunreta)	Bark	Treatment of yaws
15.	*Allophyllus africanus (*Eekan ehoro)	Leaf	Pile, lactation and fecundity
16.	*Alstonia boonei de wild (*Ahun)	Leaves, roots	Snake bite, rheumatism
17.	*Annona comosus*	Fruits juice	Malaria
18.	*Azadirachta indica (*Neem margosa tree)	Leaves, stem, seeds, root bark	Parasitic skin diseases
19.	*Baphia pubescens (*Benin camwood)	Bark	Disinfectant urinary tract
20	*Blighia sapida*	Leaves	Weak penile/ erection
21	*Boerhavia diffusa*	Leaves	Female infertility
22.	*Byrsocarpus coccineus (*Orikoteni)	Leaves, roots	Gonorrhea and jaundice
21.	*Cajanus cajah*	Leaves	Small pox
22.	*Canna bibentata bertolori* (ido)	Juice of unripe fruit leaves	Fever haemostatic
23.	*Carica papaya*	Juice in unripe fruit, leaves	Proteolytic enzyme BPC
24.	*Chenopodium ambosioides*	Fresh plant	Ascaride, hook work
25.	*Cinchona spp (*Quinine bark)	Bark	Tonic, stomachic and malaria
26.	*Cinnamomum zeylanicum*	Leaves, bark	Dental dressing, flavouring agent & powerful germicide

Table 1 cont'd

27.	*Citrus limon*	Fruits/leaves	Abortion/malaria
28.	*Coffae Arabica*	Seed kernel	Cardiac and respirator stimulant
29.	*Cucurbita pepo*	Seed kernel	Ascaride and tapeworm
30.	*Curcuma longa*	Rhizome	Antibiotics
31	*Dacryodes edulis*	Bark / leave	Rashes in body
32	*Daniellia oliveri*	Leaves	Skin disease
33.	*Datura stramonium*	Leaves &seed	Bronchitis & asthma
34	*Derris elliptica*	Roots	Scabies
35.	*Garcinia kola*	Seeds/fruits	Cough/snake bite
36.	*Guphorbia hurta*	Plant	Astmha
37.	*Holarrhera Africana*	Stem-bark	amoebic dysentery
38.	*Melalueca leucadendron*	Fresh leave	Urinary tract, skin disease, rheumatism
39	*Morinda lucida*	Leaves	Treatment of infertility in both men/women and treatment of high sugar in body.
40.	*Musa paradisiacal*	Leaves	Swollen stomach
41.	*Okoubaka aubrevillie*	Fruit, bark, leaves, seed	Sickesses by evil spirits, Rheumatism, malaria fever, convulsion in children, insanity, stroke,asthma,
42	*Pentenclethra macrophylla*	Leaves/fruits	Poison
43	*Piper guinensis*	Seeds	Newly born mother for soup
44.	*Rauwolfia vomitoria*	Bark, roots, leaves, juice	Hypertension
45	*Sacharum officinarium*	Juices	Restoration of vitality
46.	*Sida cordifolice*	Seeds	Migraine
47	*Strychnos nux vomica*	Seeds	Nervous & circulatory stimulant
48.	*Tamarindus indica*	Fruits pulp	Laxative
49	*Telfera occidentalis*	Leaves	Convulsion
50	*Tetrapleura tetraptera*	Fruits	Snake bite
51	*Terminalia catappa (*ebelebo)	Leaves, bark, roots, fruit, seed	Reduces blood sugar, prolongs ejaculation, anaemia, dysentery, coughs, asthma and relieves joint pains
51	*Tridax procumbers*	Leaves	Ulcer & hypertension
52.	*Vemonia amygadalin (*bitter leaf*)*	Leaves, stem, roots	Cough/mouth wash, worm expeller, aphrodisiac,
53.	*Xylopia aethiopica*	Seeds	Dislocation
54.	*Zanthoxylum spp*	Leave/seeds	Abdominal pain, toothache
55.	*Zolanum Torvuly*	Leaves	To Stop Bleeding

Source: PROTA, 2008; Idu, 2009

Conclusion

Medicinal plants represent a reliable fraction of the innate biodiversity bequest of the world. These species offer a vital part to health care delivery, local economy, cultural veracity and ultimately the well-being of the people, particularly the rural communities (women, children and the elderly). Their role has been increasingly acknowledged over the last decade which has brought interest on these medicinal plants. The use of ethno-medicinal information has contributed to health care worldwide, even though efforts to use it have been irregular. It is recommended that government should make research grants available for more studies to be done as regards medicinal plants to discover more flora species of great ethno-botanical potentials. Great public awareness should be introduced of the therapeutic value of herbs and forest.

Abstract
Assessment of forestry activities was made in some selected villages in Surulere Local Government Area Ogbomoso, Oyo State with the aim of examining the various forestry related activities, benefits derived in engaging in forestry activities and identifying the factors affecting availability of forest products in the study area. The number of respondents selected from each village was based on proportional allocation. A total of 117 questionnaires were retrieved for analysis. Data collected were analysed using simple descriptive statistics. Findings showed that majority (54.7%) of those who participated in forestry related activities were female. Majority (52.1%) also had household number of 1 – 4 and 47.9% had house hold number of 5 – 10. Agro forestry was the major (52.1%) forestry related activity engaged in by the residents of the study area, followed by firewood gathering (22.2%). From the study, food (49.5%) and firewood (24.8%) were the most important benefits derived from the forestry activities. The factors responsible for the availability of these forest products include seasonality (37.6%), transportation (33.3%), legislation (17.1%) and depletion of resources (12.0%). To ensure rural involvement in forestry related activities, it is therefore recommended that rural people should be given rights to access forest resources in the locality where they live, there should be public enlightenment through forestry extension agent on the need to use the resources sustainably and avoid over – exploitation, encourage afforestation and reforestation.
Keywords: Communities, Forest Products, Benefits, Assessment, Livelihood and Involvement

Introduction
Forestry is the skillful management of all natural resources which occur on, and in association with forest lands for greater human benefits. Under good management, a forest should be able to fulfill its key roles to humanity, notably, that of production, protection and recreation (Etukudo, 2000). Rural households are strongly dependents on the services that ecosystems provide such as forest and environmental resources. A large proportion of rural dwellers are dependents on forest and environmental resources for commercial utilization (e.g. Timber and charcoal) and to fulfill subsistence needs for example fuel wood, wild fruits and roots, bush meat and natural medicine (Pantal *et al,* 2009; Howell *et al*, 2010). Forest resources extraction and its related activities also generate employment (e.g. larger timber extraction operations) and support the livestock sector in the form of fodder. In addition, forest helps to regulate the quality and supply of water and provide other ecological services, wild life habitat, biological diversity, soil conservation and carbon sequestration which are essential for human well-being (Pagiola *et al,* 2004). Studies have shown that rural people are involved in forest conservation in many ways, their true roles in forest conservation receive insufficient recognition by policy makers and the participation can be economic and non-economic. Thus, a significant attention has to be paid to the full participation of rural people in forest conservation. However, rural dwellers depend on forest for their livelihood such as sources of food, medicine, raw materials for industries and income for people. Considering these importance of forest to human survival, and roles of people in forest conservation, it is necessary to assess forestry activities in Surulere Local Government Area,Ogbomoso, Oyo State.

Methodology

The study was conducted in some selected villages in Surulere Local Government Area, Ogbomoso, Oyo State. Ogbomoso is located within latitudes $8^0$2' 35.20" N and 8^0 14' 34.25" N and longitudes $4^0$10'52.92" E and $4^0$19' 40.59" E. it is located within a derived savannah region. It is 104km North East of Ibadan, 58km North West of Osogbo, 57km South West of Ilorin and 53km North East of Oyo. The population of Ogbomoso was approximately 299, 535 by 2006 census in Nigeria. Seven communities were purposively selected in Surulere Local Government Area, Ogbomoso, Oyo State (Purposive sampling) being areas where forestry activities are predominant. The number of respondents selected from each community was based on proportional allocation of the people. Hence, 10% of the estimated populations were sampled (table 1). A total of 149 respondents were randomly sampled. Only 117 questionnaires were retrieved for analysis. Data were collected through the use of a well-structured questionnaire. It contains personal characteristics of respondents such as age, (years) sex, (M/F) marital status (single / married / divorced), household size (in number), educational status (primary / secondary / tertiary), forestry activities (such as firewood gathering, logging, agroforestry, hunting) benefits derived in engaging in forestry activities (food, medicine, firewood, charcoal, timber) and factors affecting availability of forest products (Seasonality / transportation / legislation/ depletion of resources).

Date collected were analyzed using simple descriptive statistics such as frequencies, percentages and charts

Table 1: Sampled communities

S/No	Selected Communities	Estimated Population	No of respondents 10%
1	Iresa – Adu	400	40
2	Igbon	210	21
3	Iresa – Apa	150	15
4	Odandan	180	18
5	Itemu	200	20
6	Manyin	250	25
7	Onisalalu	100	10

Results and Discussion

Personal characteristics of respondents

Table 2, shows that half of the respondents fall between age ranges of 31 – 40 years; that is, they are within the youthful age and active to struggle for their livelihood. Usman *et al*. (2008) reported that farmers at their youthful ages are more productive and easily adopt agricultural innovations. Majority of the respondents (54.7%) were female while the remaining 45.3% were male. The higher number of female could be as a result of women involvement in agriculture who might want to engage in forestry related activities as a means of livelihood. The majority (51.3%) of the respondents were married. This implies that married men and women were more involved in forestry related activities in the study area. Married people are less likely to use hired labour for the forestry activities since family labour might be employed. Household size results revealed that 52.1% had household size of between 1 – 4 persons while 47.9% had household size of between 5 – 9 persons. Household size determines the availability of family labour, the larger the household size, the more human capital available to the family that can contribute to family farming labour. Table 2 also indicates that 26.5%, 61.5%, and 12% of the respondents acquired primary, secondary and tertiary education respectively. Their literacy level is likely to help in the development of individual mental ability to gain knowledge about a particular concept, understanding and utilization of technology or practice as reported by Mamen and Paxson (2000).

Table 2: Personal characteristics of respondents

Variables	Frequency	Percentage
Sex		
Male	53	45.3
Female	64	54.7
Age		
20 – 30	40	34.2
31 – 40	59	50.4
Above 40	18	15.4
Marital Status		
Single	40	34.2
Married	60	51.3
Widow	17	14.5
Number of household		
1 – 4	61	52.1
5 – 9	56	47.9
Educational Status		
Primary	31	26.5
Secondary	72	61.5
Tertiary	14	12.0

Forestry activities and its benefit in the Study Area

Figure 1 revealed that 52.1% of the respondents engaged in agro forestry, 22.2% engaged in firewood gathering and logging while 6.0% engaged in hunting. This result shows that the study area is highly rich in forest resources and people participate in various forest activities. The involvement of the respondents in agro forestry would help to maximize the available land, encourage afforestation, and improve soil fertility and structure thereby making food crop available for the people hence this would also improve the livelihood activities of the respondents (Oboho and Abiola 2010). Firewood gathering is mostly done by the female as it is the primary source of energy accounting for over 90% of the total energy used for domestic purposes in Nigeria. It is consumed mostly by the low income and lower middle income households, as well as by operators of cottage and small scale industries and commercial enterprises such as pottery, hotels, schools and hospitals. This firewood gathering serves as a source of income to majority of rural women (Ijeomah and Aiyeloja, 2010). Involvement in logging makes timber available for different constructions, furniture and electricity poles with due permission from the government for easy accessibility. Only 6.0% were involved in hunting, this could be due to the fact that indiscriminate hunting in the forest is an offence according to forest regulations

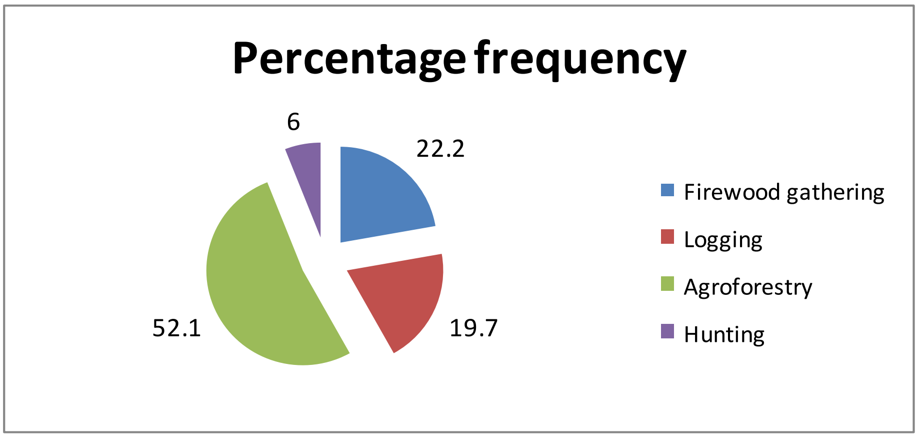

Figure 1: Forestry Related Activities in the Area
Source: Field Survey, 2017.

Factors affecting availability of forest products in the study area

The factors affecting availability of forest products in the study area include seasonality (37.6%), transportation (33.3%), legislation (17.1%) and depletion of resources (12.0%). Seasonality is the most affecting factor. This could be due to the nature of vegetation distribution in which rainfall determines the vegetation growth. Season of the year determines the availability of some forest products. *Anacardium occidentale* (Cashew), *Mangifera indica* are always in abundance towards the end of dry season and onset of rainfall (February – May) particularly in the Southwest part of Nigeria. Medicinal herbs are very abundant during the rainy periods when forests are green for easy identification of the trees, herbs and shrubs. The herbalist and herbal sellers are able to collect them and preserve for use during the dry season. Fuel woods are always readily available during the dry season when dried shrubs, herbs and dead branches are fallen for collection as fuel wood. The consumption of this fuel wood is however concentrated in the rural areas and among low income urban populations (Ijeomah and Aiyeloja, 2010) Transportation challenges could be due to hike in fuel price, and general economic recession. To transport fuel wood and timber products from point of collection to consumption point are sometime costly and difficult for consumers'. Legislation factor affects forest products availability through enacted laws that hindered free entering of the forest. For instance, it is only licensed contractor that has full right to fell approved timber from the forest. Indiscriminate hunting (i.e. Poaching) in the forest is also prohibited so as to conserve wildlife habitats, Kalu (2010). This is why forest guards and National Parks Patrol team protects the forests so as to conserve and preserve the existing natural resources. Depletion of resources arises when forest products are explored excessively or indiscriminately without planning for regeneration by the people. This means that the needs and aspirations of present generations are met at the expense of the future generations in respect of forest goods and services. This will negatively affect the benefit of the forest that the future generation will explore (Kalu, 2010).

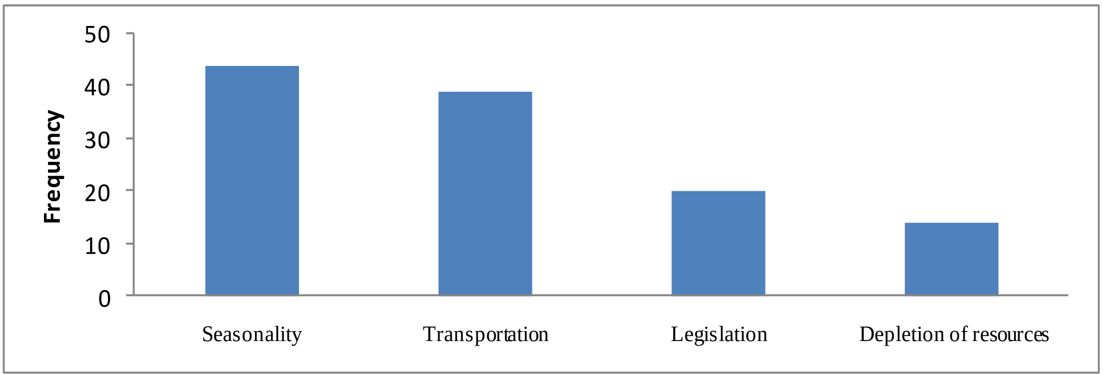

Figure 2: Factors affecting availability of forest products
Source: Field Survey, 2017.

Conclusion

The study has shown that the inhabitants actively involved in forestry related activities such as firewood gathering, logging, agro forestry and hunting. They also rely on forest for food, medicine, firewood, timber and rope. It is therefore concluded that rural people participation in forest related activities will reduce unemployment and poverty and at the same time conserve our environment if judiciously explored. Rural dwellers should therefore be given rights to access forest resources in the locality where they live. They should be enlightened on the need to use the resources sustainably and avoid over – exploitation arising from "a life for today attitude. Government at all levels should encourage people to plant and retain trees of high economic values on their farms

Environmental Management in Nigeria: Challenges and Way Forward

A.C. Ifejimalu
Department of Agriculture, Alex Ekwueme Federal University Ndufu – Alike, Ebonyi State, Nigeria
E-mail: austol20@gmail.com

Abstract
This paper discusses the challenges of environmental management in Nigeria and the way forward. The paper notes that Sustainable Environmental Management is far from being achieved in Nigeria and that the activities of man still degrade the environment. The major challenges of environmental management in Nigeria include rapid urbanisation, over population, deforestation, desertification, waste management, soil erosion, flooding and poor policies. Overcoming environmental management challenges demands the enhancement of agricultural production without compromising the natural ecosystem, strengthening of local governance for biodiversity, management of environmental resources (land, water, minerals, energy, forest wealth and biodiversity), as well as management and control of hazards. Addressing environmental management challenges requires the role of the government (at national, state and local levels), non-governmental organizations, and community based organizations, as well as individuals. Other environmental management techniques involve the conservation of wildlife, biodiversity, energy, and population resources. There should be respect and care for the environment as well as periodic environmental impact assessment.

Key words: Environmental management, challenges, environmental resources and Nigeria

Introduction
The primordial aim of development in the environment is to improve the quality of life and enable people to realize their potentials and lead lives of dignity and fulfilment. Development is real only if it makes human lives better in all these respects. A development pattern that pays little or no regards to environmental issues is essentially a disaster right from the conceptual framework (Ivbijaro, 2007). Sustainable development therefore, is the development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs. Sustainable development is economic and social development that ensures that the environment is conserved to perform its various functions including the functions to humanity. It is development that is pro-people, pro-nature and pro-job (Ivbijaro *et al.,* 2006). Environmental management on the other hand is the process of putting together those items of environmental nature where man exists so that man's penetration and exploitation do not have adverse effect on the environment. This is aimed at ensuring that the environment is free from abuse, and misuse that may result in pollution and degradation. It is aimed to promote development compatibility, balance urban land use value and upgrade the environment for present and future generation (Uchegbu, 1999). In Nigeria, Environmental Management has remained consistently bad over the years and the problem has become a monster that is difficult to solve in spite of all efforts from all arms of government. Consequently, the environment continues to deteriorate while environmental related diseases aggravate poverty (Okueso, 2008). This paper is a review of environmental management in Nigeria – challenges and way-forward.

Challenges to Environmental Management in Nigeria
a. ***Urbanization:*** This is caused by high population growth rate and rural-urban migration. In Nigeria, it is characterized by city slums with serious environmental consequences. The problem is acute and exemplifies the inability of development measures to keep pace with the rate of population growth. Environmental conditions in cities have gradually deteriorated due to the rapid growth of the cities and the attendance inability of social services and

infrastructures to keep pace with the rate of growth (Nigerian Environmental Study Action Team - NEST, 1992).

b. ***Waste management:*** Indiscriminate disposal of wastes is a serious problem in Nigeria. The problem of the disposal of refuse is quite serious because of the rapid rate of generation of non-biodegradable materials, such as plastics. Inadequate storm drains, dumping of refuse in drainage lines and construction of houses close to or even on the natural water channels have been shown to be responsible in that order for the increasing cases of flood in the urban centres (Iboaya, 2000).
c. ***Overpopulation:*** Population is a major factor in all environment-related issues. Overpopulation causes stress on the environment. Environmental problems, such as overpopulation, degradation, erosion, desertification, etc. are caused by man's misuse of environmental resources. There are evidences everywhere of rapid decline in environmental quality and human living conditions by rapid increase in human numbers. Under such stressful situation, "it will be easy for people to become so exigent, worrying only about what to get out of the environment for their own immediate needs and uses, without caring very much for the consequence, especially, for succeeding generations (Abumere, 2002).
d. ***Deforestation:*** Deforestation is a process whereby trees are felled for several purposes, but without replanting to replace the ones felled. Deforestation is dangerous to man, animals and properties. It leads to erosion of the soil and storm, which can cause destruction of properties, crops and animals. When forests are cleared, the soil are exposed to erosion devastation, floods occur, and rivers and lakes are filled up with silt. The water becomes dirty and impure for mankind. The removal of tree canopy (particularly the leaves) has effect on the rainfall of that area, as there is less leaf surface area for the transpiration of water, which in turn affects the relative humidity of the atmosphere. The repeated cultivation of crops on cleared area of plants tends to exhaust the soil of its mineral content. Deforestation in general - for agricultural development, urban growth, industrial expansion and pressure from an increasing population - has reduced the extent, diversity and stability of the Nigerian forest (Iboaya, 2000).
e. ***Desertification:*** Desert is a barren, waterless, treeless and often sand-covered land, such as Sahara, which spreads across Africa continent. Desertification is, therefore, the encroachment of the desert on the land that was once fertile. Desertification can be induced either by natural process or by the action of man. Natural hazards, such as drought and deposit by winds, are prime factors in the desertification process. Desertification is more pronounced in the northern part of the country, where the Saharah desert has eaten deep into the once fertile land (Iboaya, 2000).
f. ***Pollution:*** Environmental pollution can be categorized into three groups. These are air or atmospheric pollution, aquatic or water pollution and land or surface area pollution. The World Health Organization (WHO, 1990) defined air pollution as "limited to situation in which the outer ambient atmosphere contains materials in concentrations which are harmful to man and his environment". Man's activity on the earth surface has largely degraded the quality of the lower atmosphere. The growth and development of industries and urbanization has contributed greatly to the excess carbon monoxide produced by combustion and other human activities. Carbon monoxide reacts with the blood vessel and prevents it from taking up oxygen and the people are suffocated. In Nigeria, several rural towns that had in the past enjoyed fresh and dry air are currently experiencing air pollution problems due to industrialization process and expansion in human activities (Obajimi, 1998).
g. ***Soil Erosion and flooding:*** This problem results from human actions and natural occurrences through the action of erosional agents like excessive rainfall, wind, glacier, steep slopes and poor soils amongst others. The human activities include the construction of engineering projects involving scrubbing, quarrying and the removal of soil materials, over-grazing of green areas, the destruction of vegetation to create space for the growing population, certain mining and industrial activities. Flooding is brought about by the ineffectiveness of the river to flow according to course (such as rivers overflowing their banks) and by heavy rainfall-with poor-water infiltration and poor drainage network (Iboaya, 2000).

Adah and Abok (2013) identified the challenges facing water management in Nigeria to include lack of effective compliance to policies, weak data base, fragmented responsibility, climate change, poor state of infrastructure, cost intensive, corruption, rapid urbanization, and low rate of costs recovery as the bulk of available water supply is unmetered and where metered, ridiculously low rates are charged, the relevant data for the study were sourced from Federal Ministry of Agriculture and Water Resources (FMAWR), UN-Habitat publications, Water Aid, and other relevant paper presentations. The statistics from these sources formed core sources of statistical information. Recommendations were made as the way forward to achieving sustainable water management. There is need for total compliance to water management policies (both local and international), encourage stakeholder participation, enforcement of existing laws and regulatory responsibilities. There is also a great need for management policy that aims at financial viability and economic efficiency. More realistic water rates should be charged in order to raise the much- needed revenue to meet increasing production and distribution costs. Maren, Agontu and Mangai (2013) underscored the dangers of solely depending on oil and gas as the source of energy to every sector of the economy despite the enormous renewable energy potentials in the nation. It also highlights the need for the nation to diversify its energy supply for power stability and energy security as any major breakdown in the sector will result to economic stalemate. It suggests an implementable policy framework that will add renewable energy technology which is clean and sustainable to the nation's energy sector. The study recommended energy availability, accessibility and utilisation has remained inadequate and inefficient as occasioned by the epileptic power supply, constant queues in our filling stations and the folding up of industries in the nation to neighbouring African countries due to insufficient power supply resulting to unemployment.

Way forward to Environmental Management in Nigeria

The Nigerian environment not only plays a vital role in life support system, it particularly provides the basic resources for virtually all socio-economic activities in the country (Nwachuckwu, 2002). Nevertheless, the life support system has been subjected to series of devastations as a result of natural catastrophes and human activities. In order to save the environment from further degradation of the rich and exhaustive resources, it becomes inherent to address the challenges so as to be able to achieve environmental sustainability. Overcoming environmental management challenges demands the enhancement of agricultural production without compromising the natural ecosystem, strengthening of local governance for biodiversity, management of environmental resources (land, water, minerals, energy, forest wealth and biodiversity), as well as management and control of hazards. Other environmental management techniques are the conservation of wildlife, biodiversity, energy, and population resources. Raven, Berg and Hassenshall (2010) submitted that the elements that contribute to addressing environmental problems include scientific assessment, risk analysis, public education and involvement, political action and long term evaluation. However, they opined that solving environmental problems rarely proceeds in such a straight forward steps. Nevertheless, the five stages represent an ideal approach to systematically address environmental problems. Subsidiaries of this approach include the conservation of natural resources, pollution abatement, control of bush fires, planned industrial development, evaluation and monitoring of radioactivity, as well as resource sharing. Addressing environmental challenges requires the role of the government (at national, state and local levels), non-governmental organizations, and community based organizations, as well as individuals. It also necessitates the collaborative efforts of international organizations, law enforcement agencies, academics and technocrats, the youth, the press as well as national and multi-national companies. Hazard control process is concerned with recognizing, evaluating and eliminating/mitigating hazards that occur because of human errors and physical deficiencies in the environment (Jain and Rao, 2011). Natural events cannot be prevented from occurring but their impacts can be reduced if effective measures are taken in order to depress their severity, frequency and impacts. Strategies of mitigating the effects and/or coping with the impacts of natural challenges include proper and sound environmental education, environmental monitoring with the use of satellites, geographical information systems and remote sensing techniques, government legislations, reintroduction of species, disaster forecasting and mitigation, as well as environmental risk assessment and mapping. On the other hand, the management of man-induced challenges requires poverty alleviation, control of population growth, recycling of materials and resources, reduction of arms race, as well as women empowerment. The mitigation of anthropogenic challenges has to do with the type, cause(s), and consequences. For instance, curtailing man-induced desertification requires measures like irrigation farming, agro-forestry, rotational grazing, and prevention of illegal felling of trees, controlled use of wood as source of fuel and energy, as well as afforestation and re-afforestation programmes. Also, man-influenced flooding can be controlled through channelization and regular clearance of drainage channels, urban planning, sustainable waste management, as well as environmental sanitation. In like manner, control of soil erosion takes the form of cover cropping, contour ploughing, controlled grazing, terracing, and creation of shelter belts. In all, disaster management is all encompassing. It entails respect and care for the environment as well as periodic environmental impact assessment.

Conclusion

When man assumes a non-challant attitude towards his environment, neglecting the need for conservation in the environment, his actions will not only affect the present life, but will put the environment in jeopardy for the future generation. It is essential therefore, to know that a neglected environment stands to attract hazards. Hence the need for environmental management. Environmental management thus, is the strategy by which human activities that affect the environment are organized with a view to maximizing social well-being and to preventing potential problems by addressing their root causes. Also appropriate environmental management can be achieved through efficient use of resources for the benefit of human development. Environmental protection techniques need to be cultured, home-grown and the framework should be “Bottom – Up”. It should be community based. The framework should be organized at the village or community level. Addressing environmental challenges requires the role of the government (at national, state and local levels), non-governmental organizations, and community based organizations, as well as individuals.

Soil Conservation Practices for Food Security in Nigeria

A.C. Ifejimalu
Department of Agriculture, Alex Ekwueme Federal University Ndufu – Alike, Ebonyi State – Nigeria
E-mail: austol20@gmail.com

Abstract
This paper is a review of soil conservation practices for food security in Nigeria. Soil conservation is a practical agro-ecological approach to achieving sustainable agriculture intensification. It offers environmental, economic and social advantages as well as improved productivity and resilience, and improved ecosystem services while minimizing the excessive use of agrochemicals, energy and heavy machinery. The paper identified indigenous soil conservation practices as focused on soil and water conservation by ridging, constructing earth bunds and terraces, mulching, multiple cropping, fallowing, and tree planting. According to the literature, soil conservation measures should be site-specific depending on the local factors such as topography, soil texture, water regime, and farming system. Mulching, crop management, and conservation tillage are appropriate technologies for conserving sandy soils of high erosivity and low water-holding capacity in Nigeria.
Keywords: Soil conservation, practices, crop management and improved productivity

Introduction
One of the most severe threats to food security in Nigeria is declining productivity as a result of the loss of soil fertility. Soils in Nigeria suffer deficiency common to the soils in the tropic such as a low percentage organic matter and nitrogen, shallow depth and high acidity which predispose about 63% of agricultural soils in Nigeria to low productivity. Soil conservation is a combination of all methods of management and land use that safeguard the soil against depletion or deterioration by natural or man-induced factors (Lekwa and Whiteside, 1996). According to Food and Agriculture Organization of the United Nations (FAO, 2013), one of the main causes of soil degradation identified in various parts of Africa is the practice of inappropriate methods of soil preparation and tillage. The soil naturally replenishes itself when used properly. In an attempt to maintain optimum crop productivity, farmers are encouraged to adopt different production technologies that would conserve the soil. In relation to this, Onwudike *et al.* (2016) suggested adoption of many strategies will eventually result at improving soil productivity and crop yield.
Research on soil conservation has been conducted for many years in Nigeria. Initiatives have resulted in various so-called on-farm strategies including agronomic measures, soil management, and mechanical methods, as well as off-farm strategies, including mechanical or biological soil conservation technologies. This paper provides a review on soil conservation practices for food security in Nigeria.

History of Soil Conservation in Nigeria
In Sub-Sahara Africa, soil conservation has a long tradition. Indigenous techniques from the pre-colonial era focused on erosion control in combination with water conservation by ridging, mulching, constructing earth bunds and terraces, multiple cropping, fallowing, and the planting of trees (Igbokwe, 1996). In colonial times, the British Government worked on natural resource management as interest was high in expanding commercial farming enterprises. Longtau *et al.* (2002) recorded the implementation of terraces in several areas on the Jos Plateau in former times. Large-scale projects on soil loss control were started, especially in areas of high agricultural potential, but many of them failed as the imported technologies had little relevance in the tropics and were not adopted later by local farmers. After independence in 1960, more emphasis was put on soil fertility issues. Decrease in funds at the end of the oil boom in the 1980s

additionally restricted the performance of soil conservation schemes in Nigeria (Slaymaker and Blench, 2002). Today, the seriousness of this environmental problem still exists and is also recognized by the Federal Government of Nigeria that planned to spend about half a million US dollars on soil erosion projects all over the country in 2007 (Federal Government of Nigeria, 2007).

Agronomic Measures for Soil Conservation in Nigeria

Agronomic measures include - mulching and crop management, the use of the effect of surface covers to reduce erosion by water and wind (Morgan 1995).

a. Mulching

Mulch is a layer of dissimilar material placed between the soil surface and the atmosphere. Different types of material such as residues from the previous crop, brought-in mulch including grass, perennial shrubs, farmyard manure, compost, by-products of agro-based industries, or inorganic materials and synthetic products can be used for mulching (Lal, 1990). The impact of mulch in reducing the splash effect of the rain, decreasing the velocity of runoff, and hence reducing the amount of soil loss has been demonstrated in many field experiments conducted on several Nigerian research stations. Lal (1993) measured soil loss of about 152.9 t ha^{-1} from a plot with bare fallow and 0.2 t ha^{-1} from a plot with maize and mulch. Salako_*et al.* (2006) compared the effect of burned residues with mulched residues from *Mucuna_pruriens_*and *Pueraria_phaseoloides*. They recorded that soil loss from plots with burned residues of *M. pruriens_*were significantly higher (6 and 2.8 t ha^{-1}) than from plots with mulched residues of *M. pruriens_*and *P. phaseoloides_*(1.5 and 1.3 t ha^{-1}) in 1997. *M. pruriens_*was more effective in minimizing the detachment of soil from mounds due to its faster establishment rate, but finally *P. phaseoloides_*was more reliable for soil and water conservation as it produced more mulch. The complete removal of crop residues from the field for use as animal fodder, firewood, or as construction material is another factor that makes this soil conservation technology less applicable (Kirchhof and Odunze, 2003).

b. Crop Management

Soil loss can also be prevented or reduced by appropriate crop management.

- ***Cover Crops:*** Cover crops such as the legumes *P. phaseoloides, M. pruriens, Centrosema_pubescens, Stylosanthes_guianensis,* and *Phaseolus_aconitifolius* or the grasses *Pennisetum_purpureum, Brachiaria_ruziziensis,* and *Paspalum_notatum_*are plants that grow rapidly and close (Lal, 1995). Their dense canopy prevents rain drops from detaching soil particles and this keeps soil loss to tolerable limits, so cover crops play an important role in soil conservation. Cover crops also positively influence physical soil properties. They increase the organic matter content, nitrogen (N) levels by the use of N_2-fixing legumes, the cation exchange capacity, and hence crop yields. Tian_*et al.* (1999) estimated an amount of 84 to 202 kg N ha^{-1} fixed by P. phaseoloides within 18 months. This resulted in a higher maize grain yield (2.5 t ha^{-1}) than in the control without a legume (1.3 t ha^{-1}). Another benefit of cover crops is the suppression of weeds, such as spear grass (*Imperata_cylindrica*) or witch weed (*Striga_hermonthica*) which is common in Nigeria (Ekeleme_*et al.,* 2003).
- ***Improved Fallows:*** Improved fallows of short periods with selected tree or herbaceous species remain important as the long fallow periods that were part of the traditional shifting cultivation system for encouraging soil regeneration are no longer possible in most Nigerian locations. Shrubs of woody plants such as pigeon pea (*Cajanus_cajan*) are advantageous in improving the physical soil conditions due to the penetration of their rootlets into deeper soil layers (Salako and Kirchhof, 2003).
- ***Multiple Cropping:*** Multiple cropping involves different kinds of systems depending on the temporal and spatial arrangement of different crops on the same field (Morgan, 1995). It has been traditionally practiced and is still very common in Nigeria.
- ***Intercropping:*** Intercropping systems including different kinds of annual crops planted in alternating rows also reduce soil erosion risk by providing better canopy cover than sole crops (Morgan, 1995). Odunze_*et al.* (2004) determined the effect of grain legumes in legume/cereal treatments on soil properties in the arid ecosystem of northern Nigeria. The results showed that sole groundnut improved soil bulk density at the 0 to 10 cm depth (1.26g cm^{-3}) better than sole maize (1.34 g cm^{-3}). The cultivation of legumes also resulted in

better stability of soil aggregates in the topsoil, which generally reduces the erodibility of the soil. The highest mean weight diameter of peds developed was 0.63 mm obtained under soybean (*Glycine max*), followed by cowpea (0.58 mm), and sole maize (0.48 mm). Sole legumes and legume/maize treatments improved the soil nitrogen content (range between 65.6 and 84.8%) compared to sole maize treatments (5.9%).

- ***Planting Pattern/Time:*** Planting pattern, plant density, and time of planting also play an important role in soil conservation. Crops planted at close spacing or at a certain time provide a higher canopy during periods with high rainfall intensities and hence protect the soil from erosion. Carsky_*et al.* (2001) recommended cowpea-maize intercropping system as a relatively productive low-input system for the savannah zone. Special knowledge on the selection of species and good crop management is needed when annual crops are planted between hedgerows of woody perennials and this makes alley cropping less attractive for farmers.

Soil Management Practices

Conservation Tillage

Conservation tillage describes the method of seedbed preparation that includes the presence of residue mulch and an increase in surface roughness as key criteria. The practices therefore range from reduced or no-till to more intensive tillage depending on several factors, such as climate, soil properties, crop characteristics, and socio-economic factors (Lal, 1990).

- ***Minimum Tillage:*** Minimum tillage describes a practice where soil preparation is reduced to the minimum necessary for crop production and where 15% to 25% of residues remain on the soil surface (Morgan, 1995).
- ***No-Till:*** No-till or zero-tillage is characterized by the elimination of all mechanical seed bed preparation except for the opening of a narrow strip or hole in the ground for seed placement. The surface of the soil is covered by crop residue mulch or killed sod (Lal, 1993).
- ***Ridge Tillage and Ridge Tying:*** Ridge tillage is the practice of planting or seeding crops in rows on the top, along both sides or in the furrows between the ridges which are prepared at the beginning of every cropping season. Tied ridging or furrow diking includes the construction of additional cross-ties in the furrows between neighbouring contour ridges (Lal, 1990).

Most smallholders in Nigeria still perform soil preparation manually by using hoes. Larger farms use plows and harrows pulled by tractors, which results in the complete inversion of the top 20 to 30 cm of the soil. Hence, ridging is very common all over Nigeria, whereas tied ridging is primarily conducted in the semi-arid northern part of the country to conserve both soil and water in individual basins (Chiroma_*et al.,* 2006).

Mechanical Methods

Mechanical methods, including bunds, terraces, waterways, and structures such as vegetative barriers or stone lines installed on farm also can break the force of winds or decrease the velocity of runoff to reduce soil erosion (Morgan, 1995).

- ***Terraces***: Contour bunds made of earth or stones or terraces that consist of an excavated channel and a bank or ridge on the downhill side for cultivating crops are permanent erosion control technologies (Morgan, 1995). Field trials on terraces made by Lal (1995) in Ibadan showed that the mean soil loss from a catchment without any erosion control measures was 2.3 t ha^{-1} and from a terraced catchment 0.7 t ha^{-1}.
- ***Waterways***: Waterways such as cut-off drainage are permanent structures that aim to collect and guide excess runoff to suitable disposal points. They are constructed along the slope, often covered with grass to prevent destruction, and primarily installed in areas with high rainfall rates (Morgan, 1995). The implementation probably needs special knowledge of the water regime of the area and the construction of waterways (Lal, 1995).
- ***Structures:*** Structural barriers made of stones or vegetation installed along contour lines are another mechanical erosion control measure (Morgan, 1995). As they operate as filters, they may not reduce the runoff amount but retard its velocity and hence encourage sedimentation, increase infiltration, and facilitate the formation of natural terraces (Lal, 1990). Vegetative barriers are usually constructed as single lines or in the form of strips of several meters wide. Malgwi (1995) investigated the effectiveness of vetiver (*Vetiver_zizanioides*), a perennial grass

with a deep and fibrous root system, in northern Nigeria. He recommends this grass as an appropriate soil conservation technology for semi-arid zones as it also withstands denudation, fire, drought and flood.

Future Prospects of Soil Conservation

According to World Bank (2012) and Kassam_*et al.* (2014), there are several ways to support immediate and wide spread scaling up of soil conservation:

- Develop and implement enabling government policy and programme initiatives by encouraging and strengthening government capacity to update agricultural policies, reform perverse commodity support programmes, and institute policy reform that supports the up-scaling of conservation agriculture (i.e. soil conservation) in Nigeria.
- Develop and implement an enabling policy environment for private sector participation in development and support for promotion of soil conservation.
- In all new agriculture development projects, include conservation agriculture as the basis for sustainable production intensification and engage all relevant stakeholders to ensure success, including creating an enabling environment for private sector participation.
- Advocate for initial government support in terms of incentives to make appropriate farm equipment more readily accessible and to reduce any risks of possible productivity loss during the initial years of switching to conservation agriculture.
- Develop large scale programmes that would offer payments to conservation agriculture farmers for harnessing ecosystem services such as carbon sequestration, watershed services for increasing the quality and quantity of water resources, control of soil erosion and reduction in flood risks, and sustaining pollination services.
- Revise universities' agriculture curricula to include teaching the next generation of farmers and agricultural development practitioners about soil conservation as an alternative and sustainable way of farming.
- Provide agricultural universities and schools with relevant literature and publications about CA in the local language.
- Fund more innovative practical research to tackle soil, agronomic and livestock husbandry challenges through universities and research centres.

Conclusion

This paper is a review on soil conservation practices for food security in Nigeria. Indigenous soil conservation strategies focus on soil and water conservation by ridging, constructing earth bunds and terraces, mulching, multiple cropping, fallowing, and tree planting. According to the literature, soil conservation measures should be site-specific depending on the local factors such as topography, soil texture, water regime, and farming system. Mulching, crop management, and conservation tillage are appropriate technologies for conserving sandy soils of high erosivity and low water-holding capacity. Leguminous cover crops and residue management reduce the impact of rain, which is especially high in the tropics, and trap and store soil moisture. These measures also enhance the levels of soil organic matter and nutrients, especially nitrogen, which is generally limited in tropical soils. The future of soil conservation requires that farming and agricultural landscapes are multi-functional, ecologically sustainable and integrated into the greater ecosystems alongside non-agricultural land uses. This means that agricultural production enhancement must go hand in hand with the enhancement and delivery of desired ecosystem services, and that production systems must be efficient with high production factor and resilient in on-farm performance and socio-economic development.

Environmental Standards and Permissible Limit for "Heavy Metals" in Plants, Soil and Water

[1]O.U. Ihiegbulem, [2]D.N. Benson, [3]C.B. Isirima and [4]G. Nwankwo
Department of Agricultural Education, School of Secondary Education (Vocational), Federal College of Education (Technical), Omoku, Rivers State; ***ihiegbulemoscar@gmail.com***

Abstract
Environmental standards and permissible limits are set to check and control the release of contaminants into the environment. Many of these chemicals released into the environment contain metals that are toxic even at low concentrations. These toxic metals generically referred to as "Heavy Metals' have become an interesting subject of study by many researchers. The effects of heavy metals are evident in terrestrial and aquatic habitats affecting soil, water, and health of biological organisms. Obtaining standards and permissible limits for heavy metals in soil, plants and water by researchers is not often easy. It is on this premise that this paper compiles permissible limits for heavy metals that are commonly studied as a reference for drawing conclusions and inferences.

Introduction
Human activities generate substances that can contaminate and pollute one or more environmental compartments. To protect the environment and prevent adverse health problems, it becomes pertinent to regulate the amount of organic and inorganic substances released into environment by way of regulation and setting of standard. Organizations such as Food and Agriculture Organization (FAO) and World Health Organization (WHO) set standards which are accepted globally and are most times used by countries to set their own permissible limits considering their uniqueness and peculiarities. In Nigeria, the National Environmental Standards and Regulations Enforcement Agency (NESREA) is saddled with the responsibility of setting environmental standards and implementing these standards in union with other relevant stakeholders. Many researchers carry out studies involving heavy metals but one major problem has been getting standards upon which they can be able to discuss and classify their findings. This work is a compilation of major heavy metals that are usually studied and permissible limits for each in soil, plants and water.

Concept of heavy metals
Heavy metals are difficult to describe using the most common criteria of specific weight. According to Duffus (2002), 13 different references were cited where the lower limit in density of a metal categorizing them as heavy metal ranged from 3.5 to 7 g cm^{-3}. It was therefore concluded that as a result of not reaching a consensus, any idea of defining heavy metals on the basis of density must be abandoned as yielding nothing but confusion. According to Appenroth (2010) since neither physical nor chemical properties could be effectively used to describe heavy metals especially as it concerns plant sciences, it is suggested that heavy metals be defined by the following groups of the periodic table of elements. Thus, heavy metals refers to all transition elements, except La and Ac (Transition metals); Rare earth elements, subdivided in the series of lanthanides and the series of actinides including La and Ac themselves (Rare earth metals) and heterogenous group of elements including the metal Bi, the amphoterous oxides forming elements Al, Ga, In, Tl, Sn, Pb, Sb and Po, and the metalloids Ge, As and Te (Lead-group elements).

Sources of heavy metals
Heavy metals enter the environment through natural and anthropogenic sources. Natural sources include parent materials, volcanoes and ores. Anthropogenic sources are associated with human

activities such as waste disposal and incineration, industrial effluents, inorganic fertilizers, pesticides, mining, transport emissions, power generation, electronics, batteries, paints, rubber, metal plating, scientific instruments, hospital waste, crude and oil spills. Sources of heavy metals have been documented by Wuana and Okieimen (2011) and Roozbahani *et al* (2015)

Effect of heavy metals on Different environmental compartments

Studies in heavy metals are important because of they have far reaching implications for soil, water, plants and health. Heavy metal is caused various metals, especially Cu, Ni, Cd, Zn, Cr and Pb (Karaca *et al.*, 2010). Some heavy metals (like Fe, Zn, Ca and Mg) have been reported to be of bio-importance to man and their daily medicinal and dietary allowances had been recommended. However, some others (like As, Cd, Pb, and methylated forms of Hg) have been reported to have no known bio-importance in human biochemistry and physiology and consumption even at very low concentrations can be toxic (Duruibe *et al.,* 2007).

Heavy metals exert toxic effects on soil microorganism, changing diversity, population size and overall activity of the soil microbial communities (Ashraf and Ali, 2007). They are also known to affect vital plant processes such as photosynthesis (Bhattacharyya *et al.*, 2008). The consumption of heavy metal contaminated food can seriously deplete some essential nutrients in the body that are further responsible for decreasing immunological defenses, disabilities associated with malnutrition and high prevalence of upper gastrointestinal cancer (Khan *et al.,* 2008). Runoff containing heavy metals enter aquatic environment with potential toxicity for aquatic plants and animals (Singh and Kalamdhad, 2011). Contamination of a river with heavy metals may cause devastating effects on the ecological balance of the aquatic environment, and the diversity of aquatic organisms becomes limited with the extent of contamination (Ayandiran *et al.,* 2009). Heavy metals released into aquatic systems are generally bound to particulate matter, which eventually settle down and become incorporated into sediments. These pollutants can be taken up by rooted aquatic macrophytes and other aquatic organisms (Peng *et al.*, 2008). Drinking water contaminated with high level of heavy metals may lead to health problems such as blood shortage, abdominal pains, nausea, diarrhea, headache, dizziness and liver cirrhosis (Iqbal *et al.,* 2011; Chinedu *et al.,* 2011). Other effect of heavy metals on health, soil, plants and water have been documented by Mahurpawar (2015) and Singh and Kalamdhad (2011).

Nigerian Industrial Standard (2007)

Conclusion

Environmental standards are set to protect the environment and prevent degradation and adverse health effects. Permissible limits have been set by global organizations like the World Health Organization, European Union, United States Environmental Protection Agency and various countries. Environmental standards and limits differ from country to country depending on environmental peculiarities, best available technology, best practicable technology or best available technology not entailing excessive cost. Efforts are made to ensure that the environment is protected and contaminants kept within permissible limits so as not to cause harm to the environment.

Status of Beekeeping in Nsukka Local Government Area of Enugu State, Nigeria

N.U. Uchechukwu, H.N. Anyaegbunam and A. Amaefula
National Root Crops Research Institute Umudike, PMB 7006, Umuahia
Email:uchechukwuuzoma9@Gmail.com

Abstract
The study was conducted in Nsukka Local Government Area (LGA) of Enugu State, Nigeria. The aim of this research was to ascertain the production system and constraints of beekeeping. A total of 60 respondents were selected from the LGA under study. Primary and secondary data were used for the analysis. Data were analysed by using descriptive statistics. The result revealed that beekeeping in this area is practiced by males. Farmers in this area practice traditional beekeeping method, which restrain female participation. The major hindrances to beekeeping are absconding of bees, lack of fund and inadequate market information. This paper recommends adoption of modern beekeeping to encourage female involvement. Also recommended is provision of financial support and market information to bee farmer to advance beekeeping in Nsukka.

Introduction
The unpredictable climatic conditions are increasingly affecting livestock and crop production. Beekeeping is a livelihood option for communities who have depended mainly on production and marketing of crops and animals. The government of Nigeria, in its strategy for development of agriculture, has identified beekeeping and honey production as one of the few means by which people can earn a living without damaging the environment they depend on for survival. Beekeeping is a lucrative agricultural business for rural areas in developing countries (Kukonza, 2009). Beekeeping is the art of managing honeybees primarily for honey production. Honeybees provide honey which has great nutritional and economic values; it also enhances seed production through pollination (Klein *et al.*, 2007). Beekeeping requires little capital and less land space. Soil conditions (such as soil fertility and good drainage) are not essential in beekeeping. Therefore, beekeeping is an appropriate farming alternative in the south-eastern part of Nigeria, which is considered a low soil nutrient area. Eighty percent of Nigeria consists of arid and semi-arid lands, which have high potential for the production of honey and other bee products. However, only one fifth of this potential is being exploited. Many communities in the country use traditional production systems (for example, log hives) which are labour intensive and dangerous (Cramb, 2003); this has made the management of bees difficult. Beekeeping using the indigenous technique is less economically viable (the focus is mainly on honey, with no attention to other bee products such as beeswax, propolis and others).Traditional beekeeping in Nigeria is mainly males' occupation and unsuitable for women because harvesting of honey is mainly done at night and sometimes involves climbing of trees. Low priority is given to modern beekeeping in Nigeria; this has affected the scale of production and productivity of beekeeping. Gok (2004) reported that limited value addition is achieved due to minimal investment in technological and market development initiatives. Consequently, it is necessary to explore ways to encourage technological innovation in the honeybee sector as a means of alleviating rural poverty. Popularizing modern beekeeping enterprise in Nigeria, especially among women, will enhance productivity and improve farmers' livelihood. The objectives of this work were to assess the current status of beekeeping in Nsukka LGA of Enugu State and ascertain the constraints to beekeeping in the LGA. This study will encourage the adoption of modern beekeeping in the study area and also contribute to the existing knowledge on beekeeping in Nigeria.

Methodology

The study was carried out in Nsukka LGA of Enugu State of Nigeria. The State is situated in the south-east geographical zone of Nigeria. It shares boarder with Abia and Imo in the south, Ebonyi in the east, Benue in the north-east, Kogi in the north -west and Anambra State in the west. It has an area of 8,730km^2. The State is densely populated, and is rated at 460/km2 (1,200/sq mi).This is regarded as one of the highest in Africa. Agriculture is the main occupation of the people. It provides employment and income for more than 70% of the populace. There is a total of seventeen LGA in the State. Primary and secondary data were used for this study. Primary data were obtained from farmers by using questionnaire, interview schedule, and direct observation. Secondary data were gathered from various sources such as reports of governmental and non-governmental organization and relevant literatures. Three villages were randomly selected from the LGA. The villages selected include Ibagwa,Ede Oballa and Ibagwani. Farmers were randomly selected from each village making a total of 60 respondents. Data were analyzed with descriptive statistics such as percentages and Tables.

Results and Discussion

Socioeconomic profile of the respondents

Table 1 presents the socioeconomic characteristics of the respondents in the study area. The mean age of beekeepers was 53years. The respondents were mostly middle-aged; youth are yet to be fully involved in beekeeping in the study area. According to the report by new Agriculturalist (2011), the world has more than 1 billion young people aged between 18-30 years, majority among them are unable to fulfil their potential and lack the skills needed to gain employment because of poverty and lack of education. However, given support and the opportunity of employment, young people can play a significant role in rural development. The mean household size was 8 members. Most of the respondents were men (80%); considering the fact that traditional beekeeping is tedious, especially in log construction and bee honey harvesting activities (Cramb, 2003). The Table also indicates that majority of the respondents had primary education, which means that they are not highly educated. This could be one of the reasons for the practice of traditional method of beekeeping, otherwise known as 'honey hunting'. Table 1 also indicates that all the respondents (100%) practice traditional beekeeping, which involves the use of logs and pots for beekeeping. In the traditional system, bees are harvested by setting the colony on fire.

Table 1: Socioeconomic characteristics of the respondents

Economic activities of beekeepers in Nsukka Local Government Area

The economic activities of the respondents by gender are shown in Table 2. A higher percentage of women in the area under study were not formally employed, but were more engaged in business and crop farming than men. From the Table, it is clear that men (34%) owned more livestock. Men were more involved in beekeeping than female. Although the traditional beekeeping is strenuous and considered as a male occupation, female were involved in the traditional beekeeping. There is no strong cultural taboo that prohibits women from undertaking beekeeping activities. Equipping women with more skills on lucrative activities like modern beekeeping practice will enable them earn income and hence improve their living standard.

Table 2: Economic activities of the respondents by gender

Economic activity	Women (%)	Men (%)
Formal employment	9	12
Business	34	13
Livestock farming	22	30
Crop farming	25	20
Beekeeping	10	15
Social worker	0	5
Hired labourer	0	5
Total	100	100

Source: Field survey, 2012

Gender roles in beekeeping

With respect to bee keeping activities (Table 2), women (50%) are mostly involved in honey extraction; while, men (46% and 25% respectively) partake more in honey harvesting and traditional bee hive construction.

Table 3: Roles in beekeeping activities by gender

Economic activity	Women (%)	Men (%)
Traditional Bee hive construction	15	25
Honey harvesting	15	46
Honey extraction	50	13
Packaging/sales	20	16
Total	**100**	**100**

Constraints to beekeeping in the study area

The prevailing production constraints in the beekeeping sub sector of the country vary depending on the agro ecology of the areas where the activities is carried out (Edessa, 2002). Variations of production constraints also depends on socioeconomic conditions, cultural practices, climate (seasons of the year) and behaviours of the bees. Table 4 highlights the major constraints faced by respondents in the beekeeping activity in the study area. Absconding of bees (80%) is the major challenge faced by the beekeepers in this area. This is followed by lack of fund (73%) and inadequate marketing information (70%). Other constraints identified include aggressiveness (65%); lack of better beekeeping technologies (55%); deforestation (48%); lack of extension services (45%) and pest and disease (40%).

Table 4: Major constraints to beekeeping

Constraints	*% respondents
Absconding of bees	80
Lack of fund	73
Inadequate marketing information	70
Aggressiveness	65
Lack of better technologies	55
Deforestation	48
Lack of extension services	45
Pest and disease	40

Source: Field survey, 2012

Note:* The sum of constraints exceeded one hundred due to multiple responses

Sources of Information

Table 5 shows the farmers major sources of agricultural information. A large percentage of the respondents (46.6%) indicated fellow farmers as their main source of information, followed by radio (31%), chiefs (traditional leaders) (6.9%), television (5.2%); Newspapers (3.4%) and extension agents (1.7%) as the least source of information.

Table 5: Farmers Sources of information

Sources of information	Fellow farmers	Radio	chiefs	Television	News papers	Extension agents
% respondents	46.6%	31%	6.9%	5.2%	3.4%	1.7%

Source: Field survey, 2012

Conclusion

The investigation reveals that beekeeping in Nsukka is dominated by middle-aged male with little or no education. They practice traditional beekeeping which is mostly constrained by absconding of bees, lack of fund and inadequate market information. Beekeepers in Nigeria obtain information mainly from fellow farmers. Embracing modern beekeeping will encourage female participation in beekeeping; it will also ensure food security and improve the living standard of farmers. Access to fund and marketing information will enhance the adoption of modern beekeeping Nsukka LGA.

Abstract
This study evaluated the effect of rubber-based cropping systems on the development and yields of rubber, maize and cassava was carried out at the Rubber Research Institute of Nigeria, Iyanomo, Benin City. There were eleven treatments (rubber + natural vegetation (Control), rubber + Puereria phaseoloides, rubber + maize (0.25 x 0.75 m), rubber + maize (0.50 x 0.75 m), rubber + maize (0.60 x 0.90 m), rubber + cassava (0.50 x 1.0 m), rubber + cassava (1.0 x 1.0 m), rubber + cassava (1.5 x 1.0 m), rubber + maize + cassava (0.25 x 0.75 m/0.75 x 1.0 m), rubber + maize + cassava (0.50 x 0.75 m/1.0 x 1.0 m) and rubber + maize + cassava (0.60 x 0.90 m/1.5 x 1.0 m), organized in RCBD with each treatment replicated three times. Data were generated on the physico-chemical properties of the soil, development and yields of; rubber saplings, maize and cassava. Rubber sapling biomass was determined in lieu rubber yields. The results showed no significant changes in physico-chemical properties of the soils compared with values before cropping except for available– P, where rubber cropping systems resulted in increased P from pre-cropping values. The highest P values were recorded in the Rubber + maize (0.25 x 0.75 m). Significant increases in the ECEC of the soil were recorded in all the intercropped plots. Rubber planted with natural vegetation had a significantly higher stem girth (2.95 cm) and plant height (75.0 cm) compared with those in the intercrops. Among the intercropped, rubber + maize (0.50 x 0.75 m) had the most robust girth (2.74 cm) and height (90.7 cm^2). The result of the effect of intercropping on the grain yield of maize indicated a highest grain yield recorded in the Rubber + Cassava + Maize (0.50 x 0.75 m/1.0 x 1.0) treatment. While rubber + Cassava (1.0 x1.0 m) showed the highest Dry Tuber and Biomass yield of 9010 kg^{-1}ha and 11790 kg^{-1}ha. Rubber sapling biomass was significantly influenced by rubber based cropping systems. The Marginal rate of Returns in the rubber planted with natural and Pueraria recorded 0% compared with the ones planted with maize and cassava that recorded values ranging from 103.3 – 1826.4%. The study showed that intercropping rubber saplings with maize and cassava showed comparative advantage when compared with planting of rubber with Pueraria and natural vegetative fallow.
Keywords: Rubber saplings, intercropping, cassava, maize, Pueraria phaseoloides, crop spacing and Nigeria

Introduction
Intercropping of young rubber plantation with arable crops has been reported to be beneficial to the growth of rubber and capable of improving the economy of the rubber plantation enterprise in Nigeria. It has been reported to have the potentials of reducing farmer's need for subsidies and credit (Idoko *et al.,* 2012 and Esekhade *et al.,* 2003). Crops like maize and cassava has been found to be one of the most promising among the arable crops evaluated in Nigeria (Esekhade and Idoko, 2010; Esekhade, 2003). It an additional sources of organic materials to the soil and help create a micro climate that leads to soil moisture conservation and subsequent encouragement of a more robust girth of young rubber saplings on the field (Esekhade and Ugwa, 2000; Esekhade *et al.,* 1996; Esekhade, *et al.,* 2003). Before canopy closure, intercropping helps reduce the cost of rubber plantation establishment by generating income to farmers during the period of rubber establishment and thus less the need for subsidies and credit to rubber farmers. The intercropping of rubber with cassava and maize has been widely adopted by the small scale

farmers, but the practice is still not popular among the large scale estate in Nigeria despite the potential benefits of the practice. Some of the fears are the possibilities of component crops especially cassava reducing the growth of rubber due to competition for nutrients. However, results from research fields at Iyanomo and adoption studies carried out in some States proved otherwise. But that has not been enough in convincing major stakeholders in the rubber industries especially managers of estates.
Therefore, this paper seeks to demonstrate clearly, the impact of intercropping on the growth, development and yields of rubber, maize and cassava including possible financial benefits in rubber based cropping systems.

Materials and Methods

The experiment was conducted at the Rubber Research Institute of Nigeria, Iyanomo near Benin City located in the rainforest region of Southern Nigeria. Annual rainfalls during the two seasons of the experiment were 2352 and 2622 respectfully. The area has a bimodal rainfall distribution. The temperature is high, with a mean temperature ranges of 29.0 – 32.1 and 25.7 – 31.4 in the first and second season respectively. Selected physicochemical properties of the soils before cropping shows that the pH of the area was 6.00 and 5.70 in H_2O and KCl respectively, the organic carbon was 13.7g kg^{-1}, Total N was 2.4 g kg^{-1}, available P was 4.77 mg P kg^{-1}. The texture of the area was Loamy sand with a bulk density of 1.19 g cm^{3-1} and percentage moisture content of 12.2%. The experimental area was first opened for cropping about 50 years ago. The land utilization system since then has been 2 – 3 years of cropping followed by 5 – 6 years of bush fallow. The last fallow before the start of the experiment lasted for five years after it had been cropped to maize, yam, cocoyam, plantain and bananas for three years. The experimental plots were arranged in a randomized complete block design, with three replicates. Each plot measured 92.12 m^2 excluding 1.0 m^2 border to give a total area of 0.304 ha. The trials consisted of eleven treatments (rubber + natural vegetation fallow (Control), rubber + *Puereria phaseoloides*, rubber + maize (0.25 x 0.75 m), rubber + maize (0.50 x 0.75 m), rubber + maize (0.60 x 0.90 m), rubber + cassava (0.50 x 1.0 m), rubber + cassava (1.0 x 1.0 m), rubber + cassava (1.5 x 1.0 m), rubber + maize + cassava (0.25 x 0.75 m/0.75 x 1.0 m), rubber + maize + cassava (0.50 x 0.75 m/1.0 x 1.0 m) and rubber + maize + cassava (0.60 x 0.90 m/1.5 x 1.0 m). The natural rubber vegetation was established by allowing the growth of natural plants with rubber saplings, which was spaced at 6.7 x 3.4 m. The predominating plants were *Centrosema pubescens, Chromolaena odorata, Panicum maximum, Aspilia Africana and Talinum triangulare*. Maize (Zea mays L. cv DMR-SR-W), Cassava (Manihot esculentus Cranz cv. 30572) and Pueraria were established in the inter-rows of rubber sapling.

Agronomic parameters measured included morphological and physiological properties such as stem girth, height, leaf area, leaf area ratio and crop growth rates of rubber saplings were calculated according to Esekhade et al., (2003). Biomass of rubber saplings were determined by destructive samplings at 30, 360 and 720 days after planting (DAP). Yield of the intercrops were determined at harvest. Harvested rubber, maize and cassava were oven dried to 12 per cent moisture content at a temperature of 60°C. The soils of the experimental area were sampled before the start of the experiment and at the end of 720 days. The samples were from depth of 20 cm from the inter-rows and interlines of rubber. Particle size analysis was by the use of hydrometer method by Bouyoucos, (1965) method, organic carbon was determined using chromic acid wet oxidation method (Black, 1965), total nitrogen was by the micro Kjedahl method, available P was by the molybdenum blue colour method (Bray and Kurtz, 1945), exchangeable cations (Ca, Mg, Na and K) was determined by extracting with normal ammonium acetate and reading was with Atomic Absorption Spectrophotometer (AAS). Exchangeable acidity was determined by KCl extraction and titration with NaOH (Maclean, 1965). Based on soil test results, fertilizer were applied (uniform broadcast) at the rate of 19.0, 60.0, 36.0 and 5.0 kg ha^{-1} N, P_2O_5, K_2O and MgO; using Urea, Single super phosphate, muriate of potash and magnesium sulphate as sources respectively. The fertilizers were divided into two equal doses and applied at planting and 3 months after planting. All the data generated were analysed using the Analysis of variance (ANOVA) statistics and the means separated using the Least Significant Differences (LSD) at 0.05 level of statistical significance.

Results and Discussion

The results of the effect of rubber based cropping systems on some physic-physical properties of the soil (Table 1). Rubber + cassava system had the highest moisture content. This was as a result of effective ground cover and litter falls of cassava plants as reported by Idoko, et al, (2012). Organic carbon under the cropping systems changed from 16.5 g kg^{-1} soil before cropping to between 15.8 and 25.9 g kg^{-1} soil in the first cropping season. This is attributed to crop residue addition to the soil under the cropping systems Dalal and Mayer (1986) and Feller *et al*., 1987 showed that incorporation of crops residue provides substrate for microbial biomass resulting in increased soil aggregation, reduce erosion, BD and improved water conservation. Litter production and residue were highest in rubber + *Pueraria phaseoloides* and rubber + cassava systems respectively, but least in maize. This explains the increase in organic carbon in rubber + *Pueraria phaseoloides* and rubber + cassava systems compared with rubber + maize system. Nutrient content of crops in the intercropped plots had upward changes compared with pre-cropping values except total N. This could be as a result of the nature of crops and their combinations. This is why saplings in rubber + *Pueraria phaseoloides* systems had the highest percentage total N; while those in rubber + maize + cassava (0.25 x 0.75 m/0.50 x 1.0 m) system had the least N. This can be attributed to the N fixing capacity of *Pueraria phaseoloides.* The decrease in N content of rubber saplings on the other hand in the rubber + maize + cassava (0.25 x 0.75 m/0.50 x 1.0 m) system is attributed to the types of crops, plant population and their associated use of N and other inorganic fertilizers applied to the soil. Similar attributions were made by Zainol et al., (1993), working on the effect of intercropping systems on surface processes in an acid ultisols. Phosphorus accumulation was observed in all the soils under the rubber-based cropping system when compared with the pre-cultivated level, except rubber + *Pueraria phaseoloides* and rubber + maize (0.25 x 0.75m) systems, which both had values of 2.90 and 3.70 mg P Kg^{-1} in the soil. The observed decrease in both cropping systems is as a result of high P uptake. The accumulation of P in the soil could be attributed to P fertilizer application. The immobile nature of phosphates in soils has been implicated by some other workers (Mainstone, 1962; Pushparajah *et al.,* 1977 and Zainol *et al.,* 1993).

Build-up of exchangeable acidity and ECEC were also observed following intercropping. This is due to fertilizer application and residue addition to the soil. The observation agrees with that of Sanchez et al (1983) working on soil fertility dynamics after clearing tropical rainforest for cultivation. Rubber-based cropping systems influenced the morphological and physiological growth of rubber saplings; particularly girth and height measurements. Rubber saplings in rubber + natural vegetation, rubber + maize (0.50 x 0.75m) had the most robust and tallest height respectively (Table 2). Cropping systems involving *Pueraria phaseoloides* had the least rubber saplings; except that rubber saplings in rubber + cassava (1.0 x 1.0) and rubber + maize (0.60 x 0.90) had the highest crop growth rates (CGR) (0.10 g^{2}m$^{2-1}$ day^{-1}), net assimilation rates (NAR) (8.4 x 10^{-4}g^{2}m$^{2-1}$ day^{-1}) respectively. Rubber saplings in *Pueraria* plots also had the lowest CGR and NAR. *Pueraria phaseoloides* tends to compete more for nutrients particularly P and other resources than rubber saplings. This explains its adverse effects on the growth of rubber saplings compared with food crops. Similar observation was made by Watson (1989) in his study on the role of trees and cover crops in nutrient cycles. He observed apart from accumulation of large amount of nutrients, *Pueraria phaseoloides* strangulates young rubber of not controlled. Rubber-based cropping system did not have significant effect on morphological measurements of maize and cassava (Tables 2). The spacing/plant population seem not to have adversely affected morphological measurements. However, maize plants in rubber + maize + cassava (0.50 x 0.75 m/1.0 x 1.0m) had the tallest height and widest leaf area. While cassava plants in rubber + maize + cassava (0.60 x 0.90m/1.5 x 1.0m) and rubber + maize + cassava (0.50 x 0.75/1.0 x 1.0m) had the most robust girth and tallest height respectively.

The yield of rubber, maize and cassava were significantly ($P \leq 0.05$) influenced by intercropping (Table 2). The highest rubber biomass was 65.1 Kg ha^{-1}, while the least was 42.4 Kg ha^{-1} in rubber + cassava (1.0 x 1.0 m) and rubber + *Pueraria phaseoloides* systems respectively. This result suggest that crop population may affect the biomass of rubber saplings in a rubber based cropping systems due to increase competition for resources, also the types of crops in the mixture could also affect the rubber sapling biomass, as demonstrated by the biomass of rubber in the in rubber + *Pueraria phaseoloides* and rubber + natural vegetation systems compared with rubber + maize and rubber + cassava systems. These could be due to complementation of plants species mixture in maize, cassava and rubber intercropping systems. This is in agreement with the views of Idoko, *et al*., (2012), Ong and Black (1992) and Willey *et al.,* (1986). Maize grain yields in cropping systems did not follow definite pattern. A higher maize population per plot did not necessarily results in higher grain yield, neither did a lower maize production resulted in lower, maize grain yields. Rubber + maize (0.60 x 0.90m/18519 plants ha^{-1}) had higher mean maize grain yield (2390 Kg ha^{-1}) compared with maize yield in rubber + maize (0.25 x 0.75m/53333 plant ha^{-1}) which was 2035 Kg ha^{-1}. The same was true for rubber + maize + cassava systems where the (0.50 x 0.75m/(26667 plants ha^{-1})/1.0 x1.0/(10000 plants ha^{-1}) spacing population. However the rubber + maize (0.50 x0.75m) and rubber + maize + cassava (0.50 x 0.75m/1.0 x1.0m) systems seem to have a more positive effect on the growth of rubber saplings and yields of maize. Cassava yields were however, more consistent in terms of the effect of the cropping systems on yield. Cassava spaced at 1.0 x 1.0m/10000 plants ha^{-1} consistently maintained the highest cassava tuber yields. Rubber + cassava (1.0 x 1.0m) and Rubber + maize + cassava (0.50 x 0.75m/1.0 x 1.0m) systems had 9010 and 1790 Kg ha^{-1} cassava tuber yields respectively. The introduction of maize into cropping systems led to a decrease in tuber yields of cassava. This could be explained by the reduced space available to cassava under the rubber + maize + cassava system compared with the rubber + cassava system.

Conclusion

The study was carried out to determine the optimum spacing/plant population of maize and cassava intercropped with rubber saplings and the effect of the intercropping systems on rubber saplings growth and yield. The major findings of the trial are summarized as follows; The nature and number of intercrops with rubber saplings influenced the growth and development of rubber saplings. Rubber saplings intercropped with *Pueraria phaseoloides* had the highest growth performances compared with those planted with maize and cassava. The spacing recommendation for maize and cassava intercropping in a rubber based cropping system are 0.50 x 0.75 cm and 1.0 x 1.0 m respectively.

Table 1: Effect of Rubber based cropping systems on the morphological growth of rubber, maize and cassava

Cropping systems	Rubber growth (cm)			Maize growth (cm)			Cassava Growth (cm)

Production of Improved Timber Trees Resistance to Pests and Diseases

Koyejo, A.O[1] and Opara, E. U[2]
[1]Forestry Research Institute of Nigeria, Humid Forest Research Station Umuahia
[2]Department of Plant Health, Michael Okpara University of Agriculture, Umudike

Abstract
The biodiversity of the forest determines the health and vitality and is the basis for a wide range of ecosystem services necessary for people's livelihoods and well-being. These services are seriously impaired because of pest and diseases. In timber production, diseases and pests have caused timber degradation resulting in reduction of harvestable volumes and quality of timber. A key element of successfully managing forests for sustainable resilience to invading pests and pathogens is to harness the genetically controlled resistance mechanisms that are naturally present in trees. Breeding disease resistance timber tree species can provide a long-term solution which has no detrimental side effects to the environment unlike the use of chemicals. Though, breeding for resistance trees is challenging in Forestry due to the long maturity period of forest trees but some successes have been recorded.

Introduction
Forests provide approximately 1.6 billion people with food, medicines, fuel and other necessities. These provisions of the forest could be attributed to its biological diversity. Forests are more biologically diverse than any other land-based ecosystem. Biodiversity determines the health and vitality of forests and is the basis for a wide range of ecosystem services necessary for people's livelihoods and well-being (SCDB, 2010) Unfortunately, invasive pathogen and insect species can have a significant negative effect on the health and biodiversity of forest ecosystems, urban forests and forest plantations, which in turn can have large economic impacts, if they are kept unchecked (Lovett et al. 2016; Roy *et al.* 2014; Campbell and Schlarbaum 2014; Pimentel *et al.* 2000). In Africa and other parts of the world, there are some pest and disease problems which are often overlooked but their cumulative effect could cause great economic losses, whether in commercially exploited natural stands or in plantation. Consequently, the integrity of our natural, urban and plantation forest ecosystems, and the services they provide are seriously impaired because of pest and diseases (Sniezko and Koch, 2017). Hardwood tree species have suffered the greatest destruction. There are several examples where one or more species of either indigenous or exotic pests or diseases have caused devastating losses to forests, requiring changes in management regimes or to switch to alternative tree species (FAO, 2001). For example, in timber production, diseases and pests such as heart rots and bark beetles respectively, have caused timber degradation resulting in reduction of harvestable volumes and quality of timber (Nsolomo and Venn, 2000; Ryvarden, 1980). In addition, trees planted on farm woodlots and urban spaces have also at times succumbed to diseases and pests (Nsolomo and Venn, 2000). Utilizing naturally occurring genetic resistance can provide solution that fosters continuous coevolution of the affected tree species and the damaging agent that is vital for long-term success. Genetic resistance has the advantage of being a natural alternative to the use of chemicals or other costly management methods that may have to be continuously repeated or may have detrimental side effects to the environment (Sniezko and Koch, 2017). This review highlights pest and disease of timber trees. The challenges and successes in developing resistant forest trees.

Common Pests and diseases of forest trees
Pests and diseases can damage trees in all stages of development. For instance, some fungi and insects are pests of tree seedlings in nurseries while others attack older trees in a wide variety of ways (FAO, 2001). Some indigenous tree species in Nigeria, with endemic pest problems

include Iroko (*Milicia excelsa* and *M. regia*), African mahogany (*Khaya and Entandrophragma spp*), Afrormosia (*Pericopsis elata*), Obeche (*Triplochiton scleroxylon*), Opepe (*Nauclea diderrichii),* and *Terminalia ivorensis.* Plantation establishment of these high value indigenous timber species is impaired as a result of these endemic pest problems (Gichora *et al.,* 2017; Paul and Weber, 2013). *Milicia excelsa* suffers severe attacks from the Iroko gall maker *Phytolyma lata* (Wagner et. al., 2008). Other species of Phytolyma namely P. fusca and P. tuberculata attack M. regia. All life stages of the tree are attacked but seedlings and actively growing saplings in young plantations are most affected, often resulting in total failure of plantation establishment.
Another serious pest of regional and global significance is the mahogany shoot borer, *Hypsypyla robusta*. It attacks species of the Meliaceae family in Africa, especially African mahogany (Khaya and Entandrophragma). Shoot borer attack on mahogany often results in damage and deformation and sometimes death of plants at the nursery stage and in young plantations. Other important endemic pests include *Lamprosema lateritialis* on *Pericopsis elata* (Afrormosia), *Orygmophora mediofoveata* on *Nauclea diderrichii* (Opepe) and *Anafe venata* on Triplochiton scleroxylon (Obeche).

In addition to the problems encountered on indigenous species, introduced or exotic species such as *Gmelina arborea, Cedrela odorata, Tectona grandis* and various *Eucalyptus* species which are widely planted in Nigeria often succumb to insect pest attacks (Gichora *et al.,* 2017). In the humid forest zone, *Gmelina arborea* suffers from severe attack by *Achaea* and *Apophylia* species, these have resulted in significant damage in Nigeria in the past (Louppe, 2008). *Tectona grandis* (Teak) and *Cedrela odorata* (Cedrela) are perhaps the most commonly planted species in the humid zone of West Africa and occur in Ghana, Togo, Nigeria and Cote d'Ivoire. The two species do not have serious problems with insect pests, except for sporadic attacks by some generalist insects.

Mechanism of resistance to pest and diseases

A key element of successfully managing forests for sustainable resilience to invading pests and pathogens is to harness the genetically controlled resistance mechanisms that are naturally present in trees (Cavers and Cottrell, 2015; Ledig, 1988), as part of an integrated management strategy. Tree resistance to pests and pathogens is either at the cellular, tissue or whole tree levels (Telford *et al.,* 2015; Namkoong, 1991). Tree resistance is the ability of the tree to exclude or overcome, completely or in some degree, the effect of a pathogen or other damaging factor (Agrios, 2005). It could also be referred to as the ability of an individual host tree to use genetically encoded mechanisms to defend against or withstand attack by an invading organism, with an associated and measurable increase in fitness compared with hosts who do not employ these mechanisms (Telford *et al.,* 2015). Resistance to pathogens is often categorized as either complete (qualitative) or incomplete (quantitative) but the dichotomy between these is not always clear (Kovalchuk et al. 2013; Poland et al. 2009). Complete resistance is often the effect of a single major gene. screening for complete resistance to some fungal pathogens is relatively easy such as *Cronartium ribicola* that causes white pine blister rust, because it can often be done on very young seedlings and the ratio of canker-free (or surviving) individuals is often moderate to high versus the susceptible controls (Sniezko *et al.,* 2012; Kinloch *et al.* 2003). Unfortunately, single gene resistance can often be overcome by pathogens capable of rapidly evolving (Dowkiw *et al.* 2012; Kinloch et al. 2004; McDonald and Linde 2002). Quantitative resistance is the result of the actions of many different genes, and is therefore less likely to be overcome by evolution of the pathogen. Unlike animals, plants lack immune system but have developed an innate immunity made up of several structural, chemical, and protein-based defenses designed to detect and prevent invading organisms (microbes, pests and herbivores). These defense mechanisms can be grouped into two: Pre-existing and post-existing (Doughari, 2015; Naidoo *et al.,* 2014). The pre-existing, also called preformed, passive or pre-invasive. These defense mechanisms are those that are present before contact with the pathogen. They are natural barriers presented by healthy plants. These barriers prevent pathogen entry (Laluk and Mengiste, 2010). In order words, they are innate basal first line immune defence devices indigenously constitutive in the plant even before colonization by the pathogen hence the name constitutive defense (Doughari, 2015). These barriers may be structural/physical (the cuticle, cell wall, stomatal aperture or lenticel) or biochemical (including inhibitory compounds or the absence of stimulatory compounds needed for pathogen development (Freeman and Beattie 2008; Agrios, 2005). Saprophytes lack the ability to penetrate these natural barriers (Quest and Brown, 1997).

In summary, passive defense allows the tree to prevent or inhibit invasion, then kill or isolate the pest or pathogen and repair any damage that has been caused (Franceschi *et al*., 2005). Post-existing is active or induced defense. It is confrontation through interactive resistance mechanisms which slow or prevent infection or attack. Just like pre-existing, it could be structural or biochemical (Agrios, 2005). Induced structural defense may be histological (Lignification, suberization, abscission layers, tyloses, gum deposition) or cellular (cytoplasmic reaction, papillae). In Eucalytus species, Cell wall lignification, phenol deposition and callused papillar formation were observed more frequently in E. calophylla and E. maculate resistant to p cinnamomic. Induced defences may operate locally at the site of infection, or systemically throughout the entire plant via signalling and transportation of defence compounds to other tissues (Eyles *et al*., 2010). Cahill and McComb (1992) reported an increase in the phenilalanine ammonia liase (PAL) activity, a key-enzyme in phenol propanoid, lignin and phenol product biosynthesis. This increase was detected 48 hours after infection by P. cinnamomi in *Eucalytus calophylla* roots which were resistant in the field. However, these changes did not occur in roots of susceptible *E. marginata* species. *E.calophylla* resistance to *P. cinnamomi* was associated with phenol production. Similarly, *Laccaria bicolor* prevented *Fusarium oxysporum* from degrading the host cell wall due to production of flavanolic infusion in the cell wall. *L. bicolor* stimulated the accumulation of tanine condensates between cortex cells, which indicated that these phenolics were the root protection base (Strobel and Sinclair, 1991; Sylvia and Sinclair 1983). However, most mechanisms do not provide complete resistance. Probably plants use a combination of these mechanisms in a coordinated and integrated response to reduce the success of the pest and pathogens (Poland *et al*., 2011; Bonello *et al*., 2006).

Developing genetic resistant trees to pest and diseases

Trees are perennial, long-lived organisms, durable resistance is needed to ensure the trees survive long enough to meet ecologic goals in natural forests and economic or amenity goals in plantations or urban forests. Breeding disease resistance forest tree species can provide a long-term solution, but it can also be a long-term endeavor. The characteristics of forest trees such as long maturity period, makes breeding differs from agricultural crops especially if multiple generations are needed (Flachowsky *et al*.,2009; Fladung, 2008). In agricultural crops, pure cross-breeding is utilized, i.e. after an initial cross between a wild plant (carrying e.g. a resistance gene) with an elite line (deficient in the resistance gene), repeated back-crosses and field testing ensures the presence of the resistance gene together with the accumulation of the genomic background of the elite line. Unfortunately, the long gestation /maturity period in forest trees makes pure cross breeding not practicable. However, the term selective breeding is used in forest tree breeding. This is selection of natural occurring forest trees with the desired traits such trees are called plus trees (Haggman et al., 2016). These trees are used for seed collection or establishment of seed orchard. This makes the resistant tree not a single cultivar, but a genetically diverse progeny that resulted from inter-mating of a population of resistant parents. Seed orchards typically have an advantage over seed collected from parent trees in natural forests because all pollination is from resistant parents, increasing the level and frequency of resistance in the resulting seed (Haggman *et al.*, 2016; Sniezko *et al* 2012). Despite these challenges in breeding for resistant forest trees, there are some successes in relatively short periods of time (Sniezko *et al*., 2012; Koch 2010). For instance, *Swietenia macrophylla* and *Cedrela odorata*, resistant to *Hypsipyl grandella* were produced by grafting using *Khaya senegalensis* and *Toona ciliate* (Perez *et al.,* 2010). In addition, the tissue culture technique which has become an important tool in plant breeding to develop disease resistant plants through either micropropagation or cell culture in selective medium, in the presence of fungi phyptotoxins (Sobrosa and Martins-Corder 2001) has recorded some successes in forest tree breeding for resistance variety. In a study on breeding for pest resistance, Klopfenstein *et al.* (1993) analyzed two Populus hybrids, which were transformed with defense genes from quimeric plants developed based on the pin2 gene (potato proteinase inhibitor II). A binary vector system of Agrobacterium was used in the transformation of these hybrids. The expression of genes was conformed in Populus transformed with Nos PIN2 or 35S-PIN2. Populus transgenics expressing PIN2 showed resistance to insects (Plagioder versicolora and Chrysomela scripta) and fungi pathogens (Septoria musiva and Melampsora medusae). Cahill *et al.* (1992) observed, in roots inoculated with P. cinnamomi, that 8% of the primary roots of micro propagated

Eucalyptus maginata resistant clone could restrict and limit colonization of this pathogen. However, no root of susceptible plants of this species restricted the fungus growth. The authors also observed that while there were few lesions in the *E. marginata* clones, their length was like that found on the roots of susceptible plants. In Pines, the study of Jang and Tainter (1990), shows that expression of differential resistance in callous tissues of three Pinus species (*P. taeda, P. echinata, P. virginiana*) and a hybrid of *P.taeda x P echinata* in response to cinnamomi a fungus infection showed that *P. taeda* and the hybrid were more resistant to infection and invasion by the fungus than *P. echinata* or *P. virginiana*. Similarly, *Pinus wallichiana* which has proven blister rust resistance (caused by *Cronartium ribicola*) became desirable resistance gene donor to *Pinus strobus* which is susceptible to the disease. Currently, seedlings from the second-generation backcrosses (with 87.5% parentage from *P. strobus*) have confirmed satisfactory rust resistance (Lu and Derbowka 2009),

Conclusion

The integrity of our natural, urban and plantation forest ecosystems and the services they provide are vital for human existence. This paper has been able to establish that, the identification and selection of trees with natural genetic resistance will help to improve the long-term resistance and resilience of tree species to infection or herbivory. Therefore, policies and practices that influence forest management must aim to prevent damages cause by pests and diseases, rather than to treat/manage them once they are fully established.

Sustainable Management of Forest Resources for Food Security in Nigeria

O.D. Chukwuemeka
Department of Forestry and Environmental Management, Michael Okpara University of Agriculture, Umudike
chukwuemeka.onyinyechi@gmail.com

Abstract
This paper provides information on the relevance of forests and tree-based systems for food security and nutrition, and indicates where there is a need to further quantify the roles of these systems, allowing proper integration of their contribution into national and international developmental policies. It also highlights the important role of agricultural revamping in overturning the food insecurity problems that befell Nigeria and the coping strategies.
Keywords: Food Security, forest resources, nutrition and hunger

Introduction
The role played by forests and trees in the lives of many people appears obvious through the many uses made of tree products, including foods, medicines, fodder, fibres and fuels, and for construction, fencing and furniture (FAO, 2010). Indeed, forests and other tree-based production systems such as agroforestry have been estimated to contribute to the livelihoods of more than 1.6 billion people worldwide (World Bank, 2008). Forests have sustained life on earth through the ages. They supply food, medicine, energy, shelter, fodder, wood and non-wood forest products and are a source of economic development for individuals and communities. They have cultural and spiritual values, protect biodiversity and conserve soil and water. Forests are indeed a source of life. Forestry can contribute immensely to food security in Nigeria if properly integrated with agriculture, fish and livestock production. Forests and tree-based agricultural systems contribute directly and indirectly to the livelihoods of an estimated one billion people globally. Wild foods are important for food security and nutrition while trees and forests are vital for their role in the provision of ecosystem services to agriculture. Despite this, the role of forests in supporting human food security and nutrition remain largely under-researched and understood. With food security and nutrition high on the agenda in many political and scientific spheres, it is crucial to understand the contribution of forests and trees to a food secure and nutrition-sensitive future. This improved understanding will be essential for building on synergies and minimizing trade-offs between biodiversity conservation and sustainable management of forest resources in order to feed an estimated global population of nine billion people by 2050 (Sunderland *et al.*, 2013).

Food Security and Nutrition
Food security exists when communities "have physical and economic access to sufficient safe and nutritious food to meet their dietary needs and food preferences for a healthy and active life" (Pinstrup-Andersen, 2009). Despite advances in agricultural production globally, approximately one billion people are still chronically hungry, two billion people regularly experience periods of food insecurity and just over a third of humans are affected by micronutrient deficiencies (FAO *et al*., 2012; UN-SCN, 2010; Webb Girard *et al*., 2012). While rates of hunger (insufficient access to energy) have been falling in many parts of the Nigeria, there has been little change in the rates of micronutrient deficiencies (FAO *et al*., 2013). In particular, deficiencies of iron, vitamin A, iodine and zinc, are associated with poor growth and cognitive development in children, and increased mortality and morbidity in both adults and children (Black *et al*., 2013).

Food insecurity in Nigeria

Unfortunately, the problem of food insecurity is still relevant in Nigeria. 1/6 of the Nigerian population suffers from chronic hunger; 3.8 million of them are children, who die every year as a result. The inability of Nigeria to provide the population with the required sustenance is mainly due to stagnation of agriculture. Another reason is low income of many families.

Causes of Food Insecurity

Food insecurity is a multifaceted problem. It is quite an uphill task discussing the driving factors for food insecurity in Nigeria. The following among others have however, been identified as the prime agents of food insecurity in Nigeria.

Insufficient Production

While Nigeria only has a fixed area of arable land, its growing population will soon stretch land availability to it limits that it will not be able to sustain the population. The major problem here is that the agricultural sector has remained under developed and depended too much on primary agriculture system with degraded low fertile soils, less external farm inputs utilization and significant loss of food crops both before and after harvest, and lack of facilities for storage and preservation of food all of which have cumulatively contributed to price fluctuation of agricultural products (Ilaboya, *et al*., 2012).

Inefficient Policies and Corruption

Food insecurity has persisted in Nigeria and many developing countries because of inefficient policies especially with respect to agriculture, trade, economics and other adjourning sectors. If governments fail with these policies, hunger will naturally persist or even worsen. Indeed, many countries have failed in their efforts to develop due to failure to properly administer policies and initiatives which has connection to food (Behnassi, *et al*., 2011).

Climate Change and Natural Disasters

Global changing climate is another important driver of food insecurity that cannot be underestimated. Amongst other impacts, climate change is responsible for biodiversity loss in the ecosystem as well as other physical access (Adeagbo, 2012). Climate change has become one of the key divisor that is redefining the global food equation and thus having so much impact on the food security of particularly developing nations.

Low Technology for Processing and Storage

The use of modern technologies in the production and distribution of agricultural products is very low in Nigeria so the sector depended more on manual labour for farm activities. This is because of lack of innovation in local technology, particularly as it relate to mechanization of agriculture to improve productivity. Additionally, local farmers can hardly afford imported technologies and lack maintenance capacity (Nwajiuba, 2013). Inadequate or lack of facilities to preserve food items such as cereals, yam, beans, etc. can result in wastage thereby further deepening the insecurity level of food. Also, lack of food processing apparatus sometime leave farmers with no choice than to consume significant fraction of their harvest within short period.

Nigerian Food Security Policy Review

The Nigerian government has come up with various strategies to improve the situation. Efforts are now been made to restore agriculture back to its original status before the oil boom and stamping out food insecurity (Ojo and Adebayo, 2012). Several policies and initiatives are now being developed with the aim of providing efficient framework to address food insecurity and malnutrition in Nigeria (Akinyele, 2009).

Strategies for Achieving Food Security in Nigeria

Going by its definition, food security however will not be achieved by simply increasing the production of food. Even when food is sufficiently available, a poor hungry man will remain food insecure as long as he cannot afford to buy it (Ogbonna *et al*., 2013). Hence, all four components viz.; availability, accessibility, utilization and stability must be present. Efforts to combat food insecurity will therefore, not only make food available but also ensure that that people can consistently afford to make it ready for consumption. The panacea lies in improving forest resource production; enhancing science and technology; building farmers capacity; facilitating access to the market; and good governance amongst others (Ilaboya, *et al*., 2012).

Sustainable use of the forest resource base
Sustainable use of forest resources is critical for sustainable livelihoods. More sustainable use of natural resources has a direct impact on the improvement of natural capital. All people affect the environment, but the poor tend to be the most vulnerable to the effects of environmental degradation (FAO, 2010). The development and sustainable management of forest resources is simply the process of managing resources derivable from the forest so as to ensure persistent and sustained availability of forest goods and services for the teeming global population. Unlike the past in which forest was treated with a wave of the hands as a result of finding them everywhere, forest resources in recent times are increasingly and significantly constituting prominent element in the national economies of many countries (Ojo and Adebayo, 2012)

Conclusion
We believe that forests, biodiversity conservation and agro-ecology should feature prominently in political and scientific discourse on agricultural production and the concomitant challenge of sustainable forest resources. Greater attention to the direct and indirect benefits of forest in food security, livelihoods and nutrition should enhance local and global efforts to end hunger and improve the nutrition of communities living in forested areas as well as those living in areas removed from forests. To surmount this challenges, the government must go back to the drawing board to provide enabling environment through promoting decent employment in the agricultural sector and non-farm sectors as well as providing credit facilities to serve as platform for the most vulnerable to cope with the economic realities particularly in the rural areas. While social networking and cooperation among small holder farmers will give them a voice, the government needs to provide basic infrastructures such as access road and electricity and make education more accessible to build farmers capacity. Oil spillage and other industrial effluents constitute a major source of pollution of soil and water and other components of the environment, thereby reducing agricultural productivity. There is the need for government to develop a robust monitoring mechanism to control indiscriminate discharge of effluent. Lastly, modern science and technologies must be adopted to improve agricultural productivity.

Abstract
The study was carried out to determine the density, diversity and distribution of tree species in Kano State Zoological Garden, Kano State Nigeria. Total of Twelve plots of 50×50m were laid in the study area. All trees with diameter at breast height (DBH) 10cm and above were identified, diameter at breast height (DBH) measured and their frequencies were taken in all the sample plots. There were total of 1,030 trees which belong to 35 species and distributed among 15 families. 44.56% of the tree species encountered belongs to the family Fabaceae, 21.7% Meliaceae, 0.35% Ebanaceae and Aracaceae respectively. The Shannon Wiener diversity index (1.113) Simpson`snindex (0.001) and species richness (0.16) were estimated. The distribution of tree density per hectare was 103 trees per hectare. Khaya senegalensis has the highest mean height values 30.34m with DBH of 1.67, Terminalia catappa of 4.50m with DBH of 0.11m while Ficus platyphylla had lowest DBH value of 0.10m with mean height of 4.00m. This study provides the baseline information in relation to biodiversity of trees species in Kano State Zoological Garden, which has greater impact on survival of zoo animals and satisfaction of visitors. The result of floristic status obtained from the research indicated that Kano Zoo is moderately dense with diverse vegetation.
Keywords: Kano zoological Garden, Density, Diversity and Distribution

Introduction
Forest monitoring has become a key issue in national and international environmental and developmental policy process. This is especially true in the tropical forests where rates of the degradation and fragmentation are high. The information generated by the forest inventory and monitoring system not only feeds into national environmental policies but also plays an increasingly relevant role in international conventions (FAO, 2013). It is increasingly evident that forest provides indispensable functions in a complex ecological system which sustains not only humans but all life on the planet earth. Everyone is benefiting from the products or services of the forest. In addition forests also have added value of conservation for scenic purposes, stabilization of climate, maintenance of water supply and prevention of soil erosion (Nemetz, 1992). Conservationist widely believe that the more species an ecosystem contains, the more robust and stable it will be (William, 1994). Talman (1990) pointed out that the more species the ecosystem has, the more likely it is that such forest will be resistant to drought, disease or any other stress that can threaten it. These resistant species spread and take the place of those harmed or killed by the stress. Density of species in an area is often described by the total number of particular species per unit area, which indicates the relative abundance of particular species in a counting of different species or forest. Density technically is more effective when measuring either species recruitments or mortality (William, 1994). A density has been particularly useful in monitoring threatened and endangered species or other species of plants, because it samples the number of individual per unit area (William, 1994). Density of tree species in different size or age class is often used to quantifying how range lands are responding to different management actions and disturbances. Many threatened or endangered species are at risk because of disruptions to their habitats (NWF, 2013). While some species can rely on diverse sources of food or places to breed, a surprising number of species are very specific in their requirements. For example, certain butterflies can only lay their eggs on particular host plants

that provide food for their caterpillars. Some bird species have very particular nesting requirements that are only met by certain kinds of trees (NWF, 2013). Wildlife has four basic requirement: food, cover, water and space. Different wildlife species require different stages of forest growth to meet these needs. The arrangement and ratio of these stages dictats the kinds of wildlife that can live on your land, source www.geogiawildlife.com. Assessment and systematic observations are essential components of long term planning, for evaluating effects, quantitatively and qualitatively, and for rectifying inadequacies. Over the years information on the floral composition and density is not documented in the Kano state zoological garden. Hence vegetation survey becomes imperative since it is the vegetation that supports wildlife. The objectives of this research was to determine the floristic status (density, diversity and distribution) of Kano State Zoological Garden, Kano State, Nigeria.

Methodology

The Study Area

Kano Zoo is one of the largest state governments owned zoo in Nigeria (Bichi, *et al.,* 2016). It was established in 1971 and officially opened in 1972 by the military governor of Kano State, Alhaji Audu Bako. Kano state Zoological Garden is located within Kano metropolis with the latitude 11º 57` 48.1 and 11º 58`00.0 North and the longitude 11º 58` 09.3 and 11º 58`20.0 East. It is within the Sudan Savanna zone of West Africa. The temperature of Kano usually ranges between a maximum of 33°C and a minimum of 18.85°C although sometimes during winter it falls down to as low as 10°C (Bichi, *et al.,* 2016).The zoo covers an area of about 46 hectares with about 75 different species, comprising about 350 animals. It was registered by Pan African Association of Zoos and Aquaria (PAAZA) and International Zoo Educators (IZE) in 2007 and 2010 respectively.

Sampling techniques and data collection

Kano zoo has an estimate of 46 hectares. The zoo was divided in to plots of 50m×50m, thereby having a total number of 92plots/area. Twelve (12) plots were randomly selected for this study which was 13% of the total plots. Within each selected plot, complete enumeration and tagging method was used to collect the data. Information on total number of species per plots and relative abundance of all living tree was recorded. The measurement of tree diameter at breast height (dbh), and their respective total height was done with Spegiel Relescope, and Girth diameter tape.

Data Analysis

The data collected was arranged in Microsoft excel spreadsheet and the following growth and diversity indices were computed from the data obtained. The parameters considered include; Basal area, frequency, relative frequency, relative density, relative dominance and important value index, Shannon and Simpson diversity index.

The basal area of all trees in the sample plots was calculated using the formula:

$$BA=\frac{\pi D^2}{4} \quad (1)$$

Where, BA= Basal area (m^2), D = diameter at breast height (m) π = pie (3.143). The total basal area (m^2) for each plots was obtained by adding all the trees in the sample area and the mean basal area was calculated for individual species. Below is the quantitative formula used in calculating density and diversity indices from the study area:

$$\text{Frequency} = \frac{\text{Number of plots in which species occurs}}{\text{Total number of the plots}} \times 100 \quad (2)$$

$$\text{Relative frequency} = \frac{\text{frequency of a species}}{\text{total frequency of all species}} \times 100 \quad (3)$$

$$\text{Relative density} \frac{\text{Number of individuals of the species}}{\text{Total number of individual of all the species}} \times 100 \quad (4)$$

$$\text{Relative dominance} \frac{\text{Total basal of a species}}{\text{total basal area of all the species}} \times 100 \quad (5)$$

Importance Value Index (IVI) = Relative frequency+ Relative density + Relative dominance (6)

Below is also the formula for qualitative analysis:
Species diversity and dominance will be calculated from a Shannon diversity index given as:
Shannon Diversity index:

$$H = -\sum_{i=1}^{S} p_i \; In \; p_i \; \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots . (7)$$

H= Shannon – Weaver Index (summation of Pi × In Pi ×(-1)), Pi = the proportion of species in the population (Pi = $\frac{ni}{N}$), Where ni = number of individuals of a species,N= the total number of individuals, In Pi = the logarithmic proportion of the species.

$$\text{Species evenness} \quad E = \frac{H}{logs} \qquad (8)$$

E = evenness,
S= number of species present.
Log= logarithm

$$\text{Species richness} = \frac{\text{total number of tree species} - 1}{\text{Log of total number of all individuals of th tree species}} \qquad (9)$$

$$\text{Simpson`s Index (D)} = \frac{\sum ni\,(ni-1)}{N(N-1)} \qquad (10)$$

Where:
D = Simpson`s index
n_i = number of individual species i
N = total number of all tree species in the entire community

Results and Discussion

Table 1 shows the species compositions, families, mean height, mean diameter at breast height (dbh) as well as number of individual. *Khaya senegalensis* has the highest mean height value of 30.34m; followed by *Eucalyptus microcarpa* 30.00m; *Gmelina arborea* 24.14m; *Tectona grandis* 23.75m;; and *Delonix regia* 17.13m; *Dalbergia sisso* 15.96m, while *Terminalia catappa*, *Ficus benjamina* and *Ficus platyphylla* has the lowest mean value of 4.50m, 4.00m and 4.00m respectively. *Khaya senegalensis* had highest mean diameter at breast height (dbh) of 1.67m; *Adansonia digitata* 1.19m; *Tectona grandis* has 1.18m *Eucalyptus microcarpha* has 0.78m and *Delonix regia* 0.71m, while *Diospyros mespiliformis;; Annona squamusa; Terminalia catappa, Ficus benjamina,* and *Ficus platyphylla* had the lowest mean diameter of 0.11m, , 0.11m, 0.11m, 0.11m and 0.10m respectively. Table 2 presents the relative density of the families encountered in the study area *Fabaceae* had the highest family relative density of 44.56%; followed by *Meliaceae* with 21.75%; *Myrtaceae* has 7.02%; *Moraceae* has 4.21, while *Zygophyllaceae, Annonaceae, Casuarinaceae, Ebenaceae* and *Arecaceae* has the lowest relative density of 1.40%, 1.05%, 0.70%, 0.35% and 0.35% respectively. Table 3 shows the frequency; relative frequency; density per hectare; relative density, basal area distribution; relative dominance; important value index; species richness and Shannon weinner diversity of trees in Kano State Zoological Garden. The result indicated that *Azadirachta indica* and *Albizia lebbeck* has 100% frequency while *Diospyros mespiliformis, Annona squamosa, Casuariana equisetifolia, Ficus platyphylla, Hyphaene thebaica* has the same frequency 8.33%. *Azadirachta indica* and *Albizia lebbeck* recorded as a specie with highest relative frequency 10% while *Diospyros mespiliformis, Annona squamosa, Casuariana equisetifolia, Ficus platyphylla, Hyphaene thebaica* also has the same relative frequency of 0.33%. *Azadirachta indica* has the highest density per hectare of 103.33; followed by *Acacia tortilis* 118.67; *Acacia auricuriformis* and *Acacia sieberiana* has density of 85.33 and 57.71 plants per hectare respectively. *Diospyros mespiliformis, Eucalyptus microcarpa, Ficus benjamina, Ficus platyphylla and Vitex doniana* has the lowest density of 4.00 plants per hectare. *Azadirachta indica*; *Acacia sieberiana*; *Albizia lebbeck*; *Acacia tortilis* recorded the highest relative density 30.097; 9.806; 8.41 and 8.641 respectively. While *Eucalyptus microcarpa*, *Vitex doniana*, *Ficus benjamina* and *Ficus platyphylla* has the lowest relative density in the study area. *Khaya senegalensis* and *Adansonia digitata* has the highest basal area of 24.435m and 6.326m respectively, while *Acacia auricuriformis* 0.001m, *Polyaithia longifolia* 0.002m and *Acacia tortilis* 0.009m respectively. *Khaya senegalensis* has the highest relative dominance of 55.69; followed by *Adansonia digitata* 14.419 and *Tectona grandis* 13.824. *Ficus benjamina, Acacia auricuriformis and Polyaithia longifolia* has the lowest value of relative dominance of 0.001; 0.002 and 0.004 respectively. Species richness value of 330.253 for the entire study area was recorded. Shannon weinner diversity index (H`) was 1.113. The summary of tree species distribution and diversity in the study area is presented in Table 4. A total of 35 tree species were encountered in Kano State Zoological Garden distributed in 15 families. The Shannon Weinner diversity index for the study area was 1.13 while species evenness is 0.160. Simpson`s index 0.001.

Table 1: Tree species composition, Families, Mean Height, Mean Diameter at Breast Height (dbh) and total number of individual species

Scientific name	Common name	Family	Mean H(M)	Mean D(M)	No. of indi.
Acacia auriculiformis	Northblack watte	*Fabaceae*	8.33	0.13	64
Acacia sieberiana	Paperback thorn	*Fabaceae*	12.75	0.45	101
Acacia tortilis	Umbrella thorn acacia	*Fabaceae*	8.25	0.23	89
Adansonia digitata	Boabab	*Malvaceae*	13.74	1.19	4
Albizia lebbeck	Lebbeck tree	*Fabaceae*	9.83	0.38	89
Annona squamosa	Sugar apple	*Annonaceae*	4.00	0.11	1
Azadirachta indica	Neem	*Meliaceae*	16.50	0.58	310
Balanite aegyptica	Desert date	*Zygophyllaceae*	8.00	0.35	12
Casuariana equisetifolia	Australian pine tree	*Casuarinaceae*	15.00	0.41	2
Ceiba pentendra	Silk cotton	*Malvaceae*	12.00	0.27	34
Dalberga sissoo	Norh rose wood	*Fabaceae*	23.25	0.70	50
Deloix regia	Flame ree	*Fabaceae*	20.25	0.71	12
Diospyrs mespiliformis	Jacka berry	*Ebenaceae*	6.00	0.11	1
Eucalyptus camaldulensis	Eucalyptus	*Myrtaceae*	22.17	0.78	10

Table 4: summary of tree species diversity and distribution in Kano State Zoological Garden

Indices	NS	NF	H`	H/Hmax	D
Kano Zoo	35	15	1.113	0.160	0.001

NS= Number of species, NF= Number of families, H`= Shannon Weinner diversity index, H/Hmax= species evenness, D= Simpson`s index,

Trees density gives forester an idea of how closely trees are growing in a given area. The total numbers of individual trees in all the plots were 1030, while the numbers of tree species were 35 belong to 15 different families. I *Azadirachta indica* and *Albizia lebbeck* recorded as a species with highest relative frequency 10.00% while *Diospyros mespiliformis, Annona squamosa, Casuariana equisetifolia, Ficus platyphylla,and Hyphaene thebaica* has the same relative frequency of 0.33% respectively. Density per hectare of individuals' species were calculated, in which *Azadirachta indica* has the highest density per hectare with 103; followed by *Acacia tortilis* 118; *Acacia auricuriformis* and *Acacia sieberiana* has density of 85. and 57 plants per hectare respectively. *Diospyros mespiliformis, Eucalyptus microcarpa, Ficus benjamina, Ficus platyphylla and Vitex doniana* has the lowest density of 4.00 plants per hectare. According to Asish *et al.,* (2006) stated that tree density varies with forest community type, age, class, tree species, and size class and site conditions among others. *Azadirachta indica*; *Acacia sieberiana*; *Albizia lebbeck*; *Acacia tortilis* have the highest relative density 30.097; 9.806; 8.41 and 8.641 respectively. While *Eucalyptus microcarpa*, *Vitex doniana*, *Ficus benjamina* and *Ficus platyphylla* has the lowest relative density in the study area. *Khaya senegalensis* and *Adansonia digitata* has the highest basal area of 8.762m and 4.458m respectively, while *Diospyros mespiliformis, Ficus benjamina and Ficus platyphylla* had the lowest basal of 0.013m, 0.018m and 0.031m respectively. The differences in the basal area of trees studied could be due to differences in altitude, species composition, age of trees, and extent of disturbances and successional strategies of the stands. *Khaya senegalensis* has the highest relative dominance value 23.691; followed by *Adansonia digitata* 12.054 and *Tectona grandis* 11.803. *Diospyros mespiliformis; Ficus benjamina and Ficus platyphylla* have the lowest value of relative dominance. The *Fabaceae* and *meliaceae* families were the most abundant families in the study area which account for about 45% of the total families of trees in the Zoological garden, followed by *Meliaceae* 21.75%; *Myrtaceae* 7.02%; *Moraceae* 4.21, while *Zygophyllaceae, Annonaceae, Casuarinaceae, Ebenaceae* and *Arecaceae* has the lowest relative density respectively the variations in the families encountered in Kano state zoological garden could be attributed to the enrichment planting carried out to enhance the species composition of the garden in order to provide conducive environment in the garden for both animals and visitors

Tree species diversity, composition and richness in Kano State Zoological Garden

Typically, the Shannon in real ecosystem ranges between 1.5 and 3.5 (MacDonald, 2003). Considering the value (1.113) recorded in this study, Kano State Zoological Garden could not be considered as a species rich forest when compared with other tropical forest types. Since alots of deliberate anthrophogenic activities was conducted to introduce additional tree species and also at the same time remove the unwanted ones in order enhance the aesthetic beauty of the garden to accommodate more tourists. However, Onyekwelu *et al.,* (2007) obtained higher *H*` values of 3.12, 3.31 and 2.82 at Oluwa, Queen`s and Elephant Forests, respectively, in the tropical rain forest of Nigeria. Similarly in a research conducted by Jamala *et al.,* (2016) discovered 3.00 Shannon weinner diversity index in Nyibango forest grazing reserve. The low diversity or species richness recorded further confirms the differences across the region as influenced by the ecological and climatic variations. It was also reported that the patterns of species richness were the consequences of many interacting factors, such as plant productivity, competition, geographical area, historical or evolutionary development, regional species dynamics, regional species pool, environmental variables and human activity (Woodward, 1988; Palmer, 1991; Eriksson, 1996; Zobel, 1997). In terms of species distribution within the Zoological garden, some had few number species with large numbers of individuals and some had many species with few numbers of individuals. Species evenness (E_H) which is the measure of equitability of spread of available species was calculated (0.160) and considered to be fairly distributed due to less number of species within the Zoo. Other attributive factors to the distribution of trees resulted due to collection of food for the herbivores animals, felling of trees for the establishment of some infrastructures in the Zoological Garden as well as the soil physio-chemical properties influencing tree species richness and distribution within the Zoological Garden. Generally, Simpson index ranges from 0 to 1. Mature and stable communities have high diversity value (0.6 to 0.9), while the communities under stress conditions, exhibiting low diversity, usually show close to zero value (Dash, 2003). Simpson diversity index is always higher where the community is dominated by less number of species and when the dominance is shared by large number of species (Whittaker, 1965) in this study Simpson index in Kano Zoo was (0.001). The lower diversity associated with Kano State Zoological garden as ascribed by Shannon, and Simpson index could be attributed to lesser number of species which could be due to anthropogenic activities beside other biotic factors.

Conclusion

Conclusively, the information obtained from this study area clearly indicates the present floristic status of Kano State Zoological Garden (Density, Diversity and Distribution). Tree Species composition was ascertained. Result obtained indicated that Kano zoo is moderately dense, diverse and trees species were evenly distributed across the garden.

Abstract
This research was carried out in Okpala community of Ngor-Opkala Local Government of Imo State, South-eastern Nigeria in order to study the variability of the topsoil physic-chemical properties of forest and arable soils. Samples were collected from each of the land-uses, labelled properly and subjected to laboratory analysis to compare the variability of topsoil physic-chemical properties. Results of physical properties showed a higher sand, clay and bulk density at the arable soils compared to their forest counterparts. Sand scored 86.56 and 84.96%; clay scored 8.72 and 5.32%, bulk density scored 1.27 and 1.37% all at the arable and forest soils respectively. However, silt and silt:clay ratio were opposite as silt scored 3.12 and 5.92%; silt:clay ratio scored 0.548 and 1.78 in arable and forest soils respectively. Organic carbon, organic matter and total N were all higher at the forest soils compared to the arable soils. Organic carbon, OM and TN recorded 1.115, 1.923 and 0.105% respectively at the arable soils and 1.400, 2.409 and 0.133% respectively at the forest soils. These results are due to the present land use of the investigated soils. Calcium was very low (<2.0 g/kg) at the cultivated arable soils and low (2-5 g/kg) at the forest soils. Magnesium was also low (0.5 – 1.5 g/kg) at it scored 1.26 and 1.47 g/kg in arable and forest soils respectively. Potassium was moderate (0.3-0.6 g/kg) scoring 0.38 and 0.519 g/kg in arable and forest soils respectively. Sodium (Na) was low (<0.1 g/kg) scoring 0.055 and 0.079 g/kg) in arable and forest soils respectively. Most of the investigated physic- chemical properties varied lowly in their coefficient of variations. The topsoil's of these soils especially the cultivated soils should be carefully managed for continual sustainability and productivity.
Keywords: Soil variability, arable and forest soils, soil properties and Southeastern Nigeria

Introduction
Spatial variation is a natural phenomenon in soil that measures the differences in physical and chemical properties of soil from one point to another, soil variation can either be of a small or wide range. It could also be linked to soil formation factors such as, parent materials, climatic (in terms of rainfall and temperature), the nature of landscape relief, other factors include biological and human activities (Ogunkunle 1987). Soil variability is therefore the changes that occur within the soil as a result of the reactions happening within it day in day out and from time to time (Olantunji and Ewetola 2015). Variation in soil properties imposed limitation on the potentiality of the soil and productivity status. The precision of agriculture depends on how much knowledge a farmer have on the soil in which he is working with for optimum production. The knowledge of spatial variability of soil physical and chemical properties is essential for optimum and sustainable agriculture (Wilding, 1985). Therefore, to have a better understanding on how nutrient resources and soil properties vary across land-uses had become the focal point of much ecological research (Obasi *et al.,* 2011). Spatial variability and distribution of nutrients in relation to site characteristics such as land use and other variables are critical rate of ecosystem process (Schimel *et al*., 1991; Townsend *et al*., 1995). Differences in soil properties occasioned by vegetation and land-use could be a result of variation in leaf type, root type, canopy size, decomposition rate of

plant debris, as well as presence of decomposers. These affect organic matter content of soils (Stutter *et al.,* 2004) and soil properties in space and time. Nepstad *et al*., 1994 noted definition of topsoil varies according to the focus, as well as national tradition. From a soil science perspective, topsoil is the surface plus subsurface mineral horizons (A, as well as E if present). Agronomically, the topsoil coincides with the plow layer. FAO/UNEP (1999) does not make a distinction between these two views: "The topsoil is the upper part of the soil, with the lower limit at 30 cm, or shallower if a root growth inhibiting layer is present above that depth." Fully developed forest soils are natural bodies with a vertical sequence of layers (FAO/ISRIC, 1990). At the top is an organic surface layer or "forest floor" (O horizon) with subdivisions of fresh, un-decomposed plant debris (Oi horizon, formerly called L); semi-decomposed, fragmented organic matter (Oe horizon, formerly called F) and humus; and amorphous organic matter without mineral material (Oa horizon, formerly called H). Below this surface layer is a mineral surface horizon (A); a subsurface mineral horizon often leached (E); a subsurface mineral horizon with features of accumulation (B horizon); a mineral horizon penetrable by roots (C); and locally hard bedrock (R). Agricultural soils associated with rangelands and grasslands often have similar vertical sequences. However, if they are being cultivated (arable land)-or have been in the past-they may lack the O horizon (unless peat soils are being used), and the A horizon may have been mixed with parts of the E and even the B horizon, resulting in a plow layer (Ap horizon). The B and/or C horizons may have been broken up by deep cultivation. The soils may have been so degraded by past human actions that they are no longer cultivatable. This study however investigated the variability of arable and forest topsoils in Ngor-Okpala, southeastern Nigeria for sustained soil use.

Materials and Methods

Study area

Ngor- Okpala is located in Imo State southeastern Nigeria lying within Latitudes: 5^{o}. 28’2 – 5^{o}.4’7’N and Longitudes 7.0’ 25” – 7.1’33” E. Ngor Okpala is a Local Government Area of Imo State, Nigeria. Its headquarters are in the town of Umuneke Ngor. It has an area of 561 km^2 and a population of over159,932. It connects Abia and Rivers states of Nigeria. It is the largest local government area in Imo State and one of the largest in Nigeria. The area belongs to the low lying part of southeastern Nigeria, and soils are derived from coastal plain sands and shale. Rainforest vegetation is dominant in the area while it has a humid tropical climate. Total mean annual rainfall is between 1800 and 2500 mm, and is bimodal. Mean annual temperature ranges from 26 to 30 °C. Low-input arable farming is the dominant socio economic activity in the area.The vegetation of Ngor-Okpala is tropical rainforest located in Southeastern Nigerian. The increased activities of man which include bush burning, hunting and farming have apparently converted major part of the original vegetation to secondary forest, savanna and arable soils.

Socioeconomic activities

The major occupation of the people of Ngor-Okpala is subsistence farming with food crops dominating the practice. The agricultural type is mainly the mixed farming where foods crops predominantly planted are cassava and yam. Mixed cropping of cassava with yam or other crops like vegetables is practiced. Generally, agricultural activities at the location are intense and soil information is needed to guide the subsistence farmers on the use of necessary inputs.

Field work

This research was carried out in Okpala community of Ngor-Opkala in order to compare the topsoil physic-chemical properties of forest and arable soils. five samples were collected from each of the land-uses given a total of ten samples for the forest and arable soils. Samples were labeled properly and subjected to laboratory analysis to compare the variability of topsoil physic-chemical properties.

Laboratory soil analysis

Soil samples were air dried, pulverized, and sieved through a 2 mm sieve mesh. The properties analyzed include particle size distribution determined by hydrometer method (Gee and Bauder, 1986). Soil pH was determined in a 1:1 soil/water ratio using digital pH meter and conductivity meter respectively. Exchangeable acidity was determined by the 1N KCl method. Exchangeable basesincluding calcium (Ca), magnesium (Mg), potassium (K), and sodium (Na) were determined using NH_4OAc saturation method (IITA, 1979). Calcium and Mg in solution were determined using Atomic Absorption Spectrophotometer, while K and Na were determined using Flame Emission Photometer. Organic carbon was determined by Walkley and Black dichromate wet oxidation method (Nelson and Sommers,1982). Total nitrogen was determined by micro-kjeldahl technique (Bremner and Mulvaney, 1982). The effective cation exchange capacity (ECEC) was determined by summation method, while the available phosphorus was extracted by Bray II method (Olsen and Sommers 1982).

Statistical Analysis

Coefficient of variation (CV) was used to estimate the degree of variability existing among soil properties in the study site. Coefficient of variation was ranked as low variation ≤15%, moderate variation >15≤35%, high variation >35% was used as outlined by Wilding, (1985). Also, soils were subjected to analysis of variance according to Wahua 1999.

Results and Discussion

The physical properties of the studied soils are as shown in table 1. Arable soils were represented with A1 – A5 while Forest soils were represented with F1 – F5. Sand had means of 86.56 and 84.96% in arable and forest soils respectively. Mean silt and clay were 3.12 and 5.93% for silt, 8.72 and 5.32% for clay in arable and forest soils respectively. The higher content of mean sand in the arable soil compared to its forest counterpart may be due to the regular disturbances of the arable soils for cultivation purposes leading to the disintegration of the soil structure. Clay particles as well as some other soils minerals therefore travel further down into the subsoil through eluviation and illuviation processes. Further disturbance of the cultivated topsoils may have created granulated particles which constitutes more of clay than silt when compared to the forest counterparts. This may be the reasons why the forest soils had more mean silt than the cultivated soils and vice versa in sand and clay components of the investigated soils. Mean silt:clay ratio was higher in forest (1.78) soil when compared to the cultivated (0.548) soil suggesting a higher weatherebility of the arable over the forest soils. The mean bulk density of the arable soils is higher (1.27 g/cm^3) compared to that of the forest (1.13 g/cm^3) counterpart. This may be attributed to the higher sand content of the arable soils compared to the forest soils. Also, it is expected that due to use of the arable soils for crops cultivation, organic matter content would have depleted significantly giving room to higher bulk density.

The forest soils as expected have deposits of litter which decomposes to form organic matter. This organic matter mix p with the topsoil's as well as providing much of the needed nutrients constituents of these soils. This invariably reduces the topsoil bulk density of the forest soils. However, the bulk densities of the studied soils were all within the acceptable bulk density limits (<1.65) of tropical soils (USDA-NRCS 2016). Esheri *et al.,* (2017) noted that bulk density affects some key processes in the soil such as infiltration and microbial activities which in turn influence key soil pedogenic processes as well as productivity. The investigated Chemical properties of the studied soils are as shown in table 2. Soil pH recorded a moderately acidic condition in both arable and forest soils having means of 5.71 and 6.09 for arable and forest soils respectively.

Cropping activity and leaching due to high rainfalls may have affected the basic cations of the arable soils thereby causing the exchange complex to be dominated by more acidic cations when compared to the forest soils. Similar pH result have been documented by Okoli et al., (2017). This pH result is within the pH requirement (5.5 – 6.5) for tropical soils productivity and soil sustainability. Organic carbon, organic matter and total N were all higher at the forest soils compared to the arable soils. Organic carbon, OM and TN recorded 1.115, 1.923 and 0.105% respectively at the arable soils and 1.400, 2.409 and 0.133% respectively at the forest soils. These results are due to the present land use of the investigated soils. Organic carbon and OM of the arable soils may have depleted due to cultivation activities whereas that of the forest soils were rather being built up due to litter accumulation from forest trees. The results of organic matter and total N obtained indicated low at the arable soils and medium at the forest soils when the critical limits were considered (Obasi et al., 2015). Available Phosphorus, basic and acidic cations, total exchangeable acidity (TEA), total exchangeable bases (TEB) and effective cation exchange capacity (ECEC) were all higher in their mean values at the forest soils when compared to their cultivated counterparts. Available P scored 24.27 and 34.21 mg/kg at the arable and forest soils respectively. TEA scored 0.92 and 1.45 g/kg, TEB scored 2.743 and 4.091 g/kg while ECEC recorded 3.66 and 5.537 g/kg all in arable and forest counterparts respectively. Critical limits (Tabi *et al.,* 2012, Obasi *et al.,* 2015) revealed that available P was high (>15 mg/kg) in arable and forest soils which scored 24.27 and 34.21 mg/kg respectively. Calcium was very low (<2.0 g/kg) at the cultivated arable soils and low (2-5 g/kg) at the forest soils. Magnesium was also low (0.5 – 1.5 g/kg) at it scored 1.26 and 1.47 g/kg in arable and forest soils respectively. Potassium was moderate (0.3-0.6 g/kg) scoring 0.38 and 0.519 g/kg in arable and forest soils respectively. Sodium (Na) was low (<0.1 g/kg) scoring 0.055 and 0.079 g/kg) in arable and forest soils respectively. The mean scores of soil physic- chemical properties as well as coefficient of variation and Lsds were as presented on Table 3. Soil properties such as pH, OC, OM, TN, Available P, Ca, K, ECEC, Base saturation sand and bulk density all had low variation both at the arable and forest soils. Magnesium, H, TEA and TEB all varied moderately (MV) at the arable soils and lowly (LV) at the forest soils. Sodium exhibited moderate variation at the arable and forest soils. Aluminum and silt had high (HV) variation at the arable soils and moderate variation (MV) at the forest soils. Clay indicated high (HV) variation both at the arable and forest soils. Analysis of variance at the arable and forest soils indicated that OC, OM, TN, Ca, K, Na, H, TEB and ECEC were all highly significant at 0.01% level. Available P, Mg, TEA and Bulk density were significant at 0.05% level while Soil pH, Al, Base saturation, sand, silt and clay were non-significant (NS) at the arable and forest studied soils.

OC= Organic Carbon, Av.P= Available Phosphorus, TEA= Total exchangeable acidity, TEB= Total exchangeable bases, ECEC= effective cation exchange capacity, %BS=percentage base saturation. LV= low variation, MV = moderate variation, HV = high variation.

Conclusion

The studied soils showed that pH was within the pH requirement (5.5 – 6.5) for tropical soils productivity and soil sustainability. Critical limits revealed that calcium was very low (<2.0 g/kg) at the cultivated arable soils and low (2-5 g/kg) at the forest soils. Magnesium was also low (0.5 – 1.5 g/kg) at it scored 1.26 and 1.47 g/kg in arable and forest soils respectively. Analysis of variance at the arable and forest soils indicated that OC, OM, TN, Ca, K, Na, H, TEB and ECEC were all highly significant at 0.01% level. Careful management of these soils will ensure greater productivity and sustainability.

E-mail otimbuba@gmail.com

Abstract
The research work was conducted at the eastern farm of the National Root Crops Research Institute Umudike, Southeast agro-ecological zone of Nigeria in 2016 and 2017 cropping seasons to investigate the acidic limed soil in combination with nitrogen in Bio-solids to achieve a steady-state for optimal yam production. Initial sample of the soil was analyzed to determine the level of soil acidity, it revealed actually that the soil was acidic thereby phosphate becomes converted into insoluble iron phosphate. The risk of over liming was prevented to overcome phosphorous being converted into insoluble calcium phosphate. The design was randomized complete block design, replicated three times with a plot size of 5 x 5 = 25sq meter. Two different varieties were used which includes; D. rotundata and D. alata. Organic manure was used as nitrogen solids to achieve a steady state in the soil. Under state of lime application and inclusion of bio solids enabled mineralization to be obtained. Appropriate condition was achieved when the organic matter were added to limed soil which gave or resulted to ammonium and nitrate for effective output.

Introduction
The importance of lime stone is in its ability to neutralize soil acidity (Lurry, 2015). Chemically lime is calcium oxide (Cao) (Laura, 2011). In agriculture, lime is usually defined as calcium-magnesium containing compounds capable of reducing harmful effects of an acid soil by neutralizing soil acidity and raising the pH level. Manure nitrogen (N), in both organic and inorganic forms, inorganic (N), mostly ammonium ($NH^4 4$) and nitrate (No3), is really available to plants. Before organic N can be taken up, however, it must first be converted to inorganic forms. This process which is completed by soil microbes as a by-product of organic matter decomposition is called mineralization (David, 2004). Bryant (2013) reached that bio-solids are the nutrient rich organic materials from the treatment of sewage sludge and used in reclamation of agricultural forest and disturbed lands since the 1960s. The manure forage systems mineralization accounts for much or most of the crops needs. An understanding of the mineralization rate concept can help improve manure management to meet crop N demands while minimizing the potential for regulating concerns regarding ground water pollution (David, 2004). Organic manure are considered slow release nutrient sources so that potential for exceeding tree nutrient demands and associated environment contamination is likely reduced relative to synthetic fertilization. The uses of organic materials are often more cost effective and also promotes useful recycling (Bryant, 2013). When manure are regularly added to the soils, the organic N pool gradually increases over time until it eventually reached a plateau known as the steady-state condition (David, 2004). Indebt studies have demonstrated the value of compost and wood clip mulches applied to urban landscapes for improving soil quality and tree growth (Bryant, 2013).
(Bryant, 2013) confirmed that urban tree growth is affected by soil quality and many anthropogenic factors (e.g. pollution, management, disturbances). Compact and to soil removal associated with urban site development have immediate and dramatic negative impacts on soil quality specifically, these activities may strongly alter soil carbon (C) and nitrogen (N) pools. Consequently, soil organic matter (SOM) dynamics should be at the forefront of concerns of stewards of urban trees. The cations on the (cation exchange capacity) CEC of the soil particles are easily exchangeable with other cations and as result they are plant available. Thus the CEC of the

soil represent the total amount of exchangeable cations that the soil can adsorb (Quinne, 2007). Nitrogen mineralization is the process by which N is converted to plant- available inorganic forms. Soil regularly amended with organic wastes will accumulates organic N until they reach a steady-state condition; a concept useful for planning N management strategies (David, 2004). David (2004) had it that at a steady-state, the amount of manure organic N added in a given year will approximately equal the amount mineralized. The mineralization rate is therefore the rate at which organic N is made plant available. He concluded that several factors affect mineralization rates particularly by temperature so that release varies throughout the year a predictable pattern. An understanding of these patterns is necessary to match crop N demands with the plant available N in the soil. Cations are positively charged ions such as calcium (Ca^{2+}), magnesium (mg^{2+}), and potassium (K^{+}), sodium (Zn^{2+}) and copper (Cu^{2+}). The capacity of the soil to hold on to these cations called the cation exchange capacity (CEC). These cations are held by the negatively charged clay and organic particles in the soil through electrostatic forces (negative soil particles attract the positive cations (Quinne Kettering, 2007). Mineralization is a function of temperature, moisture, soil texture and manure characteristics, elevated temperature, dramatically accurate decay. A rule of thumb is that decay rate double for every 18 of microbes live in a film of moisture on soil particles. Too little moisture deprives them of their habitat, while too much can block needed oxygen from infiltrating into the soil as can vary timely textured soils which tends to drain slowly (David, 2004).

The manures that contain bedding materials or that are otherwise rich in carbon can temporarily immobilize nitrogen from the soil, delaying its release to plant available forms. As microbes decompose carbon, they use the liberated energy to grow and reproduce. Nitrogen is a temporary phenomenon; it has a short-term (a few weeks or month) rather than a long term impact on soil fertility (David 2004). Before organic N can be taken up .by plant, however, it must first be converted to inorganic forms. This process, which is completed by soil microbes as a byproduct of organic matter decomposition is called mineralization. This means that the actual CEC of the soil will depend on the pH of the soil. Given the same amount and type of organic matter, a neutral soil (pH ->) will have a higher CEC than a soil with e.g. pH 5 or in other words, the charge will increase with; an increase in pH. Sandy soil low in organic matter have a very, low CEC (less than 3cmol.kg) while heavier clay soils or soils high in organic matter generally have a much higher CEC (greater than 20cmol/kg). The main objective of this study is the evaluation of acidic limed soil in combination with nitrogen in bio solids to achieve a steady -state for optimal yam production. Specific objectives of the study are: To determine whether it perform the duty of supporting the plant growth effectively, To determine whether it eradicate the antagonism in plant nutrients deficiency and To determine the best optimal weight that will give the best production.

Methodology

Research Area

The experimental plots were established in the eastern farm of National Root Crops Research Institute Umudike in 2016 and 2017 respectively. It is RCBD and it is replicated 3times the plot size is 6 x 5 = 30 sqm^{2}. Due to constant cropping the soil was discovered to be acidic which range between 5.30-5.70 pH level.

Treatment Allocation

The lime application took place on the 3/6/2016. The lime application was allowed for a period of time to permeate into the soil. The field marking was followed by and planting which took effect on the 6/6/2016. In 2017 planting was carried out on the 5/6/2017. The following varieties were used; Agba ocha, Ame, Hambakroasi for white yam. The following *D. alata* were used for the trial, they includes Um680, 89/01166 and Gborogboro. The organic matter was applied 8 weeks after planting and all the cultural routine management were observed at the right time.

Statistical Analysis

The harvesting took place on the 5/12/2017. The result was analyzed with analysis of variance (ANOVA) with genstat edition 3 discovery method and significant mean separated with LSD at 5% alpha level.

Results and Discussion

Table 1 illustrates the effect of bio solids on limed soil to obtain a steady state and achieve optimal production of *D. rotundata* and *D. alata* with equal weight of the planting size. Agbaocha, Ame and

Hambakwasi were used for *D. rotundata* while Um680, 89/01166 and Gborogboro were used for *D. alata.* The planting size was l00gm weight across the board. In 2016, the mean weight value for Agbaocha was 11.8kg, Ame weighed 16.9kg while Hamabakwasi resulted gave 27.8kg; the least significant difference of the mean was 7.77. In 2017 the mean value for Agbaocha was 20.6kg; Ame gave 12.6kg while Hambakwasi was 21.67kg. The LSD for 2017 stood at 13.06 alpha level. In 2016 both Ame and Hambakwasi were quite significant, while Agbaocha was insignificant. In aspect of *D. alata,* the following species were used which includes; Um680, 89/01166 and Gborogboro. In 2016, the total mean weight for Um680 stood at 10.73kg, 89/01166 stood at 14.07kg and Gborogboro at 16.23 and the LSD at 5.017 alpha level. In .the 2017, Um680 gave 15.47kg, 89/01166 resulted to 24.43kg and Gborogboro was 23.23kg. In 2016 the result of the analysis indicated that Agbaocha was insignificant with LSD at 1.810 with a mean value of 11.80kg. For Ame and Hambakwasi, they were quite significant with mean weight value of 16.87kg for Ame and LSD at 3.729 while Hambakwasi was 27.83kg at LSD at 5.72. In 2017 the analysis indicated insignificant difference. It shows that improvement increase with respect to Agbaocha will definitely improve the status of Agbaocha production and yam generally.

Table 1: The Effect of Biosolids on Limed Soil

Cropping season Treatment	Weight of planting size	*D. rotundata* 2016 mean value (kg)	2017 mean value (kg)	Treatment	*D.alata* weight panting size	2016 mean value (kg)	2017 mean value (kg)
Agba ocha	100gm	11.8	20.6	Um680	100gm	10.73	15.47
Ame	100gm	16.9	12.6	89/01166	100gm	14.07	24.43
Hambakwasi	100gm	27.8	21.67	Gborogboro	100gm	16.23	23.23
LSD		7.77	1.306	LSD		5.077	4.261

Conclusion

A stable condition was created that limited the presence of the soluble state of Al and Fe, and liming state that necessitates phosphorous converted into insoluble calcium sulphate was addressed. A reliable balance steady state was derived, with the addition of the organic manure into the limed soil function able temperature, moisture, soil texture and "manure characteristics which accelerated the decay of the organic matter response were achieved. Total output increased which indicates a satisfactory outcome without any inclusion of in-organic fertilizer. The vegetative influx could be attributed to absence of carbon and consistent presence of nitrogen with mineralization achieved.

Abstract
In this study, initial lime application was carried out to bring down the acidic state of the soil to a pH level that will grant alkalinity. There was application of a super GRO both on the soil and aerial surface of the plants. The super GRO acted as an adjuvant, wetting agent and synergism. As an adjuvant, it is a multiple mixtures containing lead arsenate aims at decreasing the injury of the mixture to the plant through the addition of corrective, as in the case of lime added lead arsenate-lime sulfur combination or the increase in the efficiency of the mixture through the use of wetting, spreading, or sticking agents. While wetting agents, implies act by lowering the surface tension of water in which they are dissolved, they are substances in which there is a long-chain grouping in the molecule combined with a highly water-soluble group are extremely efficient in lowering surface tension in solution and a synergism is the process of working to gather, is said to occur when two materials, give a greater physiological action when applied together than when applied separately. The area for the planting, comprise of a plot size of 6 x 5 = 30sqm² and ridge of 5 meters constitute a plot size for each yam cultivar. The composition is 10litres of water to 10mls of Super GRO base on recommendation. Super GRO supplemented for organic matter or in-organic fertilizer. The introduction of Super GRO assisted in the achievement of a steady state and which created a balance state in promotion of plant nutrient availability.

Introduction
Laura (2011) noted that lime is calcium oxide and in agriculture, lime is usually defined as calcium or calcium-magnesium containing compound capable of reducing harmful effects of an acid soil by neutralizing soil acidity and raising the soil pH. He defined acidity to mean when there is presence of hydrogen ions dissolved in soil solution (water in the soil) and held on the clay and humus particles. pH. Is a measure of the degree of acidity or alkalinity. A value below 7.0 is acid, 7.0 is neutral and above 7.0 is alkaline. As the soil become more and more acidic (Laura, 2011). One the aspect of nutrient imbalance, some nutrient which supports plant growth does not act independently of one another. They function together and so necessary balance of given nutrient in relation to the other is very important. Too much or too little of a given nutrient may adversely affect the uptake of another. Nutrient imbalance is one of the concerns of soil fertility investigation. In order to make nutrient available, we need omniactivator that act as both an adjuvant and surfactant by reducing the surface tension of water in addition to acting as welting agent. With the introduction of hydrocarbon super GRO (Ethoxylated-Alkylphenol, polysilocane) will assist in the manipulation of the ecosystem in a way to maintain the soil fertility and optimal productivity. In order to make nutrient available, we need omniactivator that act as both an adjuvant and surfactant by reducing the surface tension of water in addition to acting as a welting agent. With the introduction of ethoxylation-alkylphenol and polysiloxane will assist in the manipulation of the ecosystem in a way to maintain the soil fertility and optimal productivity. The main objective of this study is accessing the impact of Super GRO (ethoxylated, alkylphenol, polysiloxane) in combination with acidic limed soil for growth and yield of yam.

Methodology

Study Area

The trial was conducted in eastern farm of National Root Crops Research Institute Umudike in 2016 and 2017 programme of activities in yam programme. It is RCBD and it is replicated 3 times. Pre-cropping soil analysis was carried out for every year planting. In the soil analysis conducted it showed that the soil was acidic with a pH level of 5.30 – 5.70.

Treatment Allocation

The land preparation was followed by application of lime and allowed to permeate in the soil. The following cultivars were used for the experiment which include; *D. rolundata* of the various varieties, Agba-ocha, Ame, Hambakwasi while the following *D. alata* were used for the trial they include Um680, 89/01166 and Gborogboro. The area for the planting, comprise of a plot size of 6 x 5 = 30 sqm^2 and each ridge of 5metres constitute a plot size for each yam cultivar of 50gms 100gms, 150gm and 250mgs weight. The yams were planted from 10/6/2016 to 2nd of June 2017. The applications were both on the floor and aerial with a composition is 10 litres of water to 10mls of Super GRO base on the recommendation of GND Int (PTY) LTD, South Africa.

Statistical Analysis

The first weeding was carried out 8 weeks after planting, followed by the necessary applications. The harvest took place on the 20/1/17 and 4/12/17 for the two planting years respectively. The yield were subjected to analysis of variance (ANOVA) by the use of genstat discovery edition 3 and means were separated with LSD and Duncan Multiple Range Test at 5% alpha level.

Results and Discussion

The results in Table 1 show a mean weight of *D. rotundata* grown in 2016 and 2017 with three major species of different sizes (50 gm, 100 gm, 150 gm, 200 gm, 250 gm). From the result, it can be observed that Agbaocha had the lowest mean yield weight in 2016 which was 2.71 kg, followed by Ame which had 3.79kg and the highest yield for Hambakwasi with a mean weight of 5.57kg. The means of the 3 species do not differ significantly from each other (P ≥ 0.05).

In Table 2 which was comprised of Um680, 89/01166 and Gborogboro, it illustrates the performance of *D.alata* for 2016 and 2017 planting season. In 2016, the highest yield, stood at 89/01166 with a total mean weight yield 15.65 kg followed by Gborogboro with a total mean weight yield of 10.35kg and UM680 with a total mean weight yield of 7.61 kg. In 2016, the planting size of 250gms for 89/01166 out yielded every other species with a mean weight yield of 21.70 kg followed by 150gm also for 89/01166 with mean weight yield of 18.60kg and lastly Gborogboro with 13.33kg using planting size of 150 gms.

	2017	8.033	2.2998	0.00***

This research focused on the boosting strength of super Gro and limed soil on the yield performance of three different varieties of *D. rotundata* and *D. alata*. The combination of this two soil treatments however successfully supported the growth of both white yam and water yam. This finding was, however, not different from the earlier report by Murwira and Kirchman (1993) who noted that combined application of organic and inorganic fertilizer had best influence on tuber characteristics of yams. From the result it was observed that among the *D. rotundata* varieties, Hambakwasi had the highest level of yield. This there confirms that the application of the lime and super Gro fertilizer was more effective on the varieties mentioned. This agrees with the report of Tschannen (2003) who reported that the combined effects of cultivar and manure treatment on the yield varied among the cultivars. Ezakwukpolo cultivar gave the highest tuber yield when treated with NPK fertilizer while Pepa cultivar gave the least under the same treatment but when organic manure was applied to Danacha, the yield was greater than where NPK fertilizer was applied. Similar in this research, 87/01166 and gborogboro had the greater yield and hence, can be said to be due to the effect of the lime soil and the fertilizer on the yield of *D. alata*. It was observed that there was effect of weight of tuber on the yield performance of the various varieties of white yam. Similarly tuber weight of 200g and 250g were generally best in yield performance which may further suggest that tuber weight lower that 200 g may not perform well even under pH control soil and fertilized soil. These two observations suggest that soil fertilization has the potential for improving yam production for early harvesting. Contrary, Akanbi *et al*. (2007) reported longer tubers under yam without fertilizer than fertilizer treatments. The mean tuber girth (cm) was not significantly influenced by fertilizer application. The poor performance of tuber of lower gram weight at harvest may suggest that with a lower weight tuber the soil treatment with super Gro and lime may not affect directly the yield of yam. This is in agreement with the fact that tuber yield was higher with fertilizer and organic manure, yet yields were high enough where no fertilizer or organic manure was applied evidently due to high native fertility of the soil (Asadu *et al*., 1998). Generally white yam grown in 2017 had better yield than that of 2016, while, water yam grown in 2016 had better yield than that of 2017. This may suggest that difference in yam species may affect the expected effect of super gro and limed soil.

Conclusion

For effective yam growth, result shows that as the planting size increases, the output continue to increase until it struck a balance, as from 200gms weight which signifies that for effective weigh yam production 200gms weight is quite appropriate. The Super GRO is efficient for yam production and could effectively substitute for organic manure to achieve balance steady state. It is important for the improvement of the farm land with the inputs to overcome the problem of soil acidity due to constant cropping and improve the soil fertility through addition of the Super GRO to enhance the maximum output of the land.

Abstract
Fertilization of soil is an attempt to balance the competition between plants and soil microbes for available soil nitrogen. Field experiments were conducted at the Teaching and Research Farm of the Abia State University, Umudike location, Nigeria, during the 2009 and 2010 cropping seasons to determine the effects of organic and inorganic nitrogen (N) sources on earthworm activities. The N sources, each applied at the rate of 120kgha-^{1} were urea (UR), sawdust (SD), poultry dropping (PD), Cow dung (CD), brewers' spent grains (BS), pig manure (PM) and combination of the entire organic N sources (CB). Applications of N sources improve earthworm activities when compared with the control (CT).Earthworm population, biomass, cast number and cast weight were all significantly higher (p = 0.05) for the poultry dropping treatment when compared with the other treatments. On the other hand, earthworm population and biomass were lowest for the urea treatment with values of 2.3 /m^{2} and 0.14 g/m^{2} respectively, while cast number and weight were lowest (8.0 /m^{2} and 21.89 g/m^{2} respectively) for the control treatment.
Keywords: Earthworm activities, nitrogen sources and ultisol

Introduction
Soil is not a dead mass but an abode of millions of organisms, which includes crabs, snails, earthworms and others. Organisms, both plants and animals are important in the soil and nutrients can be added into agricultural soil through important biological processes. By creating channels through hardpans and unstructured soil, earthworms may help plant roots to penetrate deeper into the soil, since roots tend to follow the pathways of least resistance (Logsdon and Linden, 1992). Most earthworms that dwell in the soil rearrange it to suit their needs, creating different kinds of physical structures such as burrows, chambers for aestivation or cocoon deposition and casts. Through their feeding and casting activity earthworms affect both aggregate size and stability (Mackay and Kadivko, 1985). They also affect infiltration rate of a soil through their burrowing action. In soils where earthworms are active, the soil surface configuration is generally uneven and fragmented as a result of cast deposition and burrow openings. Nitrogen is in the atmosphere, soils and biological material of the terrestrial environment. In agricultural soil, mineralization of N by soil microbes is a most important process (Boyes*et al.,* 2011). Therefore, it is the soil microbial population which controls the productivity of these soils if environmental factors are suitable. Nitrogen tied up (assimilation) in microbial cells is not available for plants and other microbes until that tissue has been decomposed by other microbes. Also reported, is that microbial biomass is a reliable pool of OM and thus serves as an important reservoir of plant nutrients such as N, P and S. There has been increase in recent years in managing earthworms to improve crop production and offset soil degradation (Baker *et al*., 1996). These studies have shown that the earthworm activity of all species is beneficial for the soil environment as well as crop growth and yield while others showed no effect (Temple smith *et al.,* 1993) and others showed decreased plant growth (Double *et al.,* 1997*).* Several studies on the use of biological wastes for improving the productivity of fragile soils have been carried out in the tropics. Mbagwu (1989) compared the effectiveness of inorganic fertilizers and cattle feed-lot manure, rice husks, poultry manure and sawdust in improving subsoil productivity under greenhouse condition. Brewers'

spent grain (BS) organic manure produced highest grain yield of maize and cowpea when compared with other organic manures used in the study and was attributed to high earthworm activity (Njoku, *et al*., 2011). These studies attempted to find ways of utilizing these waste materials so as to minimize the disposal problems associated with them. Therefore, the objective of this study is to determine the effects of different nitrogen sources on earthworm activities in Southeastern Nigeria.

Materials and Methods

Field experiment to examine the effect of nitrogen sources on earthworm activities in maize – cowpea rotation cropping in an ultisoil in southeastern Nigeria was conducted at Abia State University, Umuahia Campus Teaching and Research Farms in 2009 – 2010. Abia State is located at (5^0 25'N and 7^0 35'E) in the rainforest ecological zone of Southeastern Nigeria. The area lies at about 129 m above sea level as measured with hand held global positioning (Garmin, Ltd. Kansas, USA).The climate of the area is humid tropical and supports the lowland rain forest vegetation. It is characterized by two distinct seasons – the wet season from April to October and the dry season from November to March. The mean annual rainfall ranges between 1900 - 2000mm. The experimental design was randomized complete block (RCB) replicated three times. Maize (*Zea mays L. Var.hybrid supper Oba* - 2) was planted during raining season. Cowpea (*Vignaunguiculata L. var. IR* – 48) followed after harvesting of maize during dry season. The treatments were control (CT), urea (UR), sawdust (SD), poultry dropping (PD), cow dung (CD), brewer's spent grain (BS), pig manure (PM), combination of all the organic manure (CB) and were applied at the recommended rate of 120 kg N ha^{-1} for maize in the Southeastern Nigeria. The organic nitrogen sources used were chemically analyzed (Table 1) and were cured for 10days. First weed control was done by spraying herbicides immediately after planting of maize and cowpea respectively. Subsequent weed control was done by hoe weeding as was necessary. Earthworm cast and earthworms were collected after cowpea harvest in all the plots in 7days to determine earthworm population, earthworm biomass, earthworm cast number and earthworm cast weight. Composite soil sample was collected after cowpea harvest. Thus, data collected were subjected to standard statistical analysis of variance (ANOVA). Treatment means were separated using least significance difference (LSD) at 5% level of probability test. Data were also subjected to linear regression and correlation analysis using SAS (1996) package.

Table 1: Some chemical properties of the nitrogen sources used in the study

Nitrogen sources	(%)				
	N	Ca	Mg	K	Na
Pig dung (PM)	1.47	0.52	0.05	0.27	0.19
Poultry dropping (PD)	1.57	1.20	0.05	0.40	0.31
Brewers' spent grains (BS)	5.95	0.90	0.30	0.05	0.28
nSawdust (SD)	0.28	0.70	0.18	0.28	0.08
Cow dung (CD)	1.30	0.48	0.07	0.28	0.78
Urea (UR)	46.6	-	-	-	-

Results and Discussion

Mean effects of nitrogen sources on earthworm population and earthworm cast number sampled after cowpea harvest in 2009 and 2010 are shown in Table 2. As indicated in Table 2, earthworm population, earthworm biomass, earthworm cast number and earthworm cast weight were all highest under PD treatment. Mean values for two years, the treatment was earthworm population (4.9 /m^2), earthworm biomass (0.68 g/m^2) earthworm cast number (13.3 /m^2) and earthworm cast weight (49.05 g/m^2). On the other hand, mean values of earthworm population and earthworm biomass were lowest under UR treatment with values of 2.3 /m^2 and 0.14 g/m^2 respectively, while mean values of cast number and cast weight (8.0 /m^2 and 21.89 g/m^2 respectively) recorded for the CT treatment. Mean values of earthworm population measured in 2009 and 2010 were of the order PD > SD > CD = PM > CB > CT > BS > UR, while mean values of worm biomass were of the order PD > PM > BS = CB > CD > SD > CT > UR. Similarly, mean values of cast number were of the order PD > CB > BS > CD = PM > SD > UR > CT, while mean values of cast weight were of the order PD > CB > BS > PM > CD > SD > UR > CT. The results of this study showed that organic sources of nitrogen provided a good suits tract for earthworm activities far above the inorganic nitrogen source and the control. As indicated in Table 3 there was significant differences (p = 0.05) in some chemical properties of earthworm cast produced under the different nitrogen sources. Soil pH in 1:1 soil-water suspension did not show any significant difference indicating that pH of the casts ranged from moderately acid to very strong acid (USDA – NRDS, 1998). Soil organic carbon, total nitrogen and C: N ratio indicated significant differences in their soil properties among the different nitrogen sources. SOC highest under SD and lowest under CT, highest Total nitrogen was recorded under UR and lowest under CT. The highest C: N ratio was recorded under SD treatment while the lowest was recorded under UR treatment. Among the organic nitrogen sources, there were no significant differences in C: N ratio between PD, CD, BS, PM and CB treatments. The C: N ratio of the CT was significantly higher than the values obtained for all the nitrogen sources, while the C: N ratio for UR was significantly lower than those obtained for the organic nitrogen sources. Data on available phosphorous indicate that the highest value was measured under PD, while the lowest value was measured under SD. All the nitrogen sources had higher available phosphorous content than the SD and CT treatment. Exchangeable Ca was significantly high under SD, PD, CD, BS, PM and CB when compared with CT and UR. There was no significant differences in exchangeable Ca between SD, PD, CD, BS, PM and CB, as well as between CT and UR. Highest value of exchangeable Mg was measured under CD, while the lowest value was measured under CT. For exchangeable K, highest value was measured under PD, while the lowest value was measured under CT. For exchangeable Na, highest value was measured under CD, while lowest value was measured under CT. Exchangeable acidity and ECEC were highest under CD and lowest under CT. there was no significant differences in base saturation among the different nitrogen sources. Values for all base saturation were all high (>90.0%) for all the nitrogen sources. Data on chemical properties of worm casts reported in this study confirm those previous researchers (Okoro, 2010), who reported that properties of worm cast are affected by soil management practices such as organic manure and inorganic fertilizer application. Data presented in Table 4 indicate that worm cast had higher pH value than the corresponding soil. The observation confirms reports by Okoro, 2010. According to Lee (1985), the higher pH in cast could be as a result of the actions of calciferous glands in the worm pharynx when soil is ingested. Higher pH values in casts maybe beneficial particularly in the acid soils (with acid Ultisols in south-eastern Nigeria) where low pH can inhibit nitrification. Data in Table 3 also showed that earthworm casts were characterized by higher SOC, total N, available P, ECEC and exchangeable Ca, Mg, K and Na than the surrounding soil but similar exchangeable acidity and base saturation with the surrounding soil. Jouquet*et al.,* (2008) also reported that worm casts had higher SOC, total N, available P, ECEC and exchangeable Ca, Mg and K contents than the surrounding soils. The results of this study seem to indicate that the addition of nitrogen containing materials will increase earthworm population and activities in the soil.

Conclusion

The results of the study indicated that the addition of nitrogen containing materials will increase earthworm population and activities in the soil. Earthworm population and activities were all significantly higher ($p = 0.05$) for the poultry dropping treatment when compared with the other treatments and lowest for the urea treatment and control treatment.

Abstract
A study was conducted at the screen house of the Teaching and Research Farm of Akwa Ibom State University, to evaluate the effects of crude oil pollution levels and plant species on soil properties. Twelve varieties of plant species (Axonopus compressus, Pennisetum purpureum, Eleusine indica, Panicum maximum, Leuceana leucocephala, Gliricidia sepium, Talinum fructicosum, Chromoleana odorota, Cyperus rotundus, Calapogonium mucunoides, Jatropha curcas,Centrosema pubescens) and a control with four levels of crude oil (0, 2.5, 5.0 and 7.5 % (w/w)) were fitted into a Completely Randomized Design with three replications. Significant differences were observed among crude oil pollution levels and different plant species used on the soil chemical properties while there was no significant effect on the texture of the soil. At 2 and 4 months after crude oil pollution, increase in crude oil pollution level significantly (P < 0.05) decreased the soil pH, available P, exchangeable bases and ECEC while organic carbon, total nitrogen and base saturation were significantly increased relative to the control.
Keywords: Crude oil, plant species, pollution, soil properties and Niger Delta

Introduction
Contamination of soils with petroleum hydrocarbon and their subsequent degradation has become a major concern because of the critical role of soil resources in promoting sustainable environment and economic development. Both inorganic and organic compounds in soils may not only adversely affect their production potentials but may also compromise the quality of the food chain and the underlying ground water. The survival of any human being depends on the quality of the soil. Soil supports terrestrial life through detoxification of pollutants, biomass production, restoration and resilience of ecosystems and cycling of some nutrients like carbon, boron, phosphorus, sulphur and water (Lal, 2001). Soil quality is depleted as the soil is contaminated through individual or combined processes such as crude petroleum oil pollution. When a soil is polluted, its capacity to produce is reduced.Oil pollution is of a great concern the world over; contamination of the environment by crude oil is a global problem in that it leads to loss of vegetation, food insecurity and biodiversity. Considering the detrimental effects of crude oil pollution on soil and plants and its attendant implications on food security and environmental integrity, this study was designed to evaluate the effects of various levels of crude oil pollution grown with different plant species on soil physicochemical properties of the Niger Delta Region of Nigeria.

Materials and Methods
Experimental site: The experiment was conducted at the screen house of the Teaching and Research Farm ofFaculty of Agriculture, Akwa Ibom State University, Obio Akpa Campus in Oruk Anam Local Government Area. Obio Akpa is situated between latitude $4^{o}30^{1}$ and $5^{o}30^{1}$N and longitude 7^{o} 31^{1} and $8^{o}0^{1}$E (SLUK, 1989). The total rainfall ranges from 2000- 2500 mm annually

while the mean temperature ranges from 24 -30^{o}C. The mean relative humidity ranges between 75- 79%.

Experimental materials/sources and preparation: Plastic buckets (5litres capacity) were perforated at the bottom to allow for easy drainage and facilitate aeration.Top soil (0-30 cm) used for the experiment was taken from the Teaching and Research Farm of the Faculty of Agriculture, Akwa Ibom State University, ObioAkpa Campus using a spade. Crude oil was obtained from Shell Petroleum Development Company (SPDC) Limited, Port Harcourt, Rivers State, Nigeria.

Treatments, experimental design, application and planting: Twelve varieties of plant species *(Axonopus compressus*, *Pennisetum purpureum*, *Eleusine indica*, *Panicum maximum,Leuceana leucocephala*, *Gliricidia sepium*, *Talinum fructicosum*, *Chromoleana odorota*, *Cyperus rotundus*, *Calapogonium mucunoides*, *Jatropha curcas,Centrosema pubescens)* and a control (no plant) were grown in soils polluted with four levels of crude oil (0, 2.5, 5.0 and 7.5 % (w/w)). The experimental design used was a Completely Randomized Design with three replications.

To each of the perforated plastic bucket containing 5 kg of soil, the various levels (0%, 2.5% , 5%, 7.5%)of crude oil pollution were thoroughly mixed with the soil and watered to field capacity for a period of seven days before planting the species. The duration of the pot experiment was four months.

Soil sampling/processing and laboratory studies: One composite soil sample was taken before experiment and soil in each pot was sampled at 2 and 4 months after pollution for laboratory analysis. The soil samples were air dried, ground and sieved with 2 mm size sieve and physicochemical properties analyzed following standard procedures as outlined by Udo *et al*. (2009). The properties analyzed include particle size distribution, soil pH (H_2O), organic carbon, total nitrogen, available phosphorus, exchangeable bases and exchangeable acidity. Effective cation exchange capacity and base saturation were calculated.

Sample of the crude oil used for the study was also subjected to chemical analysis using standard procedures.

Results and Discussion

Properties of the soil and crude oil used for the study: The result of the physico-chemical properties of the soil before crude oil application is shown on Table 1. Particle size distribution was dominated by sand with texture being loamy sand. Soil pH was slightly acidic (6.1) organic matter and available phosphorous were high while total nitrogen was low as classified by Chude *et al*. (2012). Results of the analysis of crude oil are also presented in Table 1.

Effects of crude oil pollution levels on soil properties at 2 and 4 months after pollution

The effects of crude oil pollution levels on some physicochemical properties of the experimental soil at 2 and 4 months after pollution are shown on Table 2.At 2 and 4 months after pollution (MAP), successive increase in the concentration of crude oil had no significant ($P > 0.05$) effect on soil texture. Similar result was obtained by Marines cu *et al*. (2001) and Abosede *et al*. (2013), who reported that pollution of the soil with crude oil, had no significant influence on textural classes of the soil when compared with the control. At 2 and 4 MAP, there was significant reduction ($P<0.05$) in the soil pH level among the different pollution levels when compared with the control (Table 2). The pH value was highest in the control pot where there was no pollution and was least in the 7.5 % (w/w). It was observed that, pH decreased with increased in the concentration of crude oil. This is in line with the observation of Ijah *et al*. (2008) who observed decrease in pH value in crude oil polluted soils. This acidity may be associated with the acidic nature of the oil or may also be attributed to the leaching of basic cations in soil solution which is typical of soils of the south eastern part of Nigeria. At 2 and 4 MAP, percent organic carbon and total nitrogen contents were higher at 7.5 % (w/w) pollution level and least in the control (Table 2). Ijah *et al*. (2008); Eneje *and Abomotei* (2011) and Ogboghod *et al*. (2004) also reported increases in percent organic carbon content in the soil with crude oil pollution and attributed this to microbial mineralization of crude oil in the soil. Higher concentration of soil total nitrogen with higher pollution level of crude oil in this study agrees with the report of Udo (2008), who reported increases in percent total nitrogen in polluted soils. This observation suggest that the crude oil could contain nutrients (nitrogen) or initiate soil reactions that favour the availability of soil nutrients in polluted soils. The available phosphorus differed significantly ($P<0.05$) among the different pollution levels (Table 2). This result confirmed existing studies by (Ogboghodo *et al*.(2004), Isirimah *et al*. (1989) and Eneje and

Ebomotei (2011) who observed decreases in availablephosphorus with increases in crude oil pollution level. At 2 MAP, the control pots recorded the highest content of exchangeable bases and acidity. However, at 4 MAP, the control was not significantly different in exchangeable bases from the oil impacted soils. The reduction in Ca, Mg, K and Na may be due to nutrient immobilization or complexation in the soil after uptake by plant. Base saturation values were not significantly different ($P>0.05$) among the different pollution levels and the control at 2 MAP. At 4 MAP, values were much higher in the polluted soils than the unpolluted soil (Table 2).

Effects of different plant species grown on crude oil polluted soils on some chemical properties of the soil

The results of the effects of different plant species grown on crude oil polluted soils on some chemical properties of the soil are presented in Table 3. Soil planted with *Pennisetum purpurem* (V_2) had the highest pH value while soil planted with *Centrosema pubescens* (V_{12}) had the highest total N content. Significant ($P\leq0.05$) differences were observed in organic carbon, available phosphorus, exchangeable bases and exchangeable acidity. The result shows that, the different plant species decreased the exchange acidity of the soil. At 2 MAP, there was no significant ($P\leq0.05$) different in base saturation among soils planted with the different plant species when compared with the control (Table 3) but at 4 MAP soils planted with *Eleusine indica* (V_3) and *Pennisetum purpureum* (V_2) had the highest content of base saturation.

Conclusion

Different plant species grown in crude oil polluted soils impact on soil properties differently. Successive increases in crude oil pollution significantly ($P < 0.05$) decreased the soil pH, available P, exchangeable bases and ECEC while organic carbon, total nitrogen and base saturation were significantly increased relative to the control.

Table 1: Physicochemical properties of soil before experiment and characteristics of the crude oil used

Soil property		Characteristics of crude oil	
Parameter	**Value**	**Parameter**	**Value**

Abstract
The study assessed farmer's use of soil survey information in crop production and local classification of soils, Niger state. Nigeria. Multi stage sampling technique was used to select 120 respondents within the three agricultural zones of the state for the study. Data for the study were collected using a structured questionnaire. Descriptive statistics was used to analyse the data. The result revealed 99.2 % of the respondents know about soil information with 64.2 % introduced to soil information by extension agents. Majority of the respondents were not aware of the importance and use of soil information, with the mean level of awareness of farmers towards soil was low with average of 1.78. Majority of the respondents agreed with the notion that soil information can increase productivity and lead to sustainable agriculture, with the mean level of agreement revealed to be high with an average of 3.64. The respondents disagreed with the notion that soil information is needed for only large-scale farming. The study also revealed that 66.7 % of the respondents locally classify their soils in the study area, using topsoil physical characteristics such as soil colour, soil weight and feel as indicators for classification. The respondents were not aware of the importance of soil information, but are willing to adopt the use of soil information, if more awareness programs and reduced cost of soil analysis are in place. The respondents classify soils locally but their classification lacks depth, with need for in-cooperation of scientific classification, which can lead to a more accurate local classification of the soil.
Keywords: Soil survey information and Local classification

Introduction
Soil plays a major role in the quality of our environment. It is the foundation for food and fibre production. Knowledge of soil is required for land use planning activities and the decision of what use a particular soil type could be assigned. Moreover, understanding of soil properties and processes is important in evaluating the criteria for soil management and cultivation and agricultural production. Esu (2004), Lobry de Bruyn and Andrew (2016) noted that increase in demand and lack of information on soils contribute to the problem if soil degradation and world food crises, due to the wrong use and poor management of land resources. Achukwu *et al*. (2013), Sharu *et al*. (2013) stated that for sustainable land management, information on the soil resources and how to manage them is needed and this is achieved through characterization, classification and evaluation of the soil. Lobry de Bruyn and Abbey (2003), Lobry de Bruyn and Andrews (2016) all noted that there a lot of barriers to collecting and acting on soil information, with majority of farmers soil-information poor, or at least they are not informed as to the condition of their soil by soil testing. A challenge to agricultural production is that farmers, in particular small-scale farmers, do not know the status of their soils. The ability to have data that can move across states and borders are vital for the agricultural sector in today's global market environment (FAO, 2017), the only way agricultural production can be sustained is when farmers can assess adequate and accurate data. In Nigeria there is a lack of collection and management of agricultural data and inadequate data in agriculture will hinder foreign direct investment and governments efforts to reform the agricultural sector, since quality data improves both sectoral benefits and real economic benefits (Essiet, 2015). In Nigeria, like most developing countries, one primary

constraint to sustainable and successful agricultural program, is lack of knowledge about the soil resources and how to manage them (Achukwu *et al.,* 2013). Boonsompopphan *et al*. (2008) noted that with the ability of farmers to identify soil series farmers could obtain site-specific nutrient recommendations and as a result of applying site-specific nutrient management. In Niger, there have been wide spread survey of the soil, documenting the fertility status in conjunction with management practices which can improve the soil fertility and reduce soil degradation. However, these recommendations have majorly not been adopted by farmers, with the reason for this basically being the lack of knowledge and information by the farmers. Also, there has been lack of knowledge of the perception of farmers towards soil data and their willingness to use the data presented to them, which might have led to bridging the gap between researchers and farmers. Since, there have been few studies in Minna, that document farmers view on soil data and their utilization. The study was therefore designed to identify how soils are classified, assess the level of awareness, perception and use of soil information by farmers in crop production in Niger State, Nigeria.

Methodology

The study was carried out in the three agricultural zones of Niger State, Nigeria. It lies between longitude 6^0 25′ E and $6^0$45′ E and Latitude $9^0$24′ N and $9^0$48′ N and is at an elevation of 299 m above sea level. Niger falls under the Southern Guinea Savanna agro-ecological zone of Nigeria, the climate of Minna is sub-humid with mean annual rainfall of 1284 mm and a distinct dry season of about 5 months duration occurring from November to March (Ojanuga, 2006). The mean maximum temperature remains high throughout, about 33.5^0 C, particularly in March and June (Ojanuga, 2006). The soils of the study area are grouped under the Southern belt of forest soils which have underlying rocks of granite or clay, with soils rich in clay loam, and zone of alluvial soils which are fresh - water soil of grey to white sand, grey clay and sandy clay with humic topsoil (Iloeje, 2001). The soils are generally low in organic matter, total nitrogen and available phosphorus with high erodibility, are structurally weak, coarse textured with low organic matter status (Ahmakhian and Osemwota, 2012). A multi-stage sampling technique was used to select the respondents for the study. Stage one involved random selection of one (1) Local Government Area from each agricultural zone, stage two (2) was random selection of two (2) villages from each Local Government Area. Stage three (3) was random selection of twenty (20) rural farmers from each village to give 120 respondents for the study. Primary data was collected with the use of structured questionnaire, complimented with an interview schedule. Data collected was analysed using descriptive statistics such as mean, standard deviation, pie chart, bar chart, percentages and frequency distribution as appropriate. Attitudinal measuring scale like likert rating scale was also used to categorize the respondent responses into 3-point and 5-point likert rating scale.

Results and Discussion

Institutional characteristics

Table 1 shows that majority of the respondents (52.5 %) are permanently practising agriculture with 28.3 % utilizing trading as a secondary occupation. The table also shows that (99.2 %) of the farmers have contact with agricultural extension agents, with frequency of the contact majorly bi-weekly (42.5 %), which may lead to higher rate of adoption of information and new technologies. This is accordance with Shehu *et al*. (2016) who noted that farmers who had more contact with extension agents are more than two times likely to adopt modern technology than those with no access to extension agents.

Table 1: Some institutional characteristics of respondents

Variables	Frequency	Percentage
Secondary occupation		
Farming	63	52.5
Trading	34	28.3
Civil servant	2	1.7
Processing	21	17.5
Cooperative Membership

No	1	0.8
Frequency of Contact		
Weekly	28	23.3
Bi-weekly	51	42.5
Monthly	41	34.2

Source: Field survey, 2018

Distribution of respondents on knowledge about soil information

Majority (99.2 %) of the respondents know about soil information. This may be due introduction by extension agents, since the framers have a high level of contact with extension agents. Majority of the respondents (64.2 %) were introduced to soil information by extension agents and 57.5 % of the respondents use form soil information, while carrying out farming activities.

Local classification of soil

Table 3 shows respondents from different localities possess varying local classification of soils, which were based on colour, weight and feel of the soil, which are observable top soil characteristics. This is similar to the findings of Nethononda and Odhiambo (2011) who observed that farmers classified soils based on top soil characteristics not taking into consideration of subsoil characteristics. This may be due to the farmers believe that most crops they cultivate majorly occupy the topsoil. Kuyi village farmers classified soils based on colour (red and white soil). The red soils are regarded as light clay soils and white soils regarded as loamy dark soils, with both type of soils used for both yam and maize farming. Taxakpan village farmers classified their soils locally based on weight (light and heavy soil). Where the light soils are regarded as loamy soils used for Maize, Ground nut, Cowpea and Yam farming, while Heavy soils are regarded as clay soils used for majorly rice farming. Sabon Rijiya and Kakapanji village farmers classified their soils based on its feel. Sabon Rijiya respondents classified their soils as smooth and rough soil, with smooth soils regarded as clay soils used for majorly rice farming while rough soils are regarded as sandy to loamy soils used for maize and ground nut framing. Kakapanji village respondents classified their soils used smooth and stony soil, with smooth soils regarded as clayey soils used for rice farming while stony soils are regarded as sandy to loamy soils coarse feel used for Maize, yam and Ground nut farming. The table shows that 66.7 % of respondents within the study area classify their soils locally, which aid them in selecting crops that they cultivate, which in turn increase land sustainability. This is in collaboration with findings with of Nethononda and Odhiamo (2011) who stated farmers local classification is important for sustainable agricultural development planning and land suitability evaluation in developing countries where financial resources are scarce.

Table 3: Local classification of soils by respondents

Classification	Frequency	Percentage
KUYI VILLAGE		
Red soil	20	100
White soil	20	100
TAXAKPAN VILLAGE		
Light soil	20	100
Heavy soil	20	100
SABON RIJIYA		
Smooth soil	20	100
Rough soil	20	100
KAKAPANJI		
Smooth soil	20	100
Stony soil	20	100
Total	80	66.7

Source: Field survey, 2018

Awareness if respondents about soil information

Table 4 shows the awareness of farmers about soil information in the study area. Awareness about soil information (1.98), awareness on use of soil information (1.93) and awareness that soil information improves yield (1.79) were the statements the farmers were most aware about. All the mean scores were than 2.00 indicating they are generally not aware of all the statements on table 4. This may imply that most farmers do not use standard soil information for farming. Okunola (2009) stated that awareness is the first stage of adoption before respondents develop interest in the technology and later decide on adoption.

Table 4: Awareness of respondents about soil information

Statements	HA	A	NA	WS	WM	Decision
Awareness about soil information	0	118	2	238	1.98	Not aware
Awareness of use of soil information	0	112	8	232	1.93	Not aware
Awareness on importance of soil information	9	49	62	187	1.56	Not aware
Awareness that soil information improve yield	23	49	48	215	1.79	Not aware
Awareness that soil information improves fertility	13	61	46	207	1.73	Not aware
Awareness that soil information reduces cost of production	11	66	43	208	1.73	Not aware
Awareness that soil information reduces soil deterioration	14	61	45	209	1.74	Not aware

HA = Highly aware, A = Aware, NA = Not aware, WS = Weighted sum, WM =Weighted mean

Farmers' perception about soil information

Table 5 shows the perception of farmers towards soil information. Improvement of yield (3.98), improvement of soil fertility (4.20), encouragement to farm (3.86), lack of knowledge on soil information (3.83) and high cost of soil analysis (3.71) were the statements the respondents majorly agreed upon with the mean scores above 3.00. This means that if farmers are educated about soil information, they are able to understand, utilize and transfer soil information to other farmers. This is similar to the findings of Duruiheoma *et al.* (2015) who stated that highly aware farmers aid in transferring knowledge between older farmers and farm owners, through a possible knowledge transfer network, where knowledge about soils are shared.The farmers majorly disagreed with the perception that soil information is only necessary for large scale farming (2.14), which may mean farmers are willing to adopt use of soil information in their farming activities if made available to them, with reduced cost of soil analysis being the incentive they require.

Table 5: Perception of respondents about soil information

Statement	SA	A	UD	D	SD	WS	WM	Decision
Soil information improves yield	0	118	2	0	0	478	3.98	Agree
Soil information improves soil fertility	27	90	3	0	0	504	4.20	Agree
Soil information is necessary for agricultural production	22	51	43	4	0	451	3.76	Agree
Soil information encourages people to farm	30	45	43	2	0	463	3.86	Agree
Soil information reduces soil deterioration	16	35	68	1	0	426	3.55	Agree
Soil information is only necessary for large scale farming	0	0	18	101	1	257	2.14	Disagree
Soil information reduces stress	1	72	47	0	0	434	3.62	Agree
Soil information is too expensive	0	85	35	0	0	445	3.71	Agree
There is lack of knowledge on soil information	4	93	22	1	0	460	3.83	Agree
Inadequate information on soil information	5	76	38	1	0	445	3.71	Agree

SA = Strongly agree, A = Agree, UD = Undecided, D = Disagree, SD = Strongly disagree

Conclusion

The result of this research showed that majority of the farmers have been introduced to soil information but not all use it for farming. Even though, they were introduced to soil information there is a gap in knowledge regarding the relevance and use of soil information, due to the fact that extension agents did not disseminate such information to the farmers. The farmers also agree with the notion that soil information can increase agricultural productivity and bring about sustainable agriculture, although this depends on the availability of soil information to them in terms of reduced cost of soil analysis and more awareness programs. The farmers identify fertile soils based observable characteristics majorly crop yield, soil colour and soil texture, this form of identification does not take into consideration of the fertility status of the subsoil. Most of the farmers classify their soils locally and this serves as a means of selecting specific crops to suit specific crop types, although there is a gap between scientific classification of soils and local classification with local classification only taking into consideration the colour and texture of the soil, linkage between farmers, extension agents and soil scientist can bridge the gap in classification allowing for farmers to in-cooperate more parameters into their form of classification.

Water Resources Management in Nigeria: Challenges and Way Forward for Sustainable Agriculture

A.C. Ifejimalu
Department of Agriculture, Alex Ekwueme Federal University Ndufu – Alike, Ikwo, Ebonyi State
E-mail: austol20@gmail.com

Abstract
Water resources management in Nigeria is neither homogenous, nor constant or consistent overtime. They vary from one region to another, sometimes even within a single state, from one season to another, and also from one year to another. This paper is a review of water resources in Nigeria, challenges and way forward for sustainable agriculture. Climate variability, growing urban demand, unrestricted extraction, land use change and poor funding were identified as some of the challenges. Solutions to the challenges of water resources management depend not only on water availability, but also on many other factors, among which are the processes through which water is managed, competence and capacities of the institutions that manage them, prevailing socio-political conditions and expectations which affect water planning, development and management processes and practices, appropriateness and implementation status of the legal and regulatory frameworks.
Keywords: Water resources management, challenges, agriculture, and Nigeria

Introduction
Nigeria is endowed with abundant natural water resources evident in her substantial yearly rainfall, large surface bodies of water-rivers, streams and lakes, as well as in abundant reservoirs of underground water whose extent and distribution have not been fully assessed. With a population of 167 million (Oyebande, 2011), Nigeria is the most populous country in Africa, with a GDP second only to South Africa's. Yet, following several years of military rule and poor economic mismanagement, Nigeria experienced a prolong period of economic stagnation, rising poverty levels, and the decline of its public institutions in spite of her abundant human and natural resources. Water Resources Management is of direct interest to the society as a whole, as well as to most development related public institutions at central, state and municipal levels, academia, private sector and non-governmental organizations (NGOs) (Okeke and Uzoh 2009). Such widespread interest in water is not a unique situation, as many water professionals have often claimed: it is equally applicable to other important sectors like food, energy, the environment, health, communication or transportation (Akpor and Muchie, 2011). All these issues command high levels of social and political attention in all modern societies, although their relative importance may vary from one state to another, and also overtime. In an increasingly interrelated and complex world, many issues are of high interest for assuring good quality of life of the people (Velayutham, 1999).
Development had been conventionally based on the use of natural resources since the vast population is rural and agricultural production is the main occupation. However, if land is expected to continue to produce, this and other resource base must at least be maintained, rehabilitated and properly managed. Fortunately, however, government and some non-government agencies, for instance the Nigeria conservation society are getting involved in creating an awareness of the need to use judiciously and to preserve the Nigerian environment (UN Water Report, 2012). Although preservation and other measure so far taken are steps in the right direction, they do not appear to be adequate, particularly in ensuring a widespread knowledge, especially among farmers of the relationship between the use of the environmental resources and its effects on agricultural and

sustainable development, hence, this paper is a highlight on water resources management in Nigeria – challenges and way forward for sustainable agricultural production.

Challenges of Water Resources Management in Nigeria

According to Salami *et al.* (2013), the main challenges facing the development and management of water resources in Nigeria include:

a. *Climate variability:* Increasing evidence of variability in earth's climate has prompted concern and controversy. The need to cope with existing variability and to adapt and build resilience brings significant implications for water resources availability and reliability associated with the greater likelihood of extreme events. There is mounting evidence of trends in hydrological series. Many areas face a drying and warming climate and thus potentially less water availability. Notwithstanding, flood experience which sub-merged some communities in some states once more called to remind the need for adequate measures and exigency of a structured plan that would serve as comprehensive guide in water resources management in Nigeria.
b. *Growing urban demand:* Due to the pressure of rapid population growth as well as poor management, the available resources of water are being depleted at a faster rate and the situation seriously underlines the need for taking up integrated plans for water conservation and utilization for every agro-ecological area to meet the increasing demands of irrigation, water harvesting, human and livestock consumption, expanding industry, hydro-electric power generation, recreation, navigation and other uses. Demand for water has increased dramatically resulting from, inter alia, increased wealth and increased demand for food and energy generation.
c. *Lack of basic planning data:* A major constraint to water resources development and management in Nigeria is lack of basic planning data. The role of data collection has regrettably either been underplayed or ignored. "It is therefore always very difficult to assemble reliable and adequate technical and socio-economic data capable of assisting in the assessment, planning, design, construction and maintenance of various development projects". Many projects have therefore failed because of the unreliable and inadequate data on which analysis planning, development and management were based.
d. *Allocation of water resources:* The water in many supply systems has been allocated on the basis of past availability or existing demand and has not been kept in line with current or future availability; thus, many systems are over-allocated. Also, the situation of water supply in urban and rural area is far from adequate. In many states, a sizeable population is not served by pipe borne water. Most of the populations in this zone do not have access to portable pipe borne water; most families collect water from unsafe sources, such as rainfalls, ponds, streams and rivers for domestic use and most of these sources are contaminated, thus leading to death of thousands due to water borne diseases. Lack of equitable access to potable water and sanitation, particularly in rural areas leads to greater time and effort spent on water collection by vulnerable groups including women, the poor, the aged, and children.
e. *Unrestricted extractions:* In many areas, there are no management plans or restrictions on water extractions (for example, pumping from rivers and groundwater extractions). These have resulted in less water being available. The expansion of farm dams in some areas also reduces the supply of water entering river systems, the indiscriminate springing up of boreholes across the various communities, states of Nigeria and even the unruly attitude of people toward building in water-ways, require precautionary measures that would prevent future flooding.
f. *Land-use change:* Clear-felling, expanding plantations and the opening of new areas to agriculture, all have impacts on the water resource. Some event, such as bush fires, leads to a reduction in the available water and water-quality problems. Changes to land use, even within agricultural areas and industrial area, have implications on both water availability and water use.
g. *Funds:* The challenge confronting the water sector in the area lies in meeting the staggering financing and capital investment required to increase the management of water resources. Unsustainable funding schemes for the provision of water and sanitation infrastructure and services, and hence a concentration on delivery with limited attention to issues of sustainability. Insufficient financial resources to meet investment demand for infrastructural development, inadequate cost recovery to recover the full costs of water supply services.

Government would hide behind the excuse of lack of money, in water resource management; the real problem is how the money is being spent and the competence of persons in-charge of spending such funds.

h. *Unfinished Projects:* Checks revealed that abandoned and uncompleted projects abound in the Ministry of water resources and other water development and management agencies in Nigeria.
i. *Water resources maintenance:* Overuse of water resources, primarily for agriculture, and diffuse contamination of freshwater from urban regions and from agriculture are stressing the water resources in the terrestrial water cycle. As a consequence, the ecological functions of water bodies, soils and groundwater (e.g. filtration, natural decomposition of pollutants, buffer capacity) in the water cycle are hampered. Most of its infrastructures are rarely maintained, for example pipe bursts and pipes in filthy drains are commonly found in almost all the areas of the zone, this leads to poor management of water resources.
j. *Inadequate institutional capacity-building:* Insufficient institutional capacity and cooperation to operationalize the concepts of sustainable water resources management and also lack of policy to promote the conservation of water contributed to challenges of water resources development and management.
k. *Insufficient technology:* This is manifested in the transfer from innovators to practitioners, limited application of appropriate technologies, information and knowledge to support decision-making and implementation.
l. *Sectorial management:* Each sector (domestic use, agriculture, industry, environmental protection, etc.) has been managed separately, with limited coordination between them. This led to fragmented and uncoordinated development of water resources. Water is by nature a flowing resource, which crosses sector boundaries. Many uses of water have spill-over effects on other uses, and water development projects have unintended social and environmental consequences. This is especially true for river basins where upstream water and land practices impact directly the quantity and quality of water in downstream areas. As water becomes scarcer, it is becoming increasingly inefficient to manage water without recognizing the interdependencies between agencies, jurisdictions, sectors and geographical areas. Each agency has been made responsible for only a limited aspect of water resources development and management. In addition, agencies in each subsector have largely independent strategies and programmes for resource development and operations. This has often created confusion, resulting in uncoordinated efforts in administering regulatory policies and site-specific issues in water resources management. Conflicts of interest in the utilization of water and overlapping of development activities are becoming more and more apparent.
m. *Non-viable and Unplanned Schemes:* Schemes (e.g., water supply schemes) which do not have assured water in the source, or which do not have favourable cost benefit ratios, are sometimes taken up for implementation purely for political considerations. Sometimes, schemes are announced by politicians and even foundations stones are laid, but there has been no exploration or thinking about the scheme by competent authorities about its feasibility and relevant departmental (e.g., environmental) clearances. Due to political compulsions, officials are often forced to implement the scheme – leading to further problems or incompletion, and hence, to a wastage of valuable water resources.
n. *Undue political interference:* Several politicians harass officials for a cut of the funds allocated for development of large government projects (e.g. irrigation), and derail planned work and/or victimise government officials (e.g. with punitive transfers) if their demands are not accommodated.
o. *Long delay in implementing planned water resources projects:* A combination of a lack of sufficient fund allocation (despite a higher agreed budget) and political conflicts over water rights and allocations have caused a large number of sanctioned irrigation projects to proceed slowly and hence overshoot their estimated costs due to inflation. This has led not only to continued hardship to the expected beneficiaries (and the frustration due to unfulfilled expectations), but also to a lack of belief in governmental and political promises.
p. *Low quality constructions:* Institutionalized corruption (where contractors, for instance, pay bribes to get contracts) has led to poor quality construction as these contractors try to reduce the quality of construction (e.g. in using less than required cement in concrete or substandard materials) to make up their profit margins. This leads to dangerous construction, and collapsing water resources structures.

q. *Institutionalized Corruption:* While there are established systems (of percentages) of corruption in sanctioned projects, corrupt politicians and bureaucrats inflate costs of new proposals as well. Upright bureaucrats, who protest these systems or take strict action against corrupt officials or politicians, are victimized – often with allegations of corruption.
r. *Non-availability of good NGOs:* Although there are good NGOs who have the competence and experience to do community level mobilization and encourage people's participation, there are several NGOs who are given charge of doing similar work, but do not have the required competence to carry out their stipulated functions. The consequence is a lack of adequate community involvement on the ground (as opposed to on paper), in schemes where people's participation is stipulated (e.g., in watershed management, irrigation management, forest management, among others).
s. *Water quality issues:* Water is a vast network of branching rivers, springs, creeks, swamps, estuaries, wetlands, lakes, bays, etc. Each water body can contain dramatically different levels of pollution. Water quality issues influence human and environmental health. Measuring base-level pollution in existing water bodies in different watersheds in the state to identify areas where new water-using industries (both as a source and a sink) can be located is rarely done or water quality is not monitored.

Way Forward

Having identified some of the challenges in water development and management in Nigeria, possible solutions or way-forward include:

i. *The Policy Framework and Existing Institution:* States in Nigeria have enormous quantity of water resources, surface and underground water, that requires a well-articulated administrative structure that can manage the resources effectively. The present position of management of water resources in Nigeria is grossly inadequate (Nwankwoala, 2011). The Federal, States and Local Governments have over the years been intervening from time to time in terms of the provision of potable water to the people. Federal Ministry of Water Resources, Petroleum Trust Fund (PTF), River Basin Authorities, DFRRI, National Water Supply Rehabilitation Project, National Borehole Programme and of course, the present government Legislative Boreholes are major players in this sector.
ii. *The need to improve coordination within government:* Although a significant amount of literature exists on laws, policies, and rules and regulations governing the provision of water supply services to the citizens of each state, there is a great need for clarity on roles and responsibilities within government institutions. Better coordination is needed both within government structures, and in the way in which government bodies interact with local communities for provision of water services. Greater coordination and streamlining within government departments needs to go beyond official statements affirming commitment to coordination, to implementing the changes required in the rules, regulations and procedures critical to effective coordination.
iii. *The need to build capacity at all levels:* Capacity building is vital at different levels within government institutions, as also within local communities, in order to improve the provision and maintenance of water resources services. These capacities do not only relate (as is commonly understood) to technical issues, but more importantly to a range of social, managerial and institutional issues from organizing effective community participation, building solidarity, vision and a sense of purpose within communities, and starting and running efficient community based organizations to dealing with government procedures and legal requirements and conflict resolution.
iv. *The need for effective involvement of local communities:* Even after capacities have been enhanced, there is a need to develop institutional space and mechanisms for governments and local communities to interact effectively. Official consultations with local communities need to be judicious in choosing between full participation and participation by representation, using existing democratic institutions. Explicit mechanisms have to be drafted into government rules and regulations, explained to concerned officials, and back-stopped by a capable body till it become accepted practice.
v. *The need for good quality information for decision-making:* Participation in decision-making is a means to an end, and the goal of informed decision-making requires good quality information on a range of issues, technical, social, economic, legal and institutional.

vi. *Efficient and judicious use of water resources:* Protection of water resources, drastic decrease in specific water consumption particularly in irrigation and industry, complete cessation of the practice of discharging waste water into the hydrological systems (such as, rivers and lakes), harvesting of precipitation and making a more efficient use of runoff.

Conclusion

In many regions of Nigeria, rising demand for water are forcing communities, stakeholders, and governments to explore new ideas and find new solutions that will help ensure stable, secure water supplies for future generations, and especially for sustainable agriculture. Just as the country is blessed with oil resources, it also has seemingly abundant water resources that are not being efficiently utilized. To provide fully effective water management, the capability to understand and predict the movement and availability of water within all components of the hydrological cycle and to be able to simulate the impacts of various landscape changes on the distribution and availability of water is essential. Effective water resources development and management must be underpinned by knowledge and understanding of the availability of the resource itself, the uses to which water is put and the challenges facing the managers at all levels of government. There should be protection of water resources, drastic decrease in specific water consumption particularly in irrigation and industry, complete cessation of the practice of discharging waste water into the hydrological systems (such as, rivers and lakes), harvesting of precipitation and making a more efficient use of runoff, use of water stored in lakes and underground aquifers.

Evaluation of Nutrient Status of Olokoro Soils for Cassava / Upland Rice Intercropping System

I.N. Onyekwere, P.C. Muogbo, and T.O. Sijuwola
National Root Crops Research Institute (NRCRI), Umudike, Nigeria
07089432737 innonyeoma@gmail.com

Abstract

Cassava and upland rice are important staple crops in Nigeria and commercially produced solely in most parts of Southeastern Nigeria; as a result of increase in population demand of both crops is on the increase. Based on this, there is need to intensify the production of both crops through intercropping system to meet up with the demand, therefore the nutrient status of Olokoro soils, Abia State southeastern Nigeria were evaluated for production of cassava and upland rice in an intercropping system. The soils were sampled with auger at 0-20 cm depth and the samples were taken to laboratory for analyses. The analytical results revealed that the soils have the following characteristics , soil texture, is sandy loam , pH, 4.9 , Organic Carbon, 20.8 g kg^{-1}, total N, 0.12 gkg^{-1}, P, 36.00 mg kg^{-1}, CEC, 3.10 cmol (+) kg^{-1} and Base sat, 38.00 % . Based on the nutrient status of the soils studied, suggestions were made and if adopted will result to an increase in production of both crops in an intercropping system.

Introduction

Cassava is an important crop and Nigeria is the highest producer of the crop in the world, with production rate of 57. 13 million metric tons (FAO, 2016). The crop plays a major role in the economy of the country as it supplies more than half the calorie intake of her inhabitants (Abam *et al.*, 2006) .And rice is an important staple crop in Nigeria and indeed most countries in the world. It is the sixth major crop in cultivable area after sorghum (*Sorghum bicolor*), millet (*Pennisetum spp*), cowpea (*Vigna ungiculata*), maize *(Zea mays*) and cassava (*Manihot spp*) It is estimated that 4.6 million ha of land could be put into rice cultivation in the country (Ukwungwu, 2000). These crops are produced as sole crops in most parts of Nigeria. Increase in the production of these crops through crop intensification is of strategic important to Nigeria, this is to cushion the effects of population pressure, enhance poverty reduction sustainable food and nutrition security and income generation. This led to the development of cassava and upland rice intercropping system by the Farming Systems Research Programe of the National Root Crops Research Institute, Umudike. Evaluation of the nutrients status of soils is helpful in the appraisal of the productivity of a such soils. This also assists in making recommendations for soil fertility management options to be adopted for yield increase of crops grown on the soils. Therefore, there is need to evaluate soils of Olokoro to ascertain the status of their nutrients for cassava and upland rice intercropping system. The objective of this study was to evaluate the nutrients status of Olokoro soils in southeastern Nigeria for cassava/upland rice intercropping system.

Materials and Methods

Study Area

The study area is Olokoro in Abia state southern Nigeria and it lies between latitude 5^0 45 to 49^1 N and longitude7^0 48 to 53^1 E. The climate is characterized by distinct wet and dry seasons. The wet season lasts for about seven months (April to October), with a mean annual temperature range between 22 and 31^0C, mean annual rainfall range of 1,570 to 2,800 mm, and relative humidity varying from 60 to 81 %. The vegetation consists of tropical rainforest. The underlying geology of the location consists of the Benin formation/unconsolidated sands and sandy clays (coastal plain sand).

Soil Studies

Two hundred sub soil samples were collected at the depth of 0-20 cm using auger from the study area and composited into ten composite samples. The samples were taken to the laboratory for physicochemical analyses. All the soil samples collected were air dried; gently ground and sieved using a 2 mm sieve preparatory for laboratory analysis. Samples for total N and organic C were passed through a 0.5 mm sieve.

Soil Analysis

The soil samples Soil were analysed for some physical and chemical proprieties using the standard laboratory methods as contained in the method of soil analysis by International Soil Reference and Information Center and Food and Agricultural Organization. **(**ISRIC and FAO, 2002).

Results and Discussion

The result from the analytical data (Table1) indicates that sand fraction dominated the particle size of the soils studied with a value of 814 g kg^{-1}, with silt particles having the least value of 38 g kg^{-1}. The higher sand proportion of the soils implies that basic cations such as Ca, Na, K and Mg would be leached more easily as texture determines the degree of retention or ease of leaching of basic cations (Wapa *et al*., 2013).

Consequently, it is an indication of high infiltration rate and low water holding capacity of the soils. This might result into moisture stress as was reported by (Fagbami and Udoh 1982). Furthermore, this condition encourages rapid leaching of nutrients from the soil beyond the rooting zone of the planted crops, a situation that threatens increase in food productivity and food security (Senjobi, *et, al.* 2013). The rather lower clay content in the soils could be attributed to the sorting of soil materials by biological and agricultural activities, clay migration or surface erosion by runoff or a combination of these (Malgwi *et al*., 2000). Therefore, there is need to incorporate plant residues and other organic materials into the soil to improve the aggregates quality of the soils, as this will lead to an increase in yields of the crops.

Generally, the textual classification of the soils agreed with optimum criterion of light medium loam sandy soil (Onyekwere *et al*., 2009) required for unhindered anchorage and bulking of roots and tubers including cassava and for easy harvest. The texture of the soils studied can as well retain enough moisture for upland rice production; these attributes give the indication that these soils are suitable for both cassava and upland rice production. The mean pH value of the soils is 4.9, an indication that they are slightly acidic and included among the excessively leached acid latosols with low to medium humus found in areas of rainfall approximately 2,200 to over 5,000 mm per annum in hot lowland (Udoh *et al*., 2013). According to Okusami *et al*. (1997) the acidity nature of the soils studied is an indication of influence of pre-weathered parent material on the chemical properties of some soils within the tropics. There is need to incorporate organic materials in the soils, to reduce the soil acidity. According to Onyekwere *et al* (2012), addition of organic fertilizer to soil reduces soil acidity because organic fertilizer has some liming effect on the soil. The low organic carbon content in the soils studied can be attributed to any or all of the following: inadequate supply of organic litter, bush burning, long dry season and intensive mineralization during the rainy season (Dogie *et al.,* 2008). Maintenance of a satisfactory organic matter status is essential to the production of most of the nitrogen and half of the phosphorus taken up by unfertilized crops, including cassava and rice (Von Uxekull, 1986). The total N content of the soils have a mean value of 0.12 , a value less than the critical level of 0.15 g kg^{-1} established for soils (Senjobi, *et al*., 2013). The low content of total N in the soils studied could be attributed to low organic matter of these soils, since inorganic N is accounting for only a small portion of total N in soils (Almu and Audu 2001). It could also be as a result of high rainfall that brought about leaching of soil nitrates (Eshett *et al.,* 1989). The total N content of the soils is a reflection of the organic carbon content of the soils. The low level also could be attributed to the intense cultivation of the soils which normally increases the rate of mineralization of organic matter, thus negatively affecting the level of soil total N content (Senjobi, *et al.,* 2013). There will be a positive response in yield increase of cassava and upland rice upon the application of Nitrogen fertilizer in the soils studied. The mean values of the available phosphorus obtained from the soils studied was 36.00 mg kg^{-1} . The value was far above the critical limit of 8.0 mg kg^{-1} P established for crops in southeastern Nigeria including cassava and rice (FPDD, 1989) and the critical level of 15 mg kg^{-1} P recommended by Thomas and Peaslee (1973) cited by Onyekwere *et al.* (2009). The result from the study confirmed the findings of Onyekwere et *al*. (2013). Who observed that soils derived from coastal plain sands contain moderate to high levels of available P. The mean value of exchangeable Ca of the soils studied had a value of 1.65 $cmolkkg^{-1}$. The value was below 4 cmol kg^{-1} regarded as lower limit for soils (Onyekwere *et al.,* 2001). The mean values of exchangeable Mg content of the soils studied was 0.58 cmol (+) Kg^{-1} , a value below the critical level (0.02 - 0.40 cmol (+) Kg^{-1} of exchangeable Mg in soils established by Adeoye and Agboola (1985). The low level of exchangeable Mg in the soils could be attributed to the nature of the parent material, as the total Mg content of the soils appeared to be influenced by the parent material and weathering (Osenwota *et al*., 2009). The mean value of exchangeable K was 0.07 cmol (+) Kg^{-1} , the soils had mean value below the critical limit of 0.20 coml (+)kg^{-1}, a value recommended for soils of southeastern Nigeria (FPDD, 1989, Enwezor *et al*.,1981), for production of cassava and upland rice. There will be a positive response in yield increase of cassava and upland rice upon the application of potassium fertilizer in the soils studied. The mean value of exchangeable Na was 0.09, a value below 0.20 cmol (+) kg^{-1} regarded as the critical value needed in soils (Amalu 1997). The low level of exchangeable bases in the soils studied could be attributed to as a result of soil loss through soil erosion. Mbagwu (1988) reported that soil loss through soil erosion had resulted in the deficiencies of exchangeable bases in soil. The result indicates that the Effective Cation Exchange Capacity of soils was low with a value of 3.80 and the value was below 20 cmol kg^{-1} regarded as being suitable for crop production if other factors are favourable (Onyekwere, *et al*., 2003), quoting FAO (1976). The low ECEC and nutrient reserves of the soils have been attributed to the fact that soils of southeastern Nigeria are strongly weathered, have little or no content of weatherable minerals in sand and silt fraction and have predominantly kaolinite in their clay fractions (FPDD 1989).

Conclusion

The soils are acidic, low in total N and exchangeable K and high in available P. The soil texture is favourable for production of the intercrops. For sustainable production of the intercrops organic manure including the harvested residues need to be incorporated to the soil and application of NPK at 90 Kg N, 20 Kg P_2O5, 75 Kg K_2 O ha^{-1} and 80 Kg N, 40 Kg P_2O_5, 40 Kg K_2O ha^{-1} fertilizer for cassava and upland rice respectively, are therefore recommended.

Abstract
Characterization of soils under two different types of land-use options - groundnut (GNL) and maize (ML) was carried out. An overview of the study area was obtained through a free survey technique. One profile pit was sank in each land-use option and described following FAO guidelines and soil samples were collected from each identified genetic horizon for laboratory analyses. The result indicates that the soils under GNL were brownish and well drained; while soils under ML were very dark grayish brown and poorly drained. The soils under both land-use options generally have favorable pH, high base status, but low to medium fertility status. The soils under GNL are classified as Typic Haplustalfs/Haplic Luvisol; while the soils under ML are classified as Aquic Haplustalfs/ Anthraquic Luvisol.

Introduction
Soil characterization gives a potent resource for the benefits to man in regard to food sustainability and environmental protection (Esu, 2004). It provides data on the potentials, constraints and distribution of major soils types. Agricultural landuse typifies the arrangements, activities, and inputs by individuals to produce, change and maintain a certain land cover for crop production and sustainability (Di. Gregoria and Jansen, 1998). Chanchaga (Minna) have great agricultural potential for both wet season and dry season farming due to its proximity to river Chanchaga. The major agricultural landuse in Chanchaga are suited for the cultivation of yam, maize, rice and groundnut. The study aims at providing and comparing data on the properties of some Alfisols under two different landuse (G/nut and maize) in Chanchaga, Minna, Niger State.

Methodology
The Study Area
The study area is located in Chanchaga, Minna, Southern Guinea savanna and lies within latitude 9º 31ʹ 54.94ʹ N and latitude 9º 31ʹ 21.4ʹ N, and longitude 6º 35ʹ 53.3ʹ E and longitude 6º 35ʹ 55.29ʹ E with elevation range of 209 m to 258 m above sea level. Two locations within the study area with different land-use options (G/nut and maize) were selected by free survey. The first location underground-nut land-use (GNL) was situated on a nearly flat land and lies within latitude 9º 31ʹ 50.12ʹ N and longitude 6º 35ʹ 58.64ʹ E. The second location under maize land-use (ML) was located on gently sloping land and lies within latitude 9º 31ʹ 38.69ʹ N and longitude 6º 36ʹ 4.08ʹ E. Minna falls under sub-humid tropical climate, with two distinct seasons, namely dry and rainy season. Minna possess an ustic moisture condition with mean annual rainfall of 1229 mm, and an isohyperthermic temperature condition. Its temperature (about 35ºC) remains high throughout the month of March and June (Ojanuga, 2006).

Field Study
A free survey technique was first carried out in the month of February and the first week of March 2017; in order to have an overview of the study site, and to generate information that could aid in the planning of the detailed field work. One profile pit was dug in each land-use location. The profile pits were described based on FAO guidelines for soil description and bulked soil samples were collected from each identified genetic horizons, and taken to the laboratory for analysis.

Taxonomic classification of the soils were according to USDA Soil taxonomy (Soil Survey Staff, 2014) and WRB for Soil Resources.

Laboratory Analysis

The soil samples were air-dried and sieved with 2 mm. The following soil physical and chemical properties were determined: Particle size distribution was by determined by the Bouyoucous hydrometer method, and textural classes established from the USDA soil textural triangle; Bulk density was determined by the undisturbed soil core method; Soil pH in water solution (soil ratio 1:1) was determined using the electrometric method; Soil organic carbon (OC) was determined by the wet dichromate method; Total N was obtained by the Macro-Kjedahl method; Available P was determined calorimetrically after Bray-1 extraction; Exchangeable bases (Ca, Mg, Na, K) was determined using 1N NH_4OAc extractant method, after which Ca and Mg was obtained from an Atomic Absorption Spectrometer, while Na and K obtained by the Flame Photometer; Exchangeable acidity (Al^{3+} + H^+) was determined by titremetric method; CEC was obtained by the NH_4OAc displacement; and base saturation (BS) calculated as follows:

$$BS = \frac{\text{total exchangeable bases}}{CEC} X\ 100$$

Results and Discussion

Morphological and Physical Characteristics

The field morphological and physical properties of the study area are presented in Table 1. The soils under GNL were well drained, while poor drainage condition featured in soils under ML. Soil colour varied predominantly from brown (7.5YR 4/4) in soils under GML to very dark grayish brown (10YR 3/1) in soils under ML. The structural groupings featured on surface horizons were massive structureless (ML) and moderate medium crumby structure (GNL). Sand particles were the dominant fractions in both soils, and generally decreased with depth in the soils; while clay particles alternately increased with soil depth. According to Fasina *et al.*, (2005) smaller size mineral particles usually increase down profile depths due to sorting, migration, and eluviation. Sand fractions ranged from 720 g kg^{-1} in surface horizons to 430 g kg^{-1} in sub-horizons (GNL), and 520 g kg^{-1} to 420 g kg^{-1} in surface and sub-horizons of soils under ML. Silt particles exhibited irregular pattern of increase and decrease down profile depth in soils under GNL, varying from 200 g kg^{-1} to 220 g kg^{-1} in surface and sub-horizons respectively. Both soils (under ML and GNL) also exhibited sandy loam texture on surface horizons. Generally the Bulk density values of the soils ranged from 1.41 g cm^{-3} to 1.55 g cm^{-3}, and were considered favorable for plant growth, falling within the range of 1.00 – 1.60 g cm^{-3} for mineral soils (Akapan-Idiok *et al.*, 2012).

Soil Chemical Properties

The field chemical properties of the study area are presented in Table 2. Soil pH increased irregularly with depth in the soils of GNL, but decreased irregularly in soils of ML, varying from 6.31 to 6.37 and 5.86 to 6.21 respectively. The soils are generally slightly acidic in reaction. Organic carbon content in the soils was generally low, and ranged from 2.59 g kg^{-1} to 8.18 g kg^{-1}. Land use activities such as livestock grazing, bush burning and the kind of arable farming in the area may have contributed to the low carbon content in the soils. For most Nigerian soils, optimum crop production can be achieved when critical level of carbon content stands at about 10 g kg^{-1} to 15 g kg^{-1} (Esu, 1991). Carbon values below this critical level may encourage more leaching losses of basic cations into sub-soils. Total N in all the soils were high i.e. > 0.2 g kg^{-1}. The application mineral fertilizers by the farmer in the area may have contributed to the high N values recorded in the soils. The N values generally ranged from 0.48 g kg^{-1} to 0.50 g kg^{-1} in surface horizon, and considered adequate for plant uptake. Distributions of available P contents in the soils (3.33 mg kg^{-1} to 3.50 in surface horizons) were irregular down the profile depths in both horizons and were considered low to moderate. The concentration of exch. bases (Ca, Mg, K, Na) in soils were also irregular in distribution across both profile depths. Ca ranged from 1.50 cmol kg^{-1} to 6.22 cmol kg^{-1}, Mg ranged from 0.36 cmol kg^{-1} to 1.04 cmol kg^{-1}, Na ranged from 0.21 cmol kg^{-1} to 0.24 cmol kg^{-1}, and K ranged from 0.05 cmol kg^{-1} to 0.13 cmol kg^{-1} on surface horizons. CEC ranged from 5.80 cmol kg^{-1} to 9.40 cmol kg^{-1} in soils under ML, and 3.20 cmol kg^{-1} to 5.40 cmol kg^{-1} in soils under GNL. The soils generally exhibited high base saturation values (66.3 % to 91.2 %). The base saturation values of the soils agrees with the results of Lawal *et al*., (2012) and Afolabi *et al.*, (2014) that the soils of Minna have high base saturation values. High base status of the soils shows that basic nutrients may occur in available form for plant uptake despite low cation reserve in the soils (Aki *et al.*, 2014).

PGNL = soil profile under Groundnut land use; PML = soil profile under maize land use; * auger sample depth

Conclusion

Under the USDA soils taxonomy, both soils under GNL and ML are classified as Ustalfs at Suborder level, and Haplustalfs at Great group level. However, under Subgroup level, the soils are classified as Typic Haplustalfs (GNL) and Aquic Haplustalfs (ML). The soils are also classified as Haplic Luvisol (GNL) and Anthraquic Luvisol (ML) under WRB for soil resources. The soils of the study area generally have favorable pH, high base status, but low to medium fertility status. However, with adequate application of mineral fertilizers and organic inputs, the soils can be more productive. Soils of ML will require the installation of drainage structures in order to manage the poor drainage condition of the location.

Fertility Capability Classification: Calibration of Soil Fertility Classes from the Sokoto-Rima Flood Plain, Nigeria

A.A. Yakubu
National Agricultural Extension and Research Liaison Services, Ahmadu Bello University Zaria
Corresponding email: Adamuyakubu3@gmail.com

Abstract

The study was conducted in the Sokoto-Rima flood plains at Sokoto Nigeria, with the aim of calibrating the soil Fertility Capability Classes (FCC) obtained in the previous work (Yakubu et al, 2008) with fertilizer Nitrogen response for appropriate and sustainable agricultural landuse. Soil samples from the two fertility classes delineated (Yakubu et al, 2008) were prepared and used for pot experiment in the screen house to compare crop response using nitrogen rates (0, 40, 80 and 120kg N) and maize (Zea mays) as test crop. Results show that although there was no significant statistical difference between the two soil classes, absolute figures show that soil class Lghm (Loamy soils, low in organic matter with gleying and pH limitation) has higher fertility/yield potential followed by the class Lgm (Lgm- Loamy soils low in organic matter with gleying limitations)/ Sgm class (Sandy soils low in organic matter and with gleying limitations). Periodic monitoring of soil quality, adding organic manure and applying ameliorative measures such as liming can improve and sustain the productive capacity of the soils.

Keywords: Fertility classes, Calibration. Soils and Floodplains

Introduction

The fertility of a soil is related to its capacity to store, retain and release plant nutrients in such kinds and proportions as are required for crop growth. This soil quality can be derived from a combination of many soil properties: Organic matter content, clay content and clay mineralogy, presence of weatherable minerals, pH, base saturation and biological activity (FAO, 1993). While most crops thrive best on fertile soils, some do yield reasonably well on moderately fertile soils (FAO, 1993). In Nigeria, one of the major problems of farmers is poor fertility replenishment strategy that could allow for a sustainable agricultural productivity (Mutsaers, 1990). In its effort to reduce this problem, the Federal Government, through its policies on creating enabling environment for agricultural production to smallholder farmer, once introduced fertilizer subsidies so that farmers could afford the fertilizers for replenishing the fertility of their soils. This policy further aggravated the problem because farmers fertilize their soils without the knowledge of the basic fertilizer nutrient requirement and capacity of their soils. This results in a lot of wastage of fertilizer and possible inhibition of the activity of other nutrient elements in the soil, rendering some soils physiologically deficient of certain nutrient elements. The need for FCC therefore arises out of the identified technical problem of fertility maintenance in our fragile soils and the need for technology to improve fertility management of Nigeria soils, particularly Sokoto State soils. The paper aimed to identify appropriate scientific fertility management strategies for a sustainable agricultural land use in the Sokoto flood plains so as to increase food security in Sokoto state with the following objectives: to calibrate the FCC classes shown on the map using fertilizer regimes and maize (*Zea mays*) as a test crop and interpret the calibrated FCC classes so as to assist in land use management of the flood plains

Materials and Methods

Location of Study Area

The study was conducted in a representative area 100ha (1km^2) out of 3600ha of the Sokoto Rima floodplains located east of University road in Sokoto environment (13^{o}1'N, 7^{o}E) (Bashir and Duru, 2000). The area is located in the Sudan savanna vegetation zone of the semi-arid sub-Sahara region of Africa where a long dry (October-May) season and short (June-September) rainy seasons prevail (Bashir and Duru, 2000). It is characterized by a cold dry spell (November-January) in the harmattan period and a hot dry spell in February-May. The mean annual rainfall is about 400-700mm, which is often erratic in distribution (Singh, 1995). Temperatures according to Arnborg (1988), ranges between 15°C during the cool nights, to 40°C during the warm days. The mean annual temperature is about 27°C. The soils are poorly drained in a relatively flat topography. They are prone to seasonal water logging and usually show gleying within 1metre of the surface.

Treatments and Experimental Design

Composite soils of the two FCC classes obtained from the study area were used for pot experiment in the screen house to determine the dry matter yield of maize (Z*ea mays).* Four (4) levels (0, 40, 80 and 120kg N ha^{-1}) of nitrogen as urea were administered as treatments in order to determine the appropriate rates of N application suitable for the FCC classes. Treatments consisted of two (2) FCC classes (Se and Le soils) with four (4) N rates (0, 40, 80 and 120kg N ha^{-1}) making 12 treatment combinations. The 12 treatment combinations were laid out in a completely randomized design (CRD) replicated three (3) times making a total of 36 treatment combinations.

Soil preparation and Potting

The air dried and sieved soil samples were composited in accordance with the determined FCC classes and mixed thoroughly before potting. Small portions of the samples were oven dried to determine the moisture content to confirm the extent of drying. Three kilograms of soil of the two different FCC classes (Se and Le) were weighed in each of the 36 pot. Filter papers were placed at the inner bottom of the pots to reduce loss of soil through drainage holes.

Planting Materials and Planting

A local cultivar of maize (English: Sweet Maize. Hausa: Jan masara) was sourced from the farmers cultivating the flood plains, and was used for the pot experiment. Planting was done at a depth of 2.5cm. three seeds were planted in each pot, which were later thinned to one plant per pot after emergence. Fertilizer P as single super phosphate (SSP) was applied basally during potting at the rate of 40 Kg ha^{-1}

Fertilizer Application, watering and pest control

Amount of fertilizer N (0, 40, 80 and 120kg N /ha^{-1}) to supply the nutrient under test were applied two weeks after planting as top dress 5cm deep and covered with soil. Water was added every day to moisten the entire soil volume. Care was taken not to add excess water to avoid infection by damping off organisms. There was no incidence of pests and diseases throughout the period of the experiment.

Data collection

Data on growth parameters like plant height, number of leaves per plant and dry matter accumulation were collected from each pot. The number of leaves in each pot was counted and recorded every week from two weeks after planting. Plant height was determined by measuring the height of the plants from the soil surface to the tallest leaf using a meter rule, every week from two weeks after planting (WAP). Dry matter accumulation was determined by harvesting the aboveground biomass in each pot and oven dried to constant weight at 65°C for 48hours at 7 WAP.

Statistical Analysis

Data generated was subjected to analysis of variance, and means separated using least significant difference (lsd)

Results and Discussion

The FCC Map

The FCC map and the physical, chemical and morphological characteristics of the different FCC classes were discussed in details in Yakubu et al, (2008). This paper therefore describes it in brief. Three symbols are shown on the map, (Fig. 1) which denotes the FCC units that commonly occur in the Sokoto-Rima flood plain represented by the study area. They are *Leg, Legh*, and *Seg* in order of extent. The *Le* and *Leh* constitute the dominant FCC units. There also some minor areas of *Se,* and *Sek* as inclusions within the dominant soil units.

a. *Leg*

They are well cultivated. They have high water holding capacity because of their high silt content and medium infiltration capacity. They also exhibit redoximorphic properties close to the surface.

They are however prone to surface sealing because of the high silt content. Moreover, they have low ability to retain nutrients against leaching. They are in association with patches of *Seg,*.

b. *Legh*

This FCC unit, Legh, is very similar to the Leg, except that it is found in association with small patches of Ceg and Seg. It differs from the Leg only by having a strong to moderate acid problem. Acid problems affect nutrient availability to plants and microbial activities in the soil.

c. *Seg*

This FCC unit contains soils that occupy in the basin of the flood plains with inclusions of Sek patches. They are coarse textured well-drained soils. They have low water holding capacity and high infiltration rate

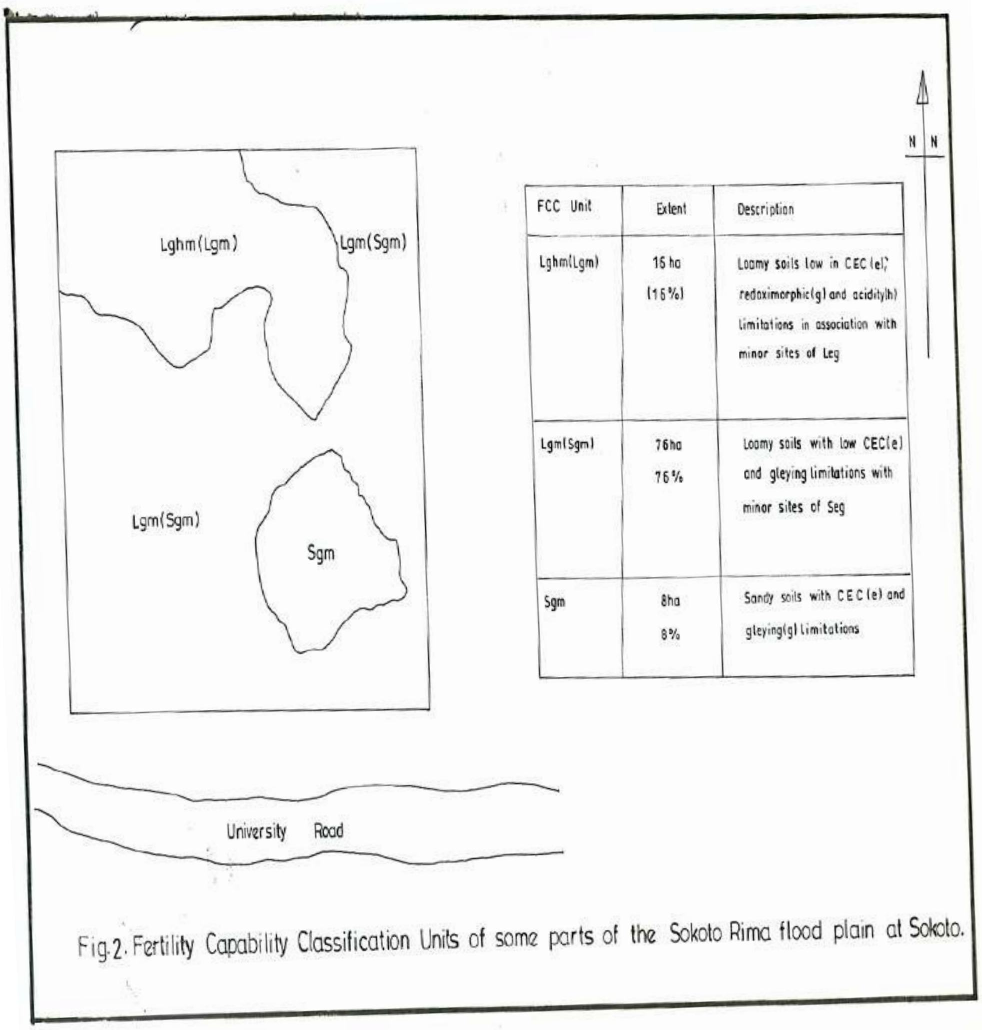

Fig.2. Fertility Capability Classification Units of some parts of the Sokoto Rima flood plain at Sokoto.

Figure 1: Free sketch map showing the three FCC classes which were resolved to two soil units.
Source: Yakubu et al, (2008)

The results of plant height (Table 1.) showed that the fertilizer rates had no effect on plant height at 2 weeks after planting. This could be due to the plant's dependence on appreciable quantities of mineral nutrients stored in the seed before proper root establishment as indicated by Singh, (1995) The effect of the fertilizer rates started to manifest significantly ($P<0.05$) at 3 weeks after planting (3 WAP). At 4 to 6 WAP, the effect was highly significant. This implies that N was deficient in the soils under test. In other words, N is highly critical at vegetative growth stage. Generally, the table indicates that throughout the growing period, nitrogen applied at the rate of 40Kg ha^{-1} gave the highest height (35.23cm), followed by N applied at 80Kg ha^{-1} (30.217cm) and control (N0)

(27.500cm). The lowest being N applied at 120Kg ha^{-1}(24.500cm). This could be due to the cultivar of maize being local and cannot respond to N rates above 80kg/ha^{-1}. it could also be due to low CEC of the soil and the dilution of P and K nutrient elements by the N rates, that appeared to be higher than the other inherent nutrients especially the highest rate (N120) that is suspected to be responsible for P and K deficiencies,

Means in a column followed by similar letters in a treatment group are not significantly different at 5% level of significance

The effect of N rates and soil types on number of leaves per plant (Table 3) showed that N rates influenced significantly the leaf production at 2 and 3 WAP. But there was no significant effect of the N rates at 4 to 6 WAP. However, at 7WAP the influence of the N rates was highly significant. The two soil types had no statistical significant effect on leaf number. However, in absolute terms the loamy soils performed better than the sandy soils relative to number of leaves produced from maize grown in them. This result implies that as from germination to 3 WAP the plants absorbed significant quantities of N for leaf production. But from 4WAP the N absorption was then significant for plant height (table 2.). At 7WAP, fertilizer N was again significantly used for leaf production. This dwindling situation could be because of the low content of P and K over N rates which caused nutrient imbalance.Generally pots supplied with 40kg and 80kg N h^{-1} produced the highest number of leaves (10 leaves) throughout the growing season, 0 Kg N ha^{-1} (8 leaves) and 120 kg N ha^{-1} (7 leaves), which were not statistically different at 7 WAP. Although not statistically significant, absolute values indicated that Se soil type gives better conditions for the growth of the crop than Le. .This is because it is well drained and can allow good aeration at the root zone. The results of the effect of N rates and soil type on dry matter (Table 3.) shows that N rates affected significantly the production of above ground and root dry matter. Throughout the growing period, N rates contributed significantly in the production of above ground dry matter. High significance was recorded on root dry matter. This implies that, of the assimilates produced due to N rates, larger concentrations were partitioned to the roots than the shoot. This was probably done to increase root development and network (Singh, 1995). The two soil types had no effect on dry matter accumulation although absolute values show little variation. This implies that the soils were statistically the same. The results show that 80kg N ha^{-1} produced the highest dry matter (4.2g), followed by 120 kg N ha-1 (4.11g), 40kg N ha^{-1} (3.4g) and 0kg N ha-1 (1.9g), which were not statistically different.

Fertilizer Response Curve.

Figure 2 shows the response of N rates applied to the corn on dry matter. The figure indicated dry matter accumulation of 1.33g from zero to 3.4g when N was applied up to 40k N ha-^{1} and rose to 4.2g at 80kg N ha-1. Application at 120kg N ha-^{1} rate yielded 4.11g which indicated a gradual dry matter yield decline.

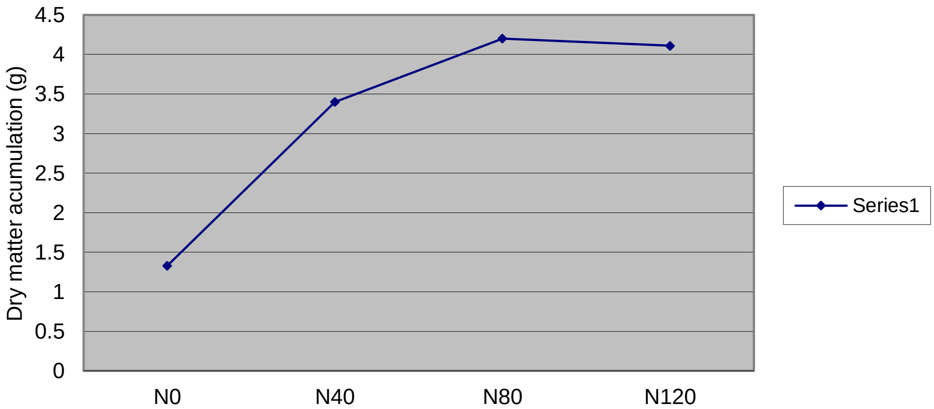

Figure 2: Response curve on the effect of N rates on dry matter yield

This implies that if the limitations of the soil FCC classes are not managed, application of fertilizer N at rates above 120 kg N ha^{-1} may result into economic wastage.

Conclusion

Results show that after calibration with four N rates (N0, N40, N80 and N120), the fertilizer response curve indicated that applying N above 80kg N ha^{-1} resulted into yield decline and that the two soil FCC classes were statistically the same in terms of fertility status. In the light of the above findings, there is need for regular addition of plant residues and organic manures the soils in order to check soil erosion and improve the physical conditions and fertility of the soils is necessary to improve CEC and contribute nutrients especially P and N. Ameliorative measures like liming and addition of gypsum to classes with pH, K and Na problems. Cultivate salt tolerant crop. Periodic monitoring of soil and water quality in the area so that appropriate ameliorative measures could be embarked upon as and when due.

Abstract
This study investigated the soil physical and chemical characteristics of surface and sub-surface soils of mining and dumps sites in Abia State. The soil samples were collected from two different refuse dump (Ntigha dump; ND site, and Ariaria dump AD site) and two mining sites (Leru mining- LM site, and Ohiya mining-OH site,). A total of forty (40) samples were collected at random, ten (10) per site at the depths of 0-20 and 20-40 cm. The soil chemical and physical characteristics studied include: soil pH, organic carbon, total nitrogen, particle size, bulk density, total porosity and Ksat. The laboratory data collected were subjected to analysis of variance (ANOVA) for experiment in Randomized Complete Block Design (RCBD). The mean was separated using fisher's least significant difference at a probability level of 5%. The result obtained indicated that the particle size distribution (% sand, silt and clay particles) of Leru mining site was significantly ($p \leq 0.05$) different from Ohiya mining site, Ntigha dump site and Ariaria dump site. Ohiya mining site had the highest bulk density of 2.02 and 2.18 mgm^{-3} at both surface and subsurface soils depths, it also had the lowest total porosity of 23.77% and 17.74% at surface and subsurface depth. Generally the bulk density of the soils increased significantly ($p < 0.05$) in the lower depth, total porosity decreased significantly ($p \leq 0.05$) in the lower depth. Similarly Ksat decreased in the lower depth. The Ariaria dump site had the highest pH value (6.20 and 5.90), organic matter content at the lower depth, compared to the other sites with low aluminum and hydrogen ion content. Generally the study indicated that the dumping of refuse in the Ariaria and Ntigha sites could have impacted positively on physical and chemical properties studied while mining activities in the Leru and Ohiya sites impacted negatively on the soil properties studied.

Keywords: Mining and dump sites, organic carbon, Soil pH, bulk density, Ksat

Introduction
Mining involves the movement of large volumes of soil from the surface of the earth and removal of large amounts of regolith and rock to extract valuable ore. In some areas, this has been occurring for a considerable period of time (50 years) (Banning *et al.,* 2008; Koch, 2007). The common practice in a mine site is the mounding of soil into piles and storage until the mining operation is complete (Banning *et al.,* 2008; Ingram *et al.,* 2005). On a global scale about 20 percent deforestation in developing countries may be attributable to mining (Bahrami *et al.,* 2010). Ghosh (1990) reported that every one million tons of coal extracted by surface mining methods damages a surface area of about 4 ha. Mining soil has high content of rock fragments in comparison to fine earth. Mining activities disrupt partially or totally the original characteristics and qualities of soils and re-set the pace of soil formation. Mining influences soil physical and structural properties (Shukla,*et al.,* 2004). Generally, mining affects the available land suitable for cultivation (Banerjee *et al.,* 2004; Dutta and Agrawal., 2002; Ghose, 1996; Singh *et al.,*2006). These spoils are not suitable for both plant and microbial growth because of low organic matter content, unfavorable pH (Agrawal *et al.,*1993; Burgharadt, 1993; Rodrigue and Burger, 2004) which affects the drainage system and prevent natural succession of plant growth, increases water stable aggregates and initiates differences in water stable aggregation among soil horizon(Wali, 1987; Gorman and Sencindiver, 1999; Thomas *et al.,* 2000;Wilson *et al.,*2002; De and Mitra.,2002).Mined soils can

have poor water retention resulting from high coarse fragment content, lack of fine earth, poor soil structure which allow water to drain quickly from the soil profile, disturbs farmland, forests and waterways (Rodrigue and Burger, 2004), increases water stable aggregates (Thomas *et al.,*2000) and initiates differences in water stable aggregation among soil horizons(Gorman and Sencindiver, 1999). In the process of mining, several changes of the physical and structural properties, chemical and microbiological properties of soils occur (Reich *et al.,*2001; Shukla *et al.,* 2004). The most common method of waste disposal is dumping on land, because it is the cheapest method of waste disposal. However, this requires large area and proper drainage. The land disposal of municipal and industrial solid waste is potential cause of soil degradation, groundwater contamination and soil pollution. Unscientifically managed dumping sites are prone to groundwater contamination which invariably results in chemically unfavourable soil status that influence immediate environment for crop productivity. Therefore, the specific objectives of this study are to determine the soil physical and chemical characteristics of surface and subsurface soils of mining and dump sites in Abia state and correlate the soil properties of the soil studied.

Materials and Methods

Site description

The study was carried out in two different sites of mining and dump sites in Abia State. The first site is a Kaolin mining site located at Ohiya community in Umuahia south LGA, Ohiya is located near the Abia Tower junction on the Umuahia Enugu-Portharcourt express way, lies at latitudes 05^{0}26N and longitude 07^{0}22E, this area is characterised by high temperature with an altitude of 92m above sea level. The second mining site is located at Leru Umuneochi LGA. In this site, sand and gravels are mined, and lies between latitudes 05^{0}30N and longitude 07^{0}20 E. The area is sparsely populated and occupies areas of farm land with an altitude of 3m above sea level. The dumping sites are located at Ntigha along Umuahia-Enugu Portharcourt express way in Isialangwa North LGA, lies at latitude 05^{0} 27'N and longitude 07^{0} 24'E with an altitude of 147m above sea level. The second dumpsite is located at Ariaria international main market at Aba-Portharcourt express high way in Aba north LGA. Lies at latitude 05^{0}06'N and longitude 07^{0} 19'E with an altitude of 59m above sea level.

Sample collection and laboratory analysis

Soil samples were collected from these locations using core sampler and soil auger at surface 0-20cm and subsurface 20-40cm levels, ten (10) samples were collected from each land use and the disturbed samples were air dried at room temperature and passed through a 2mm sieve mesh. The sample was subjected to the following laboratory analysis: Soil particle size distribution was determined by the hydrometer method Bouyoucus, (1951). Bulk density was determined using (Anderson and Ingram, 1993). Soil pH was determined with pH meter in water (McLean, 1982). Organic carbon was determined by dichromate-oxidation method of Walkley and Black wet oxidation method as described by Nelson and Somner (1982), organic matter was calculated by multiplying organic carbon with Van Bremmelen factor (1.724). Total nitrogen in the soil sample was determined by the Micro-Kjeldahl method (Brookes *et al.,* 1985).

Statistical analysis

The data collected was subjected to analysis of variance (ANOVA) for experiment in Randomized Complete Block Design (RCBD). The mean was separated using fisher's least significant difference at a probability level of 5%.

Results and Discussion

Particle size distribution

The particle size distribution of the soils studied as shown in Table 1. Showed the texture of soil under the three land use systems was sandy loam except under Ariaria dumpsite (AD) at the surface which had loamy sand (LS) texture. At both depths, the highest sand contents were observed under Ariaria dumpsite (AD), while Ohiya mining site (OM) had the lowest. With regard to the silt contents, Leru mining site (LM) and Ntigha dumpsite (ND) recorded the highest at surface depth, while Leru mining site (LM) recorded the highest depth. Ohiya mining site (OM) recorded the lowest at the surface. Whereas, Ntigha and Ariaria dumpsites were observed to have the lowest OM at the sub-surface. The highest clay contents were observed under the Ohiya mining site at both surface and sub-surface depths. The lowest clay contents at both depths were observed in Ariaria dumpsite. Generally, the sand content decreased with depth, while the silt and clay

contents increased. However, the silt content of Ariaria dumpsite (AD) and the clay content of Leru mining site (LM) did not change. As shown in Table.1, and with regards to surface and sub-surface depths, the particle sizes were significantly ($P \leq 0.05$) different. With regards to the land use systems and depths, the sand, silt and clay particles of Leru mining site (LM) were significantly ($P \leq 0.05$) different from OM, ND and AD. Generally, the sand, silt and clay particles of Ariaria dumpsite (AD) were significantly ($P \leq 0.05$) different from others in both surface and sub-surface depths. The high sand contents of both the mining and refuse dump sites could be attributed to the geology of the area. The geology of the area is unconsolidated sand deposits formed over coastal plain sand which are characterized by sandy soils over a wide land area (Asawalam *et al*., 2009). The variations in particle sizes with depth could be as a result of the pedogenetic processes of eluviation and illuviation (Chukwu, 2012). The high sand, low clay and silt contents, observed in refuse dump sites, corroborated the report of Ideriah *et al*. (2006), who reported sandy loam texture for a refuse dump site in Porthacourt, Rivers State. Anikwe and Nwobodo (2002) and Ideriah *et al.* (2006) observed that dumping of household municipal wastes resulted to high sand, low clay and silt contents leading to a sandy loam texture. The increase in clay content with increasing soil depth maybe due to translocation, (Agoume and Birang, 2009), dissolution, and leaching of clay materials as a result of intense torrential rainfall, argillation of clay, lessivage and sorting of soil materials (Ojanuga, 2013). The bulk density and total porosity of the soils studied are shown in Table 2. At both depths, Ohiya mining site (OM) had the highest bulk density. The lowest bulk density was observed in Ariaria dumpsite at both depths. With regard to total porosity, AD had the highest TP. Ohiya mining site (OM) was observed to have the lowest total porosity. Generally the bulk density of the soils increased significantly ($P \leq 0.05$) with depth, whereas total porosity decreased significantly ($P \leq 0.05$) with depth (Table 2). These observations reflected the influence of organic matter on the parameters. With reference to land use systems in both surface and sub-surface depths, the bulk density of Ohiya mining site (OM) was significantly ($P \leq 0.05$) higher than LM, ND and AD. The total porosity under OM was significantly ($P \leq 0.05$) different from LM, ND and AD at both depths.
The variation in bulk density, total porosity and aggregate stability may be attributed to the level of organic matter in the soil (Ahukaemere *et al.,* 2012). The organic materials in the mining sites and municipal wastes help to increase the soil matrix thereby reducing soil bulk density and consequently increasing total porosity and aggregate stability.

The Correlation between soil properties under investigation
The correlation result (table 3), indicated that sand correlated ($P<0.05$) negatively with silt and clay. Sand has negative influence on silt and clay fraction content. This may have resulted from the nature of soil parent material, illuviation and eluviations (Chukwu, 2012). Soil pH correlated negatively with clay ($P<0.05$) and positively with sand ($P<0.05$). While phosphorus was positively correlated with sand and pH ($P \leq 0.05$).The positive correlation between pH and sand indicates the influence of pH on the sand. Also the positive correlation between phosphorus, sand and pH indicate that in acidic soil, P is fixed. Hence it is influence by sand and low pH of the soil Aluminium (Al) was also negatively correlated ($P<0.05$)with sand, pH and phosphorus and positively correlated ($P<0.05$) with clay. The negative correlation between Al, sand, P and pH indicates Al exerts a negative influence on sand, P, and pH properties of the soil by fixing phosphorus, increase soil acidity with increased sand content (Anderson-cook *et al.,* 2002). Hydrogen was negatively correlated ($P \leq 0.05$) with sand, pH, P, and OM while H correlated positively with clay and Al. The negative correlation between H^+, pH, P, OM and sand indicates the effect of H+ influence in the soil acidity, fixing of P, low content of OM, while the positive correlation between H^+, clay and Al indicates the nature of the clay mineral in the soil (Jegede *et al.,* 2011). Ksat negatively ($P \leq 0.01$) correlated with sand, P and bulk density and correlated ($p<0.01$) positively with silt. Ksat increases the silt content thereby decreasing the soil bulk density and increases the P content of the soil.

Conclusion
The results of this study showed variations in some of the measured soil properties in the different sites. To some extent the waste had positive and negative influence on the surface and subsurface properties studied. The OM site recorded the highest bulk density at both depths (0-20 and 20-40cm). We observed that the soils from the dump sites (AD and AD) had good potentials for arable

crops since the physical, chemical and moisture characteristics observed are indicative of the high fertility potentials in these soils.

Uptake Characteristics of Lead (Pb) and Cadmium (Cd) by Turmeric (*Curcuma longa* Linn) as Influenced by Single and Mixed Pb and Cd Treatments

C.C. Nwokocha
National Root Crops Research Institute, Umudike. P.M.B. 7006. Umuahia Abia State. Nigeria. E-mail: chrisnwokocha@gmail.com

Abstract
Greenhouse experiments were carried out to study the uptake of lead (Pb) and cadmium (Cd) by turmeric (Curcuma longa Linn) plant. The experiment investigated how adding Pb and Cd singly and simultaneously to Amakama and Ajata-Ibeku soils affected turmeric uptake of Pb and Cd. Results obtained revealed that Amakama soil had a sandy clay loam texture and Ajata-Ibeku soil a clayey texture. In Ajata-Ibeku soils, the values of effective cation exchange capacity (ECEC), pH, clay and organic matter (OM) were higher than the corresponding values obtained in Amakama soils. Background values of Pb and Cd were 26.30 and 1.05 mg/kg, respectively in Amakama soil and 17.55 and 0.45 mg/kg, respectively in Ajata-Ibeku soils. Both soils are deficient in macronutrients. Lead and Cd accumulation in turmeric followed the order: rhizome > root > shoot. Though over 50% of total Cd and Pb taken up by turmeric was transferred to the rhizomes, their presence did not pose any health risk to the consumers of turmeric spice as their computed provisional tolerable weekly intake (PTWI) values (< 0.25 mg Pb/person/week and 0.08 mg Cd/person/week) were far below recommended safe limits of 1.50 mg Pb/person/week and 0.42 mg Cd/person/week. Monitoring heavy metals in soils and edible plant parts should be regarded as a requirement for safe consumption of crops grown in contaminated agricultural fields. The need to conduct similar studies on other root and tuber crops was also highlighted.

Introduction
Hitherto, abandoned refuse dumpsites are usually invaded by peri-urban farmers for crop production. These sites are normally used for production of high-value-crops such as vegetables, ginger and turmeric. Farmers are attracted to those sites because of the high rate of returns on investment associated with crop production on such sites. The potential of heavy metals to accumulate in toxic concentrations at refuse dump sites have received wide attention. Alhough, Bushra *et al.* (2011) studied the heavy metal contamination of herbal drugs by environmental pollution, results showed that ginger (*Z. officinalis*), a close relation of turmeric (*C. longa*) contained toxic concentrations of Cd (1.63 μg/g) and Pb (13.13 – 22.63 μg/g). Similar research has not been carried out on the genus *Curcuma* to which turmeric belongs, and no known study has determined Pb and Cd uptake characteristics of turmeric plant. Turmeric (*Curcuma longa* Linn) is a tropical perennial herb. The rhizome of turmeric is used to make spice. Turmeric spice is a natural food colourant and preservative. It is the principal ingredient in curry powder. Turmeric's active ingredient is curcumin, which is found in the plant's rhizome, and is reputed to have a wide range of therapeutic effects. Turmeric is presently attracting a lot of interest because of the health benefits in the consumption of the rhizomes; however, people are expressing concerns over the high levels of Pb reported in turmeric processed spice (*http://www.nowfoods.com/M101512.htm assessed 9th June,2009*). Nevertheless, the report did not indicate the source of contamination. The absence of studies on Pb and Cd uptake by turmeric plant represents a gaping hole in vital scientific information considering that the crop is gaining acceptance in Nigeria as an herbal plant. The main objective of this investigation was to determine the effect of single and mixed Pb and Cd contaminations on the metals' uptake characteristics of turmeric.

Materials and Methods

Three sets of experiments were set up in the greenhouse at National Root Crops Research Institute, Umudike (Longitude 07° 33´E and Latitude 05° 29´N), each in a completely randomized design to study the effect of single Pb contaminations (0, 50, 10, 0, 150 and 200 mg/kg Pb), single Cd contaminations (0, 1.5, 3.0, 4.5 and 6.0 mg/kg Cd) and mixed Pb and Cd contaminations (0, 50 Pb + 1.5 Cd, 100 Pb + 3.0 Cd, 150 Pb + 4.5 Cd and 200 Pb + 6.0 Cd mg/kg) on metals' uptake characteristics of turmeric. All treatments were replicated three times. Five litres volume plastic pots were packed with 5 kg of soil and thereafter the potted soils were appropriately contaminated with lead nitrate [$Pb(NO_3)_2$] and cadmium chloride ($CdCl_2$), the inorganic sources of Pb and Cd respectively, according to the relevant treatment level. The soils were allowed to equilibrate for 3 days. Turmeric (*Curcuma longa* Linn) mother rhizome was planted in the potted soils. In order to eliminate nutrient deficiency, single fertilizers were added 8 weeks after planting (WAP) at the rates of 60 kg N, 13 kg P and 25 kg K/ha (Nwokocha *et al.,* 2009) using $(NH_4)_2SO_4$, $Ca_3(PO_4)_2$ and K_2SO_4 respectively. The plants were grown in the green house for a period of 20 WAP. The harvests (at 20 WAP) were separated into; shoots rhizomes and roots per plot. Samples were subsequently washed with deionized water and oven dried at 65°C to a constant weight. Dried samples were weighed to determine their dry matter yield. The samples were thereafter milled using a milling machine (THOMAS WILEY MILL model ED-5). The milled plant samples were oven-dried at 105°C for 2 hours. The plant samples were digested in a solution containing 3:1 HNO_3:$HClO_4$ solution. The samples were thereafter analyzed for Pb and Cd using Atomic Absorption Spectrometer (AAS) of UNICAM 919 model (Algeria *et al* (1991). Data obtained were subjected to statistical analysis of variance for a CRD experiment. Means were compared at 5% probability level using Duncan new multiple range test (DNMRT). Values of Pb and Cd in the rhizomes were compared with the WHO (1993) minimum allowable standards. All reagents used in the analysis were of analytical grade. Analysis was done in duplicate. In all determinations, blanks were included.

Results and Discussion

Background Soil Data

The two soils, Amakama (Fine-loamy, mixed, semi-active, isohyperthermic Rhodic Kandiudult) and Ajata-Ibeku (Fine, mixed, semi-active, isohyperthermic Aquic Haplustalf) soils (Chikezie *et al*., 2010) studied represent the most important agricultural soils of Abia State, southeastern Nigeria. Nonetheless, the background soil physicochemical properties (Table 1) showed that the soils have differing physicochemical properties, as a result of their contrasting parent materials. Amakama soil showed a sandy clay loam texture and Ajata-Ibeku soil a clayey texture. In Amakama soils, the values of ECEC (11.75 cmol/kg), pH (4.6), clay (22.6%) and OM (0.86%) were lower than corresponding values (ECEC (25.15 cmol/kg), pH (5.0), clay (56.3%) and OM (2.14%) obtained in Ajata-Ibeku soils. Background values of Pb and Cd were 26.30 and 1.05 mg/kg, respectively in Amakama soil and 17.55 and 0.45 mg/kg, respectively in Ajata-Ibeku soils. Both soils have acidic reaction and are deficient in macronutrients. Similar results were reported by Chikezie *et al.* (2010).

Uptake characteristics of Pb and Cd by turmeric plant

Concentrations of Cd and Pb in the organs of turmeric plant due to single and mixed Cd and Pb applications in the study soils are as presented in Table 2. Cadmium concentrations in *C. longa* L tissues were in the order of: rhizome > root > shoot in Amakama and Ajata-Ibeku single and mixed Cd treatments. However, amount of Cd accumulated in turmeric organs and whole plant varied with treatments and soil. High accumulation of Cd (≥ 50%) in the rhizome, out of the total accumulated Cd in the plant could be attributed to plant physiological processes and not to treatments applied in both soils, since they did not confer any significant ($P < 0.05$) difference in Cd accumulated in the rhizome (Table 2). Lasat *et al.* (1998) identified this as a plant mechanism responsible for immobilization. They explained that metals can be complexed and sequestered in cellular structures (e,g,, food vacuoles), becoming unavailable for translocation to the shoot. Their report may explain the amount of Pb and Cd accumulated in the rhizomes of turmeric relative to other plant parts. It is important to note that, out of the total amount of ions associated with the root (0.14 - 0.245 mg/kg), only a small part may have been absorbed into cells. According to Lasat (2000) a significant ion fraction is physically adsorbed at the extracellular negatively charged sites (COO^-) of the root cell walls in non-accumulators. The cell wall-bound fraction cannot be translocated to the shoots and, therefore, cannot be removed by harvesting shoot biomass (phytoextraction) (Lasat, 2000). In support of this, Blaylock and Huang (1999) concluded that the limiting step for most metal phytoextraction is the long-distance translocation from roots to shoots. In Amakama soils, co-presence of Pb and Cd caused a 21% increase in the rate of uptake of Cd levels in *C. longa* L above the uptake in single treatments and 23% in Ajata-Ibeku soils (Table 2). Miller *et al.* (1977) observed that the accumulation of Cd was increased by the addition of Pb in *Zea mays.* Similarly, Pb was observed to increase uptake of Cd in rye and Fescue (Carlson and Roffe, 1979). Lead concentrations in *C. longa* L tissues were in the order of: rhizome > root > shoot in Amakama single and mixed Pb treatments. However, in Ajata-Ibeku soil, Pb uptake was almost equally distributed in the organs (Table 2). A comparison of total Pb absorbed by *C. longa* L in the two study soils indicated that under single and mixed Pb treatments, *C. longa* L in Amakama soil absorbed higher Pb (1.623 mg/kg) under mixed Pb treatments, than it did under single Pb treatments (1.450 mg/kg). In Ajata-Ibeku soil, similar trend was not followed. Co-presence of Pb and Cd reduced Pb uptake by 9%. The differential Pb absorption under mixed treatments in the study soils may be due to differences in soil physicochemical properties which favoured Pb adsorption on soil particles in Ajata-Ibeku soils and less Pb being in solution for plant uptake. Results from this study showed that though over 50% of total Cd and Pb uptake by *C longa* L was transferred to the rhizome (Table 2), their presence in the rhizome did not pose any health risk as they were far below the recommended tolerable rhizome limits (10.7 mg Pb/kg d.w. and 3.0 mg Cd/kg d.w.) and having Provisional Tolerable Weekly Intake (PTWI) values (< 0.25 mg Pb/person/week and < 0.08 mg Cd/person/week, against WHO (1993) PTWI standards of 1.50 mg Pb/person/week and 0.42 mg Cd/person/week) were under safe limits. A daily intake of turmeric rhizome of 20 g was assumed to be consumed by an average body weight of 60 kg and was used to calculate the PTWI values used in this study.

Conclusion

Though over 50% of total Cd and Pb taken up by turmeric was transferred to the rhizomes, their presence did not pose any health risk to consumers of turmeric spice as their computed provisional tolerable weekly intake (PTWI) values (< 0.25 mg Pb/person/week and 0.08 mg Cd/person/week) were far below WHO (1993) safe limits of 1.50 mg Pb/person/week and 0.42 mg Cd/person/week. There is scope to carry out similar research on Pb and Cd uptakes in other root and tuber crops and in other soil types since they have not been studied locally. A study in which accumulation of Pb and Cd in animal organs are investigated and related to their levels in root and tuber crops and soils would assist policy makers to draw up management practices and policies on risk assessment of Pb and Cd in the country.

Abstract
Biochar is the by-product obtained when biomass is burned or heated with a minimum or absence of oxygen. Research consistently reveals that poor soils enriched with biochar grow bigger and stronger plants that yield higher crop quantity and quality. Organic agricultural wastes are annually available on small holder farms in abundance in developing countries. These agricultural wastes are of low monetary value and can cause environmental pollution. These agricultural by products could be a principal source for value added products for use in improving agricultural soil condition for enhanced crop productivity and disease suppression. Using crop residues for the developments of biochar products (such as: Biochar bokashi, glomali, biochar compost and other blends) for agricultural applications could provide an additional source of revenue for small holders farmers; while at the same time, reducing environmental pollution, mitigating climate change and improving the aesthetic value of small farms. Determining where and how to apply biochar begins with the characterization of the biochar material. Characteristics of biochar materials will vary depending on what the biochar is made from, and how it is made. When applying biochar to soil for improving its fertility, the biochar should ideally be located near the soil‟s surface in the root zone, where the bulk of nutrient cycling and uptake by plants takes place. Certain systems may benefit from the application of biochar in layers below the root zone, for example during landscaping for C sequestration or if using biochar for moisture management. When deciding how to apply biochar to soil, the specific cropping system must be taken into consideration.

Introduction
Biochar is a fine-grained, highly porous biological charcoal substance that is distinguished from other charcoals in its intended use as a soil amendment. Biochar is charcoal that has been produced under conditions that optimize certain characteristics deemed useful in agriculture, such as high surface area per unit of volume and low amounts of residual resins, Nkongolo et.al. (2002), Ekebafe (2011). Biochar is a fine-grained charcoal high in organic carbon and largely resistant to decomposition. It is produced from pyrolysis of plant and waste feedstocks. As a soil amendment, biochar creates a recalcitrant soil carbon pool that is carbon-negative, serving as a net withdrawal of atmospheric carbon dioxide stored in highly recalcitrant soil carbon stocks. The enhanced nutrient retention capacity of biochar-amended soil not only reduces the total fertilizer requirements but also the climate and environmental impact of croplands Ekebafe et., al. (2011). Char-amended soils have shown 50 - 80 percent reductions in nitrous oxide emissions and reduced runoff of phosphorus into surface waters and leaching of nitrogen into groundwater. The heat treatment of organic biomass used to produce biochar contributes to its large surface area and its characteristic ability to persist in soils with very little biological decay, Lehmann et.al (2006). While raw organic materials supply nutrients to plants and soil microorganisms, biochar serves as a catalyst or a conditioner that enhances plant uptake of nutrients and water. Compared to other soil amendments, the high surface area and porosity of biochar enable it to adsorb or retain nutrients and water and also provide a habitat for beneficial microorganisms to flourish, Lehmann et.al (2006), Glaser (2007), Warnock et.al (2007). The production and application of biochar over the years by small holder farmers has been a challenge because of the lack of simple and cost effective technology and technique to effectively harness the benefits of these materials to soil.

Available data shows that current use of biochar is on a mechanized scale. There is need therefore to create a bridge between the small holder farms and the mechanized in the subject matter. Hence the need for the study with the specific objective of unveiling the technology and technique that could be used by small holder farmers for the production and application of biochar to soils.

Biochar Production

Biochar is produced after pyrolysis of biomass, typically within a temperature range of 200°C to 700°C. Pyrolysis is the thermal degradation of biomass under the (partial) absence of oxygen. Pyrolysis results in three products: biochar, non-condensable gases and condensate (tars and water). The proportion of each is a strong function of the feedstock and the operating conditions of the pyrolyser, Ekebafe et., al. (2013ab). As such, the design of the pyrolysis kiln or retort is important in determining temperature range and biomass to biochar conversion efficiency Reddy, (2014). For small holder farmers particularly in the rural areas where biochar is simply the end-product left behind after meals have been prepared on biomass stoves; stove design determines the rate of energy generated, biochar and ash produced as by products. With its higher efficiency, a typical „good stove" reduces biomass fuel consumption and produces 20% to 60% biochar of the original biomass used as fuel by weight, Reddy (2014), Antal and Gronli (2003). However, there are other methods of producing biochar which include: trench mould kilns, mould kiln, pit kiln, biochar kiln, magh biochar retort, and the Geo mini metal retort. In all, the small holder farmers can produce high quality biochar using the traditional biochar stove, biochar kiln, pit kiln and the traditional moulds. The typical rural charcoal burning mound is about 4 m in diameter at the base and about 1 m to 1.5 m high, looking somewhat like a flattened hemisphere. Six to ten air inlets are made at the base, with an opening at the top of about 20cm in diameter to allow smoke to exit during the burning. All openings must be sealed with earth when burning is complete and the mound should be allowed to cool as shown in Figure 1. Biochar pit kiln is one of the simplest methods of converting crop residue and other biomass into biochar. Farmers can easily create pits or trenches and convert the biomass residue. As shown in Figure 2. About 60% biochar production is possible with biochar kiln technology (Figure 3). Three to four hours are required to produce a batch of charcoal. These kiln are highly suitable for making biochar. Many small holder farmers can generate biochar from the following sources: Campfires with chunks of charcoal remaining after fires. Wood burning stoves may be operated in such a way as to produce a small amount of charcoal. In most regions, it is possible to purchase "lump wood charcoal" for grilling food. Charcoal "briquettes" and Spent charcoal from an aquarium filter.

Characterization and Testing of Biochar

Determining where and how to apply biochar starts with the characterization of the biochar material. Characteristics of biochar materials will vary depending on what the biochar is made from, and how it is made (That is the feedstock and the technology). Change in the pH, ash content, surface area, and other characteristics of biochar is the basis for the concept of designer biochar, Novak et., al., (2009), where the characteristics of a biochar are matched to the specific needs of a soil and/or soil management system. For example, certain high-pH biochars may be best for applying to acidic soils, while others with elevated contents of highly recalcitrant C (but which are amorphous in structure) might be better suited to situations where C sequestration is the main goal, Blackwell et., al. (2009). Before adding biochar or any amendment to field soil, one should ensure it will not be harmful in that environment at the intended application rate. Biochar made under certain conditions may contain substances that are harmful to plants, and the suitability for soil application may therefore be in doubt. It is therefore necessary to determine the suitability of a biochar for soil application by carrying out the tests below, designed to assess the presence of harmful substances. These tests are also described in IBI Technical Bulletin 101, Julien Major (2010), they include the germination test, the worm avoidance test and the field test. The goal of germination tests is to determine whether adding biochar to soil has an effect on seed germination. It is assumed that a negative effect indicates the presence of undesirable compounds in the biochar material. Lettuce (Lactuca sativa L.) is the most widely recommended species to use, due to its sensitivity to the presence of toxins and contaminants in general (US EPA 1994). Other species that could be used include radish (Raphanus L.) and clover (Trifolium L.). The worm test is more complex test, since it requires live worms to complete. However, it may be more sensitive than a germination test with plant seeds. A common type of worm used for this test is the white worm (Enchytraeus albidus). Alternatively, worm species Eisenia fetida and Eisenia andrei, commonly known as redworms, brandling worms, tiger worms and red wiggler can be used. In the field test, two concepts should be kept in mind when doing field trials: 1) biochar amended soil needs to be compared to an appropriate alternative treatment, the "control"; and 2) it is best to replicate your treatments by planting multiple plots of the biochar amended and control treatments across the field. Testing biochar in more than one location is desirable because there is a chance that the location which was chosen for the biochar is different from the location where the control is applied, and this can affect the results either positively or negatively.

Soil Application of Biochar

The particle size of biochar affects its mode of application. With small particles, it is important to apply biochar in ways that minimize loss due to wind or water erosion. A best management practice to greatly reduce such wind losses is to moisten biochar, however adding water increases the weight of the material and this can increase transport costs. While water is usually added to biochar immediately after exiting the pyrolysis unit in order to quench it, more water could be applied to reduce dustiness prior to field application Ekebafe et., al. (2015), Blackwell et., al. (2007). Moisture content must always be taken into consideration when determining application rate, whether or not the end user adds water themselves. Biochar that is seemingly dry can contain a high percentage of moisture, and application rates can be overestimated. It is helpful to apply biochar during mild rain conditions where light rain will dampen biochar dust and hold it on the soil surface until it can be tilled in. The application rate of Biochar materials are greatly influenced by their characteristics, thus the nature of a specific biochar material (e.g. pH, ash content) also influences application rate. In the published literature, several studies have reported positive effects of biochar application on crop yields with rates of 5-50 tonnes of biochar per hectare, with appropriate nutrient management. This is a large range, but often when several rates are used, the plots with the higher biochar application rate show better results (Chan et al., 2007, 2008; Major et al., 2010). Since the C content of biochar materials varies, it may be appropriate to report application rates in tonnes of biochar-C per hectare, as opposed to tonnes of bulk biochar material. A 10 t/ha application of poultry manure biochar contains much less C (and more ash) than an equivalent application of wood waste biochar. However, ―high-ash biochar can constitute a source of various plant nutrients, and these should be taken into consideration when managing soil fertility at the field level. Due to its recalcitrance to decomposition in soil, single applications of biochar can provide beneficial effects over several growing seasons in the field (Steiner et al., 2007; Major et al., 2010). Most biochar materials are not substitutes for fertilizer, so adding biochar without necessary amounts of nitrogen (N) and other nutrients cannot be expected to provide improvements to crop yield. Since biochar itself cannot be considered a source of nutrients (unless it has a high ash content), there is interest in blending it with other materials such as synthetic fertilizers, compost, composites and manures to enhance its value as a soil amendment. Furthermore, biochar has been shown to retain nutrients against leaching (Major et al., 2009; Novak et al., 2009), potentially improving the efficiency of nutrients applied alongside biochar. Adding biochar to sewage sludge or poultry manure during composting has been shown to reduce N losses (Dias et al., 2009; Hua et al., 2009) and the mobility of some heavy metals was also reduced in sewage sludge compost with biochar (Hua et al., 2009). Dias et al. (2009) compared biochar to other bulking agents for compost making, and found that adding biochar resulted in greater humification or —maturity of the compost at the end of the study period. It is also believed that adding biochar to composts and manures can reduce odour. When applying biochar to soil for improving its fertility, the biochar should ideally be located near the soil‟s surface in the root zone, where the bulk of nutrient cycling and uptake by plants takes place, Ekebafe (2011). Certain systems may benefit from the application of biochar in layers below the root zone, for example during landscaping for C sequestration or if using biochar for moisture management. Similarly, if biochar were to be applied to soil solely for C sequestration purposes, placement deeper in the soil, for example in new landscaping or construction areas, would be desired since microbial activity that can degrade biochar carbon is reduced deeper in the soil profile. When deciding how to apply biochar to soil, the specific cropping system must be taken into consideration. The likelihood of wind and water erosion losses of biochar is reduced when biochar is thoroughly incorporated into soil, however, plowing and soil mixing are not possible or desirable in all cropping systems, at all times, Julien Major (2010).

Conclusion

Biochar production and application in small holder farms may create a triple wins scenario, where farmers get higher yields and compensation for environmental services; society gets reduced eutrophication and less negative environmental impacts from intense farming practices; and humanity gets sustainable food production at the same time as climate change effects and the connected risk of reaching climate tipping points are reduced. Biochar contribute to a sustainable society in its true meaning for future generations by closing the cycles between arable land and human habitations. The technique is democratic, since it can be applied anywhere around the globe where plants are growing and it is not dependent of economic, technical or infrastructural development. It is independent of scale, too, so also home gardeners and small holder farmers may transform garden waste into a soil improver to use in their own garden or farms.

Abstract
A study was conducted at the agroforestry plantation of the Forestry Research Institute Nigeria, Ibadan (latitudes 7°N to 7.2°N and longitudes 26°E to 27°E) in year 2016 to evaluate the effects of tree species, age and soil depth on soil physical and chemical properties. The experiment was a 3×3×2 factorial arrangement in Randomised Complete Block Design with three replications comprising of three tree species (Tectona grandis, Gmelina arborea and Terminalia superba), three tree age intervals (5-10yrs, 10-15yrs and 15-25yrs), and two soil depths (0-15 cm and 15-30 cm). Soil properties determined included pH, particle size distribution, available P, total N, organic carbon, exchangeable cations, effective CEC and micronutrients and data collected were subjected to Analysis of Variance and means were separated using Duncan's Multiple Range Test at p<0.05. Results showed that 15-25 years old Gmelina arborea had soils with the greatest clay content (29.1 g/kg) while 5-10 years old Terminalia superba had the least clay content (6.90g/kg). Soils of Terminalia of all the age groups tend to have the highest silt content(86.0 g/kg). Soil pH was moderately acidic (5.88) and did not vary significantly (p<0.05) under the tree species, age group and soil depth. The interaction effect of tree species and age showed significant difference in soil organic carbon. Terminalia at 5-10 years old and Gmelina at 15-25 years old had the highest soil organic carbon content (27.5 g/kg) while Terminalia at 15-25 years old had the least soil organic carbon content (15.3 g/kg).The study concluded that agroforestry tree species and tree age had varying effects on soil chemical and physical properties.
Keywords: Agroforestry, Tectona grandis, Gmelina arborea, Terminalia superba, physical and chemical properties.

Introduction
Agroforestry is a collective name for land use system and practices where woody perennials are deliberately integrated with crops and / or animals in some form of spatial arrangement or temporal sequence (ICRAF, 2000). The role of agroforestry to agricultural sustainability is very significant. It provides opportunities to balance productivity and profitability with environmental stewardship and pass on healthy and sustainable agricultural systems to future generation (Adekunle, 2009). Agroforestry is a scientific approach for eco- restoration of degraded lands and sustainable resource management. Several factors have contributed to a rising interest in agroforestry since the 1970, the deteriorating economic situation in many parts of the world, increased tropical deforestation, degradation and scarcity of land because of population pressures and growing interest in farming systems, intercropping and the environment (Adekunle, 2009). Agroforestry practices encompass an entire spectrum of land use systems in which woody perennials are deliberately combined with agricultural crops / or animals in some spatial or temporal arrangement (lundgren and Raintree 1982). The presence of woody perennials in agroforestry systems may affect biophysical and biochemical processes that determine the health substrate (Nair *et al*., 1995). The effects of trees on soil may include; amelioration of erosion, primarily through surface litter cover and under storey vegetation maintenance or increase of

organic matter and diversity, through plant root and decomposition of litter, nitrogen fixation, enhancement of physical properties such as soil structure, porosity and moisture retention due to the extensive root system and the canopy cover, and enhanced efficiency of nutrient use because the tree- root system can intercept and recycled nutrients in the soil that would have been lost through leaching. Nigeria is blessed with a large area of land and vegetation, but the use of this important resource has been abused, not sustainably used or managed. Recently everyone now realise that forest is at the verge of going to extinction if nothing is done to reverse the unsustainable use. Jama(2000) reported that Nigeria is witnessing the depletion of reserves due to hunger for more land for food production in agriculture, shifting cultivation as well as urbanization. Agriculture, Forestry and Urban development, remained the three major uses to which land is subjected. These various uses to which land is subjected have resulted in environmental stress and degradation, which has consequently led to the reduction of land area available for farming. Hence farmers have been restricted to consisted farming on the same land area for a long time, which has often resulted into decline in crop yield as well as environmental degradation. It has been hypothesized that, under agroforestry systems, soil organic carbon can be maintained at levels that are satisfactory for soil fertility due to the contribution of decomposed residues from the tree component. The contribution may come from above-ground litters and pruning, root residues, or indirectly as farmyard manure where pruning are fed to livestock. The presence of trees in a crop field influences soil structures via two main phenomena.Firstly, according to (Seiters *et al*, 1999) the trees bring organic matter to the soil through litter fall, stwigs, root turn over, pruning bye product, and an important increased was been observed in alley cropping systems planted with red alders (Seiter *et al*, 1999). Secondly, the trees develop important roots system that explore and improve notably deep and compacted soil layers that crop roots do not reach. These two phenomena have seven major effects on soil structure. By increasing the cover of the soil, the presence of the trees limits the effects of wind and rain erosion. The increase of organic and the development of root system limit soil compaction, improves water infiltration (Chander *et.al*, 1998) and increases basan soil respiration (Chander *et. al*, 1998). Moreover, they increase the weight of soil aggregates and so increase soil stability and decrease erosion risk in response to rainfall (Gupta *et.al*, 2009). The above effect can be beneficial for crops because the root ability to permeate the soil and plant capacity to uptake and export water and nutrients from the soil is improved.

Materials and Methods

Experimental site

The study site is at the agroforestry plantation of the Forestry Research Institute of Nigeria (FRIN) Ibadan, Oyo state, Nigeria (Figure 1). The area is between Latitude 7°N to 7.2°N and Longitude 26°E to 27°E. The climate is mainly tropical with rainfall patterns ranging between 1,000 mm and 14,500mm, the average temperature is about 30°C while relative humidity is about 65%.

Experimental Design

The experiment was a 3 x 3 x 2 factorial in Randomised Complete Block Design with three replications (3 agroforestry species, 3 Age series, and 2 soil depths). The 3 agroforestry species include; *Gmelina arborea, Terminalia superba,* and *Tectona grandis*. The three age series include: 5-10 years, 10-15years, 15-25years, and the two depths were 0-15 cm and 15-30 cm soil depth.

Soil sample collection and preparation

Soil samples were collected from 0-15 cm and 15-30 cm depth using auger (plate 1,2 and 3) and the coordinate of each sampling point were determined with the aid of geographical positioning system (GPS). The bulk samples were then air dried and passed through 2 mm sieve to remove rock and un-decompose organic material.

Result and Discussion

Table 1 show that the effect of agroforestry tree species, tree age and soil depth was only significant on the clay content of the soil (Table 1). *Gmelina* had significantly greater clay content than soils under *Terminalia* and *Tectona*. The age group 15-25 years had the highest clay content. The subsoil had greater clay content. The interaction between tree species and tree age was significant on the clay and silt contents of the soil though other possible interaction effects were not significant. *Gmelina* 15-25 years old had soils with the greatest clay content while *Terminalia* 5-10 years old had the least clay content (Table 2). *Terminalia* at all the age groups tend to have the highest silt content. The soil pH was moderately acidic and did not vary significantly under the tree species, age group and soil depth. There was no significant interaction between tree species and age group, tree and soil depth, and tree, age and soil depth on the medium of soil reaction. The total nitrogen, exchangeable sodium, potassium, magnesium and the micronutrients (Mn, Fe, Cu and Zn) all followed the same trends as the soil pH. The soil organic carbon was high but did not vary significantly under the agroforestry tree species. The age of the trees had significant effect on the organic carbon. Trees of 15-25 years had greater soil organic carbon. Depth wisely, there was no variation in the soil organic carbon of the surface and subsurface. The interaction between tree species and age showed significant effect on soil organic carbon. *Terminalia* at 5-10 years old and Gmelina at 15-25 years old had the highest soil organic carbon content while *Terminalia* at 15-25 years old had the least soil organic carbon content though not significantly different from those of *Tectona* at 5-10 and 10-15 years old. Exchangeable calcium varied significantly from 5.28 – 1.61 cmol kg-1 under the *Gmelina* and *Terminalia*, respectively. The effect of tree age was also significant, trees of 15-25 years old had greater soil exchangeable calcium than others. The main effect of soil depth and all the interactions were not significant at 5 % probability level

Means followed by same letter are not significantly different (P>o.o5)

Conclusion

The effects of agroforestry tree species and tree age on soil physical and chemical properties were evaluated. It could be concluded that agroforestry tree species and their age have varying effects on soil physical and chemical properties. *Gmelina* of 15-25 years old had soils with the greatest clay content while *Terminalia* of 5-10 years old had the least clay content. The effect of tree age was also significant; trees with 15-25 years old had high soil exchangeable calcium among others.

Abstract
Understanding phosphorus (P) dynamics in soil in relation to plant nutrition is essential for optimizing P management and improving P-use efficiency as well as recycling P from plant litters. A study was conducted at the agroforestry plantation of the Forestry Research Institute Nigeria, Ibadan (latitudes 7°N to 7.2°N and longitudes 26°E to 27°E) in year 2016 to evaluate the effects of tree species, age and soil depth on P fractions and as well as the interrelationships between these and other soil properties. The experiment was a 3×3×2 factorial arrangement in Randomised Complete Block Design with three replications comprising of three tree species (Tectona grandis, Gmelina arborea and Terminalia superba), three tree age intervals (5-10yrs, 10-15yrs and 15-25yrs), and two soil depths (0-15 cm and 15-30 cm). Soil properties determined included pH, particle size distribution, available P, total N, organic carbon, exchangeable cations, effective CEC and micronutrients. Phosphorus fractions determined included labile P (Lab-P), Al and Fe- P (Al/Fe-P), Ca bound P (Ca-P), residual P (Res-P) and organic P (Org-P). Data collected were subjected to Analysis of Variance and means were separated using Duncan's Multiple Range Test at p<0.05. Results showed that the soil pH was moderately acidic (5.88±1.20) and did not vary significantly (p<0.05) under the tree species, age group and soil depth. Tree species and tree age, tree species and soil depth, tree age and soil depth, tree, age and depth interactions did not have significant impact on the available, labile, Al/Fe and Ca-P. There was significant interaction effect (p<0.05) between tree age and soil depth on the residual and Org-P. In all, the soils under the various agroforestry tree species, Org-P, followed by the available P were the most abundant P fractions and the least was Ca-P fraction. The specific phosphorus requirement increased with increasing tree age and Lab-P (p<0.05) negatively correlated (r = -0.6150) with Res-P, Org-P and sand content, while it positively correlated (r = 0.029) with the soil potassium content. The study concluded that agroforestry tree species and tree age had varying effects on soil chemical and physical properties and phosphorus fractions . These factors should therefore be taken into consideration in soil phosphorus management programmes.*

Keywords: Phosphorus fractions, Tectona grandis, Gmelina arborea, Terminalia superba, Agroforestry

Introduction
Phosphorus (P) is a critical macronutrient for plant growth that acts in various basic cellular functions (such as biosynthesis of adenosine triphosphate—ATP), in the activation of metabolic intermediates, as a component in signal transduction cascades and post-translational regulation of enzymes, and as a structural element in nucleic acid and phospholipids (Crews and Brookes, 2014). However, plant growth is limited due to poor availability and low mobility of P in the soil. Thus, P deficiency presents a significant global concern to crop production (Sharma *et al*. 2013). Although most soils in the world contain a significant amount of P, around 200—3,000 mg P per kg of soil (Richardson et al. 2009), only a small proportion of this (generally less than 1 %) is immediately available to plants due to its physicochemical behaviour and interaction with the soil mineral interface (Stewart and Tiessen 1987). In highly weathered soils, such as the tropical Oxisols, P deficiency is mainly attributed to the strong adsorption of phosphate by Al- and Fe-

oxides through a mechanism not completely elucidated (Grafe, 2000). Notwithstanding, plants possess a number of physiological adaptations that enhance P acquisition under conditions of low P availability. These included strategies that preserve internal P or those that increase the availability of P through the modification in root structure or function (Richardson *et al*. 2009) or even making a symbiotic association with specific microorganisms such as mycorrhizae (Xavier, 2011). The interrelations among the various forms of P within soil are complex. However, information about the distribution of soil P pools can increase our understanding about sinks and sources of P in the soil, and is essential for an efficient P management programme (Haygarth *et al*. 2014). Soil P transformations are primarily mediated by microbial activity, which is influenced by a combination of factors that can affect the P dynamics in the soil, including plant species, environmental conditions, soil type and soil management (Xavier, 2011). The challenge for cultivation of soils with low P availability, such as Oxisols, is to develop strategies of management that can enhance P acquisition by plants, for instance favouring the build-up of organic P pool. One of these important strategies is intercropping with tree species as in agroforestry systems (Gordon *et al*. 2016). Agroforestry systems have been pointed out as a major opportunity to reclaim degraded agricultural lands in the Rainforest biome (Grafe, 2000). Agroforestry systems can enhance nutrient-use efficiency in tropical soils, including P, by increasing the cycling of nutrients from tree litter and prunings; and reducing losses by erosion (Atangana *et al*., 2014). The forms of P in soils and sediments can be operationally defined by chemical extraction schemes (Adhikari *et al*., 2015). Briefly, they assumed that the major inorganic P components are: (1) adsorbed by exchange sites; (2) associated to complexes of Fe- and Al-oxides; (3) associated with calcium or carbonates; or (4) stabilized in a crystalline mineral. The organic P fraction in turn can be associated with: (1) labile organic matter; (2) humic substances; (3) acid-soluble organic components; or (4) residual or refractory phosphate esters and phosphonates (Hedley *et al*. 1982). The estimation of the various P pools in the soil is usually carried out by sequential P fractionation, which includes the use of increasingly aggressive reagents. One of the fractionation procedures often used is that of Hedley (Hedley *et al*. 1982) further modified by Tiessen and Moir (1993). The later comprises the sequential extraction of inorganic and organic P forms by using reagents with different strength of extraction, resulting in the fragmentation of soil P, taking into account their different degree of lability. H_2O–Pi and $NaHCO_3$–Pi and –Po are considered the most labile P pool; NaOH–Pi and –Po and diluted HCl–Pi as moderately labile P; whereas hot concentrated HCl–Pi and –Po and residual-P as non-labile P pool (Tiessen and Moir 1993)

Materials and Methods

Experimental site

The study site is at the agroforestry plantation of the Forestry Research Institute of Nigeria (FRIN) Ibadan, Oyo state, Nigeria (Figure 1). The area is between Latitude 7°N to 7.2°N and Longitude 26°E to 27°E. The climate is mainly tropical with rainfall patterns ranging between 1,000 mm and 14,500mm, the average temperature is about 30°C while relative humidity is about 65%.

Experimental Design

The experiment was a 3 x 3 x 2 factorial in Randomised Complete Block Design with three replications (3 agroforestry species, 3 Age series, 2 soil depth). The 3 agroforestry species include; *Gmelina arborea, Terminalia superba,* and *Tectona grandis*. The three age series include: 5-10 years, 10-15years, 15-25years, and the two depths were 0-15 cm and 15-30 cm soil depth.

Soil sample collection and preparation

Soil samples were collected from 0-15 cm and 15-30 cm depth using auger (plate 1,2 and 3) and the coordinate of each sampling point were determined with the aid of geographical positioning system (GPS). The bulk samples were then air dried and passed through 2 mm sieve to remove rock and un-decompose organic material.

Results and Discussion

Table 1 shows the The distributions of soil phosphorus fractions as affected by agroforestry species.The effect of different agroforestry tree specie and their age showed significance on the various fractions of soil phosphorus (Table 3). Soils under *Terminalia* had the highest available P while those under *Gmelina* had significantly the lowest available P. There were no significant differences in the labile P, Al, Fe and Ca bound P of the soil phosphorus fractions under the different tree species. The residual P and the organic P varied significantly under the tree specie. *Terminalia* and *Tectona* had greater residual P than *Gmelina*. *Terminalia* had the highest organic P, followed by *Gmelina* and *Tectona*. Tree age did not significantly affect the soil phosphorus fractions except the organic P fraction. Trees of 10-15 years old had the highest organic P while Trees 15-25 years old had the lowest organic P (Table 3). Likewise, the soil phosphorus fractions did not vary significantly across the soil depth. The subsoil, however, had greater soil organic P than the topsoil. Interactions between tree and age, tree and depth, age and depth, tree, age and depth did not have significant impact on the available P, labile P, Al/ Fe-P and Ca bound P (Table 5). Tree specie and tree age had significant interaction on the soil organic phosphorus. *Terminalia* 5-10 years old had the highest organic P fraction followed by *Gmelina* 15-25 years old while the least occurred in soils of *Tectona grandis* 5-10 years old (Table 5). Tree species and soil depth had significant effect on the soil organic P. The subsoil under the *Terminalia* had the highest organic P fraction while the lowest was obtained in topsoil under the *Gmelina* (Table 5).There was significant interaction between tree age and soil depth on the residual and organic P (Table 4 and 5). The residual P varied between 2.73 mg kg^{-1} and 5.12 mg kg^{-1} of tree 10-15 years and 15-25 years old, respectively of the subsoil. There was however no clear pattern in the order of variations of the residual P fraction under the interactive effect of tree age and soil depth (Table 4). The organic P varied from 18.96 – 36.19 mg kg-1 of 5-10 years old tree at the topsoil and 5-10 years old tree at the subsoil (Table 5).The 3-way interaction between tree specie, tree age and soil depth were significant on the organic phosphorus fraction (Table 5). Terminalia of 5-10 years old in the subsoil had the highest organic phosphorus fraction followed by Tectona of 15-25 years in the subsoil while the least occurred on the topsoil of Terminalia of 15-25 years old. Generally, soils of the various agroforestry tree species, organic P followed by the available P were the most abundant P fractions and the least was Ca bound P fraction. In term of abundance, the distribution of the soil phosphorus fractions across the tree age series and at varying soil depths, followed the same pattern as the agroforestry tree species

Tree: TS =*Terminalia superba*, TG= *Tectona grandis,* GA= *Gmelina arborea*
Means followed by same letter in both columns and rows are not significantly different (P>0.05)

Conclusion

The result obtained from the study showed that sinteraction between tree species and tree age, tree species and soil depth, tree age and soil depth, tree, age and depth did not have significant impact on the available P, labile P, Al/ Fe-P and Ca bound P. However there was significant interaction between tree age and soil depth on the residual and organic P. In all, the soils of the various agroforestry tree species, organic P followed by the available P were the most abundant P fractions and the least was Ca bound P fraction.

Abstract
The effects of tillage and groundnut on physico-chemical properties of an Ultisol were evaluated in Nsukka, an area located within the derived savannah zone of South-eastern Nigeria. The experiment was a randomized complete block design with six treatments and three replications. The treatments were – minimum tillage (Tm), conventional tillage (Tc), traditional tillage (Tt), conventional tillage + groundnut (TcG), minimum tillage + groundnut (TmG), traditional tillage + groundnut (TtG). Soil samples were collected before treatment application as well as at six and fourteen weeks after treatment application. Results showed that tillage practices significantly (P<0.05) influenced some soil properties relative to other treatments, the highest bulk density, state of aggregation, aggregate stability and CEC of 1.66Mg/m^3, 42%, 48% and 11 cmol/kg soil respectively, were obtained in soils that had minimum tillage treatments. However, soil under traditional tillage with or without groundnut planted had the highest available phosphorus. As a conservation practice, it is recommended that farmers in the study area should adopt minimum tillage and traditional tillage as against conservation tillage on ultisols.

Introduction
One of the important operations in the growth of arable crops in Nsukka area is tillage. The term tillage can be defined as the mechanical manipulation of the soil which usually results in structural changes. Tillage operations generally carried out in the cause of crop production include- traditional tillage, minimum tillage, conventional tillage, etc. By traditional tillage we mean the type of tillage practice adopted in most parts of Eastern Nigeria, including Nsukka area. This is making of either ridges, beds or mounds using Local Implements such as hoe and cutlass, in this method, the soil aggregates are not thoroughly broken down. Conventional tillage involves intensive working of the soil to produce a fine tilth which is often piled up in ridges, mounds, raised or sunken beds (Youdeowei and Adeniji, 1986). Minimum tillage on the other hand is the barest cultivation required to prepare the soil to establish a crop. It might include the use of chemical to kill the weed/existing vegetation followed by tillage to open only a narrow seed band (Morgan, 1991). The type of tillage operation carried out and use of crop residue to improve the physico-chemical properties and microbial activities of the soil are salient features of efficient rain fed farming. However, tillage operations have detrimental effect on surface soil structure. It greatly hastens the oxidation of soil organic matter thus reducing the aggregation effects of this soil component. Tillage also cost farmers a lot. According to Youdeowei and Adeniji (1986), the cost of mechanized tillage can be very high and when manually done it is a backbreaking job for farmers. There is dearth of research information on the effects of the different tillage operation practiced in Nsukka area on the physico-chemical properties of soils. The degradation of the soil due to tillage could be minimized when such tilled soils are planted with some crops like groundnut that will not only suppress weed growth but also have the potentials of improving soil properties. Adopting tillage method that will not lead to much soil degradation in groundnut production is important. This is against the backdrop of cost of hiring Labour or machines for this purpose. The objective of

this study is therefore to evaluate the effect of tillage and groundnut on selected physico-chemical properties of an Ultisol.

Materials and Methods

Description of the Experimental Site

The land used for the experiment is located within the Soil Science Research Farm of University of Nigeria, Nsukka. Ecologically, Nsukka belongs to the derived savannah zone of Nigeria and is located on latitude 6^0 52' North and longitude 7^0 24' East (Asadu et al., 2001). It has an average elevation of 447m above mean sea level and is characterized by tropical wet climate usually from the month of April to October and dry climate usually from the month of November to March. The mean annual rainfall is about 1700mm. Nsukka has high insulations with high temperatures throughout the year. The mean maximum temperature is about 35^0C while the mean minimum temperature is about 20^0C. The soil of the study area has been classified as Arenic Kandi Ustult (USDA, 1984), derived from false-bedded sandstone (Akamigbo and Igwe, 1990). The top 0-20cm soil is sandy loam.

Field Methods

The total experimental area measured 288m^2 and each experimental plot measured 4 x 4m. A bond was constructed round the experimental site to prevent inflow of water and control erosion. The experiment was laid out in a Randomized Complete Block Design (RCBD) with three replicates. The treatments were – minimum tillage (Tm), conventional tillage (Tc), traditional tillage (Tt), conventional tillage + groundnut cropping (TcG), minimum tillage + groundnut cropping (TmG), traditional tillage + groundnut cropping (TtG). In the Minimum tillage treatment, the only opening of the soil is to put in the groundnut seed, after planting groundnut atrazine was used to control weed at the rate of 2kg/ha throughout the period of the experiment, no other tillage was carried out on the plots. In the traditional tillage, hoe and cutlass were used to clear vegetation/weeds and land preparation. Plots that received traditional tillage were weeded twice using hoe before last soil sample collection at 14 weeks after treatment application. Conventional tillage was affected as stated in Brady and Weil (1999) this involved combined primary and secondary tillage using tractor, plough and harrow. The plots that received conventional tillage were weeded twice using hoes and cutlass. In all treatments involving groundnut, local variety obtained from the local market was used. Seeds were sown in a shallow drills 2.5cm deep at a spacing of 45cm x 30cm. Germination was monitored by counting the number of crops that emerged eight days after planting (DAP) and those that did not germinate were supplied.

Data Collection

Soil samples were collected before treatment application and at 6 and 14 weeks after treatment application. The methods used in their determination are described as follow: particle size distribution was determined by the Bouyoucos (1951) hydrometer method with sodium hexametaphoshate (calgon) as the dispersing agent. Bulk Density and moisture retention were determined using undisturbed core sampler. Aggregate Stability and mean weight diameter (WSA) indices where determined by the wet-sieving technique described by Kemper and Rosenau (1986). Soil pH was determined with the aid of the pH meter using a soil water ratio of 1:2.5. Soil Organic Matter (S0M) was determined using Walkley and Black (1934) method. Total Nitrogen was determined by the macro Kjedahl digestion procedure (Bremner, 1965). Exchangeable Bases were measured by leaching the soil with 0.1N NH_4 OAC solution. Calcium and Mg were determined by atomic absorption spectroscopy while K and Na were determined using flame photometry. Exchangeable acidity was determined by the method outlined by Mclean (1965). Available P was determined by Bray II method (Bray and Kurtz, 1945). Cation exchangeable capacity (CEC) was determined by the NH_4 OAC displacement method (Jackson, 1958).

Data Analysis

Data collected from the study were analysed using the method of analysis of RCBD experiments and Means were separated using Duncan's New Multiple Range Test (Obi, 1986).

Results and Discussion

Initial Properties of Soil Used for the study

The initial properties of soil used for this study is presented in Table 1. The soil is sandy in texture, strongly acid, low in N and K but high in available P. Soil of these properties are poor in nutrient status

Effects of Treatment on Selected Soil Properties

Physical properties

The effect of treatments on some soil physical properties are presented in Table 2. At 6 Weeks after treatment application (WATA), apart from soils of Tm and TmG treatments, all treatments reduced bulk density and increased total porosity relative to the initial values before treatment application. But at 14 WATA, the bulk density of all the soils from all treatment was lower than the initial value before treatment application. Treatments under TcG, Tc and TtG had the least bulk density and total porosity at all sampling periods. Soils of Tm and TmG treatments had the highest ($P<0.05$) aggregate stability. The decrease in total porosity of soils for some of the treatments may be due to reconsolidation and settlement occasioned by rain drop impacts (Onwualu and Ahaneku, 2001). In general, the conservational tillage practice of Tm and Tt exhibited soil moisture content significantly higher ($P<0.05$) than that for other treatments. The higher moisture retention in plots under minimum tillage and traditional tillage is attributed to the reduced soil manipulation, and higher organic matter content of these soils. On the other hand, the conventional tillage practice involves more soil pulverization and destruction of organic matter, thus Leaving soil exposed. All these combine to give more evaporation, infiltration, percolation, and hence less moisture retention at the surface soil. This finding agrees with results obtained elsewhere in Nigeria (Lal, 1979; Anazodo et al., 1991). The high aggregate stability of soils of Tm, TmG and TtG treatments may be attributed to the binding power of soil organic matter which is higher in soils of these treatments. Piccolo (1996) explained the beneficial contribution of the hydrophobic bonding of S0C in soils. Igwe et al. (1999) also, showed that S0C contributes significantly to macro aggregate stability in some soils of the tropics irrespective of their proportion in the soil. Also, Mbah and Mbagwu (2003) showed that a significant structural stability can be achieved when soils are amended with organic matter.

Soil chemical properties

Effect of treatment application on soil chemical properties is given in Table 3. Soil pH, for all treatments were generally lower than the initial value before treatment application. This general decrease may be attributed to the leaching effect or production of acidic material by micro organisms and roots of higher plants (Brady and Weil, 1999). The soil under minimum tillage was higher in acidity relative to other soils. Organic carbon values were generally higher after treatment application in all treatments. Also, soil under Tm had the highest ($P<0.05$) organic matter content. This may be as a result of the decomposition of the crop residues incorporated into the soil during the tillage and also the organic residues left on the plots on minimum tillage. Exchangeable bases Ca, Mg, K, and CEC Na were lower in soils under the different treatments when compared with the soil content of these cations before treatment application (BTA). The decrease in exchangeable bases, may be attributed to plant uptake of these bases. Annual losses from plant removal as great as 400kg/ha or more of potassium are not uncommon especially if there is a legume in the field (Brady and Weil, 1999). The decrease in exchangeable bases may also, be as a result of decrease in soil pH. Cation exchange capacity has a negative correlation with soil pH (Brady and Weil, 1999). The available phosphorus (p) of soil under different treatments were much lower than the values before treatment application. This can be attributed to plant uptake and fixation of available P due to high soil acidity . Soil available P under TtG and TcG treatments were significantly higher ($p < 0.05$) than that of other treatments. Also, total N content of soils were higher ($P>0.05$) in those soils having groundnut. The higher values obtained from these soils planted with groundnut may be attributed to the beneficial effect of groundnut, a Nitrogen fixing leguminous crop (Nnadi et al., 1981).

Conclusion

This study shows that intercropping maize with groundnut under minimum tillage and traditional tillage methods of land preparation can relatively conserve soil physical properties relative to conventional tillage as observed in the improved state of aggregation and aggregate stability of the soil. Traditional tillage also increased soil CEC relative to the other tillage methods.

Abstract

The field experiments were conducted at the National Root Crops Research Institute Farms at Umudike, Abia State, Southeastern Nigeria (Latitude 5o 29′ N and Longitude 7o 32′ E, with an altitude of 122 m above sea level) during the 2014, 2015 and 2016 cropping seasons. The land area was marked into three blocks with 1m spacing between the blocks. Each block was further marked into 9 plots of beds measuring 3 m x 2 m (6 m) with 1m spacing. The experiment was laid out in a randomized complete block design (RCBD) with three replicates. Treatments were applied only in 2014 and 2015, and comprised poultry manure (PM) and lime (LM) in t/ha. This resulted in nine treatments combinations (Control, 0 LM +10 PM, 0 LM +20 PM, 1 LM + 0 PM, 1 LM +10 PM, 1 LM +20 PM, 2 LM +0 PM, 2 LM +10 PM and 2 LM +20 PM). The treatments were incorporated in the seedbeds 14 days before planting. The planting was carried out at a planting spacing of 25cm x 50cm. Mulching was done within two days after. Gramozone with premextra was applied pre-emergence and weeded ones and supplemented with rouging. Lime treatments were broadcasted immediately after planting. A basal dressing of fertilizer application - 200kg/ha NPK (15:15:15) was added 4 weeks after planting. A composite soil sample of the experimental plot at the beginning of the field experiment as well as individual soil samples from each plot at the end of the experiment were collected at a depth of 0-15cm and processed for laboratory analysis. Harvesting of fresh rhizomes was done at 8 months after planting. The data was subjected to combined ANOVA for the three year data. Significant means were separated using the LSD at 5% alpha level. Application of Lime and poultry manure significantly (P < 0.05) influenced the rhizome yield of turmeric. Turmeric rhizome yield showed significant increases over the control, with increasing rates of poultry manure application. It was observed in this 1st year of treatment application (2014 cropping season) in Umudike that the total rhizome yield was significantly (P< 0.05) higher in plots that received poultry manure ranging from 7.54 t/ha to 12.71 t/ha with an average of 9.61 t/ha as compared with treatment without poultry manure and control which ranges from 5.20 t/ha to 6.3 t/ha with an average of 5.72 t/ha. Further observation during this 1st year cropping season was that the plots that received the highest amount of poultry manure (20 t/ha) gave the highest values of 9.87 t/ha, 11.65 t/ha and 12.71 t/ha of rhizome yield irrespective of lime rate, respectively. The above mentioned trends were also observed in the 2nd and 3rdyear planting seasons (2015 and 2016). Result of the combined analysis indicated that 20 t/ha poultry manure, irrespective of the lime rate, increases significantly (p < 0.05) turmeric rhizome yield over all the other treatments and control. The highest yield and yield parameters were obtained at lime rate of 1t/ha in combination with 20 t/ha of poultry manure. The residual impact of PM and lime on morphological growth and yield of turmeric was demonstrated in this study as tested parameters in 2016 were not significantly (P< 0.05) inferior to that of 2014.

Introduction

The Umudike soils are Ultisols and are classified as Arenic Kandiudult (Akpan-Idiok *et al*., 2012). They are strongly acidic, low in C.E.C, low in base saturation and poor in nutrient (Ita and Esu, 2013; Osodeke, 2017). They are highly leached upland ferralitic soils with kaolinite as dominant clay type. Optimum soil management for any purpose requires that soil pH be adjusted to acceptable range (Sims, 1996). Among the conditions associated with adequately limed soil are an adequate base saturation of soil's cation exchange capacity (C.E.C), the neutralization of potentially phytotoxic elements (e.g Al, Fe, Mn), the reduction in solubility of hazardous trace elements in waste-amended soils (e.g Cd, Cr, Cu, Ni, Pb and Zn). Besides, lime provides calcium which is a macro-element essential for membrane permeability, solutes transport and maintenance of cell integrity (Marchner, 1986). Organic matter application is an alternation method and superior to lime in reducing the effect aluminum toxically in acid soils (Ahmad and Tan, 1986). The organic matter content of soil also contributes to soil acidity and lime requirement because there is difference in the nature of soil acidity associates with organic matter and clay (or Fe and Al oxides), the need for lime and the means to assess lime requirement differs as well. All of soil acidity associated with organic matter on pH dependent C.E.C sites of organic functional groups such as carboxylic acid and phenols. Consequentially, most studies have shown that not only does lime requirement in soil increase with organic matter content in general, but that in soil with high organic matter contents, lime requirement increases more dramatically as target pH is raised than occurs in high clay soil (Sims,1996) . Therefore, it is the objectives of this study to ascertain the effect lime and organic matter on the yield of turmeric as well as the optimum rate of lime and organic matter application for turmeric production

Materials and Methods

The field experiments were conducted at the National Root Crops Research Institute Farms at Umudike, Abia state, Southeastern Nigeria (Latitude 5° 29′ N and Longitude 7° 32′ E, with an altitude of 122 m above sea level) during the 2014, 2015 and 2016 cropping seasons. The land area was marked into three blocks with 1m spacing between the blocks. Each block was further marked into 9 plots of beds measuring 3 m x 2 m (6 m) with 1m spacing. The experiment was laid out in a randomized complete block design (RCBD) with three replicates. Treatments were applied only in 2014 and 2015, and comprised poultry manure (PM) and lime (LM) in t/ha. This resulted in nine treatments combinations (Control, 0 LM +10 PM, 0 LM +20 PM, 1 LM + 0 PM, 1 LM +10 PM, 1 LM +20 PM, 2 LM +0 PM, 2 LM +10 PM and 2 LM +20 PM). The treatments were incorporated in the seedbeds 14 days before planting. The planting was carried out at a planting spacing of 25cm x 50cm. Mulching was done within two days after. Gramozone with premextra was applied pre-emergence and weeded ones and supplemented with rouging. Lime treatments were broadcasted immediately after planting. The fertilizer treatments were applied 2 weeks after planting (WAP). A composite soil sample of the experimental plot at the beginning of the field experiment as well as individual soil samples from each plot at the end of the experiment were collected at a depth of 0-15cm and processed for laboratory analysis. A basal dressing of fertilizer application - 200kg/ha NPK (15:15:15) was added 4 weeks after planting. Harvesting of fresh rhizomes was done at 8 months after planting. The data was subjected to combined ANOVA for the three year data. Significant means were separated using the LSD at 5% alpha level. Data on total rhizome yield are only presented in this report.

Exchangeable Potassium (cmol/kg)	0.092
Exchangeable Sodium (cmol/kg)	0.082
Exchangeable Aluminum (cmol/kg)	2.4
Exchangeable Hydrogen (cmol/kg)	1.4
Total exchangeable acidity (cmol/kg)	3.8
Organic carbon (%)	1.91
Total Nitrogen (%)	0.085
C/N ratio (%)	22.73
Effective cation exchangeable capacity (cmol/kg)	7.90
Available Phosphorus (mg/kg)	20.0
Base saturation (%)	52

Results and Discussion

The soil test results of the experimental site (Table 1) showed that the textural class is sandy clay loam and the pH was 5.30 indicating that the soil was acidic with low amount total nitrogen. The organic carbon, total exchangeable bases and effective cation exchange capacity is moderately low. The soil has high exchangeable acidity and moderate base saturation. Available phosphorus was 20.0 mg/kg which exceeded the critical level of 15 mg/kg established for crops in Southeastern Nigeria (Enwezor et al., 1990). Despite the fact that the pre-plant soil test result indicated deficiencies in most major plant nutrients (1.71% OM, N (NA), 19.8ppm P, K 0.215), the yield and yield parameters of Turmeric were significantly affected by the applied Lime and poultry manure in the 3 years (Tables 2, 3 and 4). While the year effect was significant, performance in 2015 was significantly higher than that 2014 and 2016 (Table 5). Application of Lime and poultry manure significantly ($P < 0.05$) influenced the rhizome yield and yield components of turmeric. However, treatment application in 2015 resulted in significant ($p < 0.05$) increase in rhizome yield and yield components than the value obtained in 2014. Furthermore, in combined analysis, LM+PM had significant ($p < 0.05$) higher total RY relative to sole applications and the control. This observation is consistent with the earlier findings of Sanwal *et al.*, 2007 who showed the benefit of integrated plant nutrient over sole fertilizer used in turmeric production. Similar findings were obtained in respect to other crops such as tomato (Ayeni *et al.*, 2010), amaranthus (Nwajiaku and Asadu, 2012), ginger (Ohaeri, 2016). Turmeric rhizome yield showed significant increases over the control, with increasing rates of poultry manure application ranging from 7.54 t/ha to 12.71 t/ha with an average of 9.61 t/ha as compared with treatment without poultry manure and control which ranges from 5.20 t/ha to 6.3 t/ha with an average of 5.72 t/ha. In the 1st year cropping season (Table 2) the plots that received the highest amount of poultry manure (20 t/ha) gave the highest values of 9.87 t/ha, 11.65 t/ha and 12.71 t/ha of rhizome yield irrespective of lime rate, respectively. The above mentioned trends were also observed in the 2nd and 3rd year planting seasons (Tables 3 and 4). Result of the combined analysis indicated that 20 t/ha poultry manure, irrespective of the lime rate, increases significantly ($p < 0.05$) turmeric rhizome yield over all the other treatments and control. The highest yield and yield parameters were obtained at lime rate of 1t/ha in combination with 20 t/ha of poultry manure. The residual impact of PM and lime on yield and yield of turmeric was demonstrated in this study as tested parameters in 2016 were not significantly ($P< 0.05$) inferior to that of 2014.

LM = lime; PM = poultry manure

Conclusion

From the result obtained, it was confirmed that turmeric unlike other minor root crops is not adapted to marginal lands. The use of organic manure for turmeric production in Umudike soil is imperative. The highest yield and yield parameters were obtained at lime rate of 1t/ha in combination with 20 t/ha of poultry manure. The residual impact of PM and lime on yield and yield components of turmeric was demonstrated in this study as tested parameters in 2016 were not significantly ($P< 0.05$) inferior to that of 2014. If mixed fertilizers (poultry manure+NPK) is use lime need to be applied,

Abstract
*The poultry visceral used was obtained from Sokoto meat market slaughter site. The viscera was thoroughly washed with the digesta being removed from the intestine of which some fresh quantities were crushed together to be homogenous in quantity and taken to the laboratory immediately for analysis. Four experimental diets were formulated following Pearson square method. The diets were isonitrogeneous containing (45% crude protein). The results of the proximate composition of poultry viscera show that the boiled viscera had the least moisture content (6.63±0.88%). The highest moisture content (77.67±0.33%) was recorded in fresh samples. The ash, crude fiber, and NFE follow the same trend. The boiled sample recorded the highest value of crude protein (41.12±0.01%) and crude lipid (15.51±0.01%) respectively whereas the fresh sample recorded the least content in the same order. The results of the formulated diets were Diets containing 15% level of substitution recorded highest moisture content (6.17±0.26%) and diets containing 30 and 45% level of substitution recorded the least values (5.57±0.29 and 5.62±0.08%) respectively. Diets containing 45% level of substitution recorded the highest crude protein content (43.14±1.55) and differed (P>0.05) significant from other dietary treatments. Diets containing 0% and 15% level of substitution recorded the least crude protein values (30.20±0.58 and 29.20±1.06%**)** respectively. Diets containing 45% level of substitution recorded the highest crude lipid of 9.23±0.80% and differed (P>0.05) significant from other dietary treatments. Diets containing 0% and 15% level of substitution recorded the least crude lipid values (6.22±0.30 and 5.96±0.43%) respectively. Feeding trial should be considered in order to evaluate the biological performance of these diets in growth and nutrients utilization.*

Key words: Fish feed, animal protein, nutritional values and non-conventional animal resources

Introduction
The global demand for fish from consumers around the world is increasing, reasons include, the growing population, rising average incomes and greater awareness of fish as part of a healthy diet (Hossain, 2010). The yield from the wild catch cannot be increased sustainably, therefore, in the opinion of observers such as the Food and Agriculture Organization FAO (2008), aquaculture must fill the gap. Currently the supply of fish from aquaculture approximately matches that from the wild (FAO, 2008). Domestic production base for feed premixes, binders, additives, as well as for concentrates, is quite pathetic and it is far behind requirements (Pratyush *et al*., 2014). Due to the lack of scientific and professional management, the quality of the produced feeds is often poor. Except some large-scale feed mills, most of the feed mills do not have skilled employees (Pratyush *et al*., 2014). Nowadays fish farming is leading towards the semi intensive or intensive culture (Pratyush *et al*., 2014). Equally, formulated feed inputs are shifted from farm made feeds to factory made feeds. The farmers depend only on the information given by the feed industry, about the feed composition and its effect on growth performance of fish (Pratyush *et al*., 2014). So there is a huge threat, that the farmers will be swindled by the feed manufacturer. It is very important to identify the nutritional requirements for optimum growth of a fish species as well as in formulating a balanced diet. Accurate dietary protein and energy levels are known to influence

the growth and body composition of fish (Steffens, 1994). A lot of the animal origin fish feed ingredients are considered as protein supplements, such feed ingredients are fish meal, fish silage, bone meal, fish viscera, poultry viscera, oyster shell meal, silkworm pupae, crab meal, snail muscle etc (Pratyush *et al*., 2014). Fishmeal is a high protein supplement feed ingredient (Ravindran *et al*., 1993). It is made from flesh, bones and offal of fresh or processed fish (Ravindran *et al*., 1993). It is used chiefly in diets for domestic animals and also as a high quality organic fertilizer (Cai *et al*., 1994). Poultry viscera are among such animal origin protein sources that can replace fishmeal (Webster *et al*., 1999, 2000; Gaylord and Rawles, 2005; Muzinic *et al.,* 2006; Rawles *et al.,* 2006; Thompson *et al.,* 2007). Viscera are the organs inside the body, such as the heart, lungs and stomach, etc. Research findings has revealed that recycling of wastes from poultry slaughterhouses is of economical, biological and environmental importance (Escalona *et al.,* 1987; Dale *et al*., 1993, Bohnert *et al*., 1999). The aim of this study is to assess the poultry viscera as potential ingredient in fish feed formulation.

Material and methods

Experimental Site

The site of the experiment was the fish feed mill and agricultural chemical laboratory of Usmanu Danfodiyo University, Sokoto which is located in the North-west part of Nigeria between longitudes 4^0 8E and 6^0 54E and latitude 12^0 N and 13^0 56N and annual rainfall ranging between 500mm to 1,300mm.The maximum and minimum temperature which are 35^0 and 41^0C respectively, (Singh, 1995).

Collection of ingredients

Feed ingredients were procured from Sokoto central market. The major feed ingredients used were as follows: yellow maize, fish meal, groundnut cake, blood meal. Others include mineral premix, lysine, palm oil, bone meal, Methionine and common salt, so also the poultry viscera.

Processing of poultry visceral

The poultry visceral used was obtained from Sokoto meat market slaughter site. The viscera was thoroughly washed with the digesta being removed from the intestine of which some fresh quantities were crushed together to be homogenous in quantity and taken to the laboratory immediately for analysis, and the remaining quantities were then boiled to remove fatty matter and to increase palatability and then air dried for 48hrs. The dried-product was grounded, taken to the laboratory immediately for analysis and meal was stored in a polythene sack to avoid spoilage (Pratyush, 2014)

Diet Formulation

This is the method of combining selected ground feed ingredients in varying proportions to comply with predetermined nutrient requirements. Each feed ingredients selected were then processed, then measured according to the suitable predetermined quantity and then compounded through a process of mixing (with the aid of an electric mixer), gelatinization and pelleting.

Table 1 Gross Composition of Diets

Ingredients	DIET I (0%)	DIET II (15%)	DIET III (30%)	DIET IV (45%)
Maize	28.02	21.95	16.46	3.97
Fish meal	40.92	33.53	24.07	13.99
Groundnut cake	16.36	17.88	19.25	22.38
Blood meal	8.18	8.94	9.62	11.19
Palm oil	2.0	2.0	2.0	2.0
Poultry visceral	-	11.17	24.075	41.96
Vitamin premix	0.5	0.5	0.5	0.5
Salt	0.25	0.25	0.25	0.25
Mineral premix	0.5	0.5	0.5	0.5
Bone meal	2.25	2.25	2.25	2.25
Methionine	0.5	0.5	0.5	0.5
Lysine	0.5	0.5	0.5	0.5
TOTAL	100	100	100	100
Crude protein levels	45	45	45	45

Proximate Analysis of Feed Ingredients and Diets
Proximate analysis for the chemical evaluation of the feed ingredients, including the poultry viscera and formulated diet were carried out in accordance to the AOAC (1990) procedures. Triplicate samples of each diet were used to determine the following chemical compositions:
Moisture: Moisture was determined by keeping 2 g of the commercial fish feed samples in a thermostat oven at 105°C for 24 h. The difference between the initial weight and the final weight gave the moisture content.
Crude protein: Samples (2 g) were digested in digestion unit (Digester, model 2020) for 45 min. The digester is then distilled in distillation unit (Khjeltdah System, Distilling unit, model 1026). Finally, it is titrated with 0.2 N HCL and crude protein were obtained by multiplying the total nitrogen by a conversion factor of 6.25.
Crude lipid: Crude lipid was determined by extracting a weighed quantity of sample with acetone in Sechelt Extraction Unit (model 1045).
Ash: Ash content was determined by igniting feed samples in a muffle furnace at 450°C overnight.
Crude fibre: Samples (2g) were digested with 0.128 M H_2SO_4 with a few drops of octanol in digestion unit (Hot Extractor, Model-1017) for 30 min. filtering and washing with boiling water removed acid. Residue was boiled with 0.223 M KOH for 30 min, then washed in boiling water and acetone. The residue was dried in an oven at 130°C for 2hrs and ignited in muffle furnace at 500°C for 3hrs. The loss of weight represented the crude fibre.
Nitrogen free extracts (NFE): NFE were calculated by subtracting the sum of moisture, crude protein, crude lipid, ash and crude fibre from 100 (Castell and Tiews, 1980).
Statistical Analysis
All the data obtained were subjected to analysis of variance (ANOVA) and the treatment means were separated using Duncan Multiple Range Test (Steel and Torrie, 1980). The analysis was carried out using SPSS version 20.0.

Results and Discussion

Proximate Composition of Poultry Viscera
The fresh poultry viscera were found to have an ash content of (4.65%) and fiber content of (1.17%). Obradovic (1969) reported very close values of 4.7% ash content of fresh (raw) poultry viscera. The fiber also lowers than the 5% base line for crude fiber ingredients for monogastric animals (NRC, 1993). The crude protein content of the fresh poultry viscera was found to be very low which was contrary to that of Obradovic (1969).The reason for this low protein content might be the species of poultry , the system used in rearing the poultry, the environment as well as poor dietary composition of feed fed by the poultry. The results of the proximate composition of the poultry viscera (Table 2) indicated that, the boiled poultry viscera was high in crude lipid and crude protein content with values of 15.51 and 41.12% respectively. These values were contrary to those of Pratyush *et al.* (2014) who reported 12.25% for crude lipid and 60.67% crude protein after air-drying without boiling and Vincent *et al.* (2016) who reported 22.0% for crude lipid and 35.0% crude protein after boiling without drying. The nature of processing would have resulted in the intermediate value for both the crude lipid and protein, this is because much of the protein and lipid will be lost during boiling but when dried the crude lipid and protein content increased as seen in Pratyush *et al.* (2014). Also the ash content of the boiled poultry viscera was lower than those of Pratyush *et al.* (2014) and Vincent *et al.* (2016). The method of processing might be the reason but the crude fiber content of this finding was slightly different from that of Pratyush *et al.* (2014) and was lower than 5% base line for crude fiber ingredients for monogastric animals (NRC, 1993).

Proximate Composition of Diets
The results of the proximate composition of the diets (Table 3) shows that diet I has a high ash (13.13%) and fiber content (4.32%) than those of Pratyush *et al.* (2014). These high values of both ash and fiber content were also observed in diets II, III and IV in contrast with those of Pratyush *et al.* (2014). The reason for these high values in the present study may be attributed to the high ash and fiber content of the various ingredients used in formulating the diet as well as the percentage contribution of nutrients by the ingredients in the diet. The crude protein content of diet I and II were lower than those of Pratyush *et al.* (2014) whereas that of diet III and IV were higher, this can be attributed to the crude protein content of fishmeal and poultry viscera, their percentage contribution of nutrients in the diets included in the diet as well method of

processing (poultry viscera and fishmeal), the species of poultry where the viscera is gotten from the type of water body(marine or fresh water) from where the fish which is being processed into fishmeal is obtained as well as poor dietary composition of feed fed by the poultry and the fish. Similarly, the crude protein, lipid and moisture content of diet I and III (0% and 30% poultry viscera respectively) were lower those reported in Vincent *et al.* (2016) as seen in his diet I and II containing 0% and 30% poultry viscera substituting fishmeal whereas the Nitrogen Free Extract (NFE) in the fore mentioned diets were higher than those of Vincent *et al.* (2016). These might be attributed to method of processing, source of ingredients used and the percentage contribution of nutrients from ingredients used in the diets formulation might be the reason. The moisture and lipid content of all the diets were lower than those reported by Pratyush *et al.,* (2014). The drying method and duration might be the reason in the case of moisture content as well as the method of processing (poultry viscera and fishmeal), the species, the type of poultry where the viscera is gotten from, the type of water body (marine or fresh water) from where the fish which is being processed into fishmeal is obtained as well as poor dietary composition of feed fed by the poultry and the fish. The Nitrogen Free Extract (NFE) in diets I, II and III differ much from that of of Pratyush *et al.,* (2014), but that of diet IV was lower than the report of Pratyush *et al.* (2014) which may be due to the percentage contribution of nutrients by poultry viscera and fishmeal in the diet.

Table 2: Proximate Composition of Poultry Visceral

TRT	Moisture%	Ash%	Crude Fiber%	Crude Protein%	Crude Lipid%	NFE%
Fresh	77.67±0.33	4.65±0.87	1.17±0.09	13.65±0.03	3.58±0.04	77.39±0.02
Boiled	6.63±0.88	0.50±0.01	0.01±0.00	41.12±0.01	15.51±0.01	36.37±0.01

Table 3: Proximate composition of Experimental diets

Composition%	**Experimental diets**			
	Diet I (0%)	**Diet II (15%)**	**Diet III (30%)**	**Diet IV (45%)**
Moisture	5.93±0.13^{ab}	6.17±0.26^{a}	5.37±0.29^{b}	5.62±0.08^{b}
Ash	13.13±0.13^{a}	13.86±0.33^{a}	12.31±0.92^{a}	9.75±0.40^{b}
Crude fiber	4.32±0.98^{b}	3.74±0.24^{b}	5.67±0.21^{a}	3.93±0.10^{b}
Crude protein	30.20±0.58^{c}	29.20±1.06^{c}	36.00±0.55^{b}	43.14±1.55^{a}
Crude lipid	6.22±0.30^{b}	5.96±0.43^{b}	6.69±0.10^{b}	9.23±0.80^{a}
Nitrogen free extra	39.31±2.13^{a}	40.76±0.66^{a}	33.46±0.43^{b}	22.78±0.43^{c}

Means in columns with the same letters are not significantly different (P >0.05)

Conclusion

From the present study, it can be concluded that boiled poultry viscera having a crude protein content of 41% and crude lipid content of 15% could serve as protein supplement; also the low moisture content of 6% will allow a longer storage period without spoilage for some period of time without immediate use in fish diet formulation. It can also be deduced that substitution level with 45% poultry viscera is appreciable percentage among all the dietary treatments. It recommended that Feeding trial should be considered in order to determine the effect of this diet on the growth performance and nutrient utilization of the culturable fish species

Abstract
The study of socio-economic characteristics, feed and feeding practices was conducted in New Bussa metropolitan, Niger State, Nigeria. The primary data was collected through structural questionnaires and interview of the farmers while secondary data was obtained from journals, books and internet. Data obtained was subjected to descriptive statistical analysis. The result of socio-economic characteristics revealed that 94% of the farmers were within working age group of 21-60 years while 48% of the farmers were within age group of economically productive age. Majority of farmers (72%) were married, majority of the farmers were males while considerable number had secondary education 48% and tertiary 36%. The year of experience of most farmers was 1-5 years which represent 65%. The study further revealed that 76% has no formal training on fish farming. Result for feed and feeding shows that 56% preferred culture hybrid catfish while majority (90%) use earthen pond as culture facility, types of feed majorly used is both floating and sinking pellet. Choice of feed is due to better body weight gain, low cost and readily available while 72% determine their diet formulation with very low consultation from fisheries experts (16%) . Feeding practices indicated that 86% of farmers in the study area preferred feeding to satiation by broadcasting the feed, while feeding frequency of twice per day is adopted by majority (84%) of the farmers at interval of 8 hours a day. This study revealed that, farmers are economically active and educated; therefore adoption of best feed and feeding practices were high over a period of time even though most farmers had no formal training on fish farming.
Key word: socio-economics, feed, feeding practices, New Bussa and Niger State

Introduction
Over the past decade, Nigeria aquaculture production is rapidly growing at a fast rate, attracting investment, contributing to domestic fish food security, creating wealth, generating employment and jobs for the youths and women across aquaculture value chain(Ifejike, 2012 and 2013).Thus fish feed and feeding practices remain the limiting factors for the expansion of aquaculture in Nigeria(Farhat 2011).Majority of the farmers in Nigeria had not break even due to inadequate fish feed, high cost feed and poor feeding practices(Tobor et. al., 1985 and Aghoghovwia and Ohimain 2015). According to Ajani *et. al.,* (2015) optimal feeding practices especially for African catfish is yet to be clearly defined and this has led to uncertainty in the feeding routine used by many farmers. Both over and under feeding can be detrimental to the health of fish and may cause a marked deterioration in water quality, reduced weight, poor food utilization and increased susceptibility to infection (Priestley et.al., 2006). However, fish farmers most used the right feed at suitable feeding frequency, time interval and adopting the right feeding rate and method to avoid wastage during feeding. More so, this is expected to improved survival, feed intake and growth performance in fish culture(Schnaittacher et. al.,2005 and Ali et. al., 2005). The socio-economic characteristics pertaining to demography, mean of production and investment,

income and expenditure pattern of people livening a particular location strongly influence their responses to technological changes and participation in development (Pandey and Upadhayay, 2012). Therefore, this study aims at assessing the socio-economic profile, feed and feeding practices in the study area as this will provide information on level fish feed management adoption for efficient fish production.

Materials and Methods

The study was carried out at New Bussa metropolitan, Niger State, Nigeria located on latitude $9^0$53'N,$4^0$31'E and Longitude 9.833N, 4.517^{0}E with land area of 11,782.5(square km) and population of 171,965 National Population Commission (2006). Purposive sampling was use to obtained primary data from respondent through structured questionnaire, interview of farmers, while secondary data was obtained from journals, books, and the internet. A sample of 120 farmers was randomly selected for the study. Data analysis was carried out using descriptive statistics.

Results and Discussion

Data obtained from the study on socio-economic characteristics of the respondent is presented in table 1 and fish feed and feeding practices of the farmers in the study area is showed in Table 2.

Table 1: Percentage distribution of the Socio economic characteristics of respondents

Parameter	No. of respondents	% of respondents

Socio-economic characteristics

Age of majority of the respondent (94%) were within the working population age group 21-60 while 48% of the respondents were within age group considered as economically productive age which portend better future for catfish production in the study area (Olowosegun *et.al*., 2005) . This is because fish farming requires adequate attention and a lot of sense of responsibility and also this implies that farmers were young, they are more inclined to adopt innovations (Baloronduro *et.al*., 2007). Marital status indicated that predominantly 72% were married while very few were single, widowed and separated. Gender of respondent in the study area shows majority (84%) of the fish farmers was male while 16% were female. This result can be justified by the assertion of Brummett *et al.,* (2010) that fisheries activities are mostly dominated by men and Akinrotimi *et. al*., (2011) reported that married men are more inclined to adopt new fish farming skills and practices as a result of their maturity, endurance and patience. The distribution of family size indicated that the house size of 3-4 is the highest (62%). Level of education of respondents without formal education was 10% while secondary education was 48% and tertiary 36%. This implies that, fish farming is dominated by the educated class in study area. This is so because fish farming requires a lot of technical and scientific knowledge to be successfully undertaken (Olaoye *et.al.,*2013). The years of experience of the farmers is relatively high (1-5years; 65%, 6-10 years; 30% and above 10 years; 6%). Nwachukwu and Anuegbu (2007) reported that, years of experience enhance farmer's level of participation in fish farming activities and acquiring new skills. Olaoye *et. al* (2013) reported that, farmers with longer years of experience should have good skills, better approaches to fish farming business and also able to forecast market situation in which their product will command higher price, while those with less years of experience face more risk in the early days of their fish farming business. Majority (64%) of the farmers operate on full time and 36% on part time basis. The study area indicated that 76% of the farmers has no form of formal training on fish farming business. This is similar to the finding of Sarker *et.al.*, (2006) who reported that, lack of training was among the potential obstacles facing fish farmers and Aghoghovwia and Ohimain (20015) also noted lack of training has serious negative consequence on improving competency due to poor knowledge and skills.

Feed and Feeding Practices
Majority (56%) of fish farmers in the study area prefer culturing of hybrid catfish (Heteroclaria) compared to the common Africa catfish (*Clarias gariepinus*) (12%) . Earthen pond (90%) was mostly preferred among the farmers. This may due to cheap sources of land, underground water during raining season and River Niger during dry season. This is similar to finding of Olalekan *et. al.,* (2014) who compared earthen ponds and concrete tanks and Aghoghovwia and Ohimain, 2015.

Fish Feeds
Feed types is another concern for the fish farmer, the result in this study indicated that 100% of the farmers preferred both floating and sinking pellet for better yield and least cost of production, this may be due to cheap sources of feed ingredient and nature of the culture facilities adopted by the farmers in study area. This finding disagreed with finding of Aliu et.al.,(2016) who reported farmers preferred using more of floating feed compared to sinking feed. This may due culture facilities adopted by farmers in study area. Choice of feed adopted by farmers indicated by 48% is because of better body weight, 36% low cost sinking pellet and16% is readily available in line with Aliu et. al., (2016) who reported that majority of the farmers chose feed due to availability and low cost of local feed. Majority (72%) of farmers determined there formulation while only 16% consulted the fisheries experts for feed formulation.

Feeding practices
About 86% of farmers in study area preferred to feed their fish to satiation by broadcasting the feed in the pond while 8% feed based on body weight. This may due to lack of formal training on fish farming by the respondents. This is different from the finding of Aliu *et.al*., (2016) who reported that farmers preferred to feed base on body weight. Feed frequency is the number times fish in a pond are fed daily, the frequency is important in order to reduce starvation, cannibalism and have uniform growth. The result of this study indicated that, majority (84%) of fish farmers preferred to feed their fish twice daily while 66% of the farmers feed at interval of 8 hours. This is similar to the findings of Maralikrishan *et. al*., (2010) and Ajani *et. al*., (2010) who reported that feeding of *clarias gariepinus* fingerling is the best feeding frequency in their separate studies.

Conclusion
This study revealed that, farmers are economically active and well educated, therefore adoption of best feed and feeding practices was high over a period of time. Commonly practiced is the use of earthen pond, culture of hybrid catfish and both floating and sinking pellet even though most farmers had no formal training on fish farming.

Abstract
The growth and survival of Clarias gariepinus fry fed decapsulated artemia, coppens granules and crayfish meal as starter diet were studied. Fifty (three days old) fry 0.02cm and 0.03g average length and weight were stocked in each plastic bowl of 30 litres capacity. Each experimental diet was fed to the fry stocked in bowls arranged in four replicates in a completely randomized design. The results indicate that treatment I had the highest (45.5 ± 3.86) survival rate and statistically similar to II (41.0 ± 6.21) while treatment III (1.50 ± 0.50) was lower significantly (p>0.05). The results of growth rate showed that treatment II had the highest (0.5 ± 0.03) weight gain and significantly higher (p<0.05) than treatment III (0.24 ± 0.50), but statistically similar to treatment I (0.53 ± 0.23). Percentage weight gain and specific growth rate followed the same trend. The condition factor (0.92 ± 0.17) was best in treatment I with no significant difference (p>0.05) to other treatments. The entire results indicate that in the absence of Artemia, coppens can be used as first feed to fry, while crayfish meal should be discouraged.
Keywords: Artemia, Coppens, Crayfish, Diet, Survival and Growth

Introduction
Aquaculture is one of the fastest food growing sector, contributing 316,727Mt to domestic production of 1.027m Mt in 2015. However average annual demand for fish in Nigeria was estimated to be 3.25 million metric tonnes in 2015. (FDF, 2015) a deficit yet to be met. African Catfish (*Clarias gariepinus)* is popular specie for aquaculture in Nigeria where survival of its hatchery produced larvae still poses a major problem to aquaculture growth. Nigeria current total fingerling supply from all sources is 80.7 million in 2015 (FDF 2015). Fingerling production and availability of quality fish feeds have been the bane of fish farming development in Nigeria for the past four decades. Other authors, such as Abayomi *et al.*, (2010), Adebayo and Popoola (2008) also identified lack of quality fish seeds as the major constraint of fish farming and stressed the need for increased production of fingerlings to meet ever rising fish demand. Although, there had been a lot of research work on the production of catfish fry feed and feeding and the use of cheaper feedstuffs to replace imported feeds, but catfish farmers still rely mostly on the costly imported artemia. According to Olurin *et.,al*. (2012), larval fish nutrition in aquaculture is predominantly dependent on the use of brine shrimp artemia (*Artemia spp.*), particularly for the first feedings. However, the cost of brine shrimp is prohibitive for resource-poor farmers in the developing world and this has necessitated the investigation into alternative feeds. This study aims mainly to compare the growth and survival of *Clarias gariepinus* fry fed decapsulated artemia, coppens granules and dry crayfish meal.

Materials and Methods
Experimental Site: The study was conducted at the Fisheries and aquaculture department Hatchery complex, Usmanu Danfodiyo University (UDUS), Sokoto State, Nigeria. Located on latitude 13^{0} 07’ 78”N, and longitude 05^{0} 12’ 25”E at 275m above sea level (Google Earth, 20011).

Annual rainfall ranges between 500 to 724mm, while the mean relative humidity is 14.9% and 40% in March and June, respectively (Mamman, 2000).

Experimental Diets

Diet 1: Decapsulated (shell free) *Artemia,* The feed is manufactured by Inve Aquaculture, Inve (Belgium) Ltd.

Diet 2: Coppens, the Catco Fish Concentrate (0.3– 0.5mm) is produced by Coppens International GmbH, Nettetal Germany.

Diet 3: Crayfish meal**,** the crayfish was purchased as a whole crayfish, oven dry and grinded in the laboratory.

Table 1: Proximate Composition of the Experimental Diets

Diet composition	Decapsulated Artemia	Coppen granules	Crayfish meal
Crude protein	54%	56%	19.95%
Lipid	9%	9%	1.5%
Ash	4%	8.9%	18%
Fibre	6%	0.6%	2%
Moisture Content	5%	5%	0.5%

Experimental Fish

Free swimming fry of three day old were obtained from Fisheries and Aquaculture department hatchery UDUS. The initial total weight and total length were measured using JT210N Electronic Top loading weighing balance and a plastic ruler (30cm) length. The fry were siphoned in a bowl and were counted directly using a plastic strainer and transferred into the each experiment unit.

Experimental Design

The experiment was design as three (3) treatments and replicated 4 times in a completely randomized design (CRD). Twelve plastic bowls (30litres water capacity) were used. Each experimental unit was stocked with 50 fry (3 days old). Each bowl was filled with water up to 20 litres capacity. Stocking Density of 25 fry/m^2 was used for optimum growth and survival according to Sahoo *et al.*, (2010). Aeration was accomplished using Resun Air Pump (Model ACO-008).

Feeding

Feeding was done to satiation level in each experimental unit. Daily feeding frequency was four time between the hour of: 8:00-9:00am, 1:00-2:00pm, 4:00-5:00pm and 8:00-9:00pm. Uneaten feed were usually siphoned-out before each feeding. About 60 to 70% water renewal was made every morning and the bowls carefully mopped with soft foam in order to remove dirt from the medium. Complete water renewal and washing of bowls were done weekly.

Monitoring of Growth and Survival:

Daily mortality rates were monitored; total weight and total length of fry were measured weekly using JT210N Electronic Top loading weighing balance and a plastic ruler (30cm) length respectively. Growth parameter and survival data were calculated using the following formula:

Survival Rate

$$\text{Survival Rate (\%)} = \frac{\text{Ni-Nf} \times 100}{\text{Ni}}$$ (Akinwande *et al.*, 2012)

Where Ni = initial number of fish stocked, Nf = final number of fish at the end of the experiment.

Growth Parameters

Weight Gain (WG);

The weight gain recorded was computed according to Sveier *et al.* (2000).

(WG) = Final weight (g) – Initial weight (g)

Percentage Weight gain (PWG);

This was calculated as follows:

$$\text{PWG} = \frac{\text{Final mean weight(g)} - \text{Initial mean weight(g)}}{\text{Initial body weight}} \times 100$$

Specific Growth Rate (SGR);

This was calculated according to Castell and Tiews, (1980).

$$\text{SGR (\%)} = \frac{\text{LogeWf} - \text{LogeWi}}{\text{Time (days)}} \times 100$$

Where; Loge = Natural logarithm
Wi = initial weight (g) of fish at the beginning of the experiment.
Wf = final weight of fish at the end of the experiment.

Condition Factor (K)
Condition Factor (K) of fish fry in each experimental unit was calculated at the end of experiment adopting the procedure of Bagenal and Tesch (1987).

$$K = \frac{100w}{L3} \times 100$$

Where; W = weight gain of fish (g) L= total length of fish (cm)

Water Quality Parameter
In this study, only the temperature parameter was measured. The temperature was measured in the morning, afternoon and evening, using Mercury in Glass Thermometer.

Statistical Analysis
Data collected on growth and survival was subjected to analysis of variance (ANOVA), and mean were separated using New Duncan's Multiple Range Test (DMRT) (Gomez and Gomez, 1984). The analysis was carried out using the SPSS: 20.0 (2013) package for windows.

Results and Discussion

Survival Rate
The result in Table 2, showed that the percentage survival in treatments I (Artemia fed fry) 45.5 + 3.86, and II (Coppens fed fry) 41.0 ± 6.21 were not significantly different statistically (P>0.05). Lower percent survival was observed in treatment III (Crayfish fed fry) 1.50 ± 0.50 and was significantly (P<0.05) lower than the other treatments but numerically the highest survival rate was recorded in treatment I.

Growth Rate
The result of the growth parameters (Table 1) indicates that treatment II (Coppens fed fry) recorded the highest weight gain 0.54 ± 0.03 and was significantly higher (P<0.05) than treatment III (Crayfish fed fry) and was statistically similar (P>0.05) to treatment I (0.53 ± 0.025). Similar trend was observed in the percentage weight gain of the three treatments.
Treatment II has the highest specific growth rate (SGR) 16.14 + 0.05 and was significantly higher (P<0.05) than treatment III but statistically similar to treatment I (16.11 ±0.05).

Condition Factor
Condition factor as presented in Table 1 showed that treatment III (Crayfish fed fry) recorded the highest value 3.94 ± 2.43, followed by treatment II (Coppens fed fry) 1.34 ± 0.48 and treatment I had the lowest value (0.92 ± 0.17), and the result showed that there was no significant different among the treatments.

Water Quality Analysis
The water temperatures during the experiment. The morning, afternoon, and evening temperatures varied between 27⁰C to 30⁰C, 28⁰C to 31.5⁰C, and 27⁰C to 31⁰C respectively. The overall mean temperature values for morning, afternoon and evening were shown in Table 2.

Table 2: Summary of growth performance and survival of fry at the end of feeding with Decapsulated Artemia, Coppens granules and Crayfish meal

Parameters	Diet 1	Diet 2	Diet 3
Total number of fry	200	200	200
Total final number	91	82	3
Survival rate (%)	$45.5{\pm}3.86^{a}$	$41.0{\pm}6.21^{a}$	$1.50{\pm}0.50^{b}$
Mean weight gain (g)	$0.53{\pm}0.23^{a}$	$0.54{\pm}0.03^{a}$	$0.24{\pm}0.50^{b}$
Mean percentage weight gain (%)	$1763.89{\pm}84.84^{a}$	$1811.93{\pm}100.20^{a}$	$1788.8{\pm}400.62^{b}$
Mean specific growth rate	$16.11{\pm}0.05^{a}$	$16.14{\pm}0.05^{a}$	$15.16{\pm}0.47^{b}$
Final body length (cm)	$4.03{\pm}0.27^{a}$	$3.90{\pm}0.57^{a}$	$1.50{\pm}0.50^{b}$
Condition factor	0.92±0.17	1.34±0.48	3.94±2.34

Table 3: Average Water Quality values during the experiment

Temperature	Morning	Afternoon	Evening
Minimum	27.00	28.00	27.00
Maximum	30.50	31.50	31.00
Mean (±SE)	28.70±0.73	29.80±0.64	29.20±0.72

The result on survival rate showed that treatment I and II differed from III, where the lowest survival rate (35.9 ± 4.23) was obtained. Treatment I (Decapsulated Artemia) had the highest survival rate (45.5 ± 3.86) and treatment I and II are statistically similar .This observation agreed with findings of Sorgeloos *et al.,* 2001; Olurin *et al.,* 2012, that Artemia reduces mortality thereby increasing survival rates of fish. This could be attributed to the fact that Artemia did not pollute the water, the water remained clear throughout the period of the experiment, indicating good utilization of the diet by the fry as against cloudy water in crayfish meal experimental units due to uneaten feed and water with oil films as observed in treatment fed coppens granules. Furthermore, In terms of growth performance, treatment II was higher than I. This differed from the study of some scholars (Achionye *et al.,* 2012), (Verreth and DenBiema, 1987), where fry fed Artemia had the highest growth rate i.e. SGR for Artemia was 12.56 per day compare to commercial diets with 2.98 per day. This could be attributed to the fact that treatment II had highest crude protein content (Table 1) which causes the fry to grow faster than treatment I. Treatment III had the lowest crude protein and consequently could result in lowest growth recorded. The lower growth rate and survival rate recorded in treatment III might be due to poor crude protein 19.95% compared to that of treatment I (54%) and treatment II (56%). The general high mortality recorded in this experiment could be attributed to handling from weekly sampling stress, since the fry were fragile to handle. The weight gain, percent weight gain and specific growth rate in this study showed that treatment I and II were similar, with treatment II having the highest values. While treatment III is significantly lower from I and II. The growth variation observed in this study however could be attributed to the nutrient composition of the diets (Kiriratnikom and Kiriratnikom, 2012). The condition factor was highest in treatment III, followed by treatment II and lowest in treatment I. Thus, treatment I, which had the lowest condition factor, had a better wellbeing (Viveen *et al*., 1986), which could be as a result of the low survival rate recorded in treatment three and lack of sorting to take out the outgrown fry from the culture media making the few fry remaining attain higher weight. The mean water temperature recorded during this period was within the temperature (25°C-32°C) range as recommended by Boyd and LitchoKopler (1979). The relative fluctuation of minimum and maximum morning, afternoon and evening temperature could also have influenced poor survival recorded in this experiment.

Conclusion

The study showed that survival rate was high in treatment I, While specific growth rate was higher in treatment II but not significantly different. However, both survival rate and growth rate were low in treatment III. It was concluded that Decapsulated Artemia did not pollute the water and maintained water transparency thereby increasing the survival. It was observed most time that after feeding with coppens, and Crayfish meal, the culture medium became cloudy and this result to odour in the culture medium, hence increasing mortality of the fry subjected to the two treatments. This study revealed that, when considering the wellbeing of fish fry, Decapsulated artemia proofed the best, followed by coppens which can be used as alternative to Artemia however crayfish meal was not suitable for feeding fry

Current Status of Aquaculture Management Practices in Lagos State

N.M. Achilike
Aquaculture Department, Nigerian Institute for Oceanography and Marine Research
Victoria Island, Lagos. P.M.B 12729 Lagos

Abstract
Due to low supply of fish from artisanal fisheries and high demand for animal protein food, there is serious intensification of aquaculture in Lagos State. A survey was carried out between February and May 2018 in 60 randomly selected fish farms, out of 300 existing fish farms in Lagos State to determine the personnel structure of farm owners and evaluate the farm management practices in the area. A questionnaire was designed and face-validated by experts with recording an overall reliability coefficient of 0.87%. Stratified random sampling technique was used to select the farms and data were collected from on-going farm operations. Most farm owners (80%) were male, majority (67.1%) fall between 41-50 years, more were educated (60 %), higher percentage (51.7%) were part-time farmers. 75% of the farms were monoculture of catfish species using stagnant earthen pond (23 %) and flow-through concrete tanks (16%) in semi-intensive level of production. Mostly (66.7 %) applied two production cycles per annum, most farmers (35 %) produce 30-40 tons of fish per annum. In management practices; 60 % apply high stocking density, 80 % of these farmers use earthen ponds at zero water renewal and high percentage of the farmers (70 %) feed twice a day. In conclusion the study established ineffective farm management practices, non-uniformity and non-compliance of the existing standards in fish farms in Lagos State and advocates for more in-service training and enforcement of the existing protocols in fish production.

Introduction
Management practices in aquaculture are routine farm operations that are carried out during fish production. The major management practices necessary for effective production are; water quality control, stocking, feeding, treatment of diseases, transportation, harvesting and record keeping. These practices aim at enhancing fish production but their procedures if not properly carried out could be detrimental to fish health (Gabriel *et al*. 2010). Management and practices differ among different types of aquaculture systems; pond culture, flow-through systems and recirculating systems, however, all production systems share the same environmental concerns: water use and discharge, land use, waste discharge, and the prevention of introduction and spread of invasive species and disease (Craig *et al*. 2006), therefore good practices are intended to assist growers in improving production and health status while minimizing stress. Best Management Practices (BMP) has a number of uses. They can guide those starting aquaculture projects, expanding or updating facilities, or growers maintaining present operations. Stocking marks the beginning of production cycle. Stocking density of any aquaculture media has to be considered first in management principles. This is because if a medium exceeds its carrying capacity, fish stress is bound to occur which can eventually lead to fish mortalities (Sirakov and Ivancheva, 2008). The process of stocking referred to here, starts with the collection of fingerlings from the hatchery, transporting them to the farm and, finally, putting them in either pond or tank. Poor stocking procedures, are among the major causes of low survival in grow-out systems (Nelly et al., 2009). They result in stress, diseases and reduced growth and eventually lead to mortality and financial losses. Water quality is the second aspect to consider in aquaculture management. The failure or success of production lies on this key factor. Poor water quality at high level does not spare the life of the fish for a minute. Therefore, this has to be checked regularly as prescribed below. The basic water quality parameters that are important in maintaining fish health include: dissolved oxygen (>4.0 mg/L), salinity (15-32ppm), temperature (26-30°C), pH (6.5- 8.5), nitrogen compounds [ammonia (< 0.15 mg/L), nitrate and nitrite (< 4.5

mg/L)], BOD [5day (50/30 mg/L)], hydrogen sulphide (< 0.1mg/L) and pesticides. High productivity in aquaculture production only transpires when fish are healthy and free from diseases. Fish disease management is aimed at preventing the onset of disease and measures to reduce losses from disease when it occurs (Andrew, 2007). Records are kept from the onset of stocking to the harvesting period. They are valuable in health management. Accurate records of numbers and sizes of fingerlings, time, type and quantity of the feed fed, periods of water changed, time of aeration, date of treatment and vaccination are kept. These records will help in evaluation of the status of fish populations and provides a proper guide to next farming. The fast growing human population in Lagos State with the low supply of fish from artisanal fisheries in complementing high demand for animal protein food has led to intensification in aquaculture industry (FDF, 2015). Hitherto, there was no record of the dynamics of the emerging and existing fish farms in Lagos State. This gap has the potential of militating against the production of quality fish in sustainable aquaculture in Nigeria. This study will provide relevant information and knowledge-based guidance to extension workers and regulators in aquaculture industry in Lagos State. It will provide adequate information that will assist the government in formulating effective policies, enforcement of the implementation of existing regulations and good management practices in fish farms. This study suggests that growers use this manual to conduct audits of their facilities to determine where improvements can be made. Growers may use these guidelines to develop their own farm-specific standard operating procedure (SOP) manual.

Materials and Methods

This assessment took place between February and March 2018. Data for the study was generated through structured questionnaire titled “Characteristics and management practices in fish farms in Lagos State” was designed and validated by two experts in Education Department of the University of Lagos. Cronbach alpha was used for the reliability test and an overall reliability coefficient of 0.87 % was obtained. The questionnaire sought for socio-economic characteristics of the farms owners/managers such as gender, age, marital status, educational background and level of fish farming in section one while section two elicited responses on management practices applied in their farms such as stocking rate, water renewal and feeding regime. Stratified random sampling technique was employed to select sixty fish farms; three fish farms from twenty Local Government Areas in Lagos State.

Statistical Analysis

Descriptive analysis involving the use of measure of central tendency such as frequency, percentage and chats were used for the data (Ogbeibu, 2005)

Results and Discussion

Data obtained from socio-economic characteristic of the respondents during the study are shown in figure 1. It indicated that there were more male fish farmers in Lagos State constituting 80% of the respondents, while the female farmers were 20 %. Majority of the respondents 61% were within the economically active age group of 41-50 years. These finding in agreement with Rodda (1993) who reported that the average active age of 45 years, were expected to have gained enough experience on how to efficiently manage their farms. At this age also, their marginal physical productivity is on the increase. Result obtained from this study also indicated that 62% of the fish farmers were married. While 60 % of the respondents were literate with secondary school qualification, 32 % had tertiary education and 8 % had primary school qualification; 52 % were part-time farmers while 48 % operated as full-time business. These findings compared favourably with observation made by Aromolaran (2002) and Adewuyi *et al*, (2010).

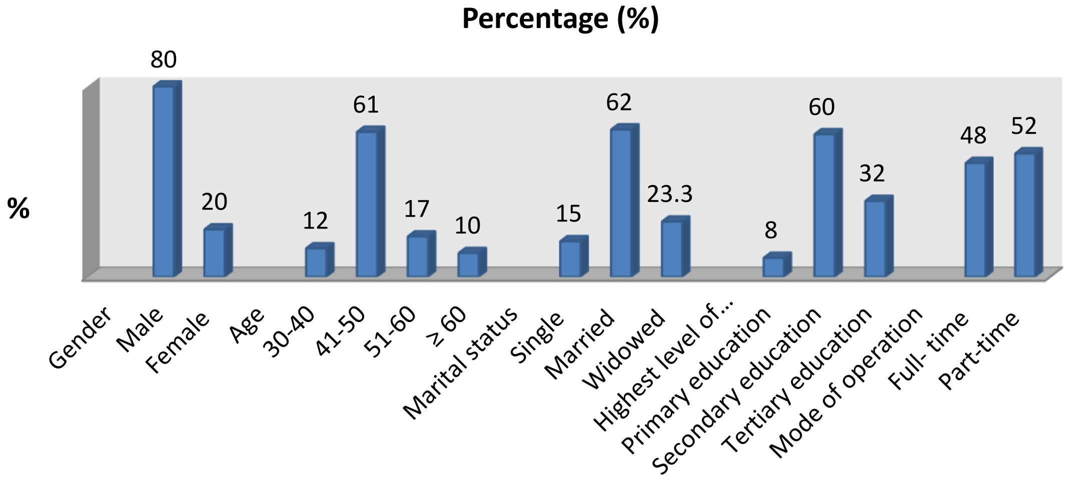

Figure 1: Socioeconomic characteristics of fish farmer/managers in Lagos State

Characteristics of fish farms in Lagos State were presented in Figure 2. Monoculture technique was found to be the most practiced culture technique in Lagos State. This might not be unconnected with less technicality involved in this system of culture, the findings of the research was similar to that of Adeogun *et al*. (2007) and Akinwole *et al* (2014). The most cultured species of fish in the study area was African catfish, *Clarias gariepinus*, the result was similar to that of Akinwole *et al*. (2014) and Adeogun *et al* (2007). This could be attributed to ease of culture of catfish, availability of market and favourable weather condition. This production amount therefore confirmed the position of Dauda *et al*. (2015) who noted that the reported increase in fish production in Nigeria (FAO, 2012) was not evenly distributed and more dependent on southern part of Nigeria. Aquaculture had been successfully practiced in different holding structures. In Lagos State Nigeria, aquaculture was practiced in different holding structures including earthen ponds, concrete tanks, plastic tanks, fiberglass tanks, as well as collapsible tanks; however, concrete tanks and earthen ponds were the most commonly used culture facilities. The result of this research in agreement with Adeogun *et al*. (2007); Akinwole and Akinnoye (2012), who opined that earthen pond and concrete tanks remained the most commonly used culture facility in Nigeria. According to them, the choice of culture facility might be influenced by availability of space, mode of operation and finance among other objectives.

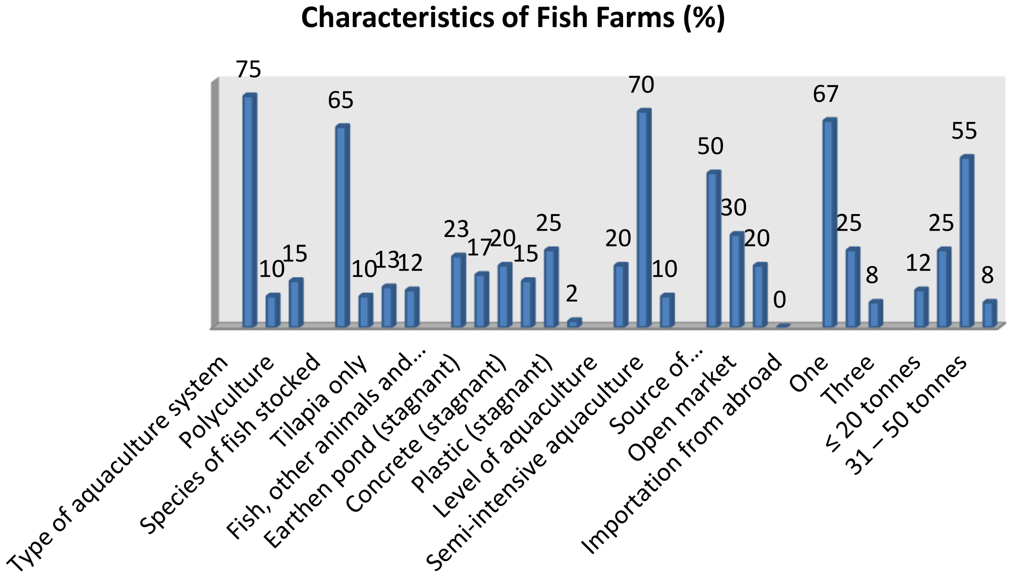

Figure 2: Characteristics of Fish Farms in Lagos State

Table 1 shows the management practices in Lagos fish farms. Water quality management has impacts on success of aquaculture venture (Omitoyin, 2007). Management of water quality was very poor in some of the studied farms as water renewal was not frequent in some concrete tanks while zero water exchange was operated by most of the earthen ponds. This water management system is not safe for the fish and could affect the health status (Akinwole and Adeola, 2012). The problem of water quality was among the factors responsible for poor growth performance in the farms. This is in line with the position of Dauda *et al.* (2015) who stated that poor water quality have adverse effect on the growth and well-being of cultured fish species. Higher stocking densities have been reported to have aggravated stress that resulted in reduced feeding and specific growth rate (Yousif, 2002); furthermore, high stocking densities and zero water exchange resulted to reduced specific growth rates in GIFT Tilapia Juveniles (*Oreochromis niloticus*) reared in tanks in China (Kpundeh, 2013). Varied stocking densities and zero culture water exchange rate in this study, resulted to lower specific growth and high mortality rates respectively. High density of fish may have suffered from weakened immunity that resulted to their death. Feeding is an important management practice in fish production. It has direct impact on growth performance (Biswas et al., 2006). This research finding showed that most of the farmers in the study area fed their fish twice a day which makes it difficult for fish to grow optimally (Dasuki et al., 2014). The type of harvesting system in the study area was similar to that reported by Adeogun et al. (2007), where most of the farmers harvested their fish partially and sold at farm gate.

Table 1: Management practices in Sixty Randomly Selected Fish Farms in Lagaos State

Farm Management Practices	Frequency	Percentage
Stocking density		
Overstocking	36	60
Under stocking	12	20
Standard stocking	12	20
Water renewal (in Tanks)		
Once per week	15	25
Twice per week	38	63
Thrice per week	7	12
Water renewal (in ponds)		
Once per month	12	20
Zero water exchange	48	80
Feeding regime		
Once per day	12	20
Twice per day	42	70
Thrice per day	6	10

Conclusion

The low fish yield could be attributed to poor management practices, due to non-implementation of aquaculture standards or ignorance among the fish farmers. Therefore the study recommends in-service training and enforcement of the existing protocols for fish production in all farms.

Abstract
The length-weight relationship and condition factor of Sphyraena afra from off Lagos coast (LC) and Lagos lagoon complex (LLC) in coastal waters ~~of Lagos State was studied~~ for a period of two years. The total length and weight were measured using standard methods. The parameter 'a' and 'b' of the length - weight relationship were estimated using the equation $W= al^b$ while the condition factor was also calculated for the equation $K= 100W/L^b$. The relationships of the fish's condition factor and body length, sexes and seasons in coastal waters of Lagos were determined. The species exhibited negative allometric growth ($b< 3$, $p<0.05$) for males, females and combined sexes with length exponent (b) ranging from 2.72 to 2.85. The coefficient of determination (r^2) for length-weight relationship of the species in all the station was very high (0.89 to 0.95) and correlation coefficient 'r' ranged from 0.94 to 0.97. The allometric growth values obtained in LC and LLC from length - weight relationship were indication that the fish species exhibited increase in length than mass. The overall mean condition factors (K) for Sphyraena afra in Lagos coast and Lagos lagoon complex were 1.16 ±0.13 and 0.97±0.12 respectively. The mean condition factors of female were higher than male in most of the sampling stations. Sphyraena afra was observed to be in better condition during the dry season.

Keywords: Sphyraena afra, condition factor, length-weight relationship and correlation coefficient

Introduction
Barracudas are commercial species of the Sphyraenidae Family occurring in tropical and subtropical oceans. Sphyraenidae includes only one genus, *Sphyraena* with 21 species (Nelson 2006). Four species of the genus *Sphyraena* encountered were collected from the coastal waters of Lagos state and identified as *Sphyraena afra, Sphyraena guachancho, Sphyraena barracuda* and *Sphyraena sphyraena* using FAO guides (Carpenter and De Angelia's 2016). *Sphyraena afra* is the most abundant and commonly seen in both the estuaries and marine water. The fish commands high market value and high consumer acceptability as the fish is tasty and firm. *Sphyraena afra* is a candidate for marine culture and information of the length-weight data of this fish is important for the development of successful management program in the wild and culture in the coastal waters of Lagos state. Information about the individual body length-weight relationships in population characteristics is in general of great importance for estimating the population size of a stock for the purpose of its exploitation (Atar and Secer 2003). Length-weight regressions have been used frequently to estimate weight from length because direct weight measurements can be time-consuming in the field (Sinovcic et al. 2004). Length – weight studies on fish are extensive in Nigeria. Notable among these are the reports of *Tilapia guineensis* in Elechi creek, PortHacourt (Diri 2002). Ayoade and Ikulala (2007) for *Hemichromis bimaculatus*, *Sarotherodon melanotheron* and *Chromidotilapia guentheri* in Eleyele Lake Southwestern Nigeria. Abowei et al. 2009 studied the Length–Weight Relationship and Condition Factor of Five Fish Species from Nkoro River, Niger Delta, Nigeria. Lawson (2011) for the Mudskipper *Periophthalmus papilio* in Lagos Lagoon. The condition factor expresses the condition of a fish, such as the degree of well-being, relative robustness, plumpness or fatness in numerical terms and is based on the hypothesis that heavier

fish of a given length are in better condition (Bagenal and Tesch 1978). Gallardo-Cabello et al. 2007 reported that the condition of fish diminished when the food availability in one area decreased. Some condition factors reported for fish species include; *Mugil cephalus* in Bonny estuary (Hart 1997), four cichlids species of a man - made lake in Imo state (Anene 2005), *Clarotes lateceps* from the fresh water reaches of the lower Nun river (Abowei and Davies 2009), *Liza falcipinnis* from Badagry creek Lagos (Lawson et al. 2010), Adeyemi (2011) for *Synodontis robbianus* at Idah area of River Niger, Kogi state. Length-weight relationship of marine fish resources in Nigeria are limited and the present contribution is aimed at compensating for this and due to high demand for this species in the country.

Materials and Methods

Study Area

The study area covered coastal waters of Lagos State from Yovoyan in Badagry to Lekki Lagoon. 7 stations were selected along the coastal waters: 3 stations from Lagos lagoon complex (Lagos lagoon, Lekki and Badagry lagoon) and 4 stations from off Lagos coast (Yovoyan, Ibeshe, Oshoroko and Orimedu). The stations were selected to cover both the marine and brackish water of different salinity gradients which bordered on the West by the republic of Benin and in the south stretches for 200km, along the coast of the Atlantic Ocean. The study area is located between longitude 2º 45´and 3º 60´ and latitude 6º 20´and 6º 34´ (Fig.1). Sampling stations included fishing villages and landing sites in the study area. The Lagoon coastal complex stretches from Badagry to around Agerige village where the coastline starts a southward inflection. The climate is typical of rainforest/ tropical coastal waters with prolonged wet season (April - October) and short dry season (November - March) (Awosika et al. 2001). The fringes of the Lagos coastal water are mainly colonised by white mangrove *Avicennia* and red Mangrove trees (*Rhizophora* sp.), On the southern edges much closer to the sea, coconut (*Cocos nucifera)* and giants reeds, mainly *Paspalum vaginatum* and *Spore bolus virginucus* form most of the vegetation.

Collection of specimens

Monthly sampling was carried out from four stations (Yovoyan, Ibeshe, Orimedu and Oshoroko) off Lagos Coast and three stations from Lagos Lagoon Complex (Lekki, Lagos and Badagry lagoon) of Lagos state between 07.00 am and 10.00 am from August 2009 to July 2011. Surface water samples were collected with 500 ml plastic containers from all the stations. Parameters such as water temperature, salinity, water transparency and dissolved oxygen were measured in-situ with a mercury-in-glass thermometer calibrated from 0 ºC to 100 ºC validated with Jenway DO meter, hand refractometer (Biomarine, Aquafauna model), a Secchi disc and Jenway DO meter (Model 9071) respectively.

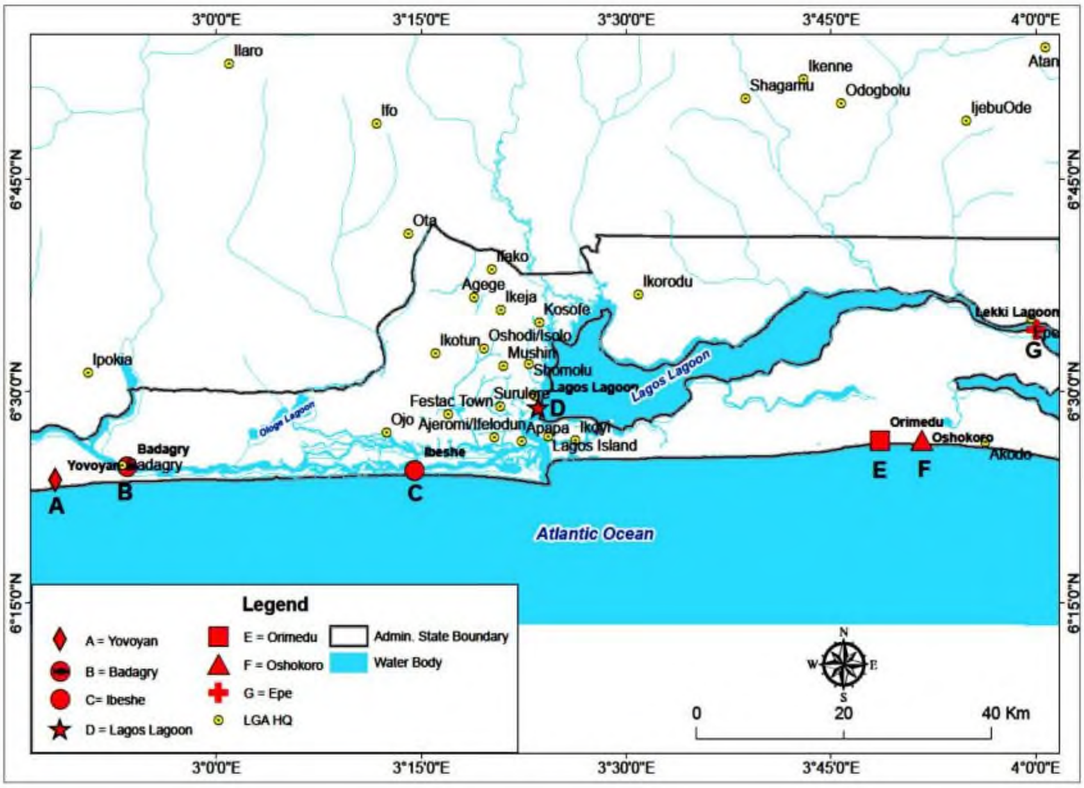

Figure 1: The map of coastal waters of Lagos state showing sampling stations.

Collection of specimens

A total of two thousand three hundred and fifty four specimens of *Sphyraena afra* (total length, 17.60 - 183.30 cm, total body weight, 27.2 - 25,000 g) were collected monthly for length-weight relationship and condition factor from August 2009 to July 2011 using a combination of fishing gears; including trawl nets, purse seines, gill nets, trammel nets and longlines with the help of fishermen. The mesh sizes of the net materials ranged from 2.5 – 6.0 inches depending on the sizes. Hook and lines were mainly used to catch large sized fish species. Fish specimens caught were transported in thermo cool boxes to the laboratory on each day of sampling. The species was identified with FAO guide.

Length and weight measurements

Total length and weight of fish specimens were measured to the nearest centimeter and grammes respectively to obtain data on the length-weight relationship. The length-weight relationship and condition factor of the fish specimen from Lagos coast (LC) and Lagos lagoon complex (LLC) were estimated using the exponential equation (Roff 1986)

$$W = aL^b. \tag{1}$$

Where, W=weight in grams, L= Total length in centimeters and 'a' and 'b' are regression constants. This relationship was transformed into a linear form by the equation.

$$\text{Log } W = \log a + b \log L. \tag{2}$$

Condition Factor

Fulton's condition factor (K) (Ricker 1975) to determine the well-being of the fish was calculated seasonally in all the stations. Calculations were made separately for both sexes
$K = 100W/L^3$
Where, K = condition factor, W = weight in grams, and L = Total length in centimeters.

Statistical Analysis
Data collected were collated and analysed using descriptive statistics (means and standard deviation). All the analysis were performed using IBM SPSS 20.0 software at P= 0.05 and P < 0.001 significance level. Analysis of covariance was used to compare the length –weight relationship between sexes, condition factors between sexes, seasons and length. The chi-square(X^2) test was used to determine if a population contains equal proportions of males and females. T-test was used to determine the level of significance of the parameters in the two water bodies.

Results and Discussion

Physicochemical Parameters
The surface water temperature ranged from 27.5±0.12 ºC to 30.7±0.08ºC during the study period. There was significant difference in the temperature between the dry and rainy season ($p< 0.05$) in the two environments (Table 1). The salinity of the coastal waters during the period of sampling ranged from 0.9±0.11‰ to 33.2±0.18‰. Off Lagos coast (LC) had higher salinity gradients than LLC and higher values were recorded during the rainy season (Table 1). There was significant difference in the temperature between the dry and rainy season ($p< 0.05$) in the two environments. The water transparency values ranged from 0.17±0.04m -0.51± 0.12m while the dissolved oxygen values ranged from 5.5±0.11mg/l to 7.5±0.13mg/l (Table1).

Length –Weight Relationship and Fulton's Condition Factors
Descriptive statistics and estimated parameters of length-weight relationship for *Sphyraena afra* from coastl waters of Lagos State is shown in Table 2. The species from LC and LLC exhibited negative allometric growth ($b< 3$, $p<0.05$) for males, females and combined sexes with length exponent ranging from 2.72 in Lagos coast to 2.85 in Lagos lagoon complex. The coefficient of determination (r^2) for length-weight relationship of the species in all the stations was very high (0.888 to 0.952) and correlation coefficient 'r' ranged from 0.94 to 0.98. The mean condition factor (K) for male, female and combined sexes were 1.15 ± 0.24, 1.19 ± 0.18 and 1.17 ± 0.11 for Lagos coast and 0.96± 0.13, 0.98 ± 0.24 and 0.97 ± 0.11 for Lagos lagoon complex respectively. The overall mean condition factor (K) for *Sphyraena afra* in LC and LLC were 1.16 ±0.13 and 0.97±0.12 respectively. Summary of the Length-weight equation of *Sphyraena afra* from coastal waters of Lagos State is represented in Table 3.

Table 1: Physiochemical parameters of the coastal waters of Lagos State

Parameters	**Mean values**			
	Off Lagos Coast (LC) (LLC)		**Lagos lagoon complex**	
	Rainy season	**Dry season**	**Rainy season**	**Dry season**

Length-weight relationship (LWR) is important for fish stock assessment. The correct interpretation of the parameters resulting from length-weight relationship will disclose information that is useful for fisheries management. A characteristic of length-weight relationship in fishes and invertebrates is that the value of the exponent b is 3 when growth is isometric (without changing shape). If b value is different from 3, growth is said to be allometric (fish changes shape as it grows larger). Allometric growth may be negative (b < 3) or positive (b > 3). Wootton (1998) indicated that allometric growth is negative (b < 3) if fish get relatively thinner as it grows larger and positive (b > 3) if it gets plumper as it grows. Statistical analysis of the length –weight data showed that *Sphyraena afra* male, female and combined sexes exhibited negative allometric growth in coastal waters of Lagos state, since the value of b (the exponential) of the regression equations representing their length- weight relationships were less than 3. The allometric growth values obtained in all the stations from length weight relationship were indication that the fish species exhibited increase in length than mass. These showed that even though there were corresponding increase in weight with increase in length, at certain stages of fish growth, increase in weight were no longer directly proportional to the increase in length as revealed in some fish species. The determined b value 2.72 to 2.85 for *Sphyraena afra* in this study is within the ranged of 2.5 to 3.49 reported for other barracuda species such as great barracuda, *Sphyraena barracuda* (Froese and Pauly 2005). Jaiswar et al. 2004 reported b value of 2.72 to 2.73 for *Sphyraena obtusata* in Bombay waters, West coast of India while b value of 2.84 to 2.89 was reported for the same species from the Jaffina Lagoon, Sri Lanka (Sivashanthini et al. 2009). Hosseini et al. (2009) also reported b value of 2.77 to 2.87 for *Sphyraena jello* from Persian Gulf. Some investigators reported that the slight differences in the b value could be due to variation in the environmental or ecological conditions of different habitats or variation in the physiology of the animal or both (Jaiswar and Kulkami 2002, Bhattacharya and Acharya, 1984). Ecological functions such as temperature, food supply, spawning conditions and other factors such as sex, age, fishing time and area and fishing vessels could also influence the value of b (King and Udo 1996). The observed differences in length weight relationship (LWR) of fish could be due to the quality and quantity of food available in one area or water body (Sparre and Venema 1992) and due to the male-female ratio. On the other hand, Schneider et al. (2000) described that the exact relationship between length and weight depends on their body shape and condition (robustness) of individual fish. Oniye et al. (2006) also reported that the weight of fishes increase when they utilize the food items available for growth and energy. Variations in a fish's coefficient of condition primarily reflect state of sexual maturity and degree of nourishment. Wootton (1998) reported fish species with high values of K are heavy for their length while low values of K are light for their length. The observed values of the condition factor of *S. afra* female higher than the male indicated that the females were healthier than the males. This could be attributed to the differences in gonad development. The highest K values are reached in species if the fish is fully mature and having higher reproductive potentiality (Ugwumba 1990 and Agboola et al*.* 2008). The overall mean condition factor (K) for *Sphyraena afra* of 1.16 ±0.13 and 0.97±0.12 obtained in off Lagos coast and Lagos lagoon complex respectively indicated better condition in LC than LLC and varied slightly with the result of other studies: Ajayi (1982) reported K value of 0.77- 0.81 for *Clarotes filamentosus* in Lake Ogonta; Nwaduaro and Okorie (1985) obtained K= 0.49-1.48 for *Chrychthys filamentosus* in Adoni River: Abowei *et al*., 2009 reported K value of 0.941 – 0.985 for five fish species in Nkoro River, Niger Delta, Nigeria. The value obtained showed that the fish specimens studied were in good condition in all the water bodies. *Sphyraena afra* was observed to be in better condition during the dry season.

Conclusion

In conclusion the LWR of *S. afra* revealed negative allometric growth in the two water bodies. The K value suggested that the condition of the coastal waters of Lagos state is favourable for the species. *Sphyraena afra* can survive off Lagos Coast (LC) and Lagos Lagoon Complex (LLC) and in good condition despite the differences in the salinity gradient of the two environments. High dissolved oxygen content indicated that the coastal water of Lagos state can successfully support aquatic life including fish. Values obtained for water temperatures in the coastal waters of Lagos state were within the acceptable levels for survival, metabolism and physiology of aquatic organism.

Incidence and Antibiotic Susceptibility Pattern of *Vibrio fluvialis* Isolated from Fresh Shrimps Sold in Makoko Fish Market, Lagos

C. E. Oramadike
Nigerian institute for oceanography and Marine Research Lagos, Nigeria
Correspondence: chigooramadike@gmail.com

Abstract
Vibrio fluvialis is an emerging food borne pathogen that is associated with the consumption of contaminated seafoods. Surveillance of the microbial susceptibility to the common antibiotics is very important. In this study, ninety (90) samples of fresh shrimps were randomly purchased from fish sellers in Makoko fish market. V. fluvialis was cultivated using standard bacteriological method on Thiosulphate Citrate Bile Sucrose agar (TCBS). The isolates were subjected to their susceptibility patterns using agar diffusion method. A total of sixteen (16) isolates were phenotypically identified as V. fluvialis. The isolates were more susceptible to ofloxacin, ciprofloxacin, gentamicin, nitrofurantoin, nalidixic acid and co-trimoxazole as compared to augmentin, ceftazidime, tetracycline and amoxicillin antibiotics. Isolation of V. fluvialis from the fresh shrimps is of public concern. There is need of regular surveillance on the use and abuse of antibiotics in Lagos and its environs.

Keywords: Vibrio fluvialis, antibiotics, Makoko and shrimp

Introduction
Vibrio species are Gram-negative, curved rod shaped, oxidase positive and non spore forming bacteria (Austin, 2010). They are naturally present in the marine environment, and are particularly resistant to high salt concentrations. A number of species within the genus *Vibrio* are associated with food borne infections and food spoilage. About twelve (12) species are pathogenic to human while eight (8) are associated with food borne illness (Dickinson et al., 2013). The majority of the food- borne illness is caused by *V. fluvialis, V. parahaemolyticus, V. vulnificus* and *V. cholera.* The immune suppressed individuals are the most susceptible to other *Vibrio* infections (Miyoshi, 2013). Seafood constitute an important food component for a large section of world population (Lutz *et al*., 2013).The rise in seafood consumption and the global warming, resulting in increased ocean surface temperatures, may cause higher prevalence of *Vibrio* species, and increase the risk of *Vibrio* food borne infections (Hassan *et al*., 2012). *Vibrio* food-borne illnesses have been reported in Asia and Africa regions (McLaughlin *et al*., 2005). Utsalo *et al*. (1992) also reported *Vibrio* infection in Calabar Nigeria. However, there is significant number of reports on food borne infections from the consumption of raw fish or improperly cooked contaminated fish and shellfish (Oyster, Clams, Mussels, Crabs, Shrimps, periwinkles and prawns) (Eja *et al*., 2008; Lutz *et al*., 2013). *V. fluvialis* is one of the emerging food borne pathogen all over the world. The distribution of virulence factors and antibiotic susceptibility pattern of this pathogen remain mostly unknown. Among the food borne infections in the United States, there has been a significant increase (43%) in the *Vibrio* mediated infections since 2012 compared with the rates reported 2006-2008 (center for disease control and prevention CDC, 2013). There is no proper documentation, assessment of non- cholera *Vibrio* species from seafood in Lagos State and there is dearth of information on incidence of *V. fluvialis* and the antibiotic susceptibility. This study would provide information on the incidence of *V. fluvialis* its antibiotic susceptibility. The study was conducted to monitor the incidence and antibiotic susceptibility pattern of *Vibrio fluvialis* from fresh shrimps sold in Makoko fish market in Lagos.

Materials and Methods

Sample collection, cultivation and identification of *V. fluvialis*

Description of collection site

This market were chosen because it was identified as an important secondary fish market in Lagos State and it plays a very critical role in selling fishery products to the citizens of Lagos Metropolis. The market operate as daily market and opens as early as 6.00 am for sales of fresh shrimps and other products from the neighboring coastal fishing villages.

Collection and Preparation of Seafood samples (fresh shrimps *Penaeus notialis*)

Fresh shrimps were randomly purchased from fish sellers at Makoko Better Life market. Purchased samples were immediately put in a sterile screw cap bottles containing enrichment medium (alkaline peptone water) with alkalinity of 8.6 and conveyed to the Microbiology laboratory of the Fish Technology and Product Development Department, Nigerian institute for oceanography and marine research (NIOMR) for further analysis.

Isolation and Identification of isolates

Samples were divided into two sets; one set of the samples was directly cultured onto Thiosulphate Citrate Bile Salt agar (TCBS) and incubated overnight at 37^{o}C. The other set was carried out with a pour plate technique after 18 h enrichment using a 10 fold serial dilution method with TCBS agar. The inoculated plates were incubated overnight at 37^{o}C. Samples were collected in four visits from April 2015 to May 2015 (one month). A total of 90 samples were collected during the period. *V. fluvialis* were identified using conventional microbiological tests which differentiates the various *Vibrio* spp. Gram reaction, oxidase test, motility, sugar fermentation and salt tolerance (Cheesbrough 2000).

Antibiotics susceptibility testing (Kirby- Bauer disk diffusion method)

Cells from each of the pure isolates were harvested from 18 h Tryptone soy broth culture supplemented with 3% NaCl, washed in phosphate buffer (0.05 M, pH 7.0) and resuspended in normal saline with turbidity adjusted to 0.5 McFarland's turbidity level (about 2.0 x108 cfu/mL). These suspensions (0.5 mL) were uniformly spread with a sterile cotton swab on Muller Hinton agar plates supplemented with 3% NaCl and allowed to stand for 5 min. before the antibiotic discs were placed aseptically on the seeded plates (Bauer *et al.,* 1966). Incubation was carried out at 37°C for 24 h. Agar plates inoculated only with bacterial test isolates without the introduction of antibiotic discs served as controls. Zones of inhibition observed around the antibiotic discs were taken with a venire caliper as indications of sensitivity. The 10 antibiotics tested, with their respective concentrations given in parentheses, were: beta-lactams — augmentin (30 μg); fluoroquinolones — ofloxacin (5 μg); ciprofloxacin (5 μg); cephems — ceftazidime (30 μg); amino glycosides — gentamicin(10 μg); nitro furans — nitrofurantoin (300 μig); tetracyclines— tetracycline (25 μg); quinolones – nalidixic acid (30 μg); beta-lactams – amoxicillin (25 μg); folate pathway inhibitors - cotrimoxazole (25 μg). The sensitivity of the isolates and the inhibition zones diameter interpretive standards were assessed in accordance with Clinical and Laboratory Standards Institute (CLSI) document M100 guidelines for Enterobacteriaceae (CLSI, 2010).

Statistical Analyses

Data were analysed using descriptive statistics

Results and Discussion

The frequency and percentage occurrence of *V. fluvialis* in fresh shrimps samples at the Makoko fish market within the four visits from April 2015 to May 2015: are presented in Table 1.

Table 1: Frequency of occurrence of *V. fluvialis* in fresh shrimp samples

No of visits to the Market	Total number of *V. fluvialis* isolates (%)
1	2(12.5%)
2	7(43.75%)
3	3(18.75%)
4	4(25%)
Total	16 (100%)

The susceptibility pattern of *V. fluvialis* against augmentin, ofloxacin, ciprofloxacin, ceftazidime, gentamicin, nitrofurantoin, tetracycline, nalidixic acid, amoxicillin and cotrimoxazole are summarized in Table 2. *V. fluvialis* was more susceptible to ofloxacin, ciprofloxacin, gentamicin, nitrofurantoin, nalidixic acid and cotrimoxazole as compared to augmentin, ceftazidime, tetracycline and amoxicillin.

Table 2: The antibiotic susceptibility pattern of *V. fluvialis* isolated from fresh shrimps brought from Makoko fish market

4	2(50.0)	4(100)	4(100)	2(50.0)	4(100)	4(100)	1(25.0)	4(100)	2(50.0)	4(100)

*AU: Augmentin (30 µg); OFX: ofloxacin (5 µg); CPX: ciprofloxacin (5 µg); CEF: ceftazidime (30 µg); GN: gentamicin(10 µg); NT: nitrofurantoin (300 µig); TET: tetracycline (25 µg); NAL: nalidixic acid (30 µg); AM: amoxicillin (25 µg); COT: cotrimoxazole (25 µg).
.* N= no of susceptible isolates
*(%) = Percentage of susceptible *V. fluvialis* Isolates

Seafood is known as a vehicle of transmission of food borne bacteria. This study has shown occurrence of *V. fluvialis* in the fresh shrimp samples studied. Similar observations were made by Eyisi et al. (2013), in their studies on distribution of *Vibrio* species in shell fish and water samples collected from Atlantic coastline of south-east Nigeria. Nsofor et al. (2014) also made the same observation in incidence of *Vibrio* species isolated from seafoods sold in Portharcourt. This occurrence may be attributed to the ecology of the study animal (shrimps) and to the high salt tolerance of the organism. It is important to note that isolation of *V. fluvialis* in shrimps might be significantly responsible for gastroenteritis and some severe diarrhea cases among the population of the Makoko community and environs, considering the sources and occurrence in shrimps as observed in this present work. More so, the growing problems with antimicrobial drug resistance are beginning to grind down our antibiotic abilities to fight antibiotic resistance and thus limiting therapeutic options to modern health delivery (Igbinosa, 2010). The epidemiological observation of antimicrobial resistance is crucial for treatment of infections and in preventing the spread of antimicrobial resistant microorganisms. The antimicrobial susceptibility pattern of *V. fluvialis* could be as a result of self-medication. The findings are also in agreement with Sahilah *et al*. (2014) that reported the presence of cefuroxime and ceftazidime-resistant *V. parahaemolyticus* isolates in shellfish samples from Terengganu, Malaysia. This finding was in contrast with Adeleye *et al*. (2008) who had reported a 100% resistance of *Vibrio* species isolated from seafood to nitrofurantoin. This is however expected due to the fact that these drugs are commonly prescribed drugs in human medicine and they are relatively cheap. In addition, the frequency of antibiotic resistance in a population is known to be highly determined by the selective pressure on the commensal microflora due to intake of antibiotics (Harwood *et al*., 2000; Sahoo *et al*., 2010).

To prevent vibriosis, it is clearly necessary to put more emphasis on food hygiene, proper cooking and avoidance of eating seafoods raw should be strongly encouraged. We also need more inspection on the handling and mode of transportation of seafoods in Makoko market.

Patients who present diarrhea symptoms should be referred to the health center for immediate diagnosis and treatment.

Conclusion

In conclusion, *V. fluvialis* was isolated from shrimps sold in Makoko market, the antibiotic susceptibility pattern of the microorganism revealed need of regular surveillance on the use and abuse of antibiotics in the Makoko area.

Abstract
The nutritional evaluation of fermented senna obtusifolia (linn) seed meal as a potential component of fish feed was investigated. The seeds of Senna obtusifolia were handpicked at Shika Zaria, Kaduna State. Three portions of Senna obtusifolia seeds of 100g each were taken and kept separately prior to treatments. The seeds were soaked in water in a 1:6 (seeds: water) i.e.1kg/6lit ratio for 24hrs, the drained soaked seeds were allowed to ferment naturally. The fermentation periods were 48, 72 and 96 hours. Corresponding to F_{48}, F_{72}, F_{96}, *respectively. The fermented seeds were sundried and grinded into fine powder and the nutrients composition was evaluated. Results revealed that fermentation significantly increased the crude protein contents of Senna obtusifolia seed meal (FSOSM) from 21.12% to 32.11% as the fermentation progressed from 48 to 96hrs. However, the lipid contents was decreased from 7.17% to 4.71% by fermentation. Fermentation also reduced the ash contents but not significantly different (P>0.05) from the raw. Significant reduction (p<0.05) of fibre contents was observed with increase in fermentation time. The moisture content decreased significantly (P<0.05) in the fermented samples. Fermentation for 48, 72 and 96hrs resulted in the decrease of the NFE in this order 51.00, 49.63 and 48.15% respectively, which is significantly different (P<0.05) from the raw sample. Fermentation significantly reduced the ant-nutritional compounds of the seeds. The amino acid (g/100g protein) composition of the raw and fermented Senna obtusifolia shows that Methionine (Met.) had the least value both in the raw and fermented seeds. Though fermentation significantly (p<0.05) improved the amino acid compositions. In conclusion fermented Senna obtusifolia seeds meal contains appreciable quantities of nutrients and amino acids but is limiting in methionine and lysine when compared to the established standard by FAO therefore, its inclusion as supplementary plant protein with other feed ingredients rich in the limiting amino acids to feed fish is recommended.*

Keywords: Fermented Senna obtusifolia seed meal and fish feed

Introduction
Fish feeds accounts for up to 50 to 60% of total expenditure in fish culture business has been reported. The reduction in the cost of fish feeds will enhance the economic status of fish culture business. In recent time, conventional ingredients utilized in fish feeds are costly, which increases the feed cost and in turn increase the cost of fish production. Therefore, the need to utilize less expensive non-conventional feed ingredients to produce fish at low costs is paramount and *Senna obtusifolia* seed meal has great potential in this context. Fermentation has been adjudged a cheap and cost effective food processing method that is affordable by the poor (Omezurike, 2008). Fermentation often results in enhanced nutrition, maintenance of the original raw ingredients and detoxification of anti-nutritional compounds. *Senna obtusifolia* belongs to the *Fabaceae* (Leguminoseae) or bean (pea) family, and sub-family *Ceasalpinoideae.* It is annual weed taxonomically known as *S. obtusifolia*. This is a small fetid herb growing up to an average height from 30 to 90cm (Parsons and Cuthbertson, 1992 and Holm *et al*., 1997). *S. obtusifolia* is extensively used in traditional medicine in tropical and warm sub-tropical countries, the leaves, roots and seeds are used in folk medicine in Asia (Ambasta, 1986). The

proximate composition of the raw seeds show a high dry matter (92.50%), crude protein (29.54%), ether extract (2.31) nitrogen free extract (NFE) (46.77) and crude fibre (10.18%) as reported by (Ingweye *et al*., 2010). It also contains alkaloid, saponin, tannins, oxalate and phytate contents in various concentrations. The hydrogen cyanide concentration is reported to be 6.98mg/100g. The essential amino acids (EAA) of *S. obtusifolia* include phenylalanine, lysine, valine, leucine, isoleucine, threonine, methionine, cystine and tyrosine while the non-essential amino acids are aspartic acid serine, glutamic acid, proline, glycine and alanine. The objective of the study was to determine the nutritional value of fermented *senna obtusifolia* (linn) seed meal as a potential component of fish feeds.

Materials and Methods

Collection and Processing of *Senna obtusifolia* Seeds

The seeds of *Senna obtusifolia* were handpicked at Shika Zaria, Kaduna State. Three portions of *Senna obtusifolia* seeds of 100g each were taken and kept separately prior to treatments. The seeds were soaked in water in a 1:6 (seeds: water) i.e.1kg/6lit ratio for 24hrs, the drained soaked seeds were allowed to ferment naturally (Udensi *et al.,* 2006) without the addition of yeast. The fermentation periods were 48, 72 and 96 hrs. Corresponding to F_{48}, F_{72}, F_{96}, respectively. $F_{48\text{-}96}$ refers to the fermentation periods in hours. The fermented seeds were air dried for two days, then ground into fine powder with hammer mill, packaged and labelled in a polythene bags in preparation for proximate analysis, amino acid profile, mineral elements and determination of anti-nutritive compounds.

Biochemical Analysis of Raw and Processed Seeds

The proximate composition of the raw and fermented seeds, were determined as described by the Association of Analytical Chemistry (A.O.A.C., 2000). The Amino Acid profile in the known sample was determined using the method described by Benitez (1989). All chemical analysis was carried out in triplicate.

Determination of Anti-Nutritional Compounds

The anti-nutritional compounds such as tannins, saponins, hydrogen cyanide, were determined as described by (AOAC, 2000), while Phytate phosphorus and oxalate were determined by the methods of Wheeler and Ferrel (1971) using the procedures of Oke (1969).

Statistical Analysis

All data collected were subjected to one way analysis of variance (ANOVA) using General Linear Model (GLM) procedure of SAS (SAS, 2004). Duncan Multiple Range Test (DMRT) was used to separate means respectively. Values of $P<0.05$ were considered significant.

Results and Discussion

Effects of Fermentation on Nutrient Composition of *Senna obtusifolia*

The proximate compositions of the raw and fermented *Senna obtusifolia* seeds meal (FSOSM) are presented in Table 1.The crude protein content of raw SOSM sample increased from 21.12 ±0.05 g/100g to 32.11±0.06g/100g for FSOSM. The crude protein content for the fermented sample differed significantly ($p<0.05$) than the raw sample. The crude lipid content of the raw *Senna obtusifolia* seed was (5.61%), the crude lipid decreased as fermentation time progressed from 48hrs to 96hrs. The ash content of the raw SOSM (5.42 ±0.38 g/100 g) was slightly higher than that of the fermented (5.40 ±0.21 g/100 g) but insignificantly different ($p>0.05$). The crude fibre content of the fermented sample was lower than the raw sample 8.63±0.35 g/100g and significantly different ($P<0.05$) among treatments and decreased from 5.51 to 5.29%. The moisture content of the fermented sample progressively decreased as fermentation period increased from 48 to 96hrs. The total NFE reduced as fermentation progressed and were significantly different ($p<0.05$).

Anti-nutritional Compound of Raw and Fermented *Senna obtusifolia* Seed Meal

The anti-nutritional compound of raw and fermented *Senna obtusifolia* seeds meal (FSOSM) samples is presented in Table 2. The phytate concentration in the raw seed was 4.22±0.13g/100g and reduced significantly ($p<0.05$) to 0.28±0.01g/100g for the fermented seed at 96hrs represents 93.4% decrease in the phytate. The tannin in the raw seed was 1.60 ±0.02g/100g which was significantly reduced ($p<0.05$) by 96.3% to 0.06±0.02g/100g in the 96hrs fermented seed. The cyanide concentration reduced from 0.47±0.01g/100g in the raw seed to 0.04±0.01g/100g for the fermented seed at 96hrs representing a reduction of 91.5% reduction. The oxalate 2.44 ±0.020 g/100g in the raw seed meal, was reduced to 0.00±0.003g/100g at 96hrs. Saponin was 2.14±0.08g/100g in the raw reduced significantly ($p<0.05$) to 0.06±0.08g/100g at 96hrs representing a reduction of 97.2% in saponin concentration.

Amino Acid Composition of fermented *Senna obtusifolia* Seed

The amino acid (g/100g protein) composition of the raw and fermented *Senna obtusifolia* is presented in Table.3 Leucine (6.23g/100g protein) had the highest value of essential amino acid while glutamic and aspartic acids (11.92 and 7.82g/100g protein respectively) were the most available non-essential amino acids in the raw seeds. Tryptophan concentration could not be determined because it was hydrolysed by the acid. Methionine (Met.) had the least value both in the raw and fermented seeds. Fermentation significantly ($p<0.05$) improved the amino acids.

Concentration of Amino Acid (g/100gcp) of Raw and Fermented *Senna obtusifolia*

The evaluation of the amino acids based on the classification of the differently fermented *Senna obtusifolia* seed meal is presented in Table 4 revealed that the total amino acid (TAA),Total Essential Amino Acid (TEAA) with histidine and Total Sulpur Amino Acids (TSAA) of the raw seeds were 69.93, 32.24 and 1.42 respectively. Fermentation enhanced the total TAA. Similarly, fermentation progressively enhanced the TEAA and TSAA from 1.57 to 2.38 in F_{48} and F_{96} respectively.

Fermentation of *S. obtusifolia* seeds resulted in increase in crude protein and free amino acids, decrease in crude lipid, crude fiber, and reduced anti-nutritional compounds in comparison to the raw. The increase in nutrient composition of fermented *Senna obtusifolia* seed meal (FSOSM) could be attributed to the biochemical activities of micro-organism that is responsible for the fermentation process and the release of nutrients Yigzaw *et al*. (2004).
The increase in crude protein value through fermentation compare favourably with the values reported for beni seed (Oshodi *et al*., 1999). Increase in protein value with fermentation time has been attributed to net synthesis of protein which results in the production of some amino acids during protein synthesis (Marero *et al*., 1989; Uwagbute *et al*., 2000). The high protein contents could also be attributed to the ability of the micro-organism to secret some extra cellular enzymes which further degraded the pulverised seeds during fermentation (Oseni and

Ekperingin, 2007). The apparent decrease in carbohydrate could be attributed to increased activity of amylolytic enzymes which hydrolyze starch and other complex carbohydrates to simple sugars (Kazanas and Fields, 1981). Similar findings were reported by Achinewhu and Isichei (1990), Nnam (1995) and Onweluzo (2009) on fermented fluted pumpkin seeds, cowpea, millet and pigeon pea respectively. Fermentation reduces the fibre content of the seed probably due to activities of hydrolyzing enzymes such as cellulase, and α-galactosidase produced by the micro-organisms leading to the conversion of insoluble fibre to soluble dietary fibre which are used as a source of energy for cellular activities by micro-organisms (Chandrasekara and Shahidi, 2012). Chitra *et al*. (1996) also reported the reduction in dietary fibre contents of fermented chick pea from 161.1 to 82.4g/kg after fermentation. Similar results were also reported by Oseni *et al*. (2011) when *Jatropha curcas* seeds were fermented. The decrease in lipid content of the fermented seed in this study might be attributed to the increased activities of the lipolytic enzymes during fermentation which hydrolyses lipids into fatty acids and glycerol (Chinma *et al*., 2009). The decrease in ash content of FSOSM could be due to losses of dry matter and volatile materials which normally occur during fermentation. A significant reduction in phytic acid composition in the fermented samples when compared with raw samples might be associated with hydrolysis of phytate via the action of microbial phytase enzymes to lower inositol phosphates (Sandberg, 1991; Hurrell, 2004). Microbial phytases originate either from the micro flora on the surface of cereals and legumes or from a starter culture inoculate (Sandberg, 1991). The lower tannin in the fermented sample could be that tannin-protein, tannic acid-starch and tannin-iron complexes are broken down during fermentation to release free nutrients (Obizoba and Atii 1991). Since tannins are known to reduce the availability of proteins, carbohydrates and minerals through the formation of indigestible complexes (Osagie *et al*., 1996), breakdown of such complexes by fermentation may improve the availability of the nutrients to fish. The lower cyanide level observed could be due to hydrolytic activities of enzymes by the fermenting microorganisms (Montgomery, 1980). Cyanide can also be reduced by boiling and fermentation as a result of alkaline condition of the reaction which breaks down cyanohydrin to hydrogen cyanide which in turn is readily reduced by soaking and fermentation (Liener, 1989). Fermentation caused reduction of 100% oxalate. There is a reduction in the level of saponins in the samples with increasing fermentation time. The amino acid Leucine was the most concentrated essential amino acid while glutamic and aspartic acids were the most concentrated non-essential amino acids in the raw seeds of *Senna obtusifolia*. The values of glutamic and aspartic acids made up to 9.79g/100g protein as the most abundant amino acids in seed sample; similar results have been reported by other workers (Olaofe *et al*., 1994; Oshodi *et al*.,1998; Adeyeye,2004). The limiting amino acids were found to be the sulfur amino acids (methionine + cystine). The lysine and methionine contents of the raw *Senna obtusifolia* seed meal is far lower than protein required for nutrition of finfish (FAO/WHO,1990) hence, this shows that there will be need for supplementation of the meal containing *S. obtusifolia* seed with lysine and methionine. The total sulphur amino acids (TSAA) for the processing method is lower than the 3.2g/100gcp recommended for *Clarias gariepinus* by Fagbenro *et al*. (1998). However, Onimisi, *et al*., (2017) reported substitution of soyabean meal with 25% of Fermented *Senna obtusifolia* seed meal in the diets of *Clarias gariepinus* without any negative effects on the growth and feed utilisation. Nutritive value of a protein depends primarily on its capacity to satisfy the needs for nitrogen and essential amino acids (Oshodi *et al*., 1998). Comparatively, the total values of essential and non-essential amino acid profiles of the fermented sample was slightly higher than in the raw samples. The increased amino acids of fermented *S. obtusifolia* seed meal sample could be attributed to one of the catabolic process which involves the breakdown of proteins into amines and amino acids during fermentation. Trans-amination and deamination reactions might be responsible for the slight changes in the amino acids of the raw and fermented seeds of *Senna obtusifolia* seed meal (Aremu *et al*., 2009).

Conclusion

In conclusion fermented *Senna obtusifolia* seeds meal for 96hrs reduced the anti-nutrient compounds considerably, contains appreciable amounts of nutrients and amino acids but is limiting in methionine and lysine when compared to the established standard by FAO therefore, its inclusion as supplementary plant protein with other feed ingredients rich in the limiting amino acids to feed fish is recommended.

Reproductive behavior and hatchability of *Tilapia guineensis* stocked in plastic tanks

M.M. Abdullahi, M.R Ajijo and M.A. Matanmi
Nigerian Institute for Oceanography and Marine Research (NIOMR), Lagos, Nigeria
Corresponding E-mail: matanmi19@yahoo.com

Abstract
Reproductive behavior and hatching rate of Tilapia guineensis egg were observed in plastic tanks in the outdoor shrimp hatchery of Nigerian Institute for Oceanography and Marine Research (NIOMR), Lagos, Nigeria. Pair of one male and female broodstock of T. guineensis each was stocked in three plastic tanks measuring 0.9 m X 0.8 m X 0.8 m. The total body weight and length ranged from 50.0-80.4 g and 14.0-16.3 cm respectively. The average body weight and length were 62.5 g and 15.0 cm respectively. Spawning was observed 2-5 days after pairing while the yolk sac absorption occurred within 4-5 days. The paired fish were fed with TOP FEED (4.5mm) at 3% of body weight. The mean number of eggs hatched was 872 eggs per female spawner with average egg diameter of 1.80mm. Hatching of eggs was observed 48-50 hours after fertilization. Egg hatchability ranged from 55.5-95.1% at a mean temperature of 27.4^{o}C. Successful propagation of T. guineensis in plastic tanks and appreciable hatching rates will increase availability of T. guineensis for aquaculture development of the fingerlings in Nigeria.

Keywords: Tilapia guineensis, reproduction, hatchability and plastic tank

Introduction
Tilapia possesses good attributes that make them ideal for aquaculture. They offer the possibility of commercial and cheaply grown protein sources where wild capture fisheries are being depleted (Mandal *et al*., 2009) and Ajiboye, O. O. and Okonji V. A. (2014). The species can be cultured in a wide range of environmental conditions and tolerates stress induced by handling (Tsadik and Bart, 2007, Uka and Sikoki, 2011). *T. guineensis* is euryhailine species found along West Coast of Africa. They are typical substrate spawners, display firm bonding during courtship with prolonged association with the pair establishing and defending a territory. They build spawning nest within the established territory (Legendre and Ecoutin 1989) and (Keremah and Ndah 2013). In recent times, there has been an increase in the culture of tilapia because of increase in demand for fish food, fish meal and other fisheries product. One of the factors responsible for the low level of fish production from brackish water environment is the scarcity of fingerling of brackish water fish species such as *T. guineensis*. As of now, demand for *T. guineensis* fingerings has far outstripped supply in recent times (Horsfall, 2006, Musa *et al*., 2006, Keremah and Ndah, 2013). The availability of fingerlings of *T. guineensis* in the wild is seasonal; hence hatchery propagation of *T. guineensis* will bridge the seasonality of the fingerlings from the wild. This study will produce scientific information on reproductive behavior and hatchabilty of *T. guineensis* in plastic tanks

Materials and Method
Experimental Site
The study was conducted between May and July, 2017 at the Department of Aquaculture, shrimp hatchery complex Nigerian Institute for Oceanography and Marine Research (NIOMR), Lagos, Nigeria.

Collection of Brood fish
Adult *T. guineensis* broodstock of average body length of 15 cm and weight of 62.5 g were obtained from NIOMR Brackish Water Station Buguma, Rivers State. The live fish were packed in

polythene bags, oxygenated and transported in air conditioned vehicle. The fish collected were separated into males and females and acclimatized in two circular tanks of $3m^3$ for a period of 4 weeks. Broodstock were fed with TOP FEED, a commercial extruded floating feed at 3% body weight daily.

Natural Spawning in tanks

Broodstock of *T. guineensis* selected for spawning were separated into males and females. The weight of the broodstock was determined with the aid of Ohaus digital scale, pioneer PA214. They were then stocked at the rate of 1 male: 1 female per plastic tank measuring 0.9 m x 0.8 m x 0.8 m and containing 250L of water. The broodstock were observed in the plastic tank to spawn naturally. They were not fed but water was aerated and changed twice weekly. After spawning the eggs were counted and size was determined by Olympus trinocular microscope equipped with photoscope digital camera DCM35E (350kpixels). The male and female broodstock were removed 3-4 days after the eggs hatched into swim up fry. The fry were siphoned into a bowl and counted. The hatching rate was determined using the equation thus;

$$\text{Percent hatchability (\%)} = \frac{\text{Number of hatched fry}}{\text{Total number of eggs}} \times 100$$

Water Quality Monitoring

Water temperatures, pH, and Ammonia were monitored daily with a mercury-bulb thermometer (0-100^{0}C), pH meter and Lamotte test kit respectively. The fish tank were continuously aerated to ensure enough dissolved oxygen

Results and Discussion

Reproductive Behavior

The female brood stock was observed to spawn 2-5 days after pairing. Prior to spawning, the female brood fish cleaned the corner of the tank where eggs will be dispersed. The females laid their eggs by spreading the eggs at a corner of the tank while the males spread milt on the eggs by swimming over them. The eggs were observed to adhere to the wall of the tanks for 24 – 36 hours before being detached and aggregated by the female to a corner of the tank. The eggs were then moved to other corners of the tank intermittently. Protection, parental care and ventilation of eggs were carried out by both parents. Fertilized eggs were observed to be removed from unfertilized eggs by the male parent with the aid of the mouth. They were deposited at another corner of the tank where the female ventilated the eggs. Hatching of eggs started 48 – 50 hours after fertilization. The fry were protected and ventilated by both parents as they were guarded from one corner of the tank to another. The spawning and hatching rate of *T. guineensis* stocked in plastic tanks is shown in Table 1.The average total body length of the broodstock ranged from 14.0-16.3 cm, while the mean value was 15.0 cm. Average total body weight ranged from 50.0-80.4g, while the mean value was 62.5 g. Spawning took place between 21 and 23 days. Egg diameter ranged from 1.49-1.89 mm, while the mean value was 1.80mm. Average number of egg produced ranged from 964-1211, while mean value was 1090. Average number of hatched eggs ranged from 672-1040, with mean value of 872. Hatching rates ranged from 55.5-95.1%, while the mean value was 74.9%. Values of some water quality parameters monitored during the study are presented in table 2. Temperature ranged from 26.0-29.0^{0}C while pH ranged from 7.50-8.00. Ammonia ranged from 0.05-0.50 mg/L while dissolved oxygen ranged from 4.50-6.50 mg/L.

Table 1: Spawning and hatching rate of *T.guineensis* eggs stocked in Plastic tank

Parameters	Tank 1	Tank 2	Tank 3	Mean Value
Pairing ratio	1:1	1:1	1:1	
Average total body length broodstock (cm)	14	14.7	16.3	15
Average total body weight of broodstock (g)	50	57	80.4	62.5
Spawning time after pairing (days)	2	2	5	3
Spawning frequency (days)	21	23	21	21
Egg Diameter (mm)	1.49	1.62	1.89	1.80
Average number of hatching	904	1040	672	872
Hatchability (%)	94.2	95.1	55.5	74.9
Duration of yolk absorption (days)	5	4	5	4.6

Table 2: Summary means value of water quality parameter recorded during the spawning

Parameter	T1			T2			T3		
	Mean ±SD	Min.	Max.	Mean ±SD	Min.	Max.	Mean ±SD	Min.	Max.
Temperature (ºC)	27.42±0.95	26.00	29.00	27.38±0.96	26.00	29.00	27.41±0.99	26.20	29.00
pH	7.70±0.17	7.50	8.00	7.69±0.15	7.50	8.0	7.64±0.16	7.50	8.00
Ammonia (mg/L)	0.16±0.18	0.05	0.50	0.10±0.06	0.04	0.20	0.07±0.06	0.12	0.30
Dissolved oxygen (mg/L)	5.12±0.47	4.50	6.50	5.31±0.60	4.50	6.50	5.28±0.41	4.50	6.00

Reproductive Behavior

The result in this study on reproductive behavior of *T.guineensis* showed that before spawning took place, female brood fish cleaned the corner of the tank where eggs will be dispersed. The females laid eggs by spreading the eggs at a corner of the tank while the males spread milt on the eggs by swimming over them. This was similar to what was reported from the wild by Campbell, (1987) and Keremah and Ndah, (2013).

Spawned eggs

The females at spawning released 964-1,211 eggs with mean value of 109 0eggs. This agreed with the range of 451-2100 eggs reported by Etim *et al*, 1989, but lower than values of 1035-11170 eggs obtained by Fagade (1978). Bagenal and Braum (1978) reported that number of eggs released during spawning varies widely depending on species, size, age and abundance of food. Average total length and weight of broodstock used in this study ranged from 14.0-16.3 cm and 50.0-80.4 g respectively. These were higher than values of 8.0-9.0 cm and 21-35 g reported by Legendre (1983) and Niyonkuru, (2012) but similar to result obtained by Bome *et al*, (1995).

Eggs and hatchability

The numbers of eggs recorded for each tank were 904, 1094 and 1211 while hatching rates were 94.2, 95.1 and 55.5% for tanks 1, 2 and 3 respectively. This was similar to results obtained by Keremah and Ndah (2013) who reported number of eggs produced as 1269 with hatching rate of 74.9%. The egg diameter ranged from 1.49-1.89 mm with a mean value of 1.80 mm. This was similar to the mean value of 1.48 mm obtained by Keremah and Ndah (2013). Jegede and Fowole (2006) reported that diameter of eggs of *T. zilli* ranged from 1.1-2.0 mm. Yolk absorption was observed for 4-5 days depending on temperature. This agreed with what was reported by Keremah and Ndah (2013).

Water Quality Parameters

This experiment was carried out in fresh water; *T. guineensis* is euryhaline species and can spawn in water environment with salinity ranging from 0 to 17 ppt (Uka and Sikoki, 2011). Water temperature range of 26-29ºC obtained in this study was within the optimal range as reported by Boyd, (1979) and Phippart and Ruwet (1982). pH values were within acceptable range of 7.5 to 8.00. *T. guineensis* can tolerate wide range of pH (5 to 10) but grow and survive best at pH of 6 to 9 (Dannis *et al*, 2009). Ammonia values were within the acceptable range of 0.07±0.06 to 0.16±0.18 mg/L. Dissolved oxygen in this study ranged from 4.5-6.5mg/L which was similar to the value of 4.2-6.2 mg/L reported by Keremah and Ndah, 2013 for *T. guineensis* spawned in glass aquaria.

Conclusion

T. guineensis used for this study exhibited parental care but did not carry out mouth brooding of eggs. The successful propagation *T. guineensis* in plastic tanks under fresh water environment will further enhance Tilapia aquaculture system in Nigeria.

Capturing, Processing and Utilization of Lantern Fish Species as Replacement for Imported Fishmeal in the Culture of *Clarias Gariepinus* Fingerlings

A. Oresegun, B. Edah, A.B. Williams, and D.A. Bolaji
Nigeria Institute for Oceanography and Marine Research (N.I.O.M.R) 3- Wilmot Point Road, Victoria Island, Lagos, Nigeria
Correspondence: bernardnda@yahoo.com

Abstract
The capturing, processing and utilization of a deep sea fish species (Lantern fish) was explored. The project was carried out at the Nigeria Institute for Oceanography and Marine Research (N.I.O.M.R) Lagos. The newly acquired research vessel R.V. Bayagbona was used for the survey and capturing of lantern fish along the Nigerian coastal waters. The Simrad EK60 was deployed to determine the depth at which the schools are located. Captured Lantern fishes were sorted into different species onboard the research vessel. A selected species of the lantern fish (Diaphus sp) was further processed into Lantern fishmeal. Absolute replacement of imported fishmeal with Lantern fishmeal in the diet of Clarias gariepinus fingerlings was carried out. Data were generated for total weight gain (TWG), specific growth rate (SGR) and feed conversion ratio (FCR), Results obtained was not significantly different (P > 0.05) in feed conversion ratio (FCR) between fishes fed Lantern fishmeal based diet and fishes fed imported fish feed. Feed conversion ratio (FCR) was best in fishes fed Lantern fishmeal based diet. However, no significant difference (P > 0.05) was observed in their growth performance. It can be concluded that, harnessing the potentials of Lantern fish vis-à-vis Lantern fishmeal in the diet of Clarias gariepinus fingerlings has proven to be a good substitute to the imported fishmeal.
Keywords: Lantern fish, R.V. Bayagbona, Fishmeal and Aquaculture

Introduction
Fishmeal is the main and preferred source of protein used in agricultural feed industry because of the excellent nutritional composition. However, the rising demand and limited supply makes fishmeal an expensive protein source (FAO, 2006). The cost of imported fishmeal in 2004 ranged from US$870 – 1, 350 per tonne, while the cost of locally produced fishmeal was US$1 500 per tonne (Ayinla 2007). The inconsistent supply, the growing demand and price among other problems are limiting the use of fishmeal and putting a great pressure on the feed resource industry. In 2000, an estimated 65, 253 tonnes of fishmeal was available in Nigeria, of which 13.4 percent was locally produced and the rest imported, mainly from Norway and Denmark (Fagbenro and Adebayo, 2005). The escalating price of fishmeal, coupled with its scarcity, has stimulated research into ways of replacing imported fishmeal with other high protein natural alternatives. Nigeria's small-scale fishmeal industry could possibly be expanded by developing a fishery for the unexploited lantern fish resources in our national waters (Ayinla, 2007).
Since nutrition represents over 70% of total variable cost of culture inputs, the major challenge facing the aquaculture industry is the production of cost effective diets for farmed fishes, using inexpensive, locally available ingredients. This simply means that searching for unconventional, cheap feed inputs as an alternative to imported fishmeal is a must. Alternative protein sources such as soybean meal (Richardson *et al.*, 1985; Gatlin and Philips, 1989), yeast (Mahnken *et al.,* 1980; Tacon and Jackson, 1985; (Tacon, 1994) have been tested using different models. Lantern fish (a deep sea fish) is abundant in Nigeria's coastal waters and are yet to be exploited. Thus, the aim of this study therefore is to harness the advantage of prolificacy of lantern fish species which

are un-taped in our coastal water bodies to produce local fishmeal and reduce the importation of fishmeal. Fish feed will be cheaper, employment generated, more fish produced, farmers income increased and aquaculture production to National GDP will greatly be increased.

Methodology

Sample collection

Field sampling for Lantern fish was done with a pre-planned and agreed sampling area starting from the west-coast along the international water boundary with Benin Republic and the eastern boundary of Ogun State with Ondo State (Figure 1). Acoustic surveys to estimate stock biomass and trial fishing using pelagic trawls were also carried out.

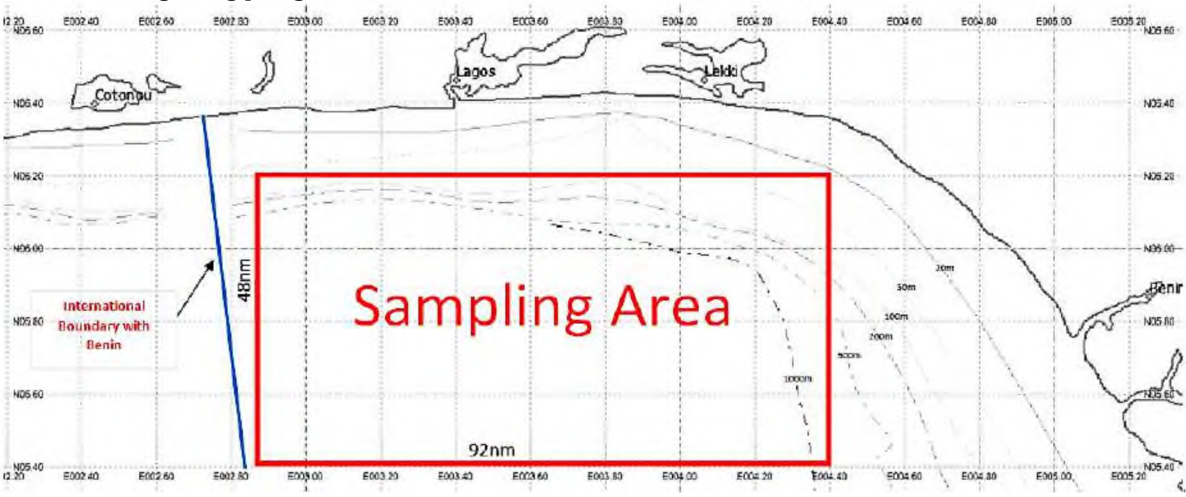

Figure 1: The sapling area for offshore Lagos and Ogun States

Table 1: Coordinates of the extremes of the sampling area

Points	Latitude	Longitude
A	6° 12' 000	2° 54' 000
B	6° 12' 000	4° 24' 000
C	5° 24' 000	4° 24' 000
D	5° 24' 000	2° 54' 000

The fish sonar and the sensor monitoring screens at the bridge were used to scan and monitor the water for school of fish before the trawl net was deployed (Fig. 2). The Simrad EK60 in the Instrumentation Room was also used to determine the depth at which the schools at located. Although the interpretation of the displayed echograms observed were not clearly understood, we still used it to search for schools of fishes based on our levels of interpretation. The sensors monitor gives the readings on the opening, height, amount of catch in the trawl net while the Simrad gives both the water depth and the depth of the schools of fish.

Deployment and Retrieval of the Trawl Net

After a school of fish had been spotted on the echogram, the trawl net would be deployed before we approach the school of fish (Fig. 2). Trawling operation is dependent on the depth at which the school was spotted and the direction of movement. Trawl duration lasted between one to two hours and the trawl speed between 2 to 4 knots.

Fig. 2: Deployment and retrieval of trawl net during the day (A) and night (B)

Trawls catch assessment and sorting

After a successful haul on deck, the sub-samples were taken to the fish processing unit for sorting, identification with each species counted and weighed (Fig. 3). Length frequencies of each species were measured and recorded. The measured samples were bagged for further laboratory analysis.

Fig. 3: Fish on deck (A), hauling into basket (B), sorting (C) and individual species sorted (D)

Processing of lantern fish into fishmeal

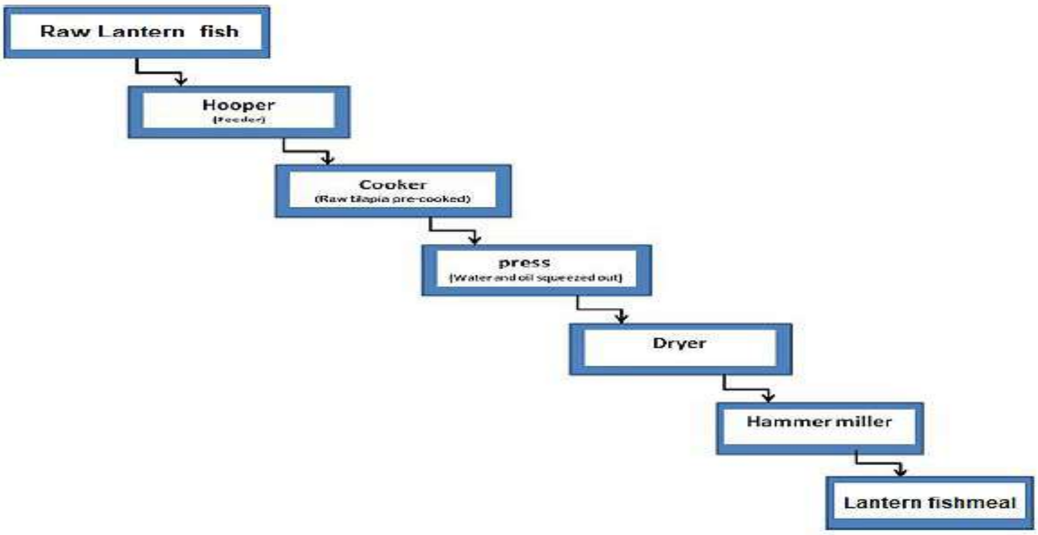

Fig 4: Flow Chart Describing NIOMR Fishmeal Processing Plant for Lantern fishmeal production

Fig. 5: Compact Fishmeal Processing Plant (Denmark, type FR100)

Processing of Lantern fish into Lantern fishmeal using a compact fishmeal processing machine (Denmark, type FR 100)

Fishes were processed into Lantern fishmeal using a compact fishmeal processing plant (Denmark, type FR100) (Fig. 5). **P**rocessing method involved feeding fresh Lantern fish into a cooker through the hopper situated above the plant. The cooker consists essentially of a long steam jacketed cylinder through which the fish is moved by a screw conveyor with a steam injector connected above it. The raw fishes are pre-cooked at a holding temperature of about 70 - 80^{o}C for about 5 - 15 minutes. The coagulated mass then enters a press situated at the middle of the component. In this component**,** the fish is conveyed through a perforated cylindrical tube whilst being subjected to increasing temperature. Water and oil are squeezed out through the perforations leaving a pressed solid cake which then enters a drum-like drier situated at the base of the machine. The product; a mixture of dried coarse Lantern fish flesh, scales and bones are then milled to produce a finely milled Lantern fishmeal powder (Fig. 4).

Proximate Analysis of Feed ingredients

Analyses of crude protein, crude fibre, ether extracts, ash and moisture contents was carried out in triplicates, generally following AOAC (1995) procedures. Dry matter (DM) was determined by drying 5 g of sample to constant weight in an oven at 103°C. Ash content was also determined by ashing the 5 g at 550°C in a muffle furnace for 4 ½ hours. Crude protein (CP) was quantified by the standard micro-Kjeldahl method, using a sample size of 0.4 g.

Determination of growth Indices

The Final weight, Total weight gain, Specific Growth Rate (SGR) and Feed Conversion Ratio (FCR), were calculated.

Statistical Analysis

All data resulting from the experiment were analyzed by one way analysis of variance (ANOVA) using the SPSS (statistical Package Computer, Software 2004 version Chicago Illinoise, USA). Duncan's multiple range test for least significant difference were used to compare differences among individual means. Differences were regarded as significant at $P < 0.05$ (Zar, 1999).

Results and Discussion

Chemical Composition

Dried Lantern fishmeal was analyzed for its chemical composition Fig 3. Results show that, crude protein, Lipid and Ash content were 62.4%, 6.32% and 6.5% respectively.

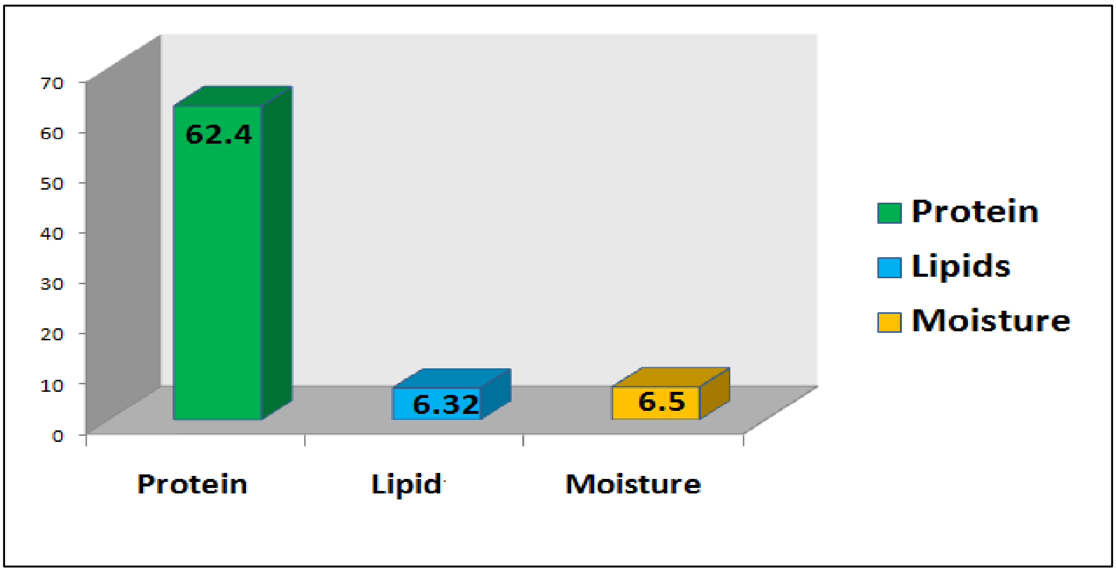

Fig 6: Chemical composition of Dried Lantern fish

Growth Performance of *C. gariepinus* Fed Plant protein based feed (A), Imported feed (B) and Lantern based feed (C)

The mean cumulative weight gain of the experimental fish (*Clarias gariepinus*) fed Plant protein based feed, Imported feed and Lantern based feed for 8 weeks revealed that. The initial weight of the fish at the point of commencement of feeding trial was 20.05g, 20.09g and 20.10g for treatment A, B and C respectively while the final weight gain was 807.0g, 1,162.5g and 1,178g for treatment A, B and C respectively. The group of fishes fed Lantern fishmeal based (C) had the highest weight gain (1,178g). While the groups of fishes fed plant protein based diet recorded the least weight gain (807.0g). The groups of fishes fed Lantern fishmeal based had the lowest FCR (2.16) while the highest FCR (3.89) was recorded for the fishes fed with plant protein based diet. However, SGR was the same for all treatments (Table 2, Fig 6 and Fig 7).

Table 2: Feed Utilization of _C. gariepinus_ Fed Plant protein based feed, Imported feed and Lantern based feed

Parameters	Plant protein based	Imported feed	Lantern based
Culture Period (weeks)	8	8	8
Initial Weight of Fish/ tank (g)	20.05	20.09	20.10
No Stocked	22.00	22.00	22.00
Final weight of Fish/ tank (g)	807.00	1,162.50	1,178.00
Weight Gain of Fish/ tank (g)	786.95	1,142.41	1,157.90
SGR	0.03	0.03	0.03
FCR	3.89	2.20	2.16

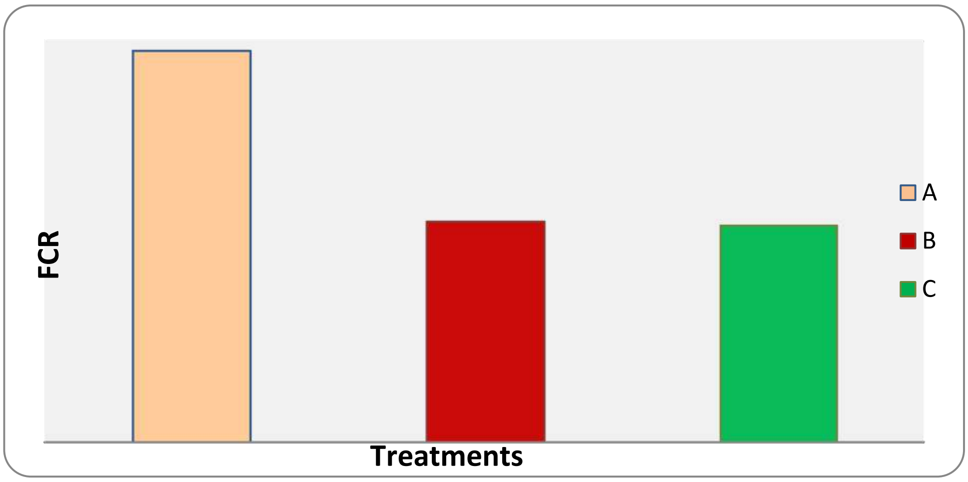

Fig 7: Feed Conversion Ratio (FCR)
Key: (A= Plant based feed, B= Imported feed, C= Lantern based feed)

Lantern fish represents a virgin resource in the Nigerian territorial waters. Because of its potential importance for fishmeal production there has been great interest by the Nigerian Institute for oceanography and marine research (NIOMR) during the last decade to start commercial exploitation of this untapped natural resource. The present study entails the feeding trial of _C. gariepinus_ fed Lantern fishmeal based diet. The nutritional quality of treatment containing Lantern fishmeal based diet as compared by Duncan's multiple range tests for least significant difference was adequate. Although final body weight and growth rate were higher in fish fed diet containing Lantern fishmeal based diet, no deleterious depression in growth was observed in fishes fed imported feed. Secondly, one of the most common difficulties observed when alternative sources of feedstuffs are used in fish diets is acceptance and palatability of the feeds by the fish (Domingues _et al._, 2003, Rodriguez _et al._, 1996 and Adewolu, 2008). Lantern fishmeal based diet treatment was accepted by _C. gariepinus_ fingerlings, indicating that absolute replacement of fish diet containing imported fishmeal with Lantern fishmeal did not affect palatability and acceptance of the diets. This might be due to the processing technique employed in this study owing to the adjusted minimal processing temperature of Lantern fish into fishmeal and of cause, the preference of fish eating fish. Feed conversion ratio (FCR) is an important economy indicator in fish production. FCR is a marker of how efficiently an animal utilizes feed, therefore minimizing feed wastage. Low FCR is usually desired in feed production. In general, the FCR observed in this study revealed that feed utilization were best in fishes fed with Lantern fishmeal based diet. The FCR of fishes fed with imported feed were also adequate.

This value supports the results by other researchers that evaluated alternative dietary protein sources to fish meal. Muzinic _et al._, (2006) reported FCR range of 1.70-1.78 when turkey meal was used at various replacement levels in diets for Sunshine bass which agrees with the results obtained in this study for _C. gariepinus_ fingerlings fed Lantern fishmeal based diet. Rawles _et al._, (2006) also reported an FCR range of 1.58-1.72 when poultry blood meal was used to replace fishmeal in diet for hybrid striped bass which is similar to the findings of this study. The carcass composition of *C. gariepinus* fishes fed diets containing Lantern fishmeal based diet and imported feed at the end of experimental period did not also differ significantly ($p > 0.05$). This might be due to the near constant protein content of the experimental diets. In conclusion, it is well known that marine resources offer a vast range of opportunity to solving the problems of fishmeal and fish oil in Nigeria. The responsible use of this deep sea fish species; Lantern fish, principally by the animal feeds industry is therefore important.

Occupational Competencies Needed by Retirees in Fish Production for Sustainable Livelihood in Rivers State

N.J.E. Alali, and P.O. Ezekiel
Department of Agricultural Education, School of Secondary Education (Vocational), Federal College of Education (Technical), Omoku, Rivers State, Nigeria
Email: alalingo4christ@g.mail.com & patrickezekiel2@gmail.com

Abstract
This study was designed to identify occupational competencies needed by retirees in fisheries production for sustainable livelihood in Rivers State. Three research questions guided the study. The sample for the study was two hundred and fifty four (254). A 74-skill item questionnaire was developed from literature reviewed. Pilot study was carried out in order to determine reliability of the research instrument through Cronbach's Alpha which measured the internal consistency. The pilot study was conducted with selected thirty (30) Extension Agents and Ten (10) Registered retired fish framers using the split half method which yielded a co-efficient of 0.81 and 0.78 respectively. Two hundred and fifty four (254) copies of the questionnaire were administered on the respondents through the help of three (3) research assistants. All the copies of the questionnaire were retrieved and analyzed using weighted mean and Improvement Need Index (INI) for the research questions. It was found out that retired fish farmers needed occupational competencies in pond construction and stocking of the pond for sustainable livelihood in Rivers State. It was recommended that the findings of this study be utilized to develop occupational competencies programmes for retaining retiree fish producers for greater efficiency.
Keywords: Occupation, Competency, Retiree, Sustainable and Livelihood

Introduction
According to FAO (1988), aquaculture is the farming of aquatic organisms, including fish, mollusks, crustaceans and aquatic plants in an open water body or in an enclosure. Aquaculture, like any other aspect of agriculture, is now a lucrative business venture for sustainable livelihood. Owing to the drive agriculture is having on the Gross Domestic Product(GDP) in Nigeria occasioned by government support to the sector, every retiree would want to practice one form of agriculture or the other to sustain livelihood. In Rivers State, with the natural disposition, retirees often opt for fish farming even though they may not have gotten the required experience. They may only realize after retirement that they did not really had pre-retirement plan for sustainable livelihood. In the observation of Amusa and Dumbiri (2010), most retirees lack basic occupational competencies for self-re-engagement after service. As a result, they associate fear with livelihood challenges on retirement. Jerry (2009) clarified that the fear of life on retirement is due to lack of productive competencies. In Rivers State, it is often observed that most to-be-retirees are frequently depressed by the uncertainty of how to continue to make sustainable livelihood on retirement. Majority of them, therefore, end up in highly strenuous and flexible business with high level of risks of failure which in most cases lead to hypertension and in extreme cases death of the individual. Owing to improper retirement plans and the bureaucratic bottlenecks associated with retirement packages provided by the government, retirees in Nigeria face hardships such as financial insufficiency, poor feeding, and inability to pay life sustaining bills. Others include dysfunctional family matters as well as psychological or behaviour disorders like depression, hypertension, identity crisis, alcoholism, loneliness, fast ageing and ill health occasioned at times by loss of good accommodation among others (Inaja, 2007). Ayodeji and Theresa (2013) also observed that many retirees in the Nigerian society and the problems they are facing draw the attention of all and sundry. These problems seem to range

from sudden loss of life, loss of the usual monthly salary, anxiety about a residential home, lack of occupation, dwindling status, decreased strength and deteriorated health condition, physical disabilities and aging. However, Harris and Cole (1980) noted that retirement may be an advantage between one career and another; it may represent the opportunity to start one's real life work or to draw two pay checks. Meanwhile, Rivers State FADAMA 111 (2010) reported that most women in agriculture and retirees have indicated interest in fish production occupation because fish thrives well in the state while its supply to the market is lower than the demand by consumers and marketers who export it outside the state. In this study, retirees in fish production solve problems and obtain information, skills and technologies to improve their livelihood and well-being. It was in the expectation of the researcher that the retirees be trained to establish and manage fish production business for sustainable livelihood, but no such record exists. Recent observation shows poor production and low income by the fish farmers due to lack of knowledge of new techniques in the methods of fish production and marketing, as such sustainable livelihood is difficult. To avert this situation therefore, retirees fish farmers needs occupational competence. But the question is what are the occupational competence needs of retirees in fish production? It is against this backdrop, that the study seeks to identify occupational competencies needed by retirees in fish production for sustainable livelihood in Rivers State.

Methodology

This study was carried out using the survey research method. The population of the study consisted of all Extension Agents and registered retiree fish farmers in Rivers State. A sample size of fifty-four (54) Extension Agents and two hundred registered retirees fish producers in the State were randomly selected from the twenty three Local Government Areas . The research instrument used for data collection was a structured questionnaire. Copies of the instrument were administered by the researcher, along with the three research assistants. This was to allow for easy administration of the questionnaire to the Extension Agents and retirees fish producers in Rivers State. The research questions were answered using weighted mean and Improvement Need Index (INI).

Occupational competencies of the retirees fish producers were determined as follows:

a. The weighted mean ($\bar{X}n$) of the competency importance rating was determined for each item.
b. The weighted mean ($\bar{X}p$) of performance rating was determined for each item.
c. The performance (PG) was determined by finding the difference between the values of $\bar{X}n$ and $\bar{X}p$. That is, $PG = \bar{X}n - \bar{X}p$

A negative PG means that occupational competency is needed because the level at which the retiree fish producer could perform that item is greater than the mean importance rating. A zero PG implies that improvement is not needed because the level at which the retiree fish producer could perform the item is equal to the mean importance rating it is needed. Whereas, a positive PG means that occupational competency is needed because the level at which the retiree fish producer could perform the item is lower than the mean importance rating (Olaitan et al. 2000). The occupational competency needs of the retiree fish producers were therefore prioritized according to the gap between improvement rating and level of possession. The higher the value, the higher the need for occupational competency.

Results and Discussion

The analysis were based on the data gathered from the 254 respondents. The data collected are presented as analyzed in the tables below:

Table 1: Performance gap analysis of the mean ratings of the responses of retiree fish producers and Extension Agents in Pond Construction in Rivers State

S/N	Items	$\overline{Xn}$	$\overline{Xp}$	PG	Remark
1.	Clear pond site for construction	3.33	3.68	–0.35	NNED
2.	Excavation of the soil	3.23	3.78	–0.55	NNED
3.	Prepare bottom soil with river sand	4.08	2.45	1.63	OCN
4.	Fence pond site	3.38	3.45	0.43	OCN
5.	Treat fish pond with antibiotics	4.05	3.74	0.31	OCN
6.	Lime the pond with calcium materials when needed	4.36	3.71	0.65	OCN
7.	Combine appropriate mixture of cow and poultry dung to make planktons bloom in the pond	4.25	2.10	2.15	OCN
8.	Use suitable plants to provide shade for the pond	3.65	3.34	0.20	OCN
9.	Fertilize pond with organic and inorganic manure	4.98	3.30	1.68	OCN
10.	Fill the pond with water	3.70	3.65	0.05	OCN

Results in Table 1 reveals that the performance gap value of eight (8) out of ten (10) items ranged from 0.05 to 2.15 and were positive. This shows that retiree fish producers need occupational competency in the 8 items on construction of ponds skill in fish production and marketing enterprise.

Two of the ten skill items had a performance gap –0.35 to 0.55 which indicate that the retiree fish producers do not need occupational competency on those items. On the average, the retiree fish producers need occupational competencies.

Table 2: Performance gap analysis of the mean ratings of retiree fish producers and Extension Agents for producing fish for sustainable livelihood

S/N	Items	$\overline{Xn}$	$\overline{Xp}$	PG	Remark
1.	Stock pond with the right fish	3.98	2.64	1.34	OCN
2.	Stocking at optimum density	3.45	3.18	0.27	OCN
3.	Remove rough vegetation such as bushes	2.85	4.24	–1.39	NNED
4.	Check the water level regularly to avoid water running through the outlet	2.70	3.69	–0.99	NNED
5.	Attend to any repairs to the outlet and inlet after proper checking on them	3.61	2.78	0.83	OCN
6.	Fill cracks, replace worn bricks or concrete	3.72	2.38	1.34	OCN
7.	Regularly drain and change water	2.52	3.96	–1.44	NNED
8.	Maintain good water quality	3.17	2.44	0.74	OCN
9.	Test cropping	3.39	2.58	0.84	OCN
10.	Keeping farm records	3.84	2.73	1.11	OCN

Table 2 reveals that the performance gap values of seven (7) skill items range from 0.27 to 1.34 and were positive. This shows that the retiree fish producers need occupational competency in the seven skill items. Three (3) out of the ten (10) skill items had a performance gap value ranging from –0.99 to –1.44 which indicate that the retiree fish producers need occupational competency in the stocking of fish. Analysis of data indicated that retiree fish producers need occupational competency in pond construction and stocking. These findings are in conformity with those of Amusa and Dumbiri (2010) who reported that most retirees lack basic occupational competencies for self-re-engagement after service. They further recommended that to-be-retiree farmers need to be properly trained to become successful farmers after retirement. Abu (2008), in a study on "improvement Needs of to-be-Retiree Farmers in Soil Conservation in Kogi State, Nigeria," also reported that they require improvement in competencies to manage their farms.

Conclusion

From all indications, retiree fish producers in Rivers State lack occupational competencies for sustainable fish production for livelihood food security. It is therefore recommended that retirees be properly trained by relevant organizations on aquaculture in all ramifications before embarking on the venture to avoid losing their investment.

Abstract

The presence of total coliform, fecal coliform, Vibrio, Salmonella and Shigella species in the muscles two common finfish Shyraena piscatorum (Baracuda) and Chrysichthys nigrodigitatus (Silver cat fish) and shell fishes Penaeus notialis (pink shrimp) and Callinectes sp. freshly caught from coastal waters in Lagos and Ondo state was assessed in April and July 2018. After culture on appropriate growth media using the traditional spread plate method, a total viable count range of 4.0 $x10^2$ to 5.0 $x10^3cfug^{-1}$ (total coliform); 4.0 $x10^2$ to 1.2 $x10^4cfug^{-1}$ (fecal coliform); 4.30 $x10^2$ to 1.44 $x10^4cfug^{-1}$ (Vibrio species.), 9.0 $x10^2$ to 3.1 $x10^3cfug^{-1}$ (Salmonella Shighella species) was observed in both the fin fish and shell fish. Although the bacterial abundance varied among the different types of seafood. There was also a significant variation in the occurrence of the organisms during the two sampling period. This study indicates possible fecal contamination of our coastal waters and poor sanitary/handling practices of the fisher folks. There is a public health threat of outbreak of foodborne infections due to consumption of these contaminated seafood especially when not properly cooked.

Introduction

Fish and other seafood has always been part of human diet, however the consumption of seafood has recently increased due to the awareness of the high nutritional value especially its low cholesterol, fat content and good quality of animal protein (Quintoil 2007, Iwamoto *et al*., 2010; Sudha *et al*., 2012; Costa 2013). Seafood are carriers of a variety of microorganisms such as bacteria, fungi, viruses and parasitic pathogens. Among these microbes are human pathogens capable of causing from mild gastroenteritis to life-threatening diseases, including *Escherichia coli, Salmonella sp., Shigella sp., Staphylococcus sp., Clostridium botulinum, Vibrio, Pseudomonas, Erysipelothrix, Leptospira, Pasteurella, Mycobacterium* and *Aeromonas*. Indeed, a significant percentage of foodborne diseases worldwide has been associated with seafood. They acquire these organisms through feacal pollution of the aquatic environment and poor handling after capture (Abeyta 1983, Iwamoto *et al*., 2010; Ariyawansa *et al*., 2016; Nrior *et al*., 2017; Sudha *et al*., 2012). Nigerian coastal waters like other coastal waters around the world is endowed with rich fishery resources, this serves as prominent source of food and income for both the people living in the coastal areas and the entire country at large. The coastal waters are also prone to contamination through domestic and industrial sewage, the main source of pathogenic microbes being domestic and hospital wastes (Thayumanavan *et al*., 2003 and Quintoil 2007**)**. As a potential source of foodborne diseases, there is need for continuous monitoring of the bacteriological status of seafood in order to establish the safety of the consumers. This study therefore is an attempt to determine the bacteriological status of our fishery resource. This will ensure effective and sustainable management system and enlighten the issues of public health and consumer safety.

Materials and methods

Collection of Fish samples

Samples of two different popular species of fresh fin fish *Shyraena piscatorum* (Baracuda) and *Chrysichthys nigrodigitatus* (Silver cat fish) and shell fishes *Penaeus notialis* (shrimp) and *Callinectes sp*. (crab) were bought from the landing sites at Makoko Lagos state and Igbokoda, Ondo state in April and July 2018. The samples were placed in clean polythene bags and preserved in ice chest and transported to the laboratory where analysis commenced within 24 hours. At the laboratory of Department of Biological Oceanography, Nigerian Institute for Oceanography and Marine Research, Lagos, the representatives of the skin of fin fish and shell of the shell fish were aseptically removed and muscles and internal tissue respectively macerated using sterile pestle and mortar.

Bacteriological Analysis

A total of ten grams (10g) of the macerated fish samples were added to ninety milliliters (90ml) of sterile peptone water, this was subsequently serially diluted and aliquots (0.1ml) of appropriate dilutions inoculated into specific agar plates for isolation and enumeration of the different groups of bacteria using spread plate method. The total coliforms and fecal coliforms were cultured on MENDO and MFC agar (Biomark Inc.) respectively. However, *Vibrio* species and *Salmonella/ Shigella* species were isolated on Thiosulphate - Citrate – Bile - Sucrose (TCBS) agar and Salmonella Shigella agar (Oxoid) respectively. Incubation of fecal coliforms was carried out at 44^{o}C while the others were at 37^{o}C for 18 to 24 hours after which the viable discrete colonies were counted.

Statistical Analysis

The analysis of variance (ANOVA) were determined using Prism version 5.03 computer software program (GraphPad Software, San Diego, CA. USA). Tests were carried out at 5% significance level.

Results and Discussion

Total viable count of bacteria in the two fresh fin fishes (*S. piscatorum* and *C. nigrodigitatus*)

During the first sampling in April, an average of 4.55 x 10^3 cfug^{-1} of total coliform, 3.15 x 10^3 cfug^{-1} of Feacal coliform; 1.44 x 10^4 cfug^{-1} *Vibrio* sp. and 9.0 x 10^2 cfug^{-1} of Salmonella Shigella sp. was observed in *S. piscatorum* (Figure 1). A lower bacteria count (2.95 x 10^3;4.0 x 10^2 and 8.50 x 10^3 cfug^{-1}) was however noted for all bacterial groups with exception of the *Salmonella Shigella* sp., which had a higher number of 1.15 x 10^3 cfug^{-1} at the second sampling in July for *S. piscatorum.* Two-way analysis of variance showed a significant difference ($p<0.0001$) in the population of the different bacteria groups, also there was a significant variation ($p<0.0001$) in the number of bacteria encountered in the two different sampling period. Similarly, *C. nigrodigitatus* had higher number of total coliform (4.45 x 10^3 cfug^{-1}), feacal coliform (7.30 x 10^3 cfug^{-1}) and Salmonella Shigella sp. (2.10 x 10^3 cfug^{-1}) in April sampling but more of the *Vibrio* sp. was observed in July (8.70 x 10^3 cfug^{-1}) compared to the initial value 6.05 x 10^3 cfug^{-1}. Nevertheless, a significant difference was noted among the bacterial group and sampling time with p-values of 0.0007 and 0.0099 respectively.

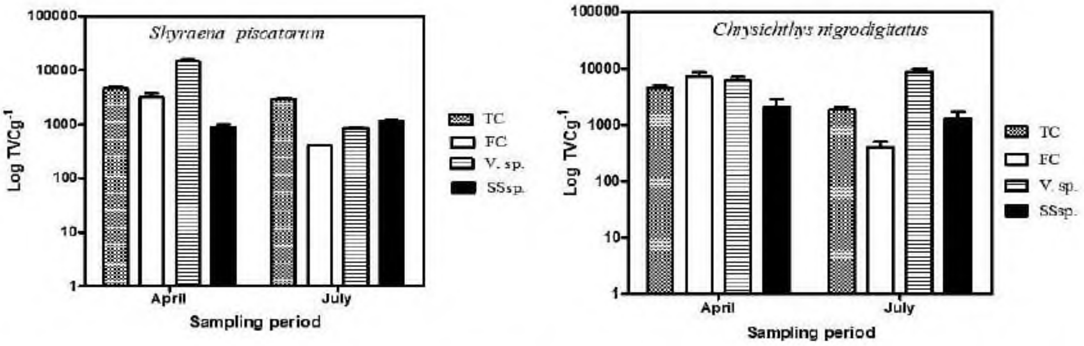

Figure 1 Total viable count of different bacterial groups total coliform (TC), Feacal coliforms (FC), *Vibrio* sp. (V.sp) and *Salmonella Shigella* sp.(SS sp.) on the two fin fish (*Shyraena piscatorum* and *Chrysichthys nigrodigitatus)*

Total viable count of bacteria in the two fresh shell fishes (*P. notialis* and *Callinectes sp.)*

As depicted in figure 2, in the first sampling period, the bacterial count noted for *P. notialis* was total coliform 5.0 x 10^3 $cfug^{-1}$; feacal coliform 1.20 x 10^4 $cfug^{-1}$; *Vibrio* sp. 9.50 x 10^2 $cfug^{-1}$ and *Salmonella Shigella* sp. 1.15 x 10^3 $cfug^{-1}$. However, the counts observed at the second sampling period for the respective bacterial groups was 2.5 x 10^3; 1.10 x 10^3; 1.28 x 10^4 and 9.50 x 10^3 $cfug^{-1}$. The bacteria viable count differed significantly among the different groups (p= 0.0006) and during the sampling periods (p=0.0115). On the other hand, *Callinectes sp.* had 2.05 x 10^3 $cfug^{-1}$ (TC); 2.40 x 10^3 $cfug^{-1}$ (FC); 3.2 x 10^3 $cfug^{-1}$ (*V. sp.)* and 1.25 x 10^3 $cfug^{-1}$ (*SS sp*.) during the April sampling. Meanwhile, at the second sampling, the population of total coliform, feacal coliform and *Vibrio* sp. reduced to 4.0 x 10^2, 1.95 x 10^3 and 4.30 x 10^2 $cfug^{-1}$ respectively but more (3.05 x 10^3 $cfug^{-1}$) of *Salmonella Shigella* sp. was noted. Interestingly, the variation in the bacteria population among the different group (p=0.34) and sampling time (p=0.08) was not significantly different for *Callinectes sp.*

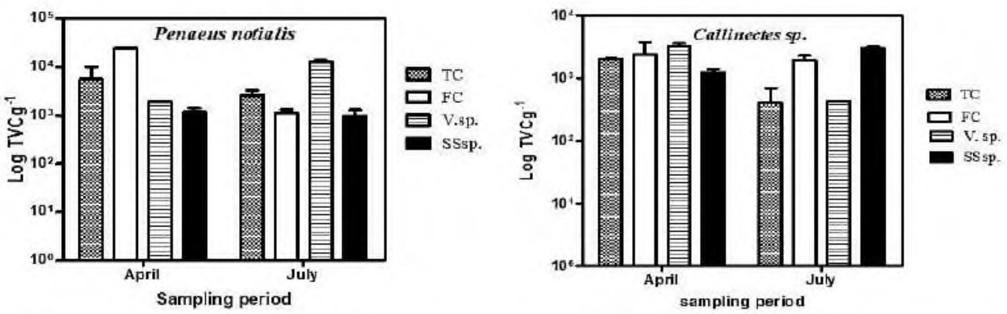

Figure 2 Total viable count of different bacterial groups total coliform (TC), Feacal coliforms (FC), *Vibrio* sp. (V.sp) and *Salmonella Shigella* sp.(SS sp.) on the two shell fishes *Penaeus notialis* and *Callinectes sp.*

The muscles of both the fin fish and shell fish in this study was contaminated with the different groups of bacteria including coliforms, fecal coliforms, *Vibrio* species and *Salmonella Shigella* species. This is contrary to the generally accepted fact that the muscles of freshly caught seafood are free from microorganisms. It has however been noted that the presence of microbes in freshly caught fish could be due to environmental contamination and poor handling by fisher folks (Iwamoto *et al*., 2010; Ariyawansa *et al*., 2016, Nrior *et al*., 2017). The coliform bacteria particularly *Escherichia coli* is a normal flora of human and other warm-blooded animals. It is usually abundant in their feces therefore; its presence in food or water commonly indicates direct or indirect fecal contamination. It is not surprising that these organisms were present in the fish from because earlier studies have reported the abundance of these organisms in Nigeria coastal waters (Ajayi and Akonai, 2005; Agwu and Oluwagunke, 2014). According to Mahalakshmi *et al* (2011), the introduction of microbial pathogens, including the ocean indigenous *Vibrios* and the allochthonous bacteria *E. coli, Salmonella* sp. and *Shigella* sp. is one of the major implications of the discharge of sewage and industrial effluents in the aquatic ecosystem. These pathogens affect the sustainability of living resources and public health. The difference in the abundance of the microorganisms during the sampling period could be attributed to the changes in the environmental factors during sampling. Environmental parameters such as temperature, salinity, dissolved oxygen, pH, nutrient concentrations are known to control the diversity, distribution and activities of microorganisms in the environment (Mahalakshmi *et al*., 2011). The two sampling periods (April and July) typically represents two different seasons and consequently different environmental factors and effects on the microbes. The fin fishes *Shyraena piscatorum* (Baracuda), *Chrysichthys nigrodigitatus* (Silver cat fish) and the shell fishes *Penaeus notialis* (pink shrimp) and *Callinectes sp*. (crab) in this study are among the commonly caught and commercially important seafood in Nigeria coastal area (Bolarinwa *et al*., 2018). They serve as a regular source of protein to the general public and there is a growing preference for fresh seafood. It is therefore pertinent that the presence of pathogenic and potential pathogenic bacteria in these fish samples should serve as an alert to consumers. There is risk of bacterial infection if seafood is not well cooked and immune-compromised individual including pregnant women, the elderly and persons with underlying medical condition are at a higher risk.

Conclusion

The occurrence of coliform and pathogenic bacteria in finfish and shell fish from the coastal waters in Lagos and Ondo state of Nigeria further indicates the pollution status of our aquatic ecosystem, and the threat it poses on our natural fishery resources. There is an urgent need for increased awareness of the possible effect of the consumption of these seafood and also improvement on the handling of fish from capture to the point of sale.

Length Weight Relationship and Condition Factor (K) of three Fish Species of *Carangidae* Trawled from Nigerian Coastal Waters

Omogoriola Hannah Omoloye
Nigerian Institute for Oceanography and Marine Research, PMB 12927, Marina Lagos, Nigeria.
Omogoriolahannah@gmail.com

Abstract
The growth pattern and condition factor for three species of family Carangid trawled from Nigeria coastal water were investigated recently. A total of 720 specimens ranging from 4.0 to 35.0cm in total length and 0.8 to 540.0g in weight were analyzed. Total length and weight were measured using standard methods and computed from linear regression. The growth pattern relationship is shown by the following equation: LogW = -1.6759+2.7615LogL (Selen dorsalis), LogW = -1.327+2.3448LogL (Chloroscombus chrysurus) and LogW = -2.1215+3.1468LogL (Caranx hippos). Selen dorsalis and Chloroscombus chrysurus exhibited negative allometric growth (b<3) while Caranx hippos was positively allometric growth with b=3.14 and the mean b= 2.75. The correlations (R^2) were 0.9071, 0.8977 and 0.8629 for Selen dorsalis Chloroscombus chrysurus and Caranx hippos respectively. The condition factor (k) ranged from 0.77±0.14 (Caranx hippos) to 5.04±3.4 (Chloroscombus chrysurus). The best condition factor was recorded for those individual within the lowest size groups. Most of the species studied are not in good condition (k≤1)
Keywords: Carangidea, Length weight relationship, Condition factor, and Nigerian coastal waters

Introduction
The family Carangidae encompasses a diverse group of fishes known variously by such common names as jacks, trevallies (crevalles), amberjacks, pompanos, scads, kingfish, pilot fish, rainbow runners among others (Randy, 2001). The length – weight relationships (LWRs) is of great importance in fishery assessment (Garcia *et.al.*. 1998; Haimovici and Velasco, 2000). Its importance is pronounced in estimated the average weight at a given length group (Beyer, 1987) and in assessing the relative wellbeing of a fish population (Bolger and Connoly, 1989).Length and weight measurement in conjunction with age data can give information on the stock composition, age at maturity, life span, mortality, growth and production (Beyer, 1987, Bolger and Connoly, 1989, King, 1996 a and b, Diaz *et. al*., 2000).In addition, the data on length and weight can also provide important clues to climatic and environmental changes and the change in human consumption practices (Ecoutin et.al., 2005, Pauly 1984). However, the size attained by the individual fish may also vary because of variation in food supply of nutrient or in the degree of competition for food. Environment deterioration, for example, may reduce growth rates and will cause a decrease in the average age of the fish. The condition factor and the relative condition factor (Le. Cren, 1951) are the quantitative parameters of the wellbeing state of the fish and reflect recent feeding condition of the fish. It is based on the hypothesis that heavier fish of a given length are in better condition (Bagenal and Tesch, 1978). This factor varies according to influences of physiological factors, fluctuating according to different stages of the development. Condition factor has been used as an index of growth and feeding intensity (Fagade, 1979). Condition factor decrease with increase in length (Bakare, 1970: Fagade 1979) and also influences the reproductive cycle in fish (Welcome, 1979). The aim of this research is to study the length-weight relationships and the variations in the condition factor among five species of sciaenid population trawled from Nigeria coast water.

Materials and Methods

Study Area

The sampling areas started from Nigeria/Benin boarder to the Western part of Ondo State. Eleven transects were sampled with seven stations on each transect line. The seven stations selected were based on the depth ranges; 10, 20, 30, 40, 50, 70 and 100m. The distances between transects was 5 nautical miles (9.26km) apart and the total distance between first and last transect was 50 nautical miles (92.6km) (Figure 1).

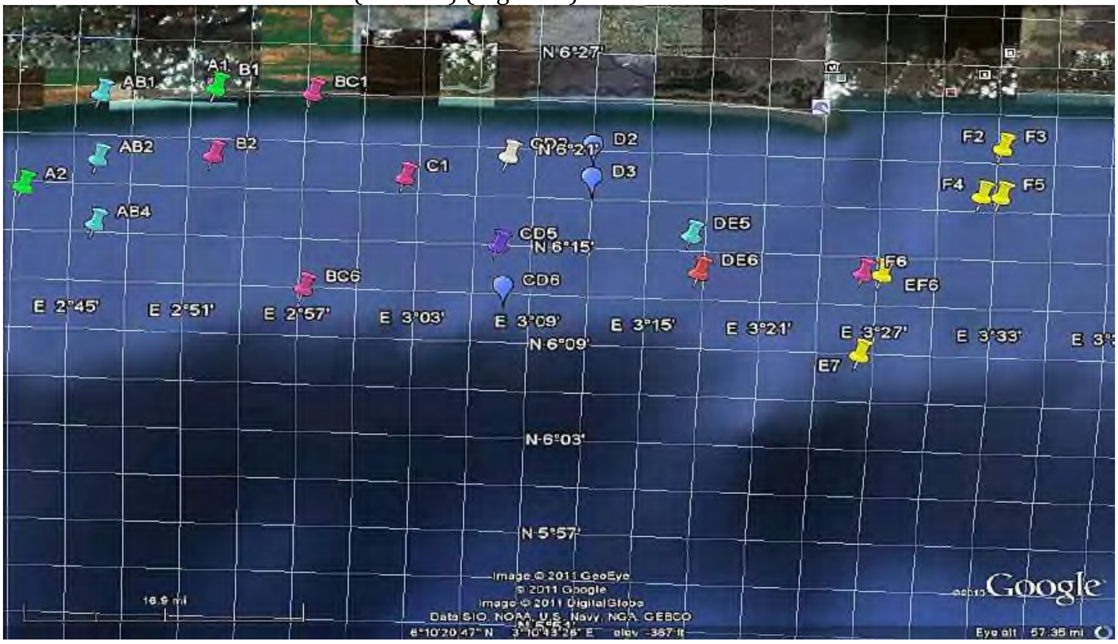

Figure 1: Map of Nigeria coastal water showing sampling stations

Fish Sampling

Fish were collected with a trawl net (cod-end 20mm mesh size), trawled at different depth, ranging from 10m-100m between May and June 2009. These species were abundant in 50m depth and above. The Total Length (cm) of the fish was measured from the tip of the snout or part of the mouth to the caudal fin using meter rule calibrated in centimeters. Fish was measured to the nearest centimeter. The weight of the fish was done with a table top weighing balance (Ohus Electronic) measured to the nearest gram. Fish weight was measured after blot drying with a piece of clean hand towel.

Length-weight Relationship

The relationship between the length (L) and weight (W) of the fish was expressed by equation (Pauly, 1984)

$$W=aL^b \qquad \text{Equation 1}$$

Linear transformation was made using natural logarithm at the observed length and weight proposed by Zar (Zar, 1984). The expression of the relationship is represented by the following formula:

$$\text{Log } W = b \log L + \log a \qquad \text{Equation 2}$$

Where: W = the weight of the fish in gram
L = the total length of the fish n centimeter
a = exponent describing of the rate of change of weight with length (intercept)
b = weight and unit length (slope)

The correlation (r^2) that is the degree of association between the length and weight was computed from the linear regression analysis:

$$R = r^2$$

Condition Factor

The degree of well being or relative robustness of the fish is expressed by coefficient of condition (also known as condition factor or length – weight factor). The condition factor as an indicator to fish welfare in their habitat was described (Gomiero and Braga, 2005). It is represented by letter K (formula 2) when the fish is measured and weighed as in the following equation (Pauly, 1984). This "k" value can be basically and directly interpreted as the higher the value, the better the condition of the fish.

$$K = \frac{100W}{L^b} \qquad \text{Equation 3}$$

Where: K = condition factor

W = the weight of the fish in gram

L = the total length of the fish in centimeters

b = the value obtained from the length weight equation in this study, the exponent

'b' value that is equal to 3 in equation 3 was used to calculate the 'k' value.

The K value is used to compare conditions between species and within their size classes (<5-9cm, 10-14cm, 15-19cm, 20-24cm, 25-29cm 30-34cm 35-39cm 40-44cm 45-49, TL etc).

Results and Discussion

A total of 720 fish were analyzed, 387 for *Selen dorsalis*, 298 for *Chloroscombus chrysurus* and 35 for *Caranx hippos*. The descriptive statistics for total length (TL) and weight (W) of the three species of Carangid were showed in Table 1.The total lengths (TL) of 720 specimens of three species of carangid examined in this study ranged from 4.0 (*Selen dorsalis*) to 35.0cm (*Caranx hippos*) while the weight ranged from 0.8 (*Selen dorsalis*) to 540.0g (*Caranx hippos*) (Table 1). The length weight patterns (GPs) of three species of carangid were showed in Table 2. Length weight relationships are shown by following equations: LogW = -1.6759+2.7615LogL (*Selen dorsalis*), LogW = -1.327+2.3448LogL (*Chloroscombus chrysurus)* and *LogW* = -2.1215+3.1468LogL (*Caranx hippos). Selen dorsalis* and *Chloroscombus chrysurus* exhibited negative allometric growth (b<3) while *Caranx hippos* was positively allometric growth with b=3.14 and the mean b= 2.75. The correlations (R^2) were 0.9071, 0.8977 and 0.8629 for *Selen dorsalis Chloroscombus chrysurus* and *Caranx hippos* respectively (Table 2 and Figures 2 - 4). In all the species the correlation coefficient found to be higher than 0.5, showing the length-weight relationship is positively correlated and vice versa. The condition factor (k) ranged from 0.77+0.14 (*Caranx hippos*) to 5.04+3.4 (*Chloroscombus chrysurus*) with mean value of 2.69+1.64. There was a general decrease in condition factor (K) with increase length for the five species (Table 3).

Table 1: Means of Length and Weight for the Three Fish Species of Carangid Trawled from Nigerian coastal waters

Species	N	Average length(cm)	Length range(cm)		Average weight(g)	Weight range(g)	
			Max	Min		Max	Min
Selen dorsalis	387	11.55	32.0	4.0	25.57	394.8	0.8
Chloroscombus chrysurus	298	13.89	22.0	5.0	25.54	98.5	1.4
Caranx hippos	35	22.83	35.0	18.0	162.54	540.4	37.6

N = Number of species, Max = Max, Min = Minimum

Table 2: Length Weight Relationship for the Three Fish Species of Carangid Trawled from Nigerian coastal waters

Fish Species	b+s.d	Logarithmic equation	R^2	K
Selen dorsalis	2.76 ± 0.37	LogW = -1.6759 + 2.7615LogL	0.9071	2.28 ± 1.29
Chloroscombus chrysurus	2.34 ± 0.38	LogW = -1.3270 + 2.345LogL	0.8977	5.04 ± 3.45
Caranx hippos	3.14 ± 0.45	LogW = -2.1215 + 3.1468LogL	0.9287	0.77 ± 0.14

N = number of fish; b = regression co-efficient; R^2 = correlation co-efficient; K = Condition factor

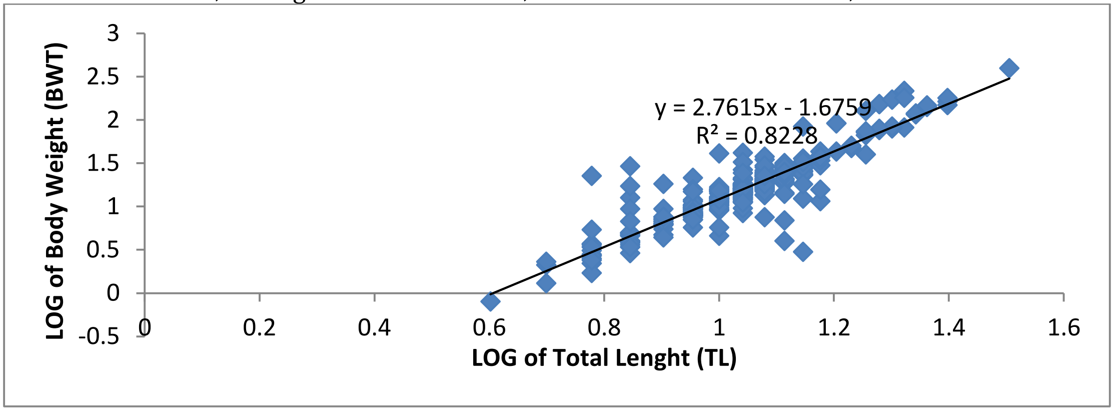

Fig. 2: Linear regression of total length-body weight relationship of *Selen dorsalis*

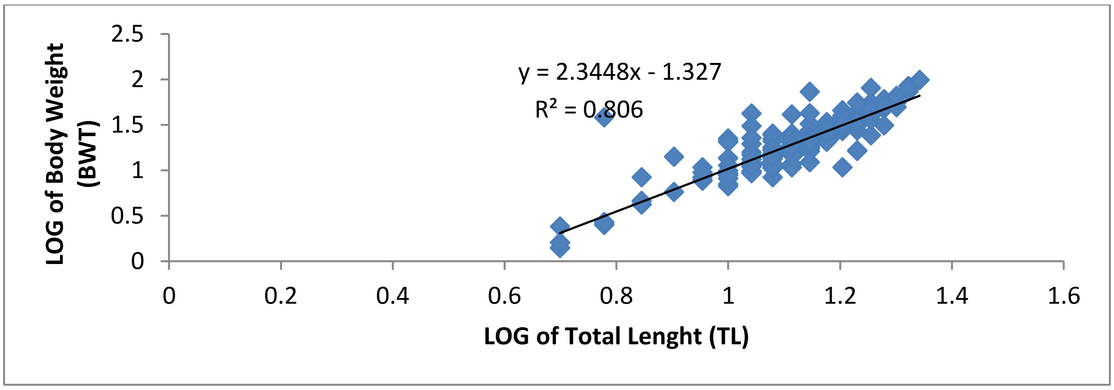

Fig. 3: Linear regression of total length-body weight relationship of *Chloroscombus chrysurus*

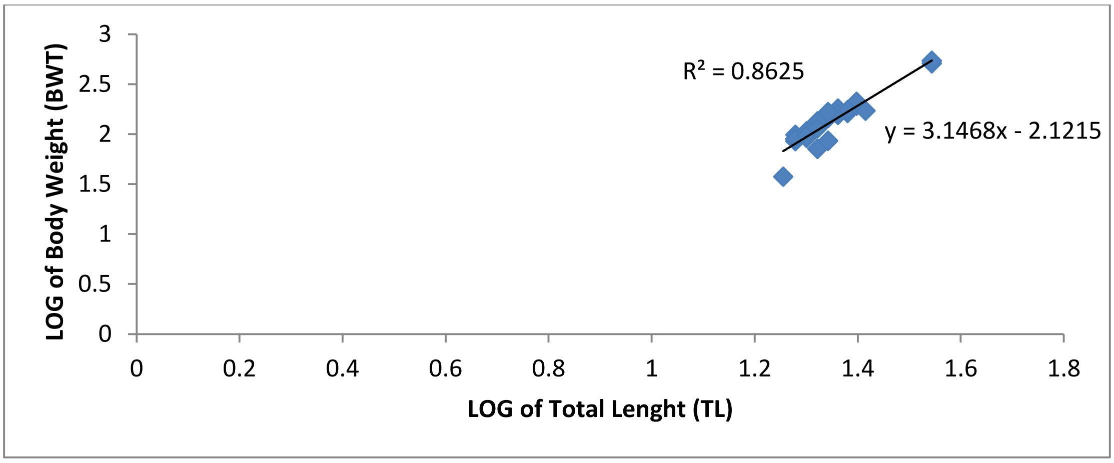

Fig. 4: Linear regression of total length-body weight relationship of *Caranx hippos*

Length-weight relationship: Length-weight relationship gives information on the condition and growth patterns of fish (Bagenal and Tesch, 1978). Fish are said to exhibit isometric growth when length increases in equal proportions with body weight from constant specific gravity. The regression co-efficient (b) for isometric growth is "3" indicates positive allometric growth which indicates that fish becomes heavier for a particular length as it increases in size (Gayando and Pauly, 1997, Wotton, 1998 Zafar *et al*.. 2003). The "b" values for *Selen dorsalis* and *Chloroscrombus chrysurus* showed a negative allometric growth, only *Caranx hippos* that showed a positive allometric growth (Table 2). According to Parsa *et al* (2017) the valves of exponents "b" usually ranges between 2.5 and 2.9. Several authors have both reported isometric and allometric growth for different fish species from various water bodies. Pauly and Gayando (1997) reported that b values may range from 2.5 to 3.5 which support the result of this study.

Thulasitha (2012) recorded "b" value of 2.64 for *Scomberoides lysan* which of the same family with this present studies. Barthelemy *et al*. (2014) reported b values ranged between 2.8 and 2.9 for family carangidae in Aby Lagoon, Southeastern Cote d'Ivoire. Sudekum *et al*. (1991) also reported the value ranged between 2.30 (Caranx ignobilis) and 2.86 (*Caranx melampygus*) from oceanic community, Hawaii. In the present study, for the length-weight relationship of carangids, weight increased proportionately to an increase in length in all the species. Correlation coefficients (R^2) were very high and highly significant which is an indication that changes in total length and weight of these fish species were directly proportional. The length weight relationship in fishes is affected by a number of factors including season, habitat, gonad maturity, sex, diet and stomach fullness, health and preservation techniques (Tesch. 1971) which are not reported in this study.

The condition factor (K): individual fish species condition are determined based on the analysis of length weight data reflected that the heavier fish at a given length is in better condition (Borgal *et.al.,* 1989) K also gives information when comparing two populations living in certain feeding density, climate and other condition (Bagenal and Tesch 1978). The condition factors ranged obtained from this study varied slightly with the result from other studies. Abowei (2010), reported the mean condition factors ranging from 0.941 – 0.985 for five fish species from Nkoro River, Nigeria although not of the same species. The values obtained from this study showed that all species studied were in good condition. Braga (1989) showed that the values of the condition factor vary according to seasons and are influenced by environmental condition. The same may be occurring in the environment under this study since Nigeria coast is influenced by many biotic and abiotic factors which favor the equilibrium of all the species in an ecosystem. Mgbenka and Eyo (1992) and Fawole (2002) attributed the difference iin condition factor to the deposition of materials for gonad formation, which led to increase in weight and actual spawning which lead to reduction in fish weight respectively. In addition, Vazzoler (1996) confirmed that lowest k values during the more developed gonadal stage might mean resource transfer to the gonads during the reproductive period.

Conclusion

The present investigation on length-weight relationships and condition factor of scieanids from Nigerian coastal water indicates that the condition is not quite satisfactory with the exception of the lower class sizes in the Nigerian coast. Again, information worldwide has shown that there is unrestricted use of marine resources and the consequent decline in the stocks. It is therefore the responsibility of the scientists and fisheries research institutes to provide scientific data and the management plan for marine resources especially for the Nigerian coast.

Climate Change on Root and Tuber Crops and Farmers' Coping Strategies in Nigeria

C.J. Eluagu and H.N. Anyaegbunam
National Root Crops Research Institute Umudike, P. M.B 7006, Umuahia, Abia State
Email:chinweeluagu@gmail.com

Abstract
The effects and implications of climate change are well documented in literatures. This review work was aimed to add to the existing knowledge on climate change on coping strategies adopted by farmers to the effect of climate change on root and tuber crops. The work reviewed the farmers' coping strategies to the effect of climate change in Nigeria. Previous studies on climate change relating to causes of climate change and the coping strategies adopted by farmers' to mitigate the effect of climate change were reviewed. It was found that climate change occurs as a result of human activities, air pollutants and ocean-atmosphere variability. Farmers' adopted the following strategies to mitigate the effect of climate change; changing their cropping systems in response to climate change, adhering to root and tuber crops tolerance enhancement programme to stress outcome, diversification of crop uses and agricultural environment adaptation and management.
Keywords: Climate Change, Coping Strategies, Root and Tuber Crops

Introduction
The term "climate change" is often used to refer specifically to anthropogenic climate change (also known as global warming). Anthropogenic climate change is caused by human activity, as opposed to changes in climate that may have resulted as part of Earth's natural processes. (The AGW, 1993). In this context of environmental policy, the term climate change has become synonymous with anthropogenic global warming. Within scientific journals, global warming refers to surface temperature increases while climate change includes global warming and everything else that increases greenhouse gas levels effect (NRC, 2010). Climate change is arguably the most persistent threat to global environmental stability. Folland, Karland Salinger, (2006), reported a warming of approximately 0.7'C over most of the African continent during the 20th century based on historical records. Smith *et al,* (2000), see coping strategies to climate change simply as a response to concerns about climate change. Coping strategies to climate change has been viewed by others as a long term phenomenon being that when farmers using traditional techniques of agricultural production noticed that climate change altered, they need time to identify potentially useful strategies, learn, organize resource and implement them (Maddison, 2006). Coping strategies here refers to "the ability a (human) system to adjust to climate change (including climate variability and extremes), to moderate potential damages, to take advantage of opportunities, or to cope with the consequences (FAO, 2009). The resources include those from farmers' own sources and those external to them; the later includes policy making and scientific knowledge systems (Yaro, 2013). Scientific knowledge encompass the use of new varieties crops and breeds of animals, integrated pest management, integrated soil fertility management principles and forest management. Coping strategies concern diversification and specialization which have observed as farm level response to climate change (Bradshaw et al, 2004). Root and Tuber crops are vulnerable to the damaging effect of climate change, however if the changes take place gradually, it may be able to adapt. Sudden changes such as water shortages, increases in crop damage as a result of new unpredictable changes in interaction among crops, weeds, insects and diseases or pathogens could have drastic effect (Ogbonna, *et al.* 2017). With varying changes in root crop yields in Nigeria and these crops being

the main staple food in low income. This review sought to assess the farmers coping strategies to the effect of climate change on root and tuber crops; cassava, cocoyam, sweet potato, yam production etc in Nigeria. Options for responding to these changes are few, but then effective policies can minimize the climate impact on food production.

Methodology

The study is a review of farmers' coping strategies to the effect of climate change. Literatures of previous studies on climate change were reviewed. Information were collected from scholarly published articles in books, journals and proceedings

Results and Discussion

Causes of Climate Change

Changes in the usual timing of rainfall or temperatures can affect the period when plants bloom and set to fruit, pollination of crops, food for migrating birds, water supplies for drinking and irrigation. On the broadest scale, the rate at which energy is received from the Sun and the rate at which it is lost to space determine the equilibrium temperature and climate of Earth. This energy is distributed around the globe by winds, ocean currents, and other mechanisms to affect the climates of different regions. Factors that can shape climate are called climate forcing or "forcing mechanisms". (Smith*, 2013*). Causes of climate change include the following among others

Human activity: The most single human activity that has large impact on climate is the burning of fossil fuels such as coal, oil and gas These fuels contain carbon and burning them produces carbon dioxide gas. The amount of carbon dioxide in the earth's atmosphere has increased to nearly50% and average global temperature appears to risen between 1^0 and 2^oF (Adiele *et al*, 2017).

Gases, such as water vapor, which respond physically or chemically to changes in temperature are seen as "feedbacks." Gases that contribute to the greenhouse effect include:

Ocean-Atmosphere Variability

The ocean and atmosphere can work together to spontaneously generate internal climate variability that can persist for years to decades at a time.

Effects of Climate Change on Root and Tuber Crop Production

This Update focuses on two primary factors that have affected and will continue to affect crop production in the coming decades: rising temperature and relative humidity. Here, we briefly discuss the various mechanisms by which each of these impacts crop physiology.

Temperature affects yields through five main pathways

First, higher temperature cause faster crop development and thus shorter crop duration, which in most cases is associated with lower yields (Stone, 2001). Second, temperature impacts the rates of photosynthesis, respiration, and grain filling. Warming during the day can increase or decrease net photosynthesis (photosynthesis-respiration), depending on the current temperature relative to optimum, whereas warming at night raises respiration costs without any potential benefit for photosynthesis. Third, warming leads to an exponential increase in the saturation vapor pressure which causes oxidative damage to photosynthetic machinery in all major crop plants (Wilkinson *et al*., 2012).

Relative humidity has remained roughly constant in recent decades over large spatial scales (Willett *et al*., 2007) and is projected to change minimally in the future as well. Increased VPD leads to reduced water-use efficiency, because plants lose more water per unit of carbon gain Plants respond to very high VPD by closing their stomata, but at the cost of reduced photosynthesis rates and an increase in canopy temperature, which in turn may increase heat-related impacts. An increased incidence of agricultural **drought** will increase crop water stress.

Coping Strategies to the effect of climate change

Cropping Systems and Crop-Specific Responses to Global Change

According to David and Sharon (2012), global change factors will have varying impacts on cropping systems around the world, due to regional differences in rates of daytime and night time warming, changes to the timing, frequency, and intensity of precipitation, and exposure to ozone and air pollution sources. Most aspects of farm management, such as the specific crops grown and level of inputs, also differ considerably by region and play an important role in shaping the impact of weather and climate change. Farmers are also likely to change these practices in response to climate change, for instance by sowing different crops or varieties, changing the timing of field operations, or expanding irrigation, and the socioeconomic capacity to make these adaptive changes will differ by region. Even atmospheric CO_2 increases, which will be uniform around the world, will have regionally disparate effects because of different mixtures of crop types and moisture conditions

Root and Tuber crops tolerance enhancement programs to stresses

Improving crop tolerance to abiotic stress and its utilization and exploiting new uses of local food crops varieties (Root and Tuber crops)

Eco- friendly cropping systems and indigenous root and tuber utilization

Integrating Eco- friendly rotation systems for specific locations; Optimizing prevention and recovery techniques to reduce crops damage from stresses; Better storage and transport methods to reduce losses of harvested produce;

Farming and networking databases containing information related to rehabilitation farming

Agricultural environment adaptation and management

Combining cultivation practice and management techniques before and after extreme weather events to reduce losses; Adjusting farming practice and crop variety to reduce emission of greenhouse gases; ncreasing soil carbon storage with improved crop and land management (Chwen- MingYang, 2016)

Conclusion

The study reviewed the farmers' coping strategies to the effect of climate change in Nigeria. Previous studies on climate change relating to causes of climate change and the coping strategies adopted by farmers' to mitigate the effect of climate change were reviewed. It was found that climate change occurs as a result of human activities, air pollutants and ocean- atmosphere variability. Farmers' adopted the following strategies to mitigate the effect of climate change, such as changing their cropping systems in response to climate change, adhering to root and tuber crops tolerance enhancement programme to stress outcome, diversification of crop uses and agricultural environment adaptation and management. It is hoped that with these strategies the effect of climate change on root and tuber crops will be reduced in Nigeria.

Micro-Analysis of Adoption of Adaptation Technologies to Climate Change by Arable Crop Farmers in Umuahia Agricultural Zone of Abia State, Nigeria

F.E. Ebe, K.C. Obike, C.I. Ugboaja and C.A. Paco
College of Agricultural Economics, Rural Sociology and Extension, Michael Okpara University of Agriculture, Umudike, P. M. B. 7267, Umuahia, Abia State.
Corresponding author's email: fellyebe@yahoo.com

Abstract
This study was conducted in Umuahia Agricultural Zone of Abia State, Nigeria. The study examined the socio-economic characteristics of the respondents, identified the adaptive technologies adopted, levels of adoption and determined the factors that influenced the level of adoption of adaptive technologies at farm-level in the study area. A multi-staged sampling technique was used to select 120 arable crop farmers. Data were collected through primary sources. The collected data were analysed with descriptive statistics, likert scale and tobit regression analysis. The result showed that the major adaptive technologies used by the farmers include; mulching, multiple/inter cropping, change in planting/harvesting dates, cover cropping, crop diversification, land fragmentation, soil and water conservation techniques and non-farming activities. The result also showed that out of fifteen adaptive technologies identified in the study area, the level of adoption was high in six technologies and low in nine technologies respectively. The findings indicated that education, membership of cooperative society, farm size, farm income and access to credit positively and significantly affected the adoption of adaptive technologies while age and household size inversely affected the adoption of the adaptation strategies to climate change. The farmers are therefore, encouraged to be planting trees, and participate in insurance scheme because presence of trees help immensely in moderation of effect of climate change and participation in insurance scheme help to protect the farmers from the uncertainty of climate change. Policy should aim at intensification of extension education to increase the farmers' knowledge about climate change and the ways of ameliorating its effect.
Keywords: Climate change, Adaptive technologies and Adoption

Introduction
In recent years, climate change is one of the challenging issues that are confronting the world at large. Climate change is a change that is attributed directly or indirectly to human activities which alters the composition of the global atmosphere and in addition to natural climate variability observed over comparable time periods (UNFCCC, 2007). In the developing countries, it is affecting pattern of life and general living conditions of people which include availability of water, food production, weather condition, health, culture, economic well-being and recreation among others. West African sub-region is acknowledged to be one of the areas that is most vulnerable to the vagaries of climate change (IPCC, 2007). In the region, most of the agricultural production system is rain-fed; the rural populace depends on streams and rivers for their water usage, forest and grassland for energy and the environment for other livelihood activities. Any change in climate affects the socio-economic activities of the people. This leads to impending catastrophe such as drought, drying of streams, irregular rain fall patterns, rise in sea level, flooding, heat stress and outbreak of newly formed diseases among rural communities whose activities are farming and livestock production (Ibrahim *et al*., 2016). In view of all these problems of climate change, farmers need to adopt adaptation measures in order to cope with the effect of the climate change. The adaptation lessens the adverse effects and takes advantage of benefits of change in climate variables (Ndaman and Watanabe, 2017). The adaptation is an

adjustment or intervention which takes place in order to manage the loses or take advantage of opportunities presented by changing climate (IPCC, 2001). It is the process of improving society's ability to cope with changes in climatic conditions across time scale, from short-term (seasonal to annual) to the long-term (eg decades to centuries) (Okezie and Simonyan, 2011). Adaptation occurs at two main scales: (a) the farm-level that focuses on micro-analysis of a farmer decision making and (b) the national level or macro-level that is concerned about agriculture at national and regional scales and its relationship with domestic and international policy (Bradshaw *et al.*, 2004; Kandlinkar and Risbey, 2000). Micro-level analysis of adaptation focuses on tactical decisions farmers make in response to seasonal variations in climate, economic and other factors (Okezie and Simonyan, 2011). This study therefore, focuses on the micro or farm level analysis of adaptation technologies adoption. These adaptation technologies are practiced by Nigerian crop farmers in order to reduce the effect of climate change which include intensification of irrigation, crop diversification, multiple/intercropping, agro-forestry/afforestation, mulching, use of new crop varieties, increased seed rate, crop rotation, tree planting, mixed cropping system, changing planting dates and use of family labour (Anyaoha *et al.*, 2008; Enete *et al*., 2011; Hassan and Nhemachena, 2008; and Owombo *et al*., 2014). In the South eastern Nigeria, most of the crop farmers are arable farmers who are invariably smallholder farmers. These farmers are characterized by use of small land that is not more than five hectares, use family labour, lack necessary inputs; depend on their farms as their main source of food security and income. They are involved in the production of arable crops such as cassava, yam, maize, rice, melon etc (Awoke and Okorji, 2004 and Eze, 2007). These people's activities are vulnerable to climate change because they depend on weather and any change in temperature and rainfall directly affect their crop productivity as well as crop output, income and well-being. In order for these farmers to reduce the adverse effect of the climate change, they need to go into adoption of adaptation practices such as mulching, crop diversification, crop rotation etc to enable them moderate the vulnerability of the climate change and survive in their enterprises. The adoption is simply the decision to start using something like new ideas, new technologies or innovation. It is a decision to continue full use of an innovation or mental process which an individual passes through in deciding to use an innovation (Orebiyi *et al.*, 2006). In the decision making, the farmers assess the benefit and possible disadvantages. In the study area, response to climate change through adoption of adaptation measures appears to be weak. It seems that there is a gap between the rate at which climate is changing and the response to reduce its effect through the use of adaptation technologies that ensure sustainable food security by the arable crop farmers. The gap on the adoption to the climate change adaptation technologies has subjected the farmers to the vagaries of climate change such as high intensity of heat for prolonged period of time, drought, and flood, low crop yields, etc. Experience at the farm level on how rural arable drop farmers perceive these changes and how they are responding to the effects of the climate change are limited. Studies on adaptation strategies to climate change at the regional and national levels had been conducted but none seem to have been conducted in Umuahia agricultural zone of Abia State which would impact knowledge to the farmers and help them reduce the effects of the climate. Hence considering this knowledge gap, the researchers deemed it necessary to carry out this study at the farm-level in order to examine the adoption of adaptive technologies to climate change by arable crop farmers in Umuahia agricultural zone of Abia State. Hence the study seeks to identify the adaptation technologies adopted, the level of adoption and determine the factors that influence the level of adoption of the adaptive technologies to climate change at the farm level in the study area.

Materials and Method

The study was conducted in Umuahia Agricultural Zone of Abia State in the South east of Nigeria. Abia state is made up of three agricultural zones, namely; Aba, Ohafia and Umuahia. Umuahia zone consists of five Local Government Areas (LGAs). The zone is located between latitudes 5^0 $49^/$N and 6^0 $92^/$ N of the Equator and Longitudes 7^0 $23^/$ E and 8^0 $02^/$ E of Greenwich meridian. First, three LGAs out of five that make up the zone were randomly selected. Secondly, two autonomous communities were randomly chosen from each LGA selected, making it six communities that were chosen. Thirdly, from each autonomous community chosen, one village was randomly selected, and then lastly, from each of the village selected, 20 arable crop farmers were randomly selected, now making it a total of 120 respondents that were used for the study.

Data were collected from primary sources through the use of structured questionnaire designed to elicit information from the respondents. Extension agents in the located area of the study assisted the researchers in the administration and collection of the questionnaire. The data collected were analysed by using descriptive statistics, Likert scale and Tobit regression analysis. The adaptation technologies adopted by the farmers were analysed with descriptive statistics while the level of adoption of the technologies was analysed using Likert scale. The rating scale was used to determine level of adoption of the respondents. A three point Likert scale was adopted. The scale is given as 1 = No adoption, 2 = Low adoption and 3 = High adoption. The mean of adoption was calculated as follows:

$$XS = \frac{\sum X}{N} \quad (1)$$

Where: X = Weight on scale, N = Total number of weight, $\sum$ = Summation

Therefore, the mean $(\overline{X}) = \frac{1 + 2 + 3}{3} = 2.0$ (2)

The mean score of each technology was computed by multiplying the total number of responses for a particular technology with the weight attached to the response chosen and then divided by the total number of respondents.

That is $XS = \frac{\sum fn}{N}$ (3)

Where: f = number of responses, n = weight attached to scale, N = total number of respondents. The rating was carried out thus; technologies with adoption score of above 2.00 was considered high level of adoption, while the ones with ≤ 2.00 were regarded low level of adoption respectively.

To determine the factors that influence the factors that influence the adoption of adaptation technologies to climate change, Tobit regression analysis model was used. The Tobit decomposition framework examined the effect of changes in the explanatory variables (Xs) on the probability of adopting measures to adapt to climate change by the arable crop farmers (Mailum *et al*., 2016). The tobit model is expressed thus:

$$V_1 = \beta Xi + Ui$$

If $V_1 > V_1^*$, $V0 = \beta Xi + Ui$ if $V_1 \leq V_1^*$ (4)

Where V_1 is the number of respondents, V_0 is the limited dependent variable, it is discrete if the farmers do not adopt climate change adaptation technologies (it assumes zero value in this case) and continues if they adopt ie equal to V_1^*, $V_1^* > 0$, it implies that V_1 is observed, $V_1^* \geq 0$, implies that V_1 is not observed, X_1 is a vector of explanatory variables, β is a vector of unknown coefficient and Ui is an independently distributed error term. The model explicitly used in determining the factors influencing the adoption of adaptation technologies to climate change is as follows:

$$Vi = \beta 0+\beta_1X_1+\beta_2X_2 +\beta_3X_3 +\beta_4X_4 +\beta_5X_5 +\beta_6X_6 +\beta_7X_7 +\beta_8X_8 +\beta_9X_9 +\beta_{10}X_{10} +\beta_{11}X_{11} +Ui$$

Where X_1 = Household size (Number), X_2 = Age of household head (Years), X_3 = Educational attainment (Years), X_4 = Membership of cooperative society (Dummy, Member = 1, Non- member = 0), X_5 = Climate change awareness (Dummy, Aware = 1, Not aware = 0), X_6 = Farm size (Ha), X_7 = Access to information (Dummy, Access = 1, No access = 0), X_8 = Extension contact (Number), X_9 = Tenure security (Dummy, Ownership = 1, Not owner = 0), X_{10} = Farm income (N), X_{11} = Access to credit (Dummy, Access = 1, No access = 0), Ui = error term.

Results and Discussion

Adaptation Technologies Adopted by the Respondents in the Study Area

Table 1 shows the adaptation technologies adopted by the arable crop farmers in order to reduce the effect of climate change in the study area. The Table shows that majority (86.7%) of the farmers adopted multiple/intercropping and 85% mulching to reduce the adverse effect of climate change. This result supports the findings of Ibrahim *et al*., (2016) who noted that multiple/intercropping and mulching were the most dominant strategies of adoption of adaptive technology measures that farmers used in their study to reduce the effect of climate change. The use of mulch could be that the farmers used it to prevent much evaporation of water from soil especially during heat period in order to retain moisture in the soil. Change in planting and harvesting dates were adopted by 71.7% of the respondents while 76.7% of the farmers fragmented their land by having good number of plots to guard against the effect of climate change. Also 73.3% of them used cover cropping technology. More so, 54%, 55% and 50.8% practiced soil and water conservation technique, increased size of mound/ridge and crop diversification as ways of reducing the adverse effect of climate change. Conversely, crop rotation, shedding/sheltering and agro-forestry and insurance cover were practiced by 39.2%, 10%, 16.7% and 8.3% of the arable crop farmers respectively to ameliorate the effect of the climate change. These findings confirm the results obtained by Enete *et al*., 2011; Anyoha *et al*., 2013; Hassan and Nhemachena, 2008 and Owombo *et al*., 2014 in their various studies carried out in different parts of Nigeria.

The Level of Adoption of Adaptation Technologies to Climate Change in the Study Area
Table 2 shows the level of adoption of adaptation of technologies to climate change. The mean of the likert scale was 2.00. Therefore, any technology in the Table whose mean score is above 2.00 was considered high adoption while the one with ≤ 2.00 was regarded low level of adoption respectively. From the Table, it could be seen that out of 15 technologies, only six were at high level of adoption, these include mulching (2.37), multiple/intercropping (2.31), crop diversification (2.22), land fragmentation (2.15), cover cropping (2.08) and change in planting/harvesting dates (2.05) respectively. Conversely, the respondents had low level of adoption in the following technologies; fallowing (1.32), off-farm employment/non-farming activities (1.63), soil and water conservation techniques (1.88), change in the size of mounds/ridges (1.95) and crop rotation (1.73),irrigation practices (0.97), shedding/sheltering (0.59), agro-forestry/tree planting (0.80) and insurance scheme respectively.

Factors that Influence the Adoption of Adaptation Technologies to Climate Change
The result of factors that influence the adoption of adaptation technologies to climate change is shown in Table 3. The result of the tobit regression analysis showed that the likelihood was 462.45 and Chi-square (X^2) was 122.8. This shows that they were highly significant ($P < 0.000$) suggesting that the model has a strong explanatory power. This implies that those factors included in the model greatly influenced the adoption of climate change adaptation technologies at farm-level in the study area. Six out of eleven factors significantly influenced the adoption of climate change adaptation technologies. Out of these factors, education, membership of cooperative society, farm income and access to credit positively and significantly influenced the adoption of climate adaptation strategies in the study area. This implies that a unit increase in educational level, membership of cooperative society, farm income and access to credit will increase the adoption of adaptation strategies by 2.0308, 1.725, 2.5412 and 2.37 respectively. The positive influence of education on adoption of the adaptative practices shows that as the farmers move from one level of education to another, their probability of adopting technologies, innovations to climate change increases. This result is in line with the study of Deressa *et al*., (2008) who reported that education had positive relationship with adaptation strategies to climate change in Nigeria. The direct relationship of membership of cooperative society implies that participation in cooperative society increases the adoption of climate change adaptation strategies because the cooperative helps the farmers to be united, share knowledge and innovative ideas and become aware of the effect of climate change. Also positive and significance of access to credit implies that this factor has positive effect on adoption of adaptation technologies to reduce the effect of climate change because access to credit empowers farmers to undertake adoption of adaptative practices to climate change (Otti, 2016). Income also has similar effect as the other factors above and in consonance with *a priori* expectation. On the other hand, age and household size were negative and significant at 5% and 1% levels respectively. This implies that as the age and household size of the farmers' increase it probably leads to decrease in the adoption of adaptation measures to climate change. These findings corroborates with the result obtained by Mailumo *et al*., (2016)

Conclusion

The results showed that the major adaptive technologies used by the farmers to reduce the adverse effect of climate change were mulching, multiple/inter cropping, change in planting/harvesting dates, cover cropping, crop diversification, land fragmentation, soil and water conservation techniques and non-farming activities. The result further showed that out of fifteen adaptive technologies identified in the study area, the level of adoption was high in six technologies and low in nine respectively. The result also showed that education, membership of cooperative society, farm size, farm income and access to credit positively and significantly affected the adoption of adaptive technologies while age and household size inversely affected the adoption of the adaptive strategies to climate change. Therefore, farmers should be encouraged to plant trees, and participate in insurance scheme because presence of trees help immensely in moderating the effect of climate change and participation in insurance scheme help to protect the farmers from the uncertainty of climate change. Policy should aim at intensification of extension education to increase the farmers' knowledge about climate change and the ways of ameliorating its effect.

Table 2: Distribution of Arable Crop Farmers According to Adaptation Technologies Adopted in the Study Area

Adaptation Technologies	Frequency	Percentage
Multiple/Inter cropping	104	86.7
Land fragmentation	92	76.7
Fallowing	47	39.2
Irrigation practices	17	14.2
Crop diversification	61	50.8
Off-farm employment/non farming activities	54	45.0
Mulching	102	85.0
Cover cropping	88	73.3
Soil and water conservation techniques	65	54.2
Agro-forestry/tree planting	20	16.7
Shedding/sheltering	12	10.0
Increased size of mounds/ridges	66	55.0
Crop rotation	47	39.2
Change in planting and harvesting dates	86	71.7
Insurance coverage	10	8.3

Abstract
Public awareness, perception and knowledge on climate change constitute essential background to deal with climate change and related problems in the Oil Palm industry. This study examined farmers' general understanding of climate change in Ikwuano and Umuahia North LGA of Abia State, Nigeria. This research Study sort to find out Oil Palm farmers' perception of climate change variables, the level of awareness on Climate Change. Data were collected by use of structured questionnaire administered to 200 farmers randomly selected from eight communities in the study area. Descriptive statistics was used to analyze data obtained from the survey. Farmers (78%) in the study sample reported that they are well aware of the climate change while 22% percent of respondents had 'low' awareness level. A 4-point Likert type Scale was used to gauge farmers' response to questions posed in the questionnaire as regards perception on climate variables. Results also showed that the dominant perception of Oil Palm farmers on climate change variables, tend to be that temperature has been increasing (or is serious) in the study area. The paper concluded that high level of awareness will in the long run increase the adaptation potential of the community and make them less vulnerable towards climate change. Also Perception is necessary because only those Oil Palm farmers who perceive change in climate will decide whether to adapt to it or not.
***Keywords**: Awareness, Perception, climate change, oil palm farmers, climate variables, and Abia State*

Introduction
In Africa, climatic change is expected to, and in some parts, it has already begun to, alter the dynamics of droughts, rainfall and heat waves, and trigger secondary stresses such as the spread of pests, increased competition for resources, and attendant biodiversity losses (Enete and Amusa, 2010). Rapid changes in the behaviour of climate elements are expected to undermine the systems that provide for food security in Nigeria and Africa in general (Gregory *et al.,* 2005; Ojemade, 2016). Climate change has become a global issue of critical importance, increasingly acknowledged as one of the main challenges to sustainable development. Climate change impacts ecosystems, livelihoods, human security and socio-economic development of societies, and has been described as the 'defining human development issue of our generation' (UNDP, 2008). Climate variability and climate change have the capacity to reverse major achievements in human development across a range of sectors if not addressed properly and managed well. Gains in the health and education sectors, for example, could be affected by food insecurity and water scarcity. Climate change is therefore a core development issue because all human societies are dependent on climate for survival and prosperity. Nigeria is already experiencing the impacts of climate change, with more extreme weather events occurring, more variability in timing and intensity of rainfall and higher temperatures over the whole country (Abiodun, Salami and Tadross, 2011). Whilst farmers in some regions may benefit from longer growing seasons and higher yields, the general consequences for Africa (Mendelsohn *et al.,* 2000) are expected to be

adverse, and particularly more adverse for the poor and marginalized farm households, who do not have the means to withstand drastic changes. Evidence from the IPCC suggests that areas south of the Sahara are likely to emerge as the most vulnerable to climate change with likely agricultural losses ranging from 2 to 7%. A better understanding of how farmers' perceive changing climate and the awareness level of farmers is needed to formulate appropriate policies and programmes aimed at promoting successful awareness of farmers and adaptation strategies to cope up with climate change. Abia state which is part of Niger Delta region is already experiencing some important climate change related hazards such as, increased temperature (including seasonal changes), more intensive and frequent storms, sea level rise, more heat waves, more flooding and extreme floods and more extreme rains including seasonal changes (Okoh *et al.*, 2011), and a greater percentage of the population of Niger Delta region lives in the rural areas. Also the capacity of farmers to adapt to climate change can be significantly influenced by the level of awareness about climate change in their communities. In this regard, Tol (1998) suggested that awareness about climate change has great capacity to drive farmers to improvise local technologies to aid adaptation. Also, perception is determined by learning factors (Maddison, 2006) where indicators such as age, experience, environment and information on weather and climate play a very important role in the awareness of climatic parameters (Roncoli *et al*., 2002). Moreover, studies (Enete and Amusa, 2010; Mendelsohn and Dalfelt; Enete and Thorton,2011; Okoh *et al*,2011;Fonta et al,2011; Ozor and Cynthia, 2010) on the science of climate change, its effects and adaptation measures have received much attention but climate change education, awareness and perception of oil palm farmers on climate change, in the oil palm industry are given very little or no attention. In order to make insight into these issues, the present research study was undertaken to find out farmer's awareness about climate change, their perception about the indicators and /or variables of climate in the oil palm industry.

Methodology

This study was conducted in Ikwuano and Umuahia North Local Government Areas (LGAs) of Abia State Nigeria. The LGAs were purposively chosen because of intensity of oil palm cultivation. Ikwuano and Umuahia North LGAs are two of the five LGAs that constitute Umuahia Agricultural Zone of Abia State Nigeria. The LGAs are located within Latitudes 05030' N and 05040' North of the Equator and longitudes 07025' E and 07032' East of the Greenwich Meridian. Its population stood at 361,127 people who are predominantly rural farmers, of which 48.0% are females and 52.0% are males, on a land mass of about 521km2 (FRN, 2006). Farmers that predominate these areas produce food crops such as yam, cassava, plantain, banana, vegetables and cash crops such as oil palm, and cocoa. A Two Stage random sampling technique was adopted in the selection of panel of farmers involved in this study. First, 4 communities each, were randomly selected from the LGAs (Ikwuano and Umuahia North), making a total of 8 communities. In the second stage, 25 oil palm-based farm households were randomly selected from each of the chosen communities giving a total sample size of two hundred (200) oil palm farm households involved in this study. The sampling frame used was provided by the Agricultural Extension Agents (EAs) of the Agricultural Development Programme (ADP) serving in the study area. Instrument of data collection was a pre-tested structured questionnaire which was administered to Oil Palm farmers across sexes and their farming households by personal interview method. However ,out of the 200 questionnaires administered, the researcher was able to retrieve information from 172 respondents representing a response rate of 86.%. The analytical technique comprised the use of descriptive statistics which was used to collect information on awareness to climate change. Climate change as a variable was measured through proxy in form of perception of intensity of the climate change among oil palm farmers. Each component of climate (e.g. rainfall, temperature sunshine, and Humidity) had its perception scale (with Likert-type scale) to reflect seriousness of the change. The scale range is noted below:

Very serious	=	4
Serious	=	3
Less serious	=	2
Not serious	=	1

Results and Discussion

Farmers (78%) in the study sample reported that they are well aware of the climate change (Table 1). Further 22% of respondents had 'low' awareness level, . Raghuvanshi and Ansari (2016) reported that to cope up with climate change depends on level of awareness about climate change. Farmers who are aware about the climate change, its causes and consequences are more likely to adopt adaptation measures and mitigation practices to cope up with adverse effects of climate change.

Table 1: Distribution of respondents according to climate change awareness

	Abia State (n=172)
Yes (1)	134 (77.9)
No (0)	38 (22.1)

Figures in parenthesis ( ) are percentages. Source: Field survey data, 2016

These findings are also supported by Adebayo *et al. (*2012) who observed that large majority of the respondents in Adamawa state (about 96%) were aware of climate change, while only about 4 percent seemed not to be aware of climate change. Sogani, (2011) in a study of documentation of climate change perceptions and adaptation practices in Uttarakhand reported that communities in the mountain areas are well aware that the weather is changing. This also corroborated the findings of Ishaya and Abaje (2008), and Egbe *et al*., (2014) which shows a high level of climate change awareness among local farmers in Kaduna and Cross River area of Nigeria.

Table 2: Source of awareness about climate change

Source	Frequency	Percentage
Extension	88	51.16
Media (radio/television)	46	26.74
Friend/neighbours	26	15.12
NGOs and input sales agencies	12	06.98

Source; field survey, 2016

Table 2 shows the source of oil palm farmers' awareness about climate change. Majority (51.16%) got their information about climate change from extension agents,15.12% from friends and neighbours, and 26.74% through media (mainly radio), while a mere (06.98%) got the information from Non-Governmental Organizations (NGOs). This underscores the importance of interpersonal communication in creating awareness.

This section portrays oil palm farmers' perception of climate change in relation to their oil palm farm. Table 3 shows that 45% of respondents indicated that the effect of rainfall was less serious while 4% said it was very serious.

Table 3 Farmers' Perception of climate change variables.

Climate variables / seriousness of change	Frequency	Percentage	Mean
Rainfall			
Not serious	37	22	
Less serious	78	45	2.16
Serious	50	29	
Very serious	7	4	
TOTAL	**172**	**100**	
Humidity			
Not serious	34	20

Very serious	81	47	
TOTAL	**172**	**100**	

≥ 2.50 = serious, < 2.50 = not serious
Source: Field survey data, 2016.

As indicated in the Table 3, most of the farmers (47%) were of the opinion that Temperature is a serious issue. Farmers perception of climate change variables was achieved using mean score derived from 4 point likert scale with 2.50 decision rule. Farmers Reponses on observed climate variables and the level of seriousness in the area were as follows: temperature (χ = 3.11), Humidity (χ = 2.44), Sunshine (χ = 2.75), and rainfall (χ = 2.16). Findings from Table 3 show that significant number of farmers (51%) believe that rainfall has declined (less serious) .The above result is in agreement with BNRCC Report (2011) which concluded that farmers (both male and female), on perception of rainfall in Southern Nigeria, observed a decline in Rainfall. In their own contribution Agboola and Ojeleye (2007) observed decline in crop yield and food crop production due to reduction in rainfall and relative humidity and increase in temperature in Nigeria. Results show that farmers believe that temperature is serious. In their own contribution, Fonta *et al.,* (2011) observed that each crop has an optimum range of temperature and temperatures higher or lower than what can be tolerated by the oil palm could lead to reduction in yield and productivity. Temperature had the highest mean score followed by sunshine. Several studies have shown that temperature is rising and rainfall frequency and intensity is fluctuating (Mendelsohn *et al.*, 2000; Ozor and Cynthia, 2010); Paavola, 2006). It has been observed in Nigeria that sunshine duration shows an increasing trend (Nwajiuba and Onyeneke, 2010). The relationship between duration of sunshine and temperature is that the more the sunshine, the more the heat. More hours of daylight translates to more hours of heating from the sun. Adverse effects of heat stress itself occur in conditions where environmental temperature is elevated.

Conclusion

The high level of awareness about climate change among farmers in developing countries is an encouragement in effective implementation of their common undifferentiated commitments to the convention on climate change. High level of awareness will increase the adaptation potential of the community and make them less vulnerable towards climate change. The awareness of climate change has spread at an unprecedented pace and it is now accepted as a major threat to human survival and sustainable development. The increased adverse impact of climate change is expected on the environment, human health, food security, economic activities, natural resources and physical infrastructure. The study shows that farmers' perception of climate change, the decision making process is important to inform and /or in formulating policies aimed at promoting successful adaptation strategies for the Oil Palm industry. Part of the problem with climate change is the incidence of pest and diseases, particularly during dry spells. This is further exacerbated by the fact that farmers are often poorer and rarely have access to safe and effective pesticides, robust varieties of plants/seeds and adequate irrigation facilities. The government can do well by assisting the farmers with these necessary inputs at subsidized rate. It is important that government make issues of climate change awareness and perception top of its political agenda.

Abstract

The agricultural tractor as marvelous as it is composed cannot be fully utilized without a compatible operator. Most tractors imported to developing countries such as Nigeria were designed without taking cognizance of the people to drive them. More so, no designer can provide necessary adjustments for all possible subjects. Thus, there is a need for continued documentation of tractor operators' anthropometric data. This study compares the anthropometric data of Nigerian and Malaysian tractor operators. This can be used by tractor fleet managers to adapt the operators with any tractor available or to be procured in the future.

Introduction

Agriculture is the mainstay of life, feeding the world's populations and producing shelter and clothing in order to survive and thrive (ISO, 2017 and Ahmed, 2000). Also, agriculture provides employment for the majority of Africa's people and generates a good share of GDP. Despite its important role, agriculture is largely underdeveloped in most African countries. There is high potential for expansion of the agricultural sector at all levels (Zhou, 2016). Over the past three decades, not only has progress delayed in agricultural mechanization in much of sub-Saharan Africa (SSA), but also there is amassing evidence that progress attained in the earlier years is being lost in many parts of the continent and achieving higher economic growth through the agricultural sector will not be easy without innovative solutions that change past strategies (Mrema et al., 2008). Africa is the only region in the world where agricultural productivity has been largely stagnant since 1960s. Average cereal production in Africa stood at 1.5 ton/ha in 2014; the world average was 3.6 ton/ha. The low levels of input use and mechanization have been cited as main constraints for agricultural development (Zhou, 2016). Mechanization of any agricultural task involves appropriate selection of energy source to power a suitable machine/equipment/implement in performing the task. Manual tools use human beings as both source of power and controller/operator (Suleiman and Imam, 1987). In animal draught technology (ADT) animals (donkeys, mules, cattle, horses and camels) provide the tractive power while humans serve as controllers/operators (Ahmed, 2000). In tractors or other automated machines powered by internal combustion engines (ICE), all power is provided by the ICE and the operators monitor the conduct of the task to be performed. There is a need to embrace tractor mechanization for medium to large scale farms in order to be self-sufficient in food production, earn foreign exchange and establish manufacturing industries to stop importation. Mechanization as an input for other inputs and largely not divisible/highly capital intensive has suffered from lack of maximum adoption in developing countries like Nigeria. Though Nigeria leads other countries in total number of tractors in West Africa (Figure 1), the situation changes when tractor usage per hectare is considered (Zhou, 2016). In year 2000, Côte d'Ivoire led the field with about three tractors per 1000 ha while Nigeria and most other countries in the region had less than one tractor per 1000 ha (Figure 2). China and India have nine and 13 tractors per 1000 ha respectively in the same year. The high number of tractors in Nigeria since 1970 was due to many programmes on tractorization aimed at harnessing the vast agricultural potentials in the country, including the establishment of tractor assembly plants in Kano and Bauchi. Tractor driving imposes a lot of physical and mental stress upon the operator. If the operator's seat is not comfortable, his work performance may be poor and there is also a possibility of accidents. The optimal design of tractor seat may be achieved by integrating anthropometric data with other technical features of the design. The seat dimensions recommended for tractor operator's comfort based on anthropometric data of 5434 Indian male agricultural workers were as follows: seat height of 380 mm, seat pan width of 420–450 mm, seat backrest width of 380–400 mm (bottom) and 270–290 mm (top) (Mehta et al., 2008). In order to enhance operational performance and reduce both fatigue and accident risk, it is fundamental to provide a safe and adequate working environment. Therefore, the working station must be adapted to the operator's anthropometric and mechanical characteristics (dos Santos et al., 2016). Yisa (2002) assessed the ergonomic suitability of two makes of Nigerian assembled tractors (Fiat and Steyr) designed and manufactured in Europe using 20 randomly selected subjects.

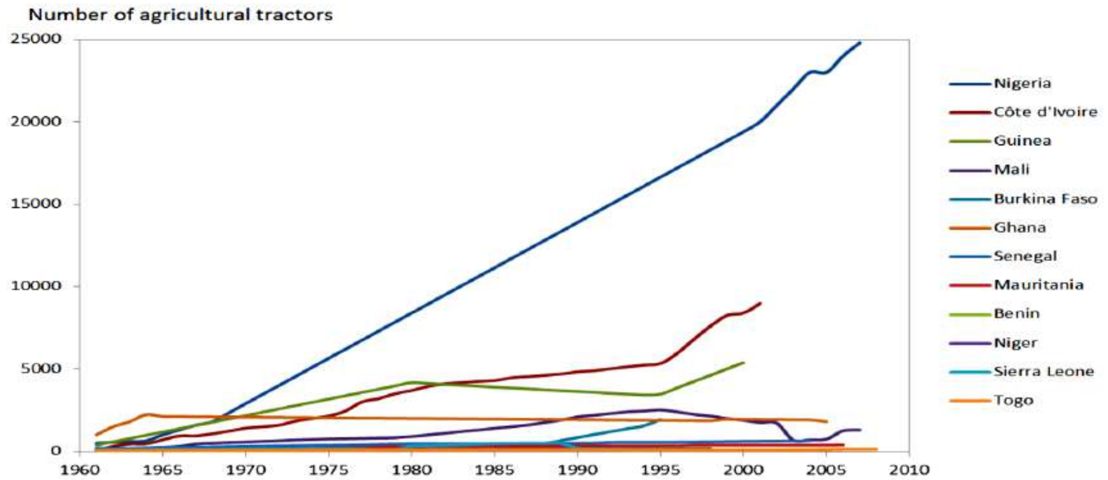

Figure 1: Number of agricultural tractors in use in West Africa, 1961-2008 (Data source: FAOSTAT)

These imported tractors need proper compatibility with operators for maximum utilization of the huge investment made. Thus, the objective of this study is to provide major anthropometric data of tractor operators from Nigeria and Malaysia for proper adaptation with ergonomic provisions of existing tractors and those planned to be procured.

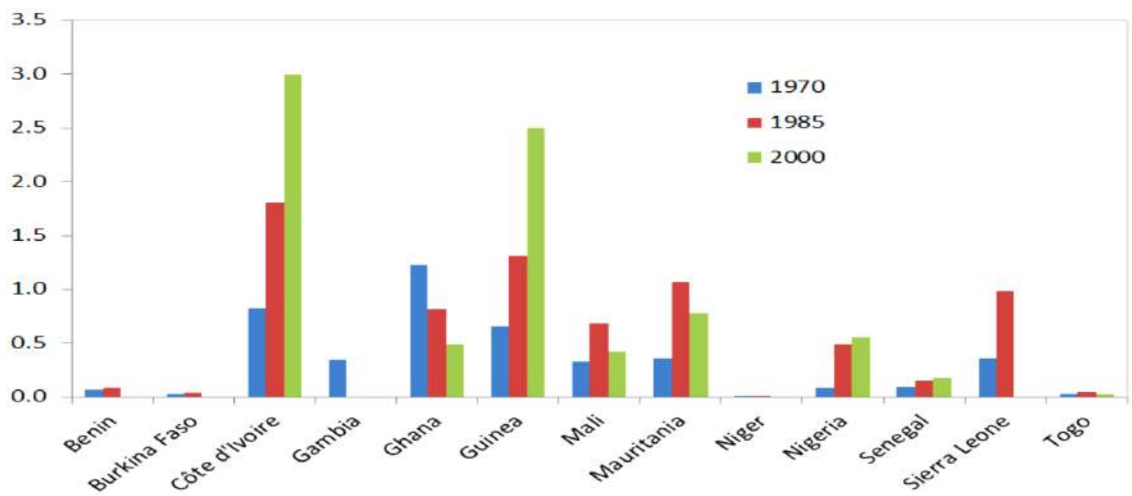

Figure 2: Agricultural tractors per 1000 ha (Data source: FAOSTAT)

Materials and Methods

Tractor operators from Refuse management and sanitation board (REMASAB) and ten local government areas in Kano State, Nigeria and Universiti Putra Malaysia (UPM) were used as subjects for the anthropometric measurements. All the subjects were treated to the same procedure as documented in Ahmad el. al., 2015. The tractor operator's anthropometric data collected were analysed to produce anthropometric model parameters of the study areas. The parameters were evaluated as was done by Yadav et al. (1999) in deriving the anthropometric model of Indian tractor operators. These include: mean, standard deviation, coefficient of variation, range and percentiles (5th, 95th and difference between the two).

Results and Discussion

The anthropometric data from Nigerian and Malaysian tractor operators are given in Table 1. The age of the Malaysian tractor operators (44 years) and that of Nigerians (45 years) are favourable. The average weight of Malaysian operators (72 kg) is higher than that of Nigerians (65.1 kg) although there is a high variation in Malaysian weights as indicated by higher standard deviation of 16.6. All other parameters show higher values of standard deviation for Nigerian data than those of Malaysia. This calls for Nigerian tractor managers to be more challenged in modifying tractor ergonomic designs for compatibility with available Nigerian operators.

Table 1: Comparison of anthropometric parameters between Nigerian and Malaysian tractor operators (Malaysian standard deviation in brackets)

Parameter	Nigerian average	Malaysian average	Range (Standard deviation)
Age (years)	45	44	(10.67)
Weight (kg)	65.1	72	7.7 (16.6)
Height (cm)	167.5	166.9	5.4 (6.7)
Full leg length (cm)	104.4	94.0	7.0 (5.0)
Full hand length (cm)	74.1	67.0	12.7 (3.8)
Knee length (cm)	52.2	49.3	3.4 (3.3)
Elbow length (cm)	47.2	44.1	2.8 (2.1)

Short operators will require lower steps for access on the tractor. Statistical analysis has revealed that 42 % of tractor accidents in a study were encountered during climbing in and out of the cab (Suutarinen, 1992). A study between 2005 and 2008, has reported 309 boarding accidents (Quendler et al., 2013). This number corresponded to 48% (309/644) of all moderate, severe and fatal tractor accidents in Bavaria, Germany. The direct costs of accidents were €11,310 (N4,524,000.00) on average! A nine-point compatibility criterion for operator anthropometry with tractor driver's seat design was proposed (Monarca et al. 2009). These points' criteria range from the seat base size to seat surface material-allowing for a suitable perspiration.

Conclusion

This study conducted a survey on tractor operators in Kano state of Nigeria and Universiti Putra Malaysia and determined their anthropometric models for adaptation with the available tractor ergonomic designs. The highest coefficient of variation (19%) among the six parameters measured Nigerian operators was in the full-hand length while the Malaysians recorded highest coefficient of variation in weight. This calls for better strategies of adapting different tractor hand controls and seat suspensions to the user population by the tractor fleet managers.

Fortification of Cocoyam (*Colocasia esculentum*) Flour with Crayfish (*Cambarus batchi*) for Improved Nutritional and Health Benefits

P.O. Nwankwo, C.O. Nwadili and M.C. Okwusi
National Root Crops Research Institute, Umudike, Umuahia. Abia State. Nigeria.
Email – pastornwankwo@yahoo.com

Abstract
This study was conducted to improve on the nutritional quality of cocoyam flour often used for various recipes with finely ground crayfish in the ratio of 75:25 (w/w). The proximate and mineral compositions of cocoyam flour (cooked, uncooked, and cooked/fortified with crayfish) were determined using standard analytical procedures. The results of the investigation showed that boiling greatly reduced the anti-nutrient compositions of the cocoyam. Calcium oxalate was reduced by 50%, tannin by 70% and phytate by 10% respectively. Cooked/fortified samples had remarkable increase in their caloric value, moisture, crude protein, crude fat, crude fibre and ash. Increase in the content of the mineral elements determined (calcium, phosphorus, potassium, magnesium and sodium) in the crayfish – fortified cooked cocoyam sample was observed with sodium having 101.99± 2-30 mg/100g and potassium 772.35± 5.78 mg/100g.

Key words: Cocoyam, crayfish, fortification, proximate and mineral composition

Introduction
Cocoyam (*Colocasia esculenta*) is an herbaceous perennial plant which is classified under the family Aracea and is mainly grown for their edible roots. Cultivars of two species, *Colocasia esculenta* and *Xanthosoma sagittifolium* tannia are generally grown for food. Cocoyam ranks third in importance after cassava and yam among the root and tuber crops that are cultivated and consumed all over the world especially in the developing countries such as Nigeria. Nigeria is the world's leading producer of cocoyam, accounting for about 40% of total production (Ajijola *et al.,* 2005). As a relatively known staple crop in the underdeveloped and developing countries, it can serve as a weaning food for children. Dietary energy is the main nutrient supplied by cocoyam as with other root and tuber crops. Cocoyam has a lot of health benefits which include cancer prevention, reduced symptoms of rheumatoid arthritis, immune system health, decreased muscle cramp, enhanced learning as well as act as a good recipe for diabetics (Nwankwo, 2015). In spite of its health benefits and importance as a staple food in many countries, cocoyam is still insufficiently studied and underutilized (Watanabe, 2002). Cocoyam however generally has a low protein content and often limited by its low content of sulphur- containing amino acids. By contrast, crayfish is of higher nutritional value, very rich in protein and essential amino acids and can complement the deficiencies of cocoyam. Crayfish also known as crawfish, fresh water lobsters or mudbugs are actually freshwater crustaceans. Taxonomically, they are members of the super families Astacoidea and/or Parastacoidea. They are nutritious and contain both major and minor mineral elements. Crayfish having lots of vitamins, mineral contents, amino acids and omega-3-fatty acids, when used in fortification of cocoyam will boost the consumers' nervous system and digestive system functions and overall body metabolism (Lewu *et al.,* 2010). It will also help in preventing the risk of anemia and other symptoms of malnutrition which are the major problems of the underdeveloped world. Research efforts need to be made and measures put in place to popularize, enhance and increase use of cocoyam as food among the populace through the adaptation of technologies used to increase the utilization of other root and tuber crops.

Materials and Methods

Source of Cocoyam: Cocoyam tubers used for this study were obtained from the cocoyam barn of NRCRI, Umudike in Abia State of Nigeria.

Production of Cocoyam flour: Cocoyam flour was prepared according to the method of Ukpabi and Oti, (2010) with slight modification. Fresh cocoyam roots were thoroughly washed, peeled and rewashed with clean water. Then the peeled tubers were sliced into small sizes, parboiled in hot water (50^{o}C for 3 hrs), steeped for 24 hrs and then dried at 50^{o}C for 8 hrs before milling into flour.

Production of finely ground Crayfish: Crayfish was purchased from a local market in Umuahia, Abia State of Nigeria. The crayfish was spread out in a tray and winnowed to remove all extraneous materials, washed with clean water and dried at 50^{o}C for 7 hrs before milling into crayfish powder.

Determination of Proximate Composition: The moisture, ash, crude fat and crude fibre contents of both the cocoyam and crayfish flour were determined according to the standard method (AOAC, 1990). Crude protein (N X 6.25) was determined by the Kjeldahl method as described by Okalebo *et al.* (2002). Carbohydrate content was obtained by difference. The caloric value of each sample was calculated using Atwater factor method (4 x carbohydrate) + (4 x crude protein) + (9 x crude fat).

Determination of Mineral Composition: The mineral content of the samples was determined using the method of Shahidi *et al.* (1999) with slight modifications. Total phosphorus was obtained using the ascorbic acid blue colour procedure of Okalebo *et al.* (2002).

Statistical Analysis

Statistical analysis system (SAS) software was used for analysis of data and the separation of means and their standard deviations.

Results and Discussion

The results of the proximate compositions of crayfish and cocoyam (cooked, uncooked and crayfish-fortified) are shown in Table 1. Parboiling has been found to decrease protein content of cocoyam due to leaching of nitrogenous substances during soaking and rupturing of molecules during steaming. Tannins have been reported to form complexes with protein, thereby limiting its availability (Otegbayo, 2014). The protein content of cocoyam is generally low (Okaka and Isieh, 2002), hence cocoyam products should be supplemented with other high-protein products for balanced nutrition. The cooked sample had higher crude fibre content than the uncooked. This observation could be due to the gelatinization and retro- gradation of the starch that occurred during the cooking process, which could change part of the starch into non-degradable polysaccharides (Olayinka *et al.,* 2017). This high fibre content of cocoyam may be why it is superior to the other root and tuber crops in protection against various ailments. The high moisture contents obtained for cocoyam in this study explains why post-harvest loss due to spoilage is always high for these tubers since high moisture content enhances microbial attack. The results also revealed an increase in the moisture content of the cooked sample. This could be attributed to the boiling effect that softens the tissue, thus increasing the water absorption and water-retention capacity of the tubers as a result of increased permeability of the cell membrane to water (Okaraonye and Ikewuchi, 2009). Cooking increased the fat content of the tubers (Table 1). This may be due to the increased extractability of the more polar lipids bound to other macro molecules in the tissue. The value however is still on the low for crude fat. Cooking reduced the ash content of cocoyam. This could be as a result of the solubilization and leaching of nutrients into the processing water. Both cooked and uncooked cocoyam samples are high in carbohydrates as common to all root and tuber crops. The results of the anti-nutrient analyses are presented in Table 2. Phytate, calcium oxalate and tannins are higher in the uncooked sample (86. 97, 669.78 and 4,198.78 mg/100g) as compared to their contents in the cooked sample (70.32, 330.75 and 1,859.67mg/100g) respectively. The results of this investigation showed that cooking greatly reduced the contents of the anti-nutrients in cocoyam. After cooking for 30 mins, the content of calcium oxalate was reduced by 50%, an indication that oxalate has a hydrothermal ability which could be attributed to the dual effect of thermal degradation and leaching. This reduction is necessary as oxalate has been found to decrease absorption of important elements as well as aid in the formation of kidney stones (Catherwood *et al.,* 2007). Phytates form complexes with the essential mineral elements and thus reduce their bioavailability and absorption. Cooking reduced the content of tannins to about 75%, which is a health benefit as tannins inhibit protein digestion and absorption. Table 3 shows the results of the mineral compositions of both crayfish and cocoyam (cooked, uncooked and crayfish-fortified). Cooking reduced the contents of all the essential mineral elements determined in this investigation with the exception of sodium. However, with the addition of crayfish to the cocoyam samples at the ratio 75:25 w/w, the results of the investigation showed remarkable increase in the nutritional and mineral contents in the cocoyam samples, thus making up for the losses due to boiling.

Conclusion

The results of this investigation showed that cooking reduced the anti-nutrient content of the cocoyam samples thereby improving its nutritive value and food quality. The cooked samples showed losses of some nutrients with respect to proximate and mineral compositions. However, fortification of cocoyam with crayfish is necessary to enhance the nutrient profile and ensure healthy diets for cocoyam consumers. Based on the results of this study nursing mothers especially in underdeveloped countries are advised to incorporate crayfish-fortified cocoyam meal in the diet of their children.

Abstract
The study evaluated the organoleptic qualities of tuwo prepared from maize grains treated and stored with natural products (raw diatomaceous earth, kaolin powder) and synthetic insecticides (Rambo®, Pestox®) against Tribolium casteneum infestation under ambient laboratory conditions of 32.5±3 ℃ and 56.6±8% relative humidity. Each treatment was applied at the dose rate of 2, 4, 6 g/kg of maize grains. Two controls were also included in the set up: infested and un-infested control. Each was later infested with twenty adults Tribolium casteneum of mixed sexes and stored for 12 months. Each treatment was replicated three times in a Completely Randomized Designed. Sensory evaluation was conducted to assess the effect of these treatments on the organoleptic qualities of treated and stored maize, using a 9- point hedonic scale, ranging from dislike extremely to like extremely. One hundred grams of treated maize as well as the controls were measured, pounded into flour using pestle and mortar; tuwo was prepared from the flour, Questionnaires were administered to panelists to assess the effect of these treatments on colour, taste, aroma, appearance and overall appearance of tuwo and their responses were analyzed. The result show that sensory attributes of tuwo prepared from grains treated with lowest dose rate of raw diatomaceous earth was significantly preferred by the panelists. Also, tuwo prepared from un infested maize grain was significantly different from tuwo made from the infested maize grains in terms of colour, taste, aroma, appearance and overall acceptability.

Keywords: natural products, synthetic insecticides, Tribolium casteneum, tuwo and organoleptic evaluation

Introduction
Maize (*Zea mays* L.) is one of the most important cereal crop grown in Nigeria and constitute important sources of carbohydrates, proteins, vitamin B and minerals (Iken *et al,* 2002). In Nigeria, maize is the third most important cereal crop after sorghum and millet (Ojo, 2000). Maize cultivation started as a subsistence crop and has now risen to a commercial crop on which many Agro allied industries depend for its raw materials (Oladejo and Adetunji, 2012). Milled flour constitutes the major form in which maize are consumed in Nigeria (Umar *et al*., 2015). Insect pests cause damage to stored grain and processed products by reducing dry weight and nutritional value (Sinha and Watters, 1985). The attack of these crops begins in the field and continues in storage, which is liable to depredation with rapid increase in population of pest organism (Pretheep-Kumar *et al*., 2006). Losses of crops during storage, processing and marketing may be as high as 50%. The estimate of losses from time of harvest until consumption by man varies (Okunola *et al*., 2007). The red flour beetle, *Tribolium castaneum* (Herbst) is one of the most serious pest in milled products worldwide causing heavy loss (Mullen, 1992; Rees, 2004). The pest can cause damage to stored-products by feeding, and severely reducing the quality of crops due to product excrement and larval faeces. This pest makes serious damage on flour and crush cereal particularly at larval and adult stages. As well as, the pest causes damage on seeds containing high humidity (usually above 12%), makes conversion color of flour to gray and creates a bad smell on nutrient materials. Continuing presence of this pest caused to mold growth on grain and flour (Bennett, 2003; Baldwin and Fasulo, 2004). Synthetic pyrethroids are broad spectrum insecticides,

widely used because they are relatively safe for humans, their insecticidal potency is elevated at low dosages and they exhibit a rapid immobilization effect (WHO, 2005; Hénault-Ethier, 2015). Pyrethroids are neurotoxic poison and targets voltage-sensitive sodium channels. It also affects voltage-gated calcium channels, voltage-gated chloride channel and GABA receptors (Schleier and Peterson, 2011). Pyrethroids are used as grain protectants and against household pests, agricultural pests, fields and green house pests. They are also extensively used in animal houses and in the field of veterinary medicine (Hénault-Ethier, 2015). Several studies have demonstrated the efficacy of synthetic pyrethroids as grain protectants against storage insect pests including *T. casteneum* (Mansee and Montasser, 2003; Abdul Mujeeb and Shakoori, 2007: Andrić *et al*., 2015). Natural products, such as raw diatomaceous earth and Kaolin are inert dust, kill arthropods by removing the epicuticular lipid layers causing excessive water loss through the cuticle (Ebeling, 1971; Subramanyam and Roesli, 2000). These dusts have been widely used as grain protectants against stored product insect pests (Arthur, 2000; Arthur and Puterka, 2002; Timlick and Fields, 2010; Mahmoud *et al*., 2010; Kabir *et al*., 2013; Storm *et al*. 2016). However, very few studies have investigated the effect of these on the organoleptic properties of treated grains. Therefore, this study evaluated the organoleptic properties of *tuwo* prepared from maize grains treated with natural products (raw diatomaceous earth, kaolin powder) and synthetic insecticides (Rambo®, Pestox®) against infestation by *Tribolium castaneum*.

Materials and Methods

Study Site

The experiment was conducted in AGT laboratory, Department of Agricultural Technology, Ramat Polytechnic Maiduguri. Maiduguri is located at latitude 11°50′N and longitude 13°09′E. It lies on a vast open plain, which is flat with gentle undulations at an average elevation of 345m above sea level. The climate of the region is characterized by a cool-dry season (October to March), hot season (April to June) and a rainy season (July to September). The area is highly susceptible to drought with relative humidity of 13% and 65% in dry and rainy seasons respectively (Hess *et al*., 1996).

Sources of experimental materials

Maize (local variety) grains were purchased from Grain merchants at Maiduguri Monday Market. The grains were cleaned and disinfected at 60^{o}C for 3 hours in a hot air oven. Before the beginning of the experiments, the grains were equilibrated for 7 days under ambient laboratory conditions. The grains were broken down into smaller pieces using pestle and mortar. Pestox® and Rambo® both synthetic pyrethroids were purchased from Agro chemical Marketers at Maiduguri Monday Market. Raw diatomaceous earth was obtained from Department of Crop Protection University of Maiduguri Nigeria. Kaolin was obtained from Alkaleri Local Government Area, Bauchi State, Nigeria.

Rearing of *T. casteneum*

The adults of red flour beetle, *Tribolium castaneum* were obtained from laboratory cultures maintained at AGT laboratory, Department of Agricultural Technology, Ramat Polytechnic Maiduguri, Nigeria. The insects were reared on broken maize grains plus baker's (5% by weight). It entailed infestation of 500 g broken maize with 100 adults *T. castaneum* in a 1 – Litre glass jar to oviposit for one week; after which the parent were sieve out. The jars were covered with perforated lids to permit ventilation and prevent escape of adult insect. The adults which subsequently emerged was used for experiment. All cultures were maintained left under ambient laboratory conditions of 32.5±3°C and 56.6±8% relative humidity.

Bioassay procedure

One hundred grams of broken maize was weighed into 500 ml glass jars using Metler® electronic balance and admixed with 2, 4 and 6 g of raw diatomaceous earth, kaolin powder, Rambo® and Pestox®. Un-infested control and infested control were also set up. After treatment, all the jars, except the controls were vigorously shaken to ensure effective admixture and the content were allowed to settle for an hour. Thereafter, each jar was infested with twenty newly emerged *T. castenum* adult of mixed sexes. The jars were covered with a mesh to facilitate ventilation and prevent escape of the insect. Each treatment was replicated three times; labelled and arranged in a completely randomized design (CRD) under ambient laboratory conditions at 32.5±3°C and 56.6±8% relative humidity. The set up was left under these conditions for 12 months.

Tuwo preparation and Sensory evaluation

After, 12 months of storage, one hundred grams of broken maize per replicates were picked, cleaned and ground into flour using pestle and mortar. The flour was package in a polythene bag

and mixed with water, it was cooked in a pot over a kerosene stove for 1 hour and 27 minutes. No additive or salt was added.
Sensory evaluation of the *tuwo* was carried out by twenty untrained panelists, which were students in the Department of Agricultural Technology, Ramat polytechnic, Maiduguri. *Tuwo* were served to the panelists with questionnaires administered to assess the effect of the treatments on the sensory parameters of colour, taste, aroma appearance and overall acceptability of *tuwo* using a 9-point hedonic scale ranging from 1- dislike extremely to 9- like extremely. The panelists were instructed to rinse their mouth with sachet water after each test.
Statistical Analysis
The sensory evaluation data obtained from the questionnaires were subjected to one-way analysis of variance (ANOVA) using the statistical software Statistix 8.0 (Statistix, 2007). Means were compared using the Tukey-Kramer (HSD) test ($p < 0.05$).

Results and Discussion

The results of the organoleptic ratings by 20 panelists of *tuwo* prepared from broken maize grains treated with natural products and synthetic insecticides and stored for 12 months are presented in Table 1. Sensory evaluation of *tuwo* prepared from the infested maize grains showed significant differences (p<0.05) in colour, taste, aroma, appearance and overall acceptability from *tuwo* prepared from un infested maize grains. Also, the different treatment had no significant effect on colour, taste, aroma, appearance and overall acceptability of *tuwo* prepared from *treated maize grains.* However, the highest score for the colour (7.6) was recorded at 2ml of raw diatomaceous earth then followed by 2ml of kaolin powders and least score was obtained at 6 ml of Rambo, which was significantly different ($p < 0.05$) from infested control. Similar trends were observed for some of the sensory attributes like taste, aroma, appearance and overall acceptability (Table 1).

The application of raw diatomaceous earth, kaolin powder, Rambo® and Pestox irrespective of the dose rates used did not significantly alter the colour, taste, aroma, appearance and overall appearance of *tuwo* prepared from the treated grains. This could be an indication that the constituents of these treatments were not absorbed by the processed grains. This confirms with Mundi *et al*. (2012) which reported that taste and flavour of 'Okpa' prepared from flour of bambara groundnut seeds treated with *Anogeissus leiocarpus* (Guill and Per.), *Antidesma venosum* (Tull.), *Maranthes polyandra* (Benth.) Prance. *Mitragyna inermis* (Willd.) Kuntze and *Vitex madiensis* (Olive) were not adversely affected by the leaf powdered treatments and rated fair in overall assessment. Ojiako and Kayode (2014) observed that pirimiphos methyl and powdered plant materials had no significant effect on the quality parameters of cooked cowpea seeds. It was observed in this study, that the colour, taste, aroma, appearance and overall appearance of *tuwo* prepared from the treated grains was accepted and preferred by the panelists, compared to *tuwo* made from the infested flour. Also, the panel of judges rated the *tuwo* made from infested flour lower than the *tuwo* prepared from un-infested flour in all the sensory attributes evaluated. This demonstrated that insect infestation has severely depleted the quality of infested flour, which as well affected the *tuwo* made from the infested flour. The findings of this study agrees with Babarinde *et al*. (2010) which reported that infestation of plantain chips by *T. castaneum* caused some physical and biophysical deterioration of the chips. Also, Babarinde *et al.*, (2013) reported that infestation of yam chips by *Dinoderus porcellus* affected the quality and acceptability of "*Amala*'.

Conclusion

In conclusion, the natural products (raw diatomaceous earth, kaolin powder) and synthetic insecticides (Rambo®, Pestox®) used did not adversely affect organoleptic properties of maize grains stored for six months. Seeds stored with some of these products also had satisfactory organoleptic characteristics.

Roles of Food Science and Technology in the Agro-Food Sector in Nigeria: A Review

[1]D.A. Adegboyega, [1]O.E. Akinyemi, [1]O.A. Idowu, [2]Femi-Oladunni Opeyemi

Abstract
The paper assessed the roles of food science and technology (FST) in the agro-food sector in Nigeria. Specifically, it explained the concept of food science, nanotechnology in food sector, the roles of FST and challenges of FST. Food Science is a multi-disciplinary field involving chemistry, biochemistry, nutrition, microbiology and engineering to give one the scientific knowledge to solve real problems associated with the many facets of the food system. Nanotechnology has the potential to improve food processes that use enzymes to confer nutrition and health benefits but there is an urgent need for regulation of nano-materials before their incorporation into food processing, packaging, and food contact. The concept of food science indicates that there are basic sciences and engineering to study the physical, chemical, and biochemical nature of foods and the principles of food processing. Previous empirical findings revealed that nano-materials can be used to provide superior enzyme-support systems due to their large surface-to-volume ratios compared to traditional macro-scale support materials in order to make enzymes highly active, long-lived and cost-effective. It was further revealed that FST improves the feeding of a nation and helps in productivity. One of the major challenges of FST is lack of basic social amenities. The review concluded that more focus should be diverted to make more research on the benefit impact of adequate provision of social amenities on FST. It was recommended that more research studies are required to investigate the hazards of nanotechnology in foods and the government should make available basic social amenities and promote research on food science and technology.
Keywords: Food science, Health, Nanotechnology, Food preservation and Food processing

Introduction
The Agro food industry is a vital integral of economic growth of any country. Various cash crops that are produced in different countries could be major sources of economy if properly managed. A strong and efficient agricultural sector would enable a country to feed its growing population, generate employment, earn foreign exchange and provide raw materials for industries. The agricultural sector has a multiplier effect on any nation's socio-economic and industrial fabric because of the multifunctional nature of agriculture (Ogen, 2007). Agriculture could be said to be the mainstay of many economies and it is fundamental to the socio-economic development of a nation because it is a major element and factor in national development. The Agro-foods industry plays a fundamental role in the creation of income and employment opportunities in developing countries. The agro-processing sector is by far the most significant component in the agro-food industry and covers a broad area of postharvest activities, packaged agricultural raw materials, industrial and technology intensive processing of intermediate goods and the fabrication of final products derived from agriculture (UNDP, 2012). Okolo, (2004) described the agricultural sector as the most important sector of the Nigeria economy which holds a lot of potentials for the future economic development of the nation as it had done in the past. Agriculture contributes over 40% of Nigeria's GDP, employs over 70% of the population, and produces about 80% of the food needs Aye, (2013). Although, agriculture still accounts for about 88% of non-oil export earnings, its contribution has seriously declined over the decade falling from about 75% of total export earnings in the 1960s to less than 3% currently Oji-Okoro,(2011). Food security has been defined in terms

of food availability and its accessibility to people (Olaoye et al, 2013). It is believed that there can be no food security without its availability; its safety must however be guaranteed. Food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for an active and healthy life (FAO, 2001). The discovery and utilization of scientific principles in food technology have provided a supply of safe, wholesome, and nutritious foods unknown before in history (Clydesdale, 1989). As a result, life spans in the industrialize world have increased. The most significant contribution and achievement of Food Science and Technology (FST) worldwide to development is possibly the supermarket. For those people not familiar with them, it is simply fascinating to walk aisle after aisle admiring the variety of attractive cartons, cans, and many other fancy containers with all kinds of foods. On the other hands, it is also fascinating to walk through the narrow passages of the colourful open markets typical of developing countries. There, the variety of foods is low, mainly cereal grains and food legumes in burlap bags. Occasionally, baskets full of foods, mainly vegetables and fruits, are also to be found, but their availability is dependent on seasonal production (Bressani, 1989). The most crucial contribution of FST to national development given a proper technological framework is seen in their effectiveness in increasing food production and productivity of some agricultural crops, decreasing food losses, increasing food availability, reducing seasonality, providing employment and higher income, making available high nutritive value foods and in general increasing the economic situation. The objective of this review is to explain the roles of FST in the agro-food sector in Nigeria. Specifically, it explained the concept of food science, the concept of nanotechnology in food sector, the roles of FST in agro foods production, preservation, processing and the challenges of FST.

Food science

Food Science is a multi-disciplinary field involving chemistry, biochemistry, nutrition, microbiology and engineering to give one the scientific knowledge to solve real problems associated with the many facets of the food system (Baianu, 2012) The basis of the discipline lies in an understanding of the chemistry of food components, such as proteins, carbohydrates, fats and water and the reactions they undergo during processing and storage. A complete understanding of processing and preservation methods is required including drying, freezing, pasteurization, canning, irradiation, extrusion, to name just a few. The ability to carry out analysis of food constituents is developed along with statistical quality control methods. The microbiology and the safety aspects of food must also be understood. Other topics it covered include food additives, the physio-chemical properties of food, flavor chemistry, product development, food engineering and packaging. Food science integrates this broad-based knowledge and focuses it on food (Sadat et al, 2017)

Nano-technology in Food Sector

Food is nanofood when nanoparticles, nanotechnology techniques or tools are used during cultivation, production, processing, or packaging of the food (Ravichandran, 2010). Nanotechnology also has the potential to improve food processes that use enzymes to confer nutrition and health benefits. For example, enzymes are often added to food to hydrolyze anti-nutritive components and hence increase the bio-availability of essential nutrients such as minerals and vitamins. To make these enzymes highly active, long lived and cost-effective, nano-materials can be used to provide superior enzyme-support systems due to their large surfaces to volume ratios compared to traditional macro-scale support materials (Ansari, 2012). Nanotechnology has the potential to revolutionize the global food system. Novel agricultural and food safety systems, disease-treatment delivery methods, tools for molecular and cellular biology, sensors for pathogen detection, pesticides, packaging materials, environmental protection and education of the public and future workforce are examples of the important impact that nanotechnology could have on the science and engineering of agriculture and food systems (Moraru *et al*., 2003; Bouwmeester *et al.,* 2009). According to Alfadul *et al,* (2010), the food market demands technologies, which are essential to keep market leadership in the food processing industry to produce fresh authentic, convenient and flavourful food products. Prolonging the product shelf life and freshness as well as improving the quality of food are the target. Nanotechnology is a technology that has the potential to revolutionize the food industry. Detection of very small amounts of chemical contaminants, virus or bacteria in food systems is another potential use of nanotechnology (Shefer *et al,* 2003**)**. Consequently, it could be noticed that nanotechnology is a scientific area of rapid growth worldwide; many consider it as the basis for the next industrial revolution. It is possible that in the near future no country would be able to escape from the necessity of reseansariod packaging within the next decade, (Reynolds, 2007). The significant purpose of nano-packaging is to set longer shelf life by improving the barrier function of food packaging to reduce gas and moisture exchange and UV light exposure, (Sorrentino *et al,* 2007). There is an urgent need for regulation of nano-materials before their incorporation into food processing, packaging, and food contact. Nano-materials must not cause any health risks for consumers or to the environment (Alfadul *et al*, 2010).

Roles of Food Science and Technology

FST has overtime played crucial roles in Agro foods production, preservation and processing. Samuel, (2017) recently revealed that an estimated 25 per cent of all food produced in some developing countries is never consumed by humans. Instead, it spoils or is eaten by insects, rats and other pests. FST helps enhance reduction in food wastage by the following measures; control of rats by trapping, poison, rat-proofing grain stores, control of insects by use of insecticides, better food stores and airtight food containers, control of fungi and food rot by storage of food in as dry a state as possible and by use of better containers, control of birds by destruction, especially in millet and wheat areas and protective measures against monkeys, baboons, porcupines, wild pigs and other destructive animals, even elephants.

Challenges Faced With Food Science and Technology

Food is the substances taken that nourishes the body and gives the body strength to function effectively. Food makes one healthy to carry out necessary duties, food has many sources the main and traditional sources of food are agriculture and water bodies. Important food crops of Nigeria are cereals, grains, legumes, pulses, oilseeds, fruits, vegetables, spices and herbs, tea, coffee, sugarcane, honey, milk, meat, poultry and egg (Ogunfowoke, 2012). Since FST plays a vital role in Nigeria, it helps in food production, processing and preservation. Food is necessary for survival. A nation or country should be able to provide food for its people either in season or out of season. FST is expected to improve the feeding of a nation and helps in productivity. Factors affecting food insecurity in Nigeria are inadequate investment in agriculture, lack of financial support for farmers (especially the rural farmers), expensive agrochemicals, poor storage facilities, poor enforcement of agricultural policies (Philips *et al.,* 2008).

The challenges faced with FST are not limited to the following:

1. Lack of scientific and technical knowhow: Most of our institutions in Nigeria lack equipment to carry out practical works in relation to food science and technology. The student are been taught theoretical aspect of the work only instead of taking the student through technical/ practical and theoretical aspect.
2. Post- harvest food losses: after harvesting of the farm produces, some of the products are been infested by insects and rodents. Some spoilage also occur due to mould and invasion by bacteria thereby reducing the quality and quantity of the farm produces.
3. Lack of adequate machines and equipment for storage and processing: some farmers especially those in the rural area still make use of local/manual farm tools such as hoes and cutlasses and methods. Mechanized farm tools are not readily available, only few mechanized farm tools and equipment are available.
4. Lack of social amenities: social amenities such as access to good road, electricity supply, water are necessary. Lack and bad access to all these basic social amenities affects the effectiveness of food science and technology

Conclusion

The review concluded that more focus should be diverted to make more research on the benefit impact of adequate provision of social amenities on food science and technology. Food science and technology institutions should be encouraged to carry out collaborative research and partnerships from different sources including the private sector, non-governmental organizations so as to guarantee food security and increase the Nation's food exportation rate. More research studies should be done to investigate the hazards of nanotechnology in foods and the government should make available basic social amenities and promote research on food science and technology

Effect of Different Methods of Extraction on Quality and Yield of Castor Oil

B. O. Apuyor, I. A. Yusuf, B.Z. Salihu, M. A. Kabaraini, H. Shehu, and O. A. Afolayan
National Cereals Research Institute (NCRI), Badeggi, Niger state ***Email:fitzapuyor@yahoo.com***

Abstract
Castor oil is a vegetable oil obtained by pressing the seeds of the castor oil plant (Ricinus communis). This study was to determine the best method for local expression of the oil without affecting the physiochemical properties. Three methods (Soxhlet, cold press and hot press) were employed for the oil expression and the physiochemical properties were measured using AOAC methods. The results revealed that Soxhlet which is laboratory method give best yield (51.87±0.18 %) compared to that of cold press (35.63± 0.70%) and hot press (13.62± 0.68%). The physiochemical properties of the oil were within recommended standard but hot press was significantly different from other methods. From the result of this study, castor oil extraction should be carried using cold press for optimum yield of the oil.
Keywords: cold press, hot press, Castor oil and oil expression

Introduction
Castor is a member of the Euphorbiaceae family that is found across all the tropical and semi tropical regions of the world (Weiss, 2000). Castor bean (*Ricinus comminus* L.) is cultivated for its seeds which yield viscous, pale and non-volatile yellow oil (Tchuenteu *et al*., 2013). The oil is nonedible and has been used almost entirely for pharmaceutical and industrial purposes. Notably it is used in the manufacture of paints, dyes, inks, waxes, varnishes, lubricants and brake fluids e.t.c (Ogunniyi, 2006). The castor oil obtained by cold pressing of seeds is also used in household for soap production and as purgatives and laxatives (Weiss, 2000). Castor oil is a vegetable oil obtained by pressing the seeds of the castor oil plant (*Ricinus communis*) (Thomas, 2005).). Castor oil is a colorless to very pale yellow liquid with a distinct taste and odor once first ingested. Its boiling point is 313 °C (595 °F) and its density is 961 kg/m3. It is a triglyceride in which approximately 90 percent of fatty acid chains are ricinoleates. Oleate and linoleates are the other significant components(Mutlu and Meier, 2010). Castor oil is unique among vegetable oils because it is the only commercial source of a hydroxylatedfatty acid (ricinoleic acid). Castor seed contains 50% oil. But due to difficulty in extraction, some parts of its oil are impossible to be extracted. Unlike high saturated degree, castor oil is one of the stable oil The oil contains around 90% of the fatty acid (Ogunniyi, 2006).

Methodology
The castor seeds were obtained from Castor Research Programme of the National Cereal Research Institute (NCRI), Badeghi, Niger State, Nigeria.

Oil Extraction

For soxhelt extraction, 2g of the milled sample was placed in a paper thimble and fed into a Soxhlet extractor which was fitted with a 500 mL round bottom flask and a condenser. The oil was extracted by using n-hexane (as an extracting solvent) on water bath for 6 h. After extraction, the extra hexane was distilled off under vacuum in a rotary evaporator at 45°C (Federation of Oils Seeds and Fats Association (FOSFA), 1982). The extracted oil was weighed and the yield was calculated. In cold pressing, oil was extracted by locally made hydraulic press without using any chemicals for 30 min. Also, hot pressing oil was extracted by locally made mechanical oil extractor.

Oil Physiochemical Analysis

Physical Properties: Percentage oil yield was determined using weight by weight method. Refractometer was used to determine the refractive index of oil at room temperature and the specific gravity was determined using density bottle (weight by weight method)

Chemical Properties: The determination of chemical properties such as acid value, iodine value and saponification value was carried out using Association of Official Analytical Chemist (AOAC) Method of 2006.

Results and Discussion

The effect of extraction methods on the oil yield of the castor seeds is as shown in Table 1. There was a significant diferent ($p > 0.05$) in % oil yield from castor seed extracted using Soxhlet, cold press and hot press methods. The oil yield obtained from Soxhlet method was highest (51.87±0.18 %) compared to that of cold press (35.63± 0.70%) and hot press (13.62± 0.68%). Different methods of oil extraction gives different yields of oil (Alirezalu *et al.,* 2011). In the present study, the highest values of oil yields (51.87±0.18%) obtained using Soxhlet extraction method was in agreement with the findings of Nadeem *et al.* (2015) who evaluated the effect of cold press and Soxhlet extraction on the physico-chemical properties of sunflower seed oil. Castor oil extraction using solvent extraction has been reported to be about 46-55 % yield (Oguniyi, 2006). Muzenda (2012) in his study on the optimization of different parameters for castor oil production reported an oil yield of 50.16 % using Soxhlet method. Yusuf *et al.* (2015) in their extraction and characterization of castor seed oil from wild *Ricinus communis* linn reported a yield (39.43 %). Similarly, Akpan *et al*. (2006) achieved an average recovery of 33.2% of castor oil through Soxhlet extraction protocol.The sharp decrease in oil yield of hot press was as a result of sludge formation which may be caused by activation of castor seed enzyme (Muzenda, 2012). All other physiochemical properties of the oil measured were within the recommended standard by American Society for Testing and Materials International (ASTM) and that of the British Pharmacoepia Standard (BPS) for industrial use of castor oil and medicinal use of castor oil respectively, but there is no significant different between Soxhlet and cold press methods but there was significant different between hot press and other two methods.

Conclusion

The study has revealed that castor oil extraction should be carried out with cold press method for improved oil yield and quality.

Table 1: Physiochemical properties of castor oil from various extraction methods

S/n	Physical properties	Soxhlet extraction	Cold press	Hot press
1	Oil yield (%)	51.87 ± 0.18^{a}	35.63± 0.70^{b}	13.62± 0.68^{c}
2	Specific gravity	0.9492±0.050^{a}	0.9592±0.012^{a}	0.9580±0.019^{a}
3	Refractive Index	1.4728±0.023^{a}	1.4781±0.062^{a}	1.4674±0.089^{a}
4	Colour	Amber	Amber	Dark ash(greyish)
Chemical Properties				
1	Acid value (mg/g)	1.148±0.23^{a}	1.152±0.11^{a}	1.094±0.08^{a}
2	Iodine value (mg/g)	87.72±0.39^{a}	88.24±0.48^{a}	84.27±0.87^{b}
3	Saponification value (mg/g)	185.85±1.24^{b}	188.58±2.16^{a}	179.68±0.98^{c}

Abstract
The shea tree which has remained neglected with limited nutritional information of the shea fruit has exceptional short, medium and long term prospects for development. The food content including Moisture, Lipid, Protein, Ash, Fibre and Nitrogen free extract content of the shea fruit mesocarp has been studied at different stages of growth using standard methods. The proximate content was determined by harvesting the fruits at weeks 4, 8, 10, 12, 14, 16, 18 and 20 after flowering and the results of the fruit content were recorded. The percentage moisture contents, lipid contents, ash contents, protein contents and nitrogen free extract content ranged from 57.50±0.06% to 67.00±0.20%, 4.30±0.05% to 22.10±0.03%, 2.50±0.32% to 6.00±0.10%, 2.27±0.02% to 9.25±0.03%, 7.70±0.10% to 15.00±0.30% and 56.75±0.29% to 77.53±0.11% respectively. The result of this study has highlighted periods of high and low food contents in a shea fruit mesocarp post flowering which could suggest the best periods of their harvest depending on the purpose for cultivation.

Introduction
The shea tree, *Vitellaria paradoxa* is typically a Savanna woodland tree species (Eneh, 2010). The shea tree is an indigenous wild tree plant of African savanna parkland (Hall *et al*. 1996) and has been included in the priority list of African Genetic Resources by the FAO (1997). The fruit consists of a green fleshy mesocarp, which is sweet when eaten ripe and locally consumed like mangoes (Eneh, 2010) or other wild seasonal fruits. Typically, the fruit consists of mesocarp with nut which houses the kernel. The kernel oil (or fat) is the shea butter. The shea tree can live for more than 200 years (Eneh, 2010). The development of the fruit from flower starts from the stage of fertilization (Fruit Development Stages, 2016). The main growth of the fruits from the seeds include three main parts which includes; Fertilization, Embryology and Fruits and Seeds maturation (Fruit Development Stages, 2016). Mbaiguinam *et al.*, (2007) stated that earlier studies elsewhere have reported the existence of important nutrients in the shea fruit pulp, normally consumed by the local population to supplement diet from staple foods. The nutritional and economic importance of shea butter has been emphasized over that of the shea fruit. The fleshy shea fruit mesocarp is sometimes fermented, given to animal or left to rot and is discarded in favour of the shea nuts for shea butter production (Enabuere *et al*., 2014). Therefore, there is need to exploit the shea fruit mesocarp (pulp) for further use in the food and drug industries. The aim of this study is to determine and compare the proximate composition of shea fruits mesocarp (pulp) at different stages of development. The nitrogen free extract (an inaccurate name because this fraction has nothing to do with nitrogen and it is not an extract either) referred to in this study is the soluble part of carbohydrate while the crude fibre represents the insoluble portion of the carbohydrates.

Materials and Methods
Shea trees were selected and marked for this experiment and shea fruits were harvested from the marked trees in the Nigerian Institute for Oil Palm Research (NIFOR) sub-station, Bida, Niger State at different weeks (4, 8, 10, 12, 14, 16, 18 and 20 weeks respectively) after flowering and analysed

for the food content (Moisture, Oil, Protein, Ash, Fibre and Nitrogen free extract) upon which data documentation and analysis were done. Before analysis, the shea fruits were peeled (to remove the mesocarp). The mesocarp was used for the analysis. The mesocarp was dried, powdered and analysed. All reagent used in the analysis were of analytical grade and standard. Percentage moisture was determined by AOCS (1997) method. Lipid content was obtained by weight difference after extracting the oil with 96% pure n-hexane (Scharau, Spain) in a soxhlet apparatus for 18 hours. AOAC (2010) method was used to measure the ash and nitrogen contents. The ash content was determined by weight difference between the sample and the ash after incinerating the samples in the muffle furnace at 550^0C. The protein content was determined by Kjeldahl method and converted to percentage protein by multiplying with the Atwater factor. Nitrogen free extract (NFE) was calculated by difference using the equation:
%NFE = 100 – (%lipid + %ash + %crude protein + %fibre)
All chemical analyses were done in triplicate. The data generated were analysed using the SPSS software version 17. The means and standard deviation were then computed to further carryout the analysis of variance (ANOVA) at $P < 0.05$ to determine difference between means.

Results and Discussion

The results for the chemical analysis of shea fruit mesocarp are presented in Table 1. The observed moisture content and NFE of the mesocarp was statistically similar all through the study period $P > 0.05$. It was also observed that the lipid content of the mesocarp increased from the fourth week (6.80%) to its highest at the eighth week (22.10%) and the decreased almost gradually until the twentieth (last) week (4.30%) $P < 0.05$. It was observed that the ash content of the mesocarp increased almost steadily from the fourth week (2.50%) to the sixteenth and twentieth week where it had its highest percentage contents (6.00% and 5.20% respectively) with a little dip in the eighteenth week. Protein content of the mesocarp was observed to be highest at the fourth, sixteenth and eighteenth week of this study (9.25%, 8.26% and 6.58% respectively) and the lowest at the eighth, tenth, twelfth and fourteenth week (2.65%, 2.40%, 2.32% and 2.27% respectively). Whereas lowest fibre contents (7.70%, ,8.80% and 8.70%) were recorded at the beginning and last weeks of this study (fourth, eighteenth and twentieth week respectively) highest fibre contents ranging from 12.20% to 15.00% were recorded in between. The matured fruits in this study at week twenty had 57.5% moisture, 4.3% lipid, 5.2% ash, 6.6% protein, 8.7% fibre and 75.2% carbohydrate in the mesocarp, which is in agreement with Onwuka (2005), that shea fruit pulp is a rich source of energy and capable of supplying the daily energy requirements of the bodies of humans and livestock. This should also support promoting consumption of shea fruit as being of great benefit to the human diet as envisaged by Enabuere et al. (2014).

Table 1: Proximate nutrient composition of the analysed shea fruits mesocarp

Weeks	Moisture (%)	Lipid (%)	Ash (%)	Protein (%)	Fibre (%)	NFE (%)
4	67.00 ± 0.20	6.80 ± 0.03	2.50 ± 0.32	9.25 ± 0.03	7.70 ± 0.10	73.75 ± 0.11
8	57.70 ± 0.60	22.10 ± 0.03	3.50 ± 0.10	2.65 ± 0.05	15.00 ± 0.30	56.75 ± 0.29
10	57.60 ± 0.65	14.60 ± 0.03	3.70 ± 0.10	2.40 ± 0.03	14.30 ± 0.06	65.00 ± 0.06
12	57.60 ± 0.06	9.40 ± 0.05	3.80 ± 0.15	2.32 ± 0.03	14.90 ± 0.15	69.58 ± 0.09
14	57.90 ± 0.10	8.30 ± 0.12	4.70 ± 0.06	2.27 ± 0.02	13.80 ± 0.10	70.93 ± 0.10
16	58.70 ± 0.06	7.70 ± 0.06	6.00 ± 0.10	8.26 ± 0.02	12.20 ± 0.15	65.84 ± 0.15
18	66.40 ± 0.00	5.50 ± 0.12	3.90 ± 0.15	4.27 ± 0.04	8.80 ± 0.10	77.53 ± 0.11
20	57.50 ± 0.06	4.30 ± 0.05	5.20 ± 0.06	6.58 ± 0.02	8.70 ± 0.10	75.22 ± 0.15

Note: Mean ±SD (n=3)

Conclusion

The result of this study has highlighted periods of high and low food contents in a shea fruit mesocarp post flowering which could suggest the best periods of their harvest depending on the purpose for cultivation.

Abstract
The major setback to attaining food security in Nigeria is substantial post-harvest losses. This study was conducted to assess the post-harvest losses and storage practices of root and tuber crops' farmers in Abia state, Nigeria. A multi-stage random sampling procedure was used to select 120 farmers from the State. Data were collected with the use of structured questionnaire and analyzed with means, percentages as well as Likert type scale. Results indicated that majority of the respondents (73.3%) were not aware of improved methods of storing root and tuber crops. Respondents' perceived that post-harvest losses due to rodents/insects (1.98); change in colour and flavour (1.88); inadequate transportation system (1.85); and traditional processing system (1.64) were moderate while losses due to mould and rot (2.05); lack/inadequate storage facilities (2.27); and inadequate drying equipment (2.14) were high. Farmers' perception on the effectiveness of the traditional storage methods of root and tuber crops revealed that none of the methods was effective while some of the constraints to adoption of adequate storage practices in the study area include lack of capital (4.33), lack of awareness on improved storage methods (2.84) and high transportation cost (4.13). The study thus recommended among other things increased dissemination of improved storage practices by ADPs and encouragement of farmers to adopt value addition technologies of root and tuber crops.

Introduction
One of the major global challenges today is how to ensure food security for a world growing population whilst ensuring long-term sustainable development. According to the FAO, food production will need to grow by 70% to feed world population which will reach 9 billion by 2050 (FAO/OECD, 2011). Furthermore, trends like increasing urban population; shift of lifestyle and diet patterns of the rising middle class in emerging economies as well as climate change put considerable pressure strain on the planet's resources. Consequently, there is a need for an integrated and innovative approach to the global effort of ensuring sustainable food production and consumption (Nellemann et al., 2009; World Economic Forum 2009; Foresight, 2011). While the number of food insecure population remains unacceptably high each year all over the world, massive quantities of food are lost due to spoilage and infestations on their journey to consumers (FAO, 2011; FAO, 2002). In some African, Caribbean and Pacific ACP countries, where tropical weather and poorly developed infrastructure contribute to the problem, wastage can regularly be as high as 40-50% (SPORE, 2011). Increasing food availability does not only entail increasing the productivity in agriculture, there is also a need to lower the losses (Kader, 2005; Parfitt et al., 2010). Food Post harvest losses all over the world is highly significant (FAO and World Bank, 2010; FAO, 2014). A large amount of food and products do not reach the consumers particularly due to post-harvest losses (Kader, 2005; FAO, 2009; FAO and World Bank, 2010). Post-harvest loss leads to an inadequate food intake and it could be manifested by seed loss, monetary loss, food loss and loss of reputation which in turn affect marketing (Gross et al., 2000; FAO and World Bank, 2010). Post-harvest losses can be caused by mechanical damage and injury, physiological processes, poor handling, lack of processing, inadequate packaging, poor logistics and sub-optimal storage conditions (Chakraverty et al., 2003). Quantitative and qualitative losses could occur in crops (Kidane et al., 2006; FAO and World Bank, 2010). Qualitative losses, such as loss in edibility,

nutritional quality, caloric value, and consumer acceptability of the products, are much more difficult to assess than quantitative losses (Kader, 2005; Adeoye, 2009; Buyukbay et al., 2011). Post-harvest losses reduce the availability of food crops and income that could be generated by selling these products. Therefore, quantitative losses are linked to food security (FAO and World Bank, 2010; Hodges et al., 2011) while qualitative losses are related directly to nutrition which are more complicated to measure. However the quantitative losses are of greater importance to measure in developing countries (Humble and Reneby, 2014). It is important to recognize that post-harvest management practices and capacities (not only just production and marketing) are consequential for many reasons including attaining high level of food and nutritional security. Considerable quantities of roots and tubers are transformed into more durable products by drying, fermentation and commination in different combinations and sequences producing a variety of materials each with distinctive characteristics. Other benefits that often accrue from transformation include the removal of toxic substances naturally present and the convenient-to-use nature of the transformed product. Although the ultimate keeping potential is constrained by environmental conditions, transformations have good prospects for long-form maintenance of root/tuber crop supply because they convert a perishable commodity into a more stable form. This study thus, seeks to assess level of post-harvest losses and storage practices of root and tuber crops' farmers in Abia State, Nigeria

Materials and Methods

The study was conducted in Abia State, Nigeria. Abia State lies between longitude 7^0 231 and 8^0 21 E and latitude 4^0 471 and 6^0 and 121 N. Multistage random sampling procedure was used to select 120 respondents. Firstly, two out of the three agricultural zones in the state were randomly selected namely Aba and Umuahia zones. Secondly, two LGAs were randomly chosen from each of the selected agricultural zones giving a total of four LGAs. The third stage involved the random selection of two communities from each of the selected LGAs and finally, fifteen respondents were also randomly selected from each of the communities selected giving a total of 120 respondents.Structured questionnaires were used in the collection of data from the respondents. Data collected were analyzed with descriptive statistics and 5-point Likert-scale.

Results and Discussion

Table 1 shows respondents' awareness and level of adoption of improved ways of storing root and tuber crops in Abia state, Nigeria. The results indicated that majority of the respondents (73.3%) were not aware of the improved methods of storing root and tuber crops mentioned in the table. The table also reveals that the adoption of improved storage practices like use of improved yam barn, use of air-tight and fungicide treated bag, and refrigeration were low in the study area. Table 2 shows farmers' perceptions of the level of post-harvest losses in Root and Tuber crops. The result revealed that farmers perceived that losses in root and tuber crops due to mould and rot, inadequate storage facilities as well as inadequate drying equipment were high while losses due to rodents/insects change in colour/flavor, inadequate transportation system, and traditional processing techniques were moderate. Table 3 which is farmers' perception on the effectiveness of the traditional storage methods of root and tuber crops revealed that traditional barn is not very effective; bags/sacks are not at all effective; Trenches/ Pits are not very effective; Underground storage is not at all effective; Piling the roots in heaps is not at all effective; while heaping under a shade is not at all effective. Since, most of the traditional storage practices adopted by farmers in the state are not effective. There is therefore, the need to encourage farmers to adopt improved ways of storing root and tuber crops. Table 4 shows constraints to the adoption of improved storage practices in Abia state. The respondents perceived that the major constraints to adoption of improved storage practices in the state are Lack of capital (4.33), High transportation cost (4.13), Poor infrastructure like roads (3.98), Lack of awareness of improved storage practices (3.84) while the minor constraints are Epileptic power supply (2.94) and Theft (2.08).

Conclusion

The study revealed a lack of awareness and very low level of adoption of improved ways of storing root and tuber crops in Abia state. The study also identified the major causes of post-harvest losses in root and tuber crops as loss due to mould and rot, loss due to lack or inadequate storage facilities, and loss due to lack of drying equipments.

Table 1: Respondents' Awareness/Adoption of Improved Ways of Storing Root and Tuber Crops

Method	Not Aware	Aware	Interest	Evaluation	Trial	Adoption	Mean	Remark
Improved yam barn	84 (0)	30 (30)	6 (12)	0 (0)	0 (0)	0 (0)	0.35	Low

Evaluation of Heavy Metals Concentration in Leafy Vegetables from Markets in Owerri, Imo State, Nigeria

J.I. Offor, D.C. Anyanwu, A.C. Offor-John, H. Anyanwu, and J.I. Ukagwu
Department of Agric Edu, A.I.F.C.E Owerri
ifeanyijohn2010@gmail.com

Abstract
The study assessed heavy metals concentrations in selected leafy vegetables from Owerri Markets. Five leafy vegetables (Telfairia occidentalis, Talinum triangulare, Occimium grattissimum, Murraya koenigii ,Gnetum Africana) were used for the study. The analysis of the heavy metals concentration was by Atomic Absorption Spectroscopy (AAS), using the standard procedure to determine the concentration of cadmium, lead, mercury, and arsenic respectively. Data generated from samples and WHO\FAO 2011 standard for heavy metals were subjected to test of significance using T-test at 95% confidence level with SPSS (Statistical Package for Social Science). Result shows that mean concentrations of heavy metals were significantly different from FAO/WHO 2011 safe limit. Mean concentrations of Lead, Mercury and Arsenic in vegetables were significantly higher than the safe limit, while mean concentration of Cadmium was lower than the safe limit. It therefore recommended that care should be taken in the production and handling of vegetables to ensure consumption of toxic free vegetables.

Introduction
Leafy vegetables are those vegetables that are cultivated and harvested primarily for the consumption of their leaves, either raw or cooked. Leafy vegetables constitute essential dietary components by contributing vitamins, protein, carbohydrates and other nutrients which are usually in short supply. Furthermore, this component also acts as neutralizing agents for acidic substances formed during digestion (Thompson and Kelly, 2009). However, leafy vegetables are believed to contain metals over a wide range of concentrations (Shaibu et al, 2013). Some heavy metals are either essential nutrients (typically iron, cobalt and zinc) or relatively harmless (such as ruthenium, silver and indium), but can be toxic in larger amounts on certain forms. Other heavy metals such as cadmium, mercury and lead are highly poisonous. Heavy metals are non-biodegradable and persistent environmental contaminants which may be deposited on the surfaces and then absorbed into the tissues of the vegetables (Suruchi and Pankaj, 2011). Heavy metals are absorbed by growing vegetable crops from contaminated soil, water or via exposure to polluted air as a result of human/industrial activities such as mining and industrial wastes, vehicle emissions, lead acid batteries, fertilizers, paints and heated timber, aging water supply-infrastructure, and micro plastics floating in the world's oceans (Orisakwe et al, 2015). Hence there is need to analyzed food items to ensure the level of these trace elements comply with permissible limits. This is why this study aimed to assess heavy metals concentration in leafy vegetables obtained from Markets in Owerri, Imo state, Nigeria.

Materials and Methods
Five leafy vegetables: Fluted pumpkin (*Telfairia occidentalis*), Water leaf (*Talinum triangulare*), Scent leaf (*Occimium grattissimum*), Curry leaf (*Murraya koenigii*), Ukazi (*Gnetum africana*), were bought from three major markets in Owerri; (Relief Market, Amakohia Market and Egbeada Market). They were sundried for a period of five days until they were completely dry. The samples were taken to the laboratory for analysis. The concentrations of Lead, Mercury, Cadmium, and Arsenic in the vegetables were assessed. The analysis of the heavy metals concentration was by Atomic Absorption Spectroscopy (AAS), using the standard procedure to determine the concentration of cadmium, lead, mercury, and arsenic respectively. Data generated from samples

and WHO\FAO 2006 standard were subjected to test of significance using T-test at 95% confidence level with SPSS (Statistical Package for Social Science).

Results and Discussion

The results for the concentration of heavy metals in selected leafy vegetables are presented in Table 1. From the table, lead concentrations in all the vegetables were higher than the safe limit. Same was the case of mercury. Concentrations of Arsenic were also higher than the safe limit except for Telferia occidentalis. Mean concentrations of Lead, Mercury and Arsenic were significantly higher than the safe limit. The result of this study is similar to the findings of Sharma et al (2009), Yusuf and Oluwole (2009), and Maleki and Zarasvand (2008). Yusuf and Oluwole (2009) reported that urban activities result in elevated levels of heavy metals in leafy vegetables. Contaminants in irrigation water and soils also account for high concentrations of heavy metals in leafy vegetables. Concentrations of Cadmium were however lower than the safe limit for all vegetables. Vegetables can absorb metals from soil as well as from deposits on the parts of the vegetables exposed to the air from polluted environments (Khairiah et al., 2004; Al-Jassir et al., 2005; Kachenko and Singh, 2006). Emission of heavy metals from the industries and vehicles may be deposited on the vegetable surfaces during their production, transportation and marketing. Al-Jassir et al. (2015) have reported elevated levels of heavy metals in vegetables sold in the market of Riyadh city in Saudi Arabia due to atmospheric deposition. Sharma et al. (2008) have reported that atmospheric deposition can significantly elevate the levels of heavy metals contamination in vegetables commonly sold in markets. In many developing countries it is a common practice to grow vegetables along banks of rivers passing through urban centres. Waters of such rivers have often been reported to be polluted by heavy metals (Mashauri and Mayo, 2010; Othman, 2011).

Table 1: Concentrations of Heavy Metals (Mg/Kg) in green leafy Vegetables

Abstract
The shea tree which has remained neglected with limited nutritional information of the shea fruit has exceptional short, medium and long term prospects for development. The food content including Moisture, Lipid, Protein, Ash, Fibre and Nitrogen free extract (NFE) content of matured shea fruit mesocarp, endocarp and kernel have been studied using standard methods. The proximate content was determined by harvesting the fruits at 20 weeks after flowering and the results recorded. The results from this study show that the mesocarp was highest in moisture (57.50%) and NFE (Soluble carbohydrate, 75.22%); the endocarp was highest in fibre (insoluble carbohydrate, 73.40%) content and the kernel was highest in lipid (56.60%), ash (5.60%) and protein (14.90%) contents. The moisture, lipid, protein and NFE contents of the mesocarp, endocarp and kernels were significantly different ($p < 0.05$) from each other. The ash and fibre content of the mesocarp (5.20% and 8.70%) and kernels (5.60% and 8.00%) were significantly different ($p < 0.05$) from that of the endocarp (0.70% and 73.40%).

Introduction
The shea tree is an indigenous wild tree wood and charcoal used for building and cooking fuel (USAID, cited in Obibuzor *et al*., 2014). The fruit consists of a green fleshy mesocarp, which is sweet when eaten ripe and locally consumed like mangoes (Eneh, 2010) or other wild seasonal fruits. Typically, the fruit consists of mesocarp with nut which houses the kernel. The kernel oil (or fat) is the shea butter. Mbaiguinam (cited in Enabuere, 2007) stated that earlier studies on plant of African savanna parkland (Hall *et al*., 1996) and in Nigeria, the cultivation, exploitation and commercial production of shea and shea butter favours the arid and semi-arid northern parts of the country (Obibuzor *et al*., 2014). The shea tree *Vitelleria paradoxa* is multipurpose and highly valued not only for the economic and dietary significance of its cooking oil, but also for the fruit pulp, bark, roots and leaves which are used in traditional medicines and for the have reported the existence of important nutrients in the shea fruit pulp, normally consumed by the local population to supplement diet from staple foods. The nutritional and economic importance of shea butter has been emphasized over that of the shea fruit. The fleshy shea fruit mesocarp is sometimes fermented, given to animal or left to rot and is discarded in favour of the shea nuts for shea butter production (Enabuere *et al*., 2014). The shea kernel and butter have been well emphasized; the shea mesocarp (pulp) has been less emphasized while little or nothing has been said about the shea endocarp (shell) which houses the kernels and most probably discarded. Consequently, there is the need to exploit the shea fruit mesocarp (pulp) and endocarp (shell) for further usefulness in the food and drug industries. The aim of this study is to determine and compare the proximate composition of shea fruits mesocarp, endocarp and kernel. The proximate composition is based on a system of analysis which divides the food (sample) into six fractions including moisture content (the amount of free water), lipid content (the amount of oil extracted by the organic solvent used), ash content (the amount of minerals), crude protein content (estimated from organic nitrogen content), fibre content (insoluble carbohydrate) and nitrogen free extract (soluble part of carbohydrate).

Materials and Methods

Shea trees were selected and marked for this experiment and shea fruits were harvested from the marked trees in the Nigerian Institute for Oil Palm Research (NIFOR) sub-station, Bida, Niger State at 20 weeks after flowering and analysed for the food content for Moisture, Oil, Protein, Ash, Fibre and Nitrogen free extract contents; upon which data documentation and analysis were done. Before analysis, the shea fruits were peeled to remove the mesocarp and the nuts were cracked to separate the endocarp (shell) from the kernel. The mesocarp, endocarp and kernels were used for the analysis. The mesocarp, endocarp and kernel were dried, powdered and analysed. All reagents used in the analysis were of analytical grade and standard. Percentage moisture was determined using moisture analyser (AND, A&D Company limited, ML-50). Lipid content was obtained by weight difference after extracting the oil with 96% pure n-hexane (Scharau, Spain) in a soxhlet apparatus for 18 hours. AOAC (2010) method was used to measure the ash and nitrogen contents. The ash content was determined by weight difference between the sample and the ash after incinerating the samples in the muffle furnace at 550^0C. The protein content was determined by Kjeldahl method and converted to percentage protein by multiplying with the Atwater factor. Nitrogen free extract (NFE) was calculated by difference using the equation: %NFE = 100 – (%lipid + %ash + %crude protein + %fibre).

The results were gotten in triplicates and subjected to analysis of variance (ANOVA) using SPSS software.

Results and Discussion

The results for the chemical analysis of shea fruit mesocarp, endocarp and kernels are presented in Table 1. The moisture, protein and NFE contents of the mesocarp, endocarp and kernels were significantly different ($p < 0.05$). The moisture content of the mesocarp (57.50%) and kernel (37.70%) in this study was different from that recorded by Mbaiguinam *et al.* (2007) and Enabuere *et al*. (2014) for the mesocarp and Mbaiguinam *et al*. (2007) and Obibuzor *et al.* (2014) for kernels. For mesocarp, Mbaiguinam *et al*. (2007) recorded an average moisture content of 79.03% and Enabuere et al. (2014) recorded moisture contents of 15.35%, 15.54% and 14.94% for Northern Guinea Savanah, Southern Guinea Savanah and Transition Zone respectively. While for kernels, Mbaiguinam et al. (2007) recorded an average of 30.11% and Obibuzor *et al.* recorded 24.03% for whole shea kernels. The lipid content of the kernels (56.60%) was found to be far more than those obtained from the mesocarp and endocarp, and is similar to that obtained by Mbaiguinam *et al*. (2007) and Obibuzor *et al*. (2014). Mbaiguinam *et al*. (2007) obtained an average of 55.94% and Obibuzor et al. (2014) 51.52% for ungerminated shea kernels, while the lipid content of the mesocarp (4.30%) was different from that obtained by Enabuere et al. (2014) for Northern Guinea Savanah, Southern Guinea Savanah and Transition Zone (19.01%, 18.98% and 11.13% respectively). This perhaps explains why the shea fruit is valued more for its oil (which is extracted from its kernels). The ash and fibre content of the mesocarp and kernels were significantly different ($p < 0.05$) from that of the endocarp. The ash content obtained from this study for mesocarp (5.20%) was similar to that reported by Enabuere *et al*. (2014) for Northern Guinea Savanah, Southern Guinea Savanah and Transition Zone (5.5%, 5.1% and 6.9% respectively). and to that of some of varieties (Komane, 5.97% and Kiankos, 5.40%) studied by Mbaiguinam *et al*. (2007) but however, the kernel ash (5.60%) was different from that of Obibuzor *et al*. (2014) for ungerminated (3.10%) and whole shea kernels (2.85%). The protein content for the mesocarp (6.58%) and kernels (14.90%) were different from those reported by Mbaiguinam *et al*. (2007) and Obibuzor *et al*. (2014) but similar to that reported by Enabuere *et al*. (2014) for mesocarp from Transition Zone (6.29%). Mbaiguinam *et al*. (2007) reported an average of 4.38% and Obibuzor *et al.* (2014) 8.58% for ungerminated and 3.87% for whole shea kernels. The fibre content of the mesocarp (8.70%) was similar to that reported by Enabuere *et al*. (2014) for the Southern Guinea Savana (9.8%). There was no report of fibre content of kernels and mesocarp record by Mbaiguinam *et al*. (2007) and Obibuzor *et al*. (2014). The fibre (insoluble carbohydrate) content was highest in the endocarp (73.40%) while the NFE (soluble carbohydrate) was highest in the mesocarp (75.22%) in this study. Variations of some of the results obtained in this study from those of Enabuere *et al*. (2014), Obibuzor *et al*. (2014) and Mbaiguinam *et al*. (2007) may be due to a combination of factors ranging from the location where samples were collected, the variety of shea fruits used for the analysis and others.

Table 1: The results for the proximate nutrient composition of shea fruits mesocarp, endocarp and kernel

Parameter (%)	Mesocarp	Endocarp	Kernel
Moisture	57.50±0.06	16.90±0.06	37.70±0.06
Lipid	4.30±0.05	2.00±0.12	56.60±0.36
Ash	5.20±0.06	0.70±0.10	5.60±0.00
Protein	6.58±0.02	0.86±0.02	14.90±0.05
Fibre	8.70±0.10	73.40±0.15	8.00±0.10
NFE	75.22±0.15	23.04±0.22	14.9±0.05

Note: mean±SD (n=3)

Conclusion

Results from this study revealed that the protein and ash content of the shea fruit was highest in kernel, suggesting that it can satisfy other nutritional purposes apart from the popular shea butter it is commonly processed for. The proximate composition of the mesocarp shows that it constitutes a dietary contribution for its consumers as it is especially high in carbohydrate. Further research should be carried out on the end use and value added products of the mesocarp, kernels and endocarp of the shea fruits respectively, to bridge the knowledge gap here in particular for the much less studied part – the endocarp.

Abstract

The study assessed information sources and benefits among artisanal fishers in lower river Benue Makurdi, Benue State, Nigeria. Random sampling technique was used to select two hundred and fifteen respondents (80%) from a list of 269 registered fishers in two landing sites – Wadata and North Bank in lower River Benue while structured questionnaire was administered to the respondents. The data collected were analyzed using frequency counts and percentages. The results showed that 26.6% of the respondents indicated radio and television as formal sources of information, 61.4% contacted fishermen as their informal source of information while 48.4% contacted friends. Purchase of fish inputs (61.9%) and more catches (36.7%) are benefits of information sources. Inadequate extension agents (67.0%) and language barrier (48.8%) are constraints to information sources. The study therefore recommends that various information sources should be strengthened by government for effective dissemination to artisanal fishers and employs more extension agents who would be effective in communicating in local language understood by the artisanal fishers.

Keywords: Artisanal, benefits, constraints, information and sources

Introduction

Fish is a source of high quality and cheap animal protein essential to balancing diet. The primary source of animal protein for more than 50% of the world's population is fish. Globally, most of the total fish supply is obtained from marine and inland capture fisheries, and the remainder is derived from aquaculture (Setsoafia *et al*, 2017). Fish production in Nigeria comes from three sources; artisanal (inland rivers, lakes, costal and brackish water), aquaculture (fish farm) and industrial fishing (Otubusin, 2011). However, the vast majority of the fish supply in most cases comes from the artisanal sub-sector. Fish production in Nigeria has not been consistent in all the sources: artisanal inland, aquaculture and industrial fishing (Chilaka, 2014). Artisanal fisheries contribute significantly to the populace in terms of income earning, food security, employment generating there by reducing rural urban movement of people looking for job. However in Nigeria, artisanal fisheries are on a subsistence level because it is made up of low technology and on a small scale. Food sufficiency through transformed agricultural programmes as advocated by the government can only be achieved when the producers in various segments of agriculture receive the right information at the right time on input supply, modern production methods, storage and marketing (Ogunremi *et al,* 2017). Information source in agriculture could be an individual, group or institution that creates or brings a message to the potential end user with the intention of increasing production or improving their welfare. Information sources are channels through which message is disseminated to the targeted group. Information source to an institution or individual is a means of creating or bringing a message that will be useful in tackling occupational challenges (Annune *et al,* 2014). Information source is essential to artisanal fishers because it determines to an extent its availability to the end users who are believed that if reached it will impact positively on their level of production. The study therefore aimed at identifying information sources and benefits among artisanal fishers in lower river Benue, Makurdi, Benue State, Nigeria. The specific objectives are: (i) identify formal sources of information among artisanal fishers. (ii) Investigate informal sources of information among artisanal fishers (iii) determine the benefits of information to the respondents (iv) ascertain constraints to information sourcing among the respondents.

Materials and Methods

The study was carried out in Makurdi, Benue State which has a landmass of about 32,518 km^2. It lies between longitudes 7º47' and 10º East and latitudes 6º25' and 8º North and shares boundaries with Nassarawa State to the North, Taraba to the East, Cross River to the South, Enugu to the South West and Kogi to the West (Federal Government of Nigeria, 2007). It also shares a common boundary with the Republic of Cameroon on the South Eastern stretch. The list and addresses of 269 registered artisanal fishers in two landing sites – Wadata and North Bank in Makurdi was obtained from Benue State Agricultural Development Programme (BESADP). Simple random sampling technique was used to select 80% (215) of the artisanal fishers from the list. A structured questionnaire and interview scheduled were used to obtain information from the artisanal fishers (Ogunremi, *et al.,* 2017b). Data from the study were analyzed using the descriptive analysis such as frequency counts and percentages.

Results and Discussion

Table 1 indicated that 26.6% of the respondents indicated radio and television as major formal sources of information. Radio is mostly accessible to most rural dwellers in Nigeria because it could be powered with batteries when there is power failure. Radio communication is one of the fastest, most powerful and the most popular used means of communication with the rural farmers. It defeats obstacles faced by extension workers (Okeke et *al,* 2015). Research institutes with 2.3% as formal source of information is an indication that researchers had little contact with artisanal fishers. This is not encouraging because researchers are supposed to disseminate findings to the end users who should benefit from their findings.

Table 1: Formal sources of information among artisanal fishers

Variable	Frequency	Percentage
Extension agents	17	7.9
Research Institutes	5	2.3
Radio and Television	56	26.6
Print	26	12.1
No response	117	51.6
Total	215	100

Source: Field Survey, 2017

Table 2 showed that 61.4% respondents contacted artisanal fishers as their informal source of information, 48.4% through personal experience and 29.8% through friends. Information sourcing is usually easier among people of same profession while personal experience overtime could assist an artisan as information source which could help in taken right decision on the profession for maximum productivity. If dissemination of information is effective, information made available to artisanal fishermen will spread like wide fire to all colleagues to enable them improve on their production rate as well as maintain adequate fish supply to the citizens.

Table 2: Informal sources of information artisanal fishers

Variable	Yes		No	
	Frequency	Percentage	Frequency	Percentage
Personal experience	104	48.4	111	51.6
Contacting fishermen	132	61.4	83	38.6
Customers	4	1.9	211	98.1
Friends	64	29.8	151	70.2
Neighbors	12	5.6	203	94.4
Total	215	100	215	100

Source: Field Survey, 2017

Purchase of fish inputs (61.9%), more catches (36.7%) and prevents fish spoilage (21.9%) are major benefits of information gathered by the respondents. Efficiency in production is determined to a large extent on the input available which is dependent on right source of information for its availability. An artisan makes more money through more catches when available information source is accurate and timely. The level of fish spoilage can be greatly reduced with adequate information source on various methods of its prevention.

Table 3: Benefits of information gathered by the respondents

Variable	Benefited		Not benefited	
	Frequency	**Percentage**	**Frequency**	**Percentage**
More Catches	79	36.7	136	63.3
More Income	5	2.3	210	97.7
Marketing	12	5.6	203	94.4
Improve my hygiene	23	10.7	192	89.3
Safety on water	5	2.3	210	97.7
Control of water weed	3	1.4	212	98.6
Prevents fish spoilage	47	21.9	168	78.1
Purchase of fish inputs	133	61.9	82	38.1
Business expansion	6	2.8	209	97.2
Relationship with government	3	1.4	212	98.6
Relationship with NGO	26	12.1	189	87.9

Source: Field Survey, 2017

Inadequate extension agents (67.0%), language barrier (48.8%) and wrong timing of information dissemination (25.1%) were indicated by the respondents as constraints to information sourcing among the respondents in table 4. Extension agents are responsible for the dissemination of research findings to the artisanal fishers; they actually serve as link between the researchers, government and artisans. Whenever this link is weak it affects the production capacity of the end users because is either technology is not made available, wrongly adopted or abandoned which causes a major setback to development. Effectiveness of information lies in the audience ability to understand the message to be passed across in an understandable language. Ability of extension agents to speak the local language improves the acceptability of extension agents as source of information to the end users as they are better able to relate in their local dialect or common language (Ogunremi, *et al*, 2015). Wrong timing of information dissemination would hinder proper planning by artisanal fishers. Statrasts (2004) opined that the characteristics of a good information source are relevance, timelessness, accuracy, cost effectiveness, reliability, usability, exhaustiveness and aggregation level. Access to the right information at the right time in the right format and from the right source may shift the balance between success and failure of the farmer (Opara, 2008).

Table 4: Constraints to information sourcing among the respondents

Variable	Constraints		Not constraints	
	Freq.	**percentage**	**Freq.**	**percentage**
Illiteracy	46	21.4	169	78.6
Language barrier	105	48.8	110	51.2
Extortion from government agencies	7	3.3	208	96.7
Wrong timing of information dissemination	54	25.1	161	74.9
Inadequate extension agents	144	67.0	71	33.0
lack of contact with researchers	39	18.1	176	81.9
Inadequate mobility of extension agents	1	0.5	214	99.5
Distance of community	0	0.0	215	100

Source: Field Survey, 2017

Conclusion

Artisanal fishers indicated radio and television as formal sources of information; fishermen were contacted as their informal source of information and friends. Purchase of fish inputs and more catches are benefits of information sources. Inadequate extension agents and language barrier are constraints to information sources. The study therefore recommends that various information sources should be strengthened by government for effective dissemination to artisanal fishers and employs more extension agents who would be effective in communicating in local language understood by the artisanal fishers.

Abstract
The study sought to assess the impact of adoption of Sesame production technologies on farmers crop yield among rural farmers in Niger State of Nigeria. Primary data were obtained from the sesame farmers in the state. The total sample size for the study was 245 respondents selected through stratified simple random sampling technique from the three agricultural zones. Primary data were obtained by means of structured questionnaire administered to the respondents. The result was analysed using descriptive statistics like frequency distribution and percentages in respect to farmers' characteristics. The paired sample student t-test was used to analyse test of significant difference in crop yield of before and after adoption. The results revealed that (85.7 %) of the respondents were men, also (60.4 %) of the respondents had between 21-40 years age bracket. The study showed that (43.7 %) of the respondents had household size ≤5 persons with mean of 8. The results of the t-test showed significant difference between crop yield of before and after adoption, the calculated t-value= -6.817 was significant at 5 % level of significance. Based on the results, it is recommended that farmers should be provided with credit and loans to enable them carry out farm work in large scale and government should create more markets to make sale of farm produce easier especially in the rural areas.

Introduction
Sesame is an important crop in Nigerian agriculture which is quite extensively cultivated. It yields in relatively poor climatic conditions and widely used within Nigeria and is an important component of Nigeria's agricultural exports. As a small holder crop, often intercropped with others, the extent of cultivation is poorly known and there is little information on yields or productivity (Abu *et al*., 2012). Beniseed (*Sesame indicum*) belongs to the family *Pedaliacea*. It is commonly called Beniseed in Nigeria. The tiny spherical seeds are edible, having milky flowering flavor. It is an important oil seed believed to have originated from tropical Africa with the greatest diversity (Raw Material Research and Development Council, 2004). Beniseed is a staple food among many ethnic groups in Nigeria and it is cultivated in most areas of the middle belt and some northern States of Nigeria (Olanyanju*et al*., 2006). The Seeds are consumed fresh, dried, fried or when blended with sugar. It is also used as a paste in some local soups. Agricultural research findings meant for farmers' adoption are designed to primarily improve farmers' yield. Study of experts (Agbarevo and Obinne, 2009) have shown that adoption of improved crop production technologies not only significantly improved resource-poor farmers' crop yield but also led to increased farmers' income, which enabled farmers to increase the purchase of production inputs. The fact is that many potential innovations emanating from research do not make it, but those that succeed can have an enormous impact. The broad objective of the study was to analyze the impact of adoption of Sesame production technologies on farmer's crop yield in Niger State, Nigeria.

Methodology

The study was conducted in Niger State, Nigeria. Niger State is divided into 25 Local Government Areas with three agricultural Zones which include Zone A (Bida), Zone B (Kuta) and Zone C (Kontagora) where each Zone is marked with a climate pattern and a defined agricultural system (Nmadu*et al*., 2012). The population of Niger State, Nigeria for 2006 census figure is 3, 954, 772, with a population density of 57 people per square kilometer (Niger State Government, 2011). Agriculture is the backbone of Niger State's economy: 85 % of the population depends either directly or indirectly on it for their livelihood, while others constituting (15 %) are involved in occupations such as white collar jobs, business, craft and arts. Crops grown in the State include cereals (guinea corn, millet, maize and rice), grains and legumes (cowpeas and bambara nuts), root and tubers (yam, cassava and potatoes), oil seeds and nuts (soya beans, sheanuts, groundnut and sesame), fruits (mango, orange, banana, melon, cashew and guava) and fibers (cotton and kenaf). Natural and mineral resources found in the state include talc, gold, silica, marble, copper, iron, lead, granite and limestone. The State is a key source of hydroelectric power, with three dams located at Kainji, Jebba and Shiroro (Niger State Government, 2011).

Data Collection Techniques

Data for this study were collected from primary source. Primary data were collected using a well-structured questionnaire. Trained enumerators who understand and speak the native language were employed in the collection of primary data. The enumerators guided the literate farmers in filling the questionnaire, while the illiterate farmers were asked questions in the questionnaire and answers filled by the enumerators.

Data Analysis Techniques/ Hypothesis Testing

Data for this study were subjected to both descriptive and inferential statistics. Frequencies, percentages and student t-test was used for analyses.

Results and Discussion

Socio-Economic Characteristics of Farmers

Evidence from the descriptive analysis of socio-economic characteristics of respondents in Table 1 showed that majority (85.7 %) of the respondents were males, while (14.3 %) of them were females. This indicates the dominance of males in beniseed production in the study area, which could be due to the tedious nature of farm work that requires enormous strength and energy. This result is consistent with the work of Agwu *et al* (2008) who reported that majority (81.5 %) of the farmers were males in their study. Majority (60.4 %) of the respondents were between 21-40 years old, while (29.4%) were between 41-60 years with mean of about 37years, indicating that most farmers were young and strong. The analysis of the data on the level of education of respondents showed that 42.0 % had no formal education, about 28.2 % had 6-12 years of education while 17.1% and 12.7% had 1-6 years and ≥ 12 years of education, respectively, with mean of about 6 years, implying that farmers in the study area had moderate educational attainment to enable them read and understand extension bulletins. Higher educational level will facilitate the adoption of appropriate agricultural technologies and skills by farmers (Ugbajah and Ugwumba, 2013). The results further showed that 43.7% of the respondents had household size ≤5 persons, while 28.6 % had household size of 6-10 persons with mean of 8persons. This implies that labor force can be sourced within the household. Household size in traditional agriculture determines the availability of labor and level of production (Ani *et al.,* 2004). Majority (72.7 %) of them had farm size ≥ 3.1 hectares of land with mean of 6ha, implying that land area used by farmers in the study area is reasonably large that will enable them to carry out large scale farming that will increase their productivity level. This result is in contrary with the findings of Agwu, *et al.* (2008) who reported that most of the farmers in the country cultivate below 2 hectares.

Table1: Socio-Economic Characteristics of Respondents

Variables	Frequency	%	Mean	Min.	Max.
Sex					
Male	210	85.7			
Female	35	14.3			
Total	245	100			
Age (yrs.)					
≤20	21	8.6			
21-40	148	60.4			
41-60	72	29.4			
≥60	4	1.6			
Total	245	100	37	10	68
Level of formal education (yrs.)					
0	103	42.0			
1-6	42	17.1			
7-12	69	28.2

Impact of Adoption of Sesame (NCRIBEN) Production Technologies on Crop Yield

The results in Table 2 showed the paired samples t-test analysis performed to test the impact of adoption of improved agricultural technologies on farmers' crop yield. Crop yield before and after adoption of sesame production technologies were used to test if there was a significant difference among them. The result showed that there was a significant difference in crop yield of farmers before and after adoption. The calculated t-value= -6.817 was significant at 5 % level thus, the null Hypothesis (Ho) was rejected. This implies that farmers crop yield increases as a result of adopting sesame (NCRIBEN) production technologies, indicating that technologies adoption has positive impact on farmers' livelihood as income from sale of crop can be used to purchase other goods needed by farmers. This result is consistent with the findings of Afolabi (2008) who reported that use of improved agricultural technologies lead to increase in crop yield.

Table 2: The Impact of Sesame (NCRIBEN) Production Technologies on Farmers' Crop Yield using the Paired Samples Student T – Test Statistics Model

	Paired Differences							
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference		T	Df	Sig. (2-tailed)
				Lower	Upper			
Yield before adoption – Yield after adoption	-3.6988	8.4755	.5426	-4.7675	-2.6300	-6.817	243	.000

Source: Computed from field survey, (2016) , t- value -6.817 is significant at 5 % level, df = 24, 2-tailed test

Conclusion

In conclusion, the adoption of sesame (NCRIBEN) production technologies by farmers leads to increase in farm output, In other words, income of farmers increases as a result of adopting the improved technologies introduced in the study area whereby resulting to improved social well-being of the rural farmers. Adoption of improved agricultural technology is unquestionably a means of increasing farm output. Based on the results, it is recommended that farmers should be provided with credit and loans to enable them carry out farm work in large scale and government should create more markets to make sale of farm produce easier especially in the rural areas.

The Role of Date Palm in the Livelihood of Farmers in Jigawa State, Nigeria

B. Adakaren, R.A. Abu and Q.E Osemwegie
Nigerian Institute for Oil Palm Research (NIFOR), Benin City, Edo State
Email: aburamanu@yahoo.com

Abstract
Date fruit (gotten from the Date palm) trade is an important economic activity for many tropical rural areas of the arid and desert regions of the world. In West Africa, date fruit holds high socio-cultural and traditional values. Farmers (traders) hawking date fruits in wheel barrows and on trays are a common sight in Northern Nigeria. The study thus attempted to explore the effect of date fruit marketing on the livelihood of farmers in Jigawa State, Nigeria, in year 2017. Structured questionnaire was used to collect primary data from 82 randomly selected respondents from the study area. Secondary data was collected from relevant literatures. Data was analyzed by means of descriptive statistics. The results of the study showed that a high percentage of the respondents were married (90%) males (96%) above 30 years of age (84%). All of them were of the Muslim faith (100%) and a fair number of them had western education (64%). Although the respondents had a good grasp of their trade, (82% of them had up to 6 years of experience in date fruit marketing), the farmers were relatively poor with farm holdings of not more than 5 acres (82%) and an annual income of not more than N200 000 (87%). As a result, 67% of the respondents had other sources of income to help carter for their large family size of above 5 persons (84%). Among the important problems of date farmers/marketers include; pest/diseases and low shelf life of the fruit (52% each) and poor financial condition of the farmers (50%). Nigerian Institute for Oil Palm Research (NIFOR) through its sub-station in Dutse has released improved date palm planting materials to farmers and helped in educating and encouraging farmers to cultivate the crop. The date palm has so many applications both health wise and nutritionally, yet its potentials are highly underutilized in Nigeria giving rise to poor performance of farmers in the sector.
Keywords: Date palm, Livelihood, Marketing, Farmers, Concentrated and Sparsely

Introduction
Phoenix dactylifera, commonly known as date palm is a diploid, perennial, dioeciously and monocotyledonous flowering plant species in the family, Arecaceae. It is cultivated for its edible sweet fruit. Although its place of origin is not quite known, it is generally believed to have originated from Iraq (Morton,1987; Khushk et al, 2009; Ata et el, 2014). The date palm is an important economic tree crop that thrives in arid/desert regions of the world, including the Northern parts of Nigeria (Jigawa, Zamfara, Kastina, Borno, Sokoto, Kano, Bauchi, Yobe, Plateau, etc). It is interesting to note that there are more than 199 different types of date fruits, yet they are all very nutritious and have lots of vitamins (A, B and D) and sugar (fructose) which makes them a great source of nutrient and energy (Divya, 2015; El-Sohaimy &Hafez, 2010). The date fruit can be consumed fresh, dry, pitted and candied, in sweet dishes, savory dishes and cookies, wines, syrups, animal feeds, etc. Nutritionally, dates contain natural fiber and lots of other nutrients like oil, calcium, magnesium and more (Al-Gboori & Krepl, 2010). Health experts said dates are easily digestible and contain simple sugars like glucose, fructose and dextrose which are sources of instant energy. Dates are also rich in ingestible fiber which makes them a good laxative for the treatment of constipation (Al-gboori & Krepl, 2010). The Nigerian Institute for Oil Palm Research, (NIFOR), a Research Institute established in 1939 near Benin City with the mandate of researching into the genetic improvement of its mandate crops (oil palm, coconut palm, Raphia palm and date palm and recently other crops like Shea and jojoba), improvement in their methods of cultivation and ways of tapping their vast potentials has released improved elite date palms to farmers. Date palm provides food, shelter, timber, income and employment to

farmers. Dates are major food sources and income for local populations in the Middle East and North Africa, and play significant roles in their economies. In Nigeria, date palm is of great socio-economic importance as it provides a wide range of products and services to the populace, especially the local people (Anon, 2005; Mahmoudi *et. el*, 2008). In addition to serving directly as food sources, dates are packed and processed in a number of ways, and other parts of the tree are used for various purposes in both households and commercial settings and these provide substantial returns to farmers (Anon, 2005; Hassan *et. el*, 2006). The study therefore, attempts to investigate the effect of date palm production and marketing in the livelihood of farmers in Jigawa (a highly concentrated date palm growing area) and Plateau (a sparsely concentrated date palm growing area) States of Nigeria. However, due to financial limitation, the study was limited to Jigawa State. The study is fueled by the research gap on the effect of date palm production and marketing in the livelihoods of farmers in Jigawa State, Nigeria.

Methodology

The study was conducted in Jigawa State of Nigeria. The choice of the State was based on the premise that it is one of the date palm concentrated states in Nigeria and it is also where the NIFOR Sub-Station for date palm research and production is established. The presence of the Research Institute in the State; has greatly improved the awareness of the importance of date palm in Northern Nigeria as well as help promote its cultivation in the country. Jigawa is a State in North Central Nigeria. Its capital City is Dutse. Multistage random sampling technique was used in selecting respondents for the study. This was to ensure that the selection of respondents was unbiased and a true representative of the population. In the first stage selection, Jigawa State was purposively selected because it was one of the densely populated dates growing States in Nigeria added to the fact that NIFOR's date palm sub-station is located in the State capital. A total of hundred (100) date farmers were randomly selected for the study. Pre-tested structured questionnaires were used to source primary data from respondents while scientific journals and other related articles were used for secondary data collection. However, of the hundred (100) questionnaires administered, only ninety (90) were successfully retrieved while eighty two (82) questionnaires were correctly filled. Data was analyzed by means of descriptive statistics and gross margin analysis.

Results and Discussion

Socio-Economic Characteristics of farmers

Sex

The sex distribution of the respondents (Table 1) indicated that about 96% of the respondents were male implying that the business of farming and marketing of date fruits was largely reserved and dominated by males in the study area. The tediousness of a farm process coupled with the cultural and/or religious settings of a particular group of people help to determine the gender distribution of its citizens in relation to a given task.

Table1: Sex Distribution of the Respondents

Sex	Frequency	Percentage
Male	79	96.3
Female	3	3.6
Total	**82**	**99.9**

Source: Field survey, 2017

Age

It is generally believed that with increase in age, an individual becomes mentally mature and takes rational decisions. The age of the respondents is as shown in Table .

Table 2: Age of Respondents

Age of respondents	Frequency	Percentage
Young (up to 30)	13	15.8
Middle aged (31-50)	39	47.5
Old (above 50)	30	36.5
Total	**82**	**99.8**

Source: Field survey, 2017

The age distribution of the farmers show that about 48% of them were middle aged, followed by 37% elderly (old) farmers and the least percentage was the young farmers (16%). This result is similar to those of Salman (2009) and Abbas (2010), that most farmers belong to the middle age and old age group. Invariably, the business of farming and marketing of date fruits is for matured adults who can initiate and execute business plans and actions. They are able to take decisions that are well guided based on past experiences and not on impose as younger people.

Marital Status

Table 3 above showed that less than 10% of the farmers were single while about 90% of them were married implying that the farmers were responsibly and had a high capacity to access and adopt productive innovations that would increase their productivity in other to support their families and provide their basic needs. This refers to any of the distinct options that describes a person's relationship with a significant other. It could be married, single, divorced, separated or widowed (Wesbster Learner's Dictionary). According to Adesope *et. al.* (2012), the marital status of a farmer is an indicator of the responsibility of the farmer and his ability to access information sources for proven agricultural innovations to be adopted for long term sustainability.

Table 3: Marital Status of the Respondents

Marital Status	Frequency	Percentage
Married	74	90.2
Single	8	9.7
Widowed	0	0
Separated	0	0
Divorced	0	0
Total	**82**	**99.9**

Source: Field survey, 2017

Religion

The result of the religious distribution of the respondents is as shown in Table 4 above is quite unique because all (100%) the respondents turned out to be Muslims. This observation could be attributed to the fact that the predominant religion in Jigawa State is Islam and date fruit is widely consumed by Muslims especially during their Ramadan fast (Al-Gboori, 2010). Religion varies from place to place and from tribe to tribe. Over time, religion has played an important role in the selection of food, dressing, occupation and association of people and gender related activities. Religion of a given people therefore affects their cultural, social and economic activities.

Table 4: Distribution of Respondents according to Religion

Religion	Frequency	Percentage
Christian	0	0
Muslim	82	100
Traditional	0	0
Total	**82**	**100**

Source: Field survey, 2017

Education

The result (Table 5) shows that the majority of the farmers had access to western education, followed by about 59% of them with Arabic education. It should be noted however, that most of these farmers had training in both western education and Arabic schooling hence the multiple responses. Regrettably, about 2% of the farmers were illiterates. The implication of this result is that a greater percentage of the respondents would readily adopt any new and innovative agricultural practices released by Research Institutes and recommended by extension workers. Education is an aggregate of all the process of learning to bring about change in the behavior of an individual. It expands knowledge thereby giving an individual the ability to be analytical and logical towards issues. Many studies have shown that education especially formal education plays a significant role in the adoption process of recommended agricultural practices. Education of a person is crucial for his food security and better livelihood (Kim and Wade, 2005).

Table 5: Distribution of Respondents according to their educational level

Type of education	Frequency	Percentage
Non (illiterate)	2	2.4
Arabic	48*	58.5
Western (formal training)	53*	64
Total	**108***	**125.5**

* = Multiple responses
Source: Field survey, 2017

Farmers farm size

The study revealed that 82% of the farmers were relatively poor with farm holdings of less than 6 acres (Table 6). This was followed by 12% with holdings of 6 to 10 acres. Only 6% of the respondents had above 10 acres of farmlands. This result is in accordance with that of Badar et al. (2007) and Ata et. el. (2014), who stated that majority of farmers, especially in developing countries, are poor and have small land holdings. This result, therefore, suggests that the respondents may not readily access agricultural innovations nor have the will power to take huge giant steps into the unknown by forsaking their forefathers' method of farming for latest trends in agricultural technology as suggested by the study of Salman (2009). The size of farm holding of a farmer refers to the piece of land cultivated by the farmer. It is often assumed that farmers with large farm sizes are richer and quicker in taking risks of adoption of new farming technologies as well as have better access to information on improved farming techniques than farmers with lesser acreages of farmland (Salman, 2009).

Table 6: Distribution of Land Holding (acres)

Total Area	Frequency	Percentage
Up to 5	67	81.7
6-10	10	12.1
11-15	2	2.4
16-20	1	1.2
Above 20	2	2.4
Total	**82**	**99.8**

Source: Field survey, 2017

Annual Income

Table 7 shows that, majority (61%) of the respondents had an annual income of up to a hundred thousand naira (₦100 000). Twenty six percent of them earned a yearly income in the range of a ₦100 000 to ₦200 000. While only 13% of them had a yearly income above two hundred thousand naira. This result suggests that majority (87%) of date palm farmers in the study area were relatively poor (with an annual income of not more than ₦200 000) given the hearse economic situation of the country (inflation) coupled with the exchange rate of a dollar to the Naira in the tune of $1 to ₦350. This observation is in consonance with those of Salman (2009) and Raza (2010), that, most farmers in developing world are small scale and poor, earning little above a hundred thousand naira yearly. The overall income of a farmer earned during a given year is referred to as his annual income for that year. The more income earned by a farmer, the more he is able to expand his business frontier without necessarily venturing into other fields of trade as suggested by Badar et. el. (2007) and the World Bank (2010).

Table 7: Distribution of farmers according to annual income (₦)

Annual income	Frequency	Percentage
Up 100 000	50	60.9
100 001-200 000	21	25.6
200 001-300 000	5	6.0
Above 300 000	6	7.3
Total	82	99.8

Source: Field survey, 2017

Sources of Income

Table 8, showed that 67% of the respondents had other sources of income to augment what they get from their date trade. The implication of this is that the income from date marketing is not sufficient to carter for the financial needs of the farmers. The few (32%) respondents who had no other means of income other than their date farm, probably, had large farm sizes and may be using improved farm technologies to increase their yearly output, hence, earn more income to sustain them and their families. Salman (2009) and Raza (2010), observed that, most farmers in developing world are small scale and poor, earning little above a hundred thousand naira yearly. Therefore, most of these rural farmers prefer to diversify their sources of income to improve on their income.

Table 8: Respondents Sources of Income

Sources of income	**Frequency**	**Percentage**
Have only one source of income (date marketing)	27	32
Have other sources of income (besides date marketing)	55	67
Total	**82**	**99.9**

Source: Field survey, 2017

Family Size

The distribution of the respondents according to household size as shown in Table 9 indicated that a great percentage (84%) of them had very large household of above 5 persons while only a negligible percentage (16%) had household size of 1-5 persons. This result stresses the need of the respondents to be more productive through diversification of income sources in other for them to be able to meet up with their family needs. Family size of the respondents is an important indicator that influences livelihood and labor force of the farmer. Generally, the larger a farm family size, the poorer the farm household due to more mouths to feed, educate, and carter for. On the other hand, the larger a farm household, the greater the labour force available to work on the farm, hence more output before the law of diminishing returns sets in.

Table 9: family size

Household Size	Frequency	Percentage
1-5	13	15.8
6-10	30	36.5
11-15	22	26.8

Respondents Years of Date Palm Farming

The years of experience of the respondents in the business of date farming and marketing in the study area showed that the highest percentage (45%) of them had between 6-10 years of experience, while about 43% of them had above 10 years farming experience (Table 10). The observation implied that the respondents were well vested in the intricacies of date fruit production and marketing. It therefore followed that with the high number of their years of experience and their high educational back ground, they would be assumed to make good informed decisions concerning their business. The longer the length of time spent on a skill, the better the understanding of the workings and applications of the skill. Studies have shown that working experience augments and compliments paper qualification. It is therefore essential that farmers improve their skill by increasing their years of experience on the job.

Table 10: Respondents Years of Date Palm Farming Experience

Years	Frequency	Percentage
1-5	10	12.1
6-10	37	45.1

Varity of Date Fruit Farmed/Marketed

The most popular date fruits variety sold in Jigawa State include the Dan Agadez, Dan Mali and the Dan Hausa. The Dan Agadez and Dan Mali are imported from Niger Republic and Mali respectively, while the Dan Hausa is indigenous to Nigeria. Dan Hausa has about five different species which include: zabia which is big in size and looks like the Saudi Arabian Ajhuwan date. It is sweet and full of fiber but expensive (it is believed to be of high quality). Farin Dabino has small seed, full of fiber and second to zabia in quality while Takanda is big in size and somewhat greenish at ripened stage (it is believed to be lower in quality). Loko is the sweetest amongst them all. It is soft, moist and has a small seed while Kaju is yet specie with two different formations at a ripened stage. One end dries up while the other side looks yellowish and full of moisture (very low quality).

Table 11: Variety of Date Farmed/Sold by the Respondents

Variety	Frequency	Percentage
Dan Hausa	82	100
Dan Agadez	5	6.0
Dan Mali	15	18.2
Total	**125***	**151.8***

*multiple responses
Source: Field survey, 2017

The responses of the farmers and marketers of date fruit in the study area is as shown in Table 11. All the respondents (100%) traded in Dan Hausa, while, a negligible few, (6% and 18%), still traded Dan Agadez and Dan Mali respectively. This is most probably because the demand for Dan Hausa is higher because it is maggot free, soft and full of fiber; resulting in higher price per unit sold. The rapid growth of date in Northern Nigeria is reducing the mass importation of Dan Agadez and Dan Mali. The release of Dan Hausa by NIFOR sub-station in Jigawa State has helped to conserve the national income as well as provide healthier food for the populace in the stead of popular Dan Agadez and Dan Mali that are usually imported as consignments with one form of maggot or the other due to long periods of storage. At present Dan Hausa is also competing with dates from Saudi Arabia (Ajhuwan date). This is because the Dan Hausa enjoys a comparative advantage over the imported dates of being softer, full of fiber and most importantly free of maggots whereas the imported dates are hard to crack and chew and are also maggot infested.

Planting Season

Table 12 showed that only 72 out of 82 respondents responded to this particular question. All (100%) the respondents as shown in Table 12 above agreed that the best planting time for date palm in the study area was at the onset of the rains. There was however a disagreement concerning the peak season for date as about 41% of the respondents said it was abundant during the rains while more than 58% of them were of the opinion that the date fruit was most abundant during the dry season. Also, about 65% of them were of the believe that the lean season for date was during the dry season, while about 35% believed otherwise. In conclusion however, it was gathered that there are different species of date palm and their peak and lean seasons may vary according to seasonal changes.

Table 12: Best Planting Season for Date in Jigawa State

	Raining Season		Dry Season	
Season	**Frequency**	**Percentage**	**Frequency**	**Percentage**
Best planting period	72	100	0	0
Peak season	30	41.6	42	58.3
Lean season	25	34.7	47	65.2
Total	**127**	**176.3**	**89**	**123.5**

Table 13: Age of Date Palm at Maturity

Age Range (years)	Frequency	Percentage
1-5	31	37.8
6-10	41	50.0
11-15	10	12.1
Above 15	0	0
Total	**82**	**99.9**

Source: Field survey, 2017

Fifty percent of the respondents were of the opinion that it takes between 6-10 years for the date palm to start fruiting while about 38% of them believed that the palm can start bearing even within the first five years of planting (Table 13). Again this may be dependent on the variety of the date palm planted.

The Table above (Table 14) showed that the greatest problems of date farmers/marketers include; pest/diseases (52%), low shelf life of the fruit (52%) and poor financial condition of the farmers (50%). These are very critical since apart from reduction of value of the dates harvested due to pests and disease attack, the value of the dates further reduces due to spoilage as a result of its low shelf life affecting even more the poor financial situation of the farmers. It is no wonder then that a substantial number of the farmers/marketers source for from other sources (Table 8). From Table 14 above, accessibility of loans from Banks seemed to be another constraint to the farmers/marketers (43%). The implication of this is that the farmers remained subsistent with little room for expansion.

Table 14: Major Constraints/Challenges Faced by the Farmers/Marketers

Constraint	Frequency	Percentage
Access to loan	36	43.9
Pests/diseases	43	52.4
Low shelf life of date fruit	43	52.4
Poor finances	41	50.0
Lack of inputs	13	15.8
Total	**176***	**214.5***

*= Multiple responses
Source: Field survey, 2017

Conclusion

Date palm is a multipurpose tree that provides job, food, shelter, timber, raw materials for industries and income to farmers as well as has a great potential to add to the foreign exchange earnings of the country if its potentials are fully harnessed. The Date palm is thus an important economic tree that fortunately strives well in the central and Northern parts of Nigeria given that the tree thrives in arid and desert regions best. The study showed that Date palm farming and marketing in Jigawa State is not a new phenomenon as many farmers were already into its cultivation. The usage of a wide range of both commercial and household date palm products in the study area was found which indicates the considerable role of date palm in sustainable livelihoods of farmers. However, low shelf life, disease/pest infestation and poor financial backing of farmers were among the bottleneck of the farmers. The presence of the Research Institute for Oil Palm Research (NIFOR) Sub-Station in Dutse has not only helped to improve on the genetics and breed of the Date palm planting materials but also helped to popularize the fruit and its uses.

Use of Information and Communication Technologies (ICTs) in Enhancing Cassava Production for Food Security in Ogba/Egbema/Ndoni Local Government Area of Rivers State

U.G. Ogunu – Ebiye
Department of Agricultural Education, School of Secondary Education (Vocational), Federal College of Education (Technical), P.M.B 11, Omoku, Rivers State.
E-mail: fridayuloma@yahoo.com

Abstract
This study focused on the use of information and communication technologies (ICTs) in enhancing cassava production for food security in Ogba/Egbema/Ndoni Local Government Area of Rivers State. Two specific objectives guided the study and two research questions were developed in agreement with the objectives. Survey design was adopted for the study. The population for the study was all the cassava farmers in the five agricultural zones in the state. A simple random technique was used to select twenty (20) respondents from each of the zones giving a sample size of 100. Instrument for data collection was structured questionnaire, which was validated by a peer review of research validates in the Department of Agricultural Education, Federal College of Education (Technical), Omoku. The researcher and two research assistants administered the questionnaire and the data collected was analyzed using weighted means. The findings from the study revealed that most cassava farmers do not have android, windows phones, tablets, and palm top etc. Most cassava farmers cannot go to cyber café for information, do not have their e-mail address, are not familiar with internet facilities and cannot make use of these ICTs facilities. It was recommended that government should provide ICTs facilities in the rural areas especially in Ogba/Egbema/Ndoni Local Government Area since it is one of the basic blocks for food production in the state.

Keywords: Cassava, food security, information, communication, technology and production.

Introduction
Generally, agriculture is an information-intensive industry. It relies upon continues flow of information from local, regional and world market (Akinbibe and Alabi, 2011). Information and communication technologies (ICTs) are new technologies that cannot be ignored in Africa especially for development in all sectors, agriculture inclusive. This is because (ICTs) is one of the main driving forces that can bring about development and change in this present digital age (Olaniyi, Adetumbi and Adereti, 2013). The recent development in ICTs has broken national and international barriers and turned the world into a global village, making information available to everyone, everywhere and at any time it's needed (Onasanya, Shehu, Ogurilade and Adefuje, 2011). ICTs are technologies that facilitate communication, processing and storing of information through electronic means. ICTs can also play important role in bringing about sustainable cassava development when use to document both modern and traditional cultivation practices. There are still very serious limitations in (ICTs) application, particularly in the study area despite world–wide ICTs revolution, these limitation according to Arokoyo (2011), includes; low level of ICT readiness, poor ICTs infrastructures, erratic and unstable power supply, limited and high cost of telephone service, limited access to computers and internet , lack of communication policy by Government, high level of rural poverty, high level of illiteracy etc. given, the urgent need for current agricultural knowledge and information system (AKIS) by cassava farmers in Ogba/Egbema/Ndoni Local Government Area, the use of farm radio, home visit and contact farmers for extension information delivery is counterproductive. These therefore, calls for the

use of (ICTs) by cassava farmers in the study area because Nigeria remains the world leader in cassava production with the annual output ranging from 30 to 40,000,000 metric tons which production is in the hands of small scale farmers. Cassava production has increased over the years because of its multifarious uses as starch rich root (Karim, Fasasi and Oyeyinka, 2008). Cassava production has been transformed from being a staple food to a source of income as well (Olaniyi, *et. al,* 2013). In submission of Erhabor and Emokaro (2007).

There has been tremendous increase in the current cassava output in Nigeria in order to meet the increasing demand both locally and internationally. In the light of the above, Adekanye, Ogunjimi and Ajala (2013) and Okune, Shittu, Olarewaju, Tolorunju and Afolabi (2004), succinctly opined that cassava production activities have the potential to improve the nation's economy as Nigeria has been consistently ranked as the world's facilitating largest producer. Increasing cassava farmer's productivity and income will require the development of appropriate technology through research and the transfer of research output through extension systems (Abalu, 1998). Promoting productivity among cassava farmers is therefore essential for national growth and food security in Nigeria. This is because how far farmers progress in whatever they do depends largely on the awareness, accessibility, utilization and relevance to accurate and reliable information. However, there is still dearth of knowledge and information and new technologies in agriculture that is yet to be exploited in the study area. Therefore, access to such new information is a crucial requirement for sustainable agricultural development especially in cassava industry as the 'wheel' of economic activities since it facilitates the economic growth and food security (Balderam, 2009). This study has no doubt that, despite the world-wide (ICTs) revolution, there are still very serious limitations in (ICTs) application and utilization in Ogba/Egbema/Ndoni Local Government Area. It was on this note that the study was designed to investigate the use of information communication technologies (ICTs) in enhancing cassava production for food security in Ogba/Egbema/Ndoni Local Government Area of Rivers State. The objective of the study was to ascertain the level of (ICTs) awareness among the cassava farmers in the study area and identify the constraints to the utilization of (ICTs) by the cassava farmers in ONELGA.

Methodology

This study adopted survey design; questionnaire was used to collect data from respondents which findings were generalized upon the entire population. The population of the study was all the cassava farmers in the five agricultural zones in the state. A simple random technique was used to select twenty (20) farmers from each zone which gave a total sample size of 100. The instrument used for data collection was structured questionnaire which was constructed on a 4 – point measuring scale of strongly agree (SA) = 4, Agree (A) = 3, Disagree (DA) = 2 and Strongly Disagree (SDA) = 1. The questionnaire was validated by a peer review of research validates in Department of Agricultural Education, Federal College of Education (Technical), Omoku. The questionnaire was administered to the farmers by the researcher and two research assistants. The rationale of using research assistants was to ensure easiness of administration and collection. The data collected was analyzed using weighted mean. Mean equal or above 2.50 was accepted while mean below 2.50 was rejected.

Results and Discussion

The result in Table 1, item 1 showed a mean score of 1.90 which implies that most cassava farmers do not have Android, Window Phones, Tablets, Palm Top etc. Item 2 with the mean score of 2.09 showed that cassava farmers do not go to cyber café for information. Item 3 showed that most of the cassava farmers do not have their e-mail addresses with the mean score of 2.10. Item 4 gave a mean score of 1.71 which implies that Cassava farmers are not familiar with internet facilities. Finally, the data in item 5 showed that cassava farmers cannot make use of these ICT facilities with the mean score of 1.94. Thus, it is accepted that cassava farmers in the study area do not have the awareness of ICT facilities regarding their cassava production. The findings is supported by Arokoyo (2011), stated that despite the importance of ICTs to agriculture, rural farmers in Nigeria, including cassava farmers have not been able to substantially adopt them to increase productivity. Reasons advanced for this scenario include; farmers not been familiar with internet, non ownership of ICT facilities by some farmers, low level of ICT readiness, poor ICT infrastructure, erratic and unstable power supply, limited and high cost of telephone services, limited access to computers and internet facilities, lack of communication policy by government, high level of rural poverty, high level of illiteracy, policy inconsistency and commercialization of radio stations, among others.

Table 1: Mean responses on the level of ICTs awareness among cassava farmers in the study area

S/N	Items	SA	A	D	SDA	Total	$\bar{x}$	Decision
1.	Most cassava farmers have Android, window phones, tablets, palm top etc.	10	15	30	45	100	1.90	Rejected
2.	Cassava farmers go to cyber café for information	11	18	40	31	100	2.09	Rejected
3.	Most of the cassava farmers have their e-mail addresses	12	13	48	27	100	2.10	Rejected
4.	Cassava farmers are familiar with internet facilities	9	12	20	59	100	1.71	Rejected
5.	Cassava farmers can make use of these ICT facilities	12	14	30	44	100	1.94	Rejected

Sources: Field survey, 2018

The result in table 2, item 6 with the mean score of 3.07 revealed that most cassava farmers cannot access ICTs facilities on their own, item 7 with the mean score of 1.50 shows that electricity is a problem to ICTs utilization, item 8 with the mean score of 3.54, indicated that most cassava farmers cannot access ICTs because of the high cost, item 9 with mean score of 3.41 showed that most cassava farmers have no knowledge of ICTs in their production, item 10 revealed that most cassava farmers do not have interest in ICTs with mean score of 3.53, while item 11 with mean score of 3.42 revealed that most cassava farmers are illiterate and do not know about the relevance of ICTs to their farming business. Finally, item 12 revealed that high cost of leaving is a bearer to ICTs usage to cassava production with the mean score of 3.61. The result is in line with the report of Bertolini (2004), who had earlier observed that several obstacles hinder ICTs usage in developing countries, especially in area of accessing (ICTs) facilities and illiteracy. Therefore, a lot has to be done in order to incorporate ICTs utilization in agriculture in the study area.

Table 2: Mean responses on the constraints to the utilization of ICTs among the cassava farmers in the study area

S/N								
6.	Most cassava farmers cannot access ICTs facilities on their own	39	35	20	6	100	3.07	Accepted
7.	Electricity is a problem to ICTs utilization	1	0	47	52	100	1.50	Rejected
8.	Most cassava farmers cannot access ICTs because of high cost of facilitiess	62	30	8	-	100	3.54	Accepted
9.	Most cassava farmers have no knowledge of ICTs in their production	60	26	9	5	100	3.41	Accepted
10.	Most cassava farmers do not have interest in ICTs	60	33	7	-	100	3.53	Accepted
11.	Most cassava farmers are illiterate and do not know about the relevance of ICTs to their farming business	54	35	10	1	100	3.42	Accepted
12.	High cost of living is a barrier to ICT usage in cassava production.	70	21	9	-	100	3.61	Accepted

Source: Field survey, 2018

Conclusion

Based on the findings of the study, it could be concluded that the level of ICTs awareness of cassava farmers in the study area is very low. The use of ICTs facilities is not encouraging in the study area because of this, the relevance of these facilities are not felt by the cassava farmers. Also illiteracy, high cost of facilities and cost of high living standard are problems that need to be addressed if cassava production is to be sustained in the study area. Government should therefore help to provide ICTs facilities in the rural areas which are the basic block of food production in the country in order to achieve food security. Rural training on the use of ICTs should be made available and affordable to the cassava farmers in the study area. There should be new techniques and methods of cassava production through seminars, television and radio to enable cassava farmers participate and practice new innovations for food security in the country. Power supply should be stable and made to reach the rural area which is the hallmark of food production for better living standard.

Constraints to Youth Participation in Agricultural Enterprises in the Central Agricultural Zone of Nasarawa State, Nigeria

[1]S.A. Bako; [1]E.S. Salau and [2]J.E. Cyril
[1]Nasarawa State University Keffi, Faculty of Agriculture, Shabu-Lafia Campus.
[2]Akwa Ibom State Agency for Community and Social Development Programme, Uyo
sanibakoadamu@gmail.com

Abstract
The study examined the constraints to youth participation in agricultural enterprises in the Central Agricultural Zone of Nasarawa State, Nigeria. The broad objective was to examine the factors limiting youth participation in agricultural enterprises in the study area. Multistage sampling procedure was used to select 120 youths as study sample. Questionnaire was used to elicit information from the respondents. Data were analyzed with descriptive statistics such as percentages, mean scores and ranking. Results show that majority (60.8%) of the respondents were males; majority (94.2%) were within the ages of 21 - 40 years; mean age of the respondents was 30 years. Most (85.8%) of them had one level of formal education or the other. Their average year of farming experience was 11years. The mean farm size of respondents was 5hectares while the mean annual income was N402, 250.00. The predominant agricultural enterprises undertaken by the respondents were- crop farming, livestock farming, farm produce processing and marketing. The major constraints to youth participation in agricultural enterprises were inadequate capital (86.7%), inadequate credit facilities (70.0%) and high cost of farm inputs (65.8%). It was recommended that agricultural credit facilities should be made more flexible to young people who want to go into agricultural enterprises.

Introduction
Agriculture remains fundamental to poverty reduction and economic growth in the 21st century since 75% of the world's poor live in rural areas involved in farming (World Bank, 2008). In Nigeria agriculture provides about 40% of the Gross Domestic Product (GDP) as well as employment and income to 70% of the rural population. Specifically, agriculture provides food for the people, raw materials for the industries and foreign exchange for the country (Olarenwaju, 2010). Youths have been differently defined by various authors worldwide. According to the Nigeria National Youth Development Policy (NYDP, 2009), a youth is described as any person between the age of 18 and 35 years. This stratum of the Nigeria population make up 80 percent of the total population and constitute about 76 percent of the agricultural labour force. Agricultural enterprise refers to small scale agriculture and other agro-business activities undertaken by individuals in order to earn a living. Agricultural enterprises include: crop farming, livestock farming, fish farming, agricultural produce marketing, feed production, agricultural produce processing, horticultural production, poultry production, and agro-chemical inputs sales among others (Afande *et al.,*2015). Youths are the successor farming generation and therefore the future of food security in Nigeria. The ageing smallholder farmers are less likely to adopt the new technologies needed to sustainably increase agricultural productivity hence the need to encourage youth participation in agricultural enterprises. A lot of agricultural enterprises abound in Nasarawa state that can provide gainful employment opportunities for the teaming youths and yet many of the rural youths are still unemployed. There is also general youth apathy towards agricultural enterprises. The need to scientifically assess the reasons behind this youth apathy to agriculture in the state is the knowledge gap this study seeks to fill. The purpose of this study is to identify the constraints to youth participation in agricultural enterprises in the Central Agricultural Zone of Nasarawa State, Nigeria.

Methodology

The study was conducted in the central agricultural zone of Nasarawa state, Nigeria. The Central agricultural zone comprises of four (4) Local Government Areas (LGAs) namely; Akwanga, Nasarawa Eggon, Wamba and Kokona. A multi-stage sampling procedure was used to select a sample of 120 respondents from three (3) LGAs within the agricultural zone namely Akwanga, Kokona and Nasarawa- Eggon. Method of data collection was through the use of a structured questionnaire. Data were analyzed using descriptive statistics such as percentages, mean scores and ranking.

Results and Discussion

Socio-economic characteristics of the respondents

Table 1 shows the distribution of the respondents according to their socioeconomic characteristics. Majority (94.2%) of them were within the age range of 21-40 years. The mean age of the respondents was 30 years. This implies that the respondents were very young and energetic people who can undertake agricultural tasks. Adebayo (2009)) in a study titled "Constraints to Participation in Income Generating Enterprises among Youths" in Birnin Gwari LGA, Kaduna State, Nigeria revealed that most of the youths are expected to be energetic, hence their commitment to participation in the development of agriculture and other income generating activities.

Also, majority (60.8%) of the respondents were males while 39.2% were females. This implies that males participated in agricultural enterprises more than females in the study area. This may be due to the drudgery associated with agricultural enterprises. Table 1 also shows that 31.6%, 30.0% and 24.2% of the respondents had tertiary, secondary and primary education respectively while only 14.2% of them had no formal education. This implies that most (85.8%) of the respondents had some form of formal education. Formal education can influence decision making concerning agricultural enterprises. This finding is in agreement with that of Amaza *et al.,* (2009) who reported that a greater percentage of the youth in Southern Borno State, Nigeria who participate in agriculture (93.64%) had some form of formal educations. They opined that formal education would help youth to use the production and technical information efficiently and to also learn new things within a short period of time. On their contact with Extension, the results in Table 1 show that majority (75.0%) of the respondents did not have access to extension service while only 25.0% had contact with extension agents. This implies that extension contact which is supposed to be one of the main sources of agricultural information/ technologies was insufficient in the study area. This may negatively affect their level of participation in agricultural enterprises. This finding is similar to that of Bello *et al.,* (2014) who reported that only 35.0% of the youth involved in rice production in Lafia LGA of Nasarawa State had access to extension services. Results in Table 1 also show that majority (75.0%) of the respondents did not have access to credit while only 25.0% were able to obtain loan. This shows that the respondents were incapacitated by inadequate finance to invest in agricultural enterprises. This would result in low scale of production, low output and also low income and therefore perpetual poverty. Majority (60.8%) of the respondents had 1-10 years of experience in agricultural enterprises. The mean year of farming experience of the respondents was 11 years. This implies that most respondents had some level of experience in agricultural enterprises in the study area. According to Salau *et al.,* (2013), experience is very important because it enhances managerial capability of an entrepreneur. The longer the years of farming experience the higher the farm management skills. Majority (65.8%) of respondents had annual income level of between N1,000 - N300,000:00 followed by 18.4% who earned between N301,000:00-N600,000:00 annually while 15.8% of respondents earned above N600,000:00. The mean annual income of the respondents was N402, 250.0 This implies that youths in the study area earned low income. Agbamu (2006) noted that it is not always easy to determine the level of income of Nigerian farmers because some of them do not keep records while others are skeptical about disclosing their income.

Table 1: Socio-economic characteristics of the respondents (n=120)

Variable	Frequency	Percentage (%)
Age (years)		
1-20	7	5.8
21-40	113	94.2
Sex		
Male	73	60.8

Types of Agricultural Enterprises

The results in Table 2 show the distribution of respondents based on types of enterprises undertaken. Majority (67.5%) were into crop production, 64.2% in livestock production and 49.2% were into agricultural produce marketing. This implies that youths in the area were involved in various agricultural enterprises as a source of livelihood.

Table: 2. Types of Agricultural Enterprises

Types of Agricultural Enterprises	Percentage (%)	Ranking
Crop production	67.5	1st
Livestock production	64.2	2nd
Agric produce marketing	49.2	3rd
Agro processing	14.2	4th
Horticultural (seedlings)production	3.3	5th
Fish farming	1.7	6th
Agric inputs marketing	0.8	7th

Constraints to Youth Participation in Agricultural Enterprises

Results in Table 3 show the constraints facing youths' participation in agricultural enterprises in the study area. These include inadequate capital (86.7%); poor access to credit (70.0%) and high cost of farm inputs (65.8%) among others. This implies that youth were faced with several constraints that reduce their participation in agricultural enterprises. Thomas, (2014) in his study "Determinants of Participation in Youth-in-Agriculture Programme" in Ondo State, Nigeria also identified the major constraints facing agricultural enterprises to include inadequate capital;

inadequate skilled personnel, poor infrastructure such as transport, processing, storage and marketing facilities among others.

Table: 3. Constraints to Youth Participation in Agricultural Enterprises

Constraints	Percentage (%)	Ranking
Inadequate capital to set up enterprise(s)	86.7	1st
Inadequate credit facilities	70.0	2nd
High cost of farm inputs such as fertilizer, pesticides, seeds, etc	65.8	3rd
Lack of good physical infrastructure for easy transportation of the farm produce to the store.	58.8	4th
Inadequate technical skills	52.2	5th
Unfavourable government policies	50.0	6th

Source; field survey 2018
Multiple responses

Conclusion

The study has revealed that youth in the central agricultural zone of Nasarawa state were involved in three major agricultural enterprises namely crop production, livestock production and agricultural produce marketing. However, they faced some major constraints such as inadequate capital, poor access to credit and high cost of farm inputs among others. It was recommended that governments at all levels should provide more incentives such as credit facilities, subsidized farm inputs and capacity training for youth in agriculture to enhance higher productivity and profit.

Gender Differentials in Decision-Making among Ginger Farmers for Sustainable Rural Households in Abia and Imo States Nigeria

M.E. Ejechi, T.U. Madu and M. Mazza
National Root Crops Research Institute Umudike, P.M.B 7006 Umuahia Abia State, Nigeria
Email: mercyebele655@gmail.com

Abstract
This study investigated gender differentials of decision-making on ginger production for sustainable rural households in Abia and Imo States, Nigeria. Multi-stage sampling technique was used to select 60 ginger farmers for the study. Data was collected by means of interview schedule with focus group discussion and analysis done using frequency tables and Pearson chi-square. The result of Pearson chi-square revealed that Area of ginger cultivated by male and female farmer is significantly different at 10% level of probability. Also, decision on ginger production, use of labour, other input and participation in farm operation were significantly different at 1% level of probability each in favour of male farmers. This implies that men take major decision in all the activities involved in ginger production. Major constraints found to militate against ginger production in the study area are Lack of funds and unavailability of planting materials. Based on the study findings, it is recommended that farmers especially female ones should be empowered financially (giving them more access to resources and farm inputs) and awareness of men on gender issues should be intensified and given utmost priority in the study area. Also, enforcement of laws and regulations at the local level to stop cattle from damaging ginger crops.
Keywords: Gender, Decision-making and Ginger production

Introduction
Gender is a sociological concept that tends to differentiate the characteristics, qualities, roles and activities of men and women. The roles are socially defined and are based on traditions, culture and beliefs of a particular group of people at a time in a particular place (Ngome, 2003). Gender differentiation in decision making among farmers families is a sex-role differential which explains the differences in the role of men and women. Gender has been demonstrated to permeate the different aspect of production and life in the agricultural settings of various countries and cultures. Traditionally, men are known to be heads of households in African setting, but certain studies of social and economic trends suggest significant increase in the number of households headed or principally maintained by women in rural areas of many developing countries (Folbre,1991). Male heads of households controls farm resources and labour, it seems logical that women engage in a formal sector work primarily because they need the additional income to sustain themselves and their families. Women are frequently neglected in economic, trade and development policies and planning because of socio-historical patterns in regard to gender based division of labour. The role of women is generally associated with non-economic and unpaid work, most of which take place within the so-called reproductive economy. However, it is the reproductive economy that supplies labour and social capital to the economy and transmits social and cultural values to communities even when such a contribution is not registered in systems of national accounts. Men and women in rural areas and throughout the world have a role to play in ginger production since both contribute to the efficiency and effectiveness of the farming. Ginger (*Zingiber officinale*) is a rhizome, which consist of numerous short finger-like structures or branches born horizontally near the surface of the soil. It belongs to the family of *Zingiberaceae*. It is a slender perennial plant with thick and branched underground stem (rhizome). Two commercial varieties are commonly cultivated in Nigeria. The yellow ginger variety locally called "TafinGiwa" is stout with short internodes. The black ginger

variety locally called "YatsunBiri" has a dull-grey colour rhizome. The yellow variety is more popular than the black variety apparently due to its high yielding capacity and pungency. Ginger is a spice and root crop grown as cash crop in Nigeria, mostly grown in the southern part of Kaduna State (Northern Nigeria) for export. Ginger is not only an income earner for individual farmers, it is as well a foreign exchange earner for the country, and the dried products are the major forms of which ginger is traded internationally. It also has various uses, which ranges from been used as spices in soups, confectionaries, zingiberone (anti-helmintic) from *Zingiber officinale*, *oloresine* are among the extracts used for medicinal purposes (Mallam, 2011). Fresh ginger is consumed as vegetable. Ginger powder is used in making ginger beer, wine, and baked foods. The essential oil obtained from ginger is used in the food and perfume industries. Ginger offers a substantial protection from stroke and heart attack because of its ability to prevent blood clotting and a multifaceted herb, crucial in the battle against cardiovascular diseases such as bowels and kidney diseases, respiratory system, colds and flu, headache, pains, stomach upsets and as well helps to clear sore throats. This study focused on gender differentials of decision-making on ginger producing households which according to Koppelman and French (Ijere,1992) is the level at which all farm decisions are made. Decisions have to be made when persons having limited resources have alternative course of action and therefore must make some choice (Oji, 2002).

Farmers make decisions on a number of pre-harvest and postharvest activities such as what to produce, input use, harvest and post-harvest issues, which according to William (2003) affect production, processing, distribution, prices and costs. Farming decisions are made to maximize farm objectives subject to available material and human resources. In all farm operations planning, farm decision is always at the core of farm management functions (Akibu, 2002). Women are key players in the Nigerian agricultural sector, especially within rural communities. They contribute between 40 and 65% of all hours spent in agricultural production and processing and also undertake 60 to 90% of the rural agricultural product marketing, thus providing more than two thirds of the workforce in agriculture (Sabo, 2006). However, despite the significant role played by women in agricultural production, processing and marketing in Nigeria (Barasa, 2006; Nweke & Enete, 1999) available literature show that men have continued to dominate farm decision making, even in areas where women are the largest providers of farm labour (Amaechina, 2002; Anyanwu & Agu,1996 & Mosha ,1992). Women have more or less been relegated to playing second fiddle in farm decision making. This could be counterproductive, because, there is bound to be conflict when women, as key players, carry out these farm tasks without being part of the decision process, especially when the decisions fail to recognize their other peculiar household responsibilities. Previous efforts at estimating women's role in agriculture have tended to concentrate on evaluating their labour contributions (Barasa., 2006; Enete., Nweke. & Tollens ,2002; FAO,1995). There has been little or no farm-level information regarding their role in farm decision-making, particularly in male dominated cash crop environment like ginger households in Abia and Imo states, Nigeria, this necessitated the study.

Methodology

Multi stage sampling techniques was used for the study. In the first stage, one local government area each was randomly selected from two ginger producing states, Abia and Imo states namely Isialangwa south from Abia and Ngor-okpala from Imo state. In the second stage, four communities from Abia state that are noted for ginger production were purposively selected they are isieketa, Uvokwu, Ngwobi and Umuojima efere. Two communities in Imo namely Nnorie and Logara were also purposively selected. Four communities were purposively selected in Abia state unlike two in Imo state because of the predominance of more ginger farmers in Abia state. In the third stage, 10 ginger farmers were randomly selected from the six communities, of the two states, making a total of sixty ginger farmers selected as respondents. Data were collected with the use of structured interview schedule and focus group discussion. Analysis of data was done using descriptive and inferential statistics.

Results and Discussion

Table 1 showed Pearson chi-square test of Involvement of male and female respondents in ginger production in the study area. The result revealed that Area of ginger cultivated by male and female farmer is significantly different at 10% level of probability which implies that there is significant difference between men involvement in ginger production than women. Men involvement in ginger farming is higher than female. Also decision on ginger production, use of labour and other input and participation in farm operation were significantly different at 1% level of probability each in favour of male farmers. This infers also that there is significant difference between men involvement in ginger production than women. This finding may be explained with the reasoning, that probably the cost of rhizome seed and other inputs for ginger production per hectare is higher than other crops cultivated in the areas, thereby making it difficult for women to acquire sufficient quantities for production due to lack of funding. Table 2 highlighted different constraints to ginger production in the study area; The result indicated that both male and female ginger farmers reported same problems such as lack of funds (26% for male and 9% for female farmers) which is the major constraint hindering ginger production in the study area. This is so because fund is important to enhance access to inputs and marketing costs like storage and transportation. It agrees with findings of Nasiru, (2010) who noted that availability of funds could have prospect in improving the productivity of farmers and contributing to uplifting the livelihoods of disadvantaged rural farming communities. This was followed by unavailability of planting materials which constituted (11 and 11%) for both gender groups while unavailability of agricultural credit and lack of extension personnel were not major constraint to ginger production in the study area. The result of the focus group discussion discovered that some farmers also see ginger as a weed in their farm, in that case, they do not maintain it well, the farmers itemized some recommendations for improvement of ginger in the study area to include provision of adequate fund by government to procure the planting materials and farm inputs such as fertilizer and herbicides and to stop cattle from damaging their ginger farms.

Unavailability of planting materials	11	11	22
Lack of Funds	26	9	35
Unavailability of agric credit	2	0	2
Lack of Extension Personnel	0	1	1
Total	**39**	**21`**	**60**

Conclusion

It is clearly indicative that there is gender inequity in decision-making among the ginger farming households surveyed. The findings of this study revealed that women are still not actively being involved in decision making as their male counterparts and this however has some effects on ginger production in the study area. The reason(s) for inactive participation of women could be linked to the gender inequity in resource allocation and asset acquisition. Lack of funds and unavailability of planting materials are found to be major constraints facing ginger production, it was therefore recommended that farmers should be empowered especially female ones financially (giving them more access to resources and farm inputs) and awareness of men on gender issues should be intensified and given utmost priority in the study area.

Abstract
This study assessed youth empowerment programmes and its implication towards community development in Ahoada East Local Government Area, Rivers State, Nigeria. Simple random sampling was used to select 60 youths from Ahoada central, Ula-upata, and Ogbele communities in the Local Government Area. Data were collected using validated structured questionnaire and interview schedule. Descriptive statistic including percentage and mean score were used for analysis. Majority 60.0% of the youths were male, 65.0% of them were singles, 93.0% were literates whereas 43.3% of them were farmers. The following youths empowerment programmes were perceived by youths as being very effective: Need for Power (N-power) ($\bar{x} = 3.25$), Igbu upata football competition ($\bar{x}$ =2.98), Niger Delta Petroleum Resources bursary ($\bar{x}$ =2.90). The youths had high level participation in NDDC skill acquisition ($\bar{x}$ = 2.76), youth initiative for sustainable agriculture ($\bar{x}$ = 2.71). The major challenges in youth empowerment programmes were: poor political will power($\bar{x}$ = 2.98), Inadequate infrastructural facilities ($\bar{x}$ =2.85). Based on the findings of this study, it was recommended that government should empower youths with effective programmes for sustainable livelihood in their communities.
Keywords: Youth, empowerment programmes and community development

Introduction
Empowerment programme is an initiative instituted to be of positive action oriented to enhance community development. Community programmes over the years have been viewed as a means of reaching out to individuals including youth in any given locality. Since youths are active, energetic and mostly in the majority; through empowerment programmes, they could identify their areas of interest, skills potentials and transform them into desired actions for potential developed. The youths through skilled empowerment programmes such as agricultural agri-business, fish farming, and poultry keeping self-sustainable. They will become employer of labour, foot their bills, manage their homes and become responsible members of their community. In agricultural production, there are lots of natural resources when put into use among the youths could make them very productive (AGRA, 2017). Youth programs when planned to their needs, potentially could counter youth risky behaviours (Ajani, Mgbenka, Onah, 2015). This can be achieved through constructive opportunities, teaching the fundamental principles and skills needed to help young people become responsible, empowered, and productive citizens. Developing countries have been faced with rise in population, food insecurity, unemployment poverty and hunger (Ajani, 2015). These have resulted to less focus on matters concerning youth empowerment and livelihood. In some areas where these programmes were established, much attention has not been paid to the benefits of the youths. Nonetheless, therefore there is need for empowerment programmes to be established based on the needs and concerns of the individuals it is meant to serve. This study aimed to assess youth empowerment programmes and implications for community development in Ahoada East Local Government Area (LGA) of Rivers State, Nigeria.

Methodology

This study adopted Ahoada East one of the 23 Local Government Area of Rivers as the place of interest in this study. The state is located in the southern region of Nigeria between latitude 40◦ 22′E and 7◦ 55′ (NPC, 2006). The population of the study comprised all youth in the various communities in the LGA. In selection of the sample, simple random sampling was used in selecting 3 (Ahoada central, Ula-upata, and Ogbele) communities in the Local Government Area. Twenty (20) youths were randomly selected from each of the selected communities; this gave a total of 60 youths (i.e. 20x3=60). Interview and structured questionnaire were used to obtain data from respondents. Descriptive statistics such as frequency, mean, and percentage were used for data analysis.

Results and Discussion

Socio-economic analysis of the respondents

Table 1 shows that majority (60%) of the respondents were males. This suggests that males are mostly targeted than females in youth empowerment programmes due to their strength and energy. About (41.7%) of the youths are young and below the age of 30. This reveals their interest, independence and commitment in community development. Marital status reveals that greater proportion (65.0%) of the respondents were single. This implies that the respondents need to be empowered to be self-sustainable. Majority (51.7%) of the respondents attained secondary education, whereas 6.7% of them had no formal education. Results show that (53.3%) of the respondents household range was 6-10, while 6.7% had 16 and above. This implies that most of the respondents are from large families who depend on each other on feeding and shelter. About (43.3%) of the respondents were engaged in farming, while 11.7% of them were civil servants. This suggests that the youths depend on agriculture for their empowerment.

Socio-economic analysis of the respondents

Variables	Frequency	Percentage (%)	Mean ($\overline{X}$)

Effectiveness of youth empowerment programme in Ahoada East LGA

Table 2 shows that nine (9) out of the 15 youth empowerment programmes were perceived by the respondents as functioning very effective, while N-power ($\bar{x}$ = 3.25) had the highest mean. This suggests that N-power contribute very effectively in empowerment programmes.

Table 2: Effectiveness of youth empowerment programme as perceived by the respondents

Variables	**Mean$(\overline{X})$**
Youth initiative for sustainable agriculture	2.80
N-power	3.25
NDDC skill acquisition	2.56
Igbuupata football competition	2.98
Ekpeye wrestling competition	2.41

Level of Youth participation in employment programmes in Ahoada East LGA

Entries in Table 3 shows the respondents always participated in four programmes out of 7. The respondents had high level of participation in programmes such as youth initiative for sustainable agriculture ($\bar{x} = 2.71$), NDDC skill acquisition ($\bar{x} = 2.76$), Igbuupata football competition ($\bar{x} = 2.50$) and Ekpeye wrestling competition ($\bar{x} = 2.55$).

Table 3: level of participation in youth empowerment programmes

Programmes	Mean$(\overline{X})$
Youth initiative for sustainable agriculture	2.71
N-power	1.68
NDDC skill acquisition	2.76
Igbuupata football competition	2.50
Ekpeye wrestling competition	2.55
Young Entrepreneurship Nigeria	1.45
Graduate Internship Scheme	1.53

Challenges of youth empowerment programmes in Ahoada East LGA

Entries in Table 4 reveal that 10 items out of 12 were perceived by the respondents as challenges of youth empowerment programme. These include poor political will power ($\bar{x}$ = 2.98) which was highly perceived by the respondents as constraints in youth empowerment programmes. This implies that inadequate physical structures and facilities might limit the impact of development efforts.

Table 4: Challenges of youth empowerment programmes as perceived by the respondents

Youth Empowerment Programmes	Mean $(\overline{X})$
Favoritism (" man know man")	2.70
Corruption	2.75
Access to loan	1.55
Poor publicity of the empowerment programme	2.63

Conclusion

It is evident that the youths are involved in sustainable agriculture programmes which were community based initiatives such Niger Delta Development Community skill acquisition. The N-power was considered very effective as youth empowerment programmes. Social infrastructure is a prerequisite to ensure for successful youth empowerment programme, though poor political will-power and inadequate infrastructural facilities were major constraints in youth empowerment programmes. There is need to adopt effective strategy to ensure full participation of youths by concerned actors. Challenges such as poor programme framework, inadequate, funding, nepotism and corruption should urgently be addressed by the programme donors and sponsors.

Abstract
Farmers indigeonus knowledge practices for conserving cassava in South Eastern Nigeria was assayed. A sample size of 480 respondents were randomly selected from Abia, Akwa Ibom and Ebonyi States. Structured interview schedule was used to elicit information from the respondents, which were analysed using descriptive statistics. The result showed that 61.5% of the respondents were males, with mean age of 26 years. Based on local conservation traits, 56.2% of the respondents conserve varieties by maintaining favoured varieties. As regards roles played by each group in conserving the materials, 47.0% of the respondents had no idea of who was actually responsible for this amongst the men, women and youths. Based on the findings, farmers' prefrred method(s) of conservation should be improved upon, given thoughts to complementary methods for maximum utilization of the resource materials.
Keywords: Cassava, Indigenous knowledge, and Conservation

Introduction
Cassava is a staple food for most Nigerians and is known as the energy giving food par excellence, given that it could provide most of the body's daily energy requirement. Cassava (*Manihot esculenta* Crantz*)* is important not just as a subsistence or food security crop, but also as a main source of cash income for producing households (Bainbridge *et al,* 1997). Cassava has the ability to adapt to marginal soils, including drought stress and produces reasonably well comparatively to other crops in marginal environments with low rainfall (El-Sharkawy, 2005), climatic factors resulting to drought-high temperature, high wind and low relative humidity. Cassava is a perennial crop and has bulking duration which ranges from 8 weeks after planting to 24 months after planting, which makes it a suitable crop for drought prone regions of the world. Plant breeders select genotypes/varieties with genetic potentials for high vigour, resistant to pests and diseases, good root size, number of roots, high dry matter content *et cetera*. In addition, cassava with high protein content, beta carotene content, starch, dry matter content, delayed shelf life of roots, are some traits farmers and end-users are looking for in Nigeria (Njoku *et al,* 2015). Agricultural practices are inextricably woven into broader traditions, customs and wisdom among humankinds enterprise. There is need for scholars to sit back and re-assess the evolution of agricultural practices in order to align them with current environmental realities and the quest for agricultural sustainability. Indigenous knowledge (traditional wisdom) is a key to sustainable rural development in Nigeria. In 1993, the United Nations declared that year as a year of indigenous people to attest to the importance of traditional technological endowment in sustainable rural development. Warren (1991) and Flavier (1995) defined indigenous knowledge as "the local knowledge that is unique to a given culture or society." The basic component of any country's knowledge system is its indigenous knowledge. It encompasses the skills, experience and insights of people applied to maintain or improve their livelihood. Indigenous knowledge is developed and adapted continuously to gradually changing environments and passed down from generation to generation and closely interwoven with peoples cultural values. Cassava genetic resources can be conserved either *in situ* or *ex situ*, or a combination of the different methods used in a complementary way. Disadvantages in one method used (for example, risks of diseases

and loss through other natural factors in the field gene bank) are compensated for by the benefits of another, example, the relatives security of *in vitro* conservation. Farmers have a lot of underutilized information as a result of long experience with cassava cultivation. These include characteristics of adaptation, resistance, morphology quality or a number of traits that may not become apparent to a researcher, even after standardized evaluations. Cassava which is widespread in the area of study has a variety of uses which emphasizes the need for conservation of crops.Genetic erosion is anticipated due to the replacement of landraces by improved cultivars produced by research (Allem and Hahn, 1991). Farmers indigenous conservation practices in this study are of essence. This paper reports the results of a survey conducted to document farmers` indigenous practices for cassava conservation in S.E. Nigeria.

Methodology

The study area was south-east agro-ecological zone of Nigeria with Abia, Akwa-Ibom and Ebonyi States purposively chosen.These States represent each from the mangrove swamp(Akwa-Ibom) rainforest (Abia) and the derived savannah(Ebonyi), where cassava is a major crop of the farming system of the people.-A sample size of 480 respondents were randomly selected from the study area.Two agricultural zones were randomly selected from each of the states in the first stage-Umuahia and Ohafia zones from Abia, Eket and Oron in Akwa-Ibom and Ebonyi South (Afikpo) and Ebonyi North (Abakaliki) from Ebonyi. Two blocks were randomly selected in each zone, while four circles were randomly selected from each block. Finally, ten cassava farmers were randomly selected from each circle giving a sample size of 160 respondants per state. Listing of correspondants was through the guidance of Extension Agents in-charge of the selected circles. Data were collected through the use of structural questionaires. Data collected were analysed by the use of frequencies, percentages and means.

Results and Disscussion

The distribution of respondents according to sex, age, farming experience and educational attainment are as indicated in Table one. About 61.5% of the respondents were males. The dominant participation of males maybe attributted to their access to land, information and other production resources more than their female counterpart. The mean age of the respondents was 26years with 38.5% in the age range of 41-50years, while 51-60 constituted 28.8%. The ages of farmers are important in determining participation in innovation (Nwaru, 2004). The age bracket of 41-50years indicates that majority of the respondents were middle aged farmers who were still active and more likely to adopt innovation better and faster than their elderly counterparts who may be conservative to try new techniques (Gul, Unal, 2008). The farming experience was 20.6% for 26-30years, 20.0% for $\geq$ 31years. The mean farming experience was 13.6years indicating that a good number of new people are embracing agriculture. farmers experience can generate or erode confidence. Educational attainment from the table shows that 32.0% of the respondents had primary school education, while 12.7% had none. Differences in educational attainment definitely will affect farmers' perception and efficiency in technology use. Educated farmers are more receptive to change than others in seeking information as particularly such information as they can obtain from extension. Table 2 shows the cassava verities planted by the farmers. About 76.0% of the respondent grew both improved varieties and landraces, while 20.5% grew improved varieties only. Certain cassava cultivars are predominantly cultivated in specific areas and farmers' preferences are based on certain characteristics. These characteristics affect farmers' perception and the dynamics of adoption of cassava varieties. Result on Table 3 shows distribution of respondents according to local conservation traits. It shows that 56.2% of the respondents conserved cassava varieties by maintaining favoured varieties while 14.6% and 12.3% were conserved by indigenous production and names respectively. Farmers preferred method(s) of conservation should be improved upon and encouraged viz-a-viz the improved conservation methods. An understanding of farmers' indigenous knowledge and technology is not that easy as indigenous knowledge may be as numerous as sampled farmers. Table 4 shows the roles played by each group in protecting cassava genetics resources. The table shows that 47.0% of the respondents had no idea of who was responsible for protecting cassava genetics resources. However, 25.6% were of the opinion that women were more involved than the men and the youths. Howard (2003) shows how gender relations inform genetic resources management and conservation, and in several cases, women predominate particularly in the management of plant genetic resources.

Conclusion

Farmers' indigenous knowledge practice for conserving cassava in the zone was assayed given the agricultural practices and the people's traditions and customs. Cassava which has diverse uses in the area of study needs to be adequately conserved for maximum utilization of the resource materials. Complementary conservation practice is key to the management of the genetic materials. Farmers and research should complement each other's effort for a sustainable system, adopting on-farm adaptive research and other participatory approaches.

Abstract
The study examined the effect of adoption of National Special Programme on Food Security (NSPFS) extension recommendations on cassava production in South-East, Nigeria. Specifically, it ascertained the level of adoption of NSPFS extension recommendations on cassava production by farmers, and determined the effect of National Special Programme on Food Security on cassava production in the study area. Multi-stage random sampling technique was utilized in selecting three hundred and sixty respondents (comprised 180 NSPFS participants and 180 non-participants) used for the study. Data were obtained with the aid of structured interview schedule and Focus Group Discussion, and analyzed using descriptive and inferential statistics, such as means and Z-test. From the results, grand mean score of 2.31 shows moderate level of adoption of NSPFS extension recommendations on cassava production by farmers in South-East, Nigeria. The findings showed significant difference between cassava yield of participants and non-participants. The National Special Programme on Food Security increased cassava production in South-East, Nigeria. The null hypothesis that the National Special Programme on Food security has not significantly increased yield of cassava was, therefore, rejected, while the alternative hypothesis was accepted. The study therefore recommended that farmers should be sensitized and educated by Government on the importance of adoption of extension recommendations for increased food production, income and enhanced standard of living.
Keywords: Adoption, extension recommendations and cassava production

Introduction
The vast majority of the world's poor lives in rural areas and is engaged in agriculture, therefore activities designed to address the vulnerability of these rural poor are often geared towards improving agricultural practices as a means of increasing productivity, efficiency and ultimately, income (Parvan, 2011). Governments, NGOs, aid agencies and extension workers have long known that the success of any programme or project depends, in part, on whether farmers adopt the offered technologies and, if they do, whether those farmers adopt the technologies in an ideal combination and for the prescribed length of time needed to produce designed results. Adoption refers to a full-scale integration of recommended practices or innovation into the on-going farm operation (Eze, 2005). According to Tokula (2008) adoption of extension recommendation is described as one important process through which systematic social change take place in rural areas. He further observed that at this stage, the individual decides to employ the new practice as not only useful but full impression of satisfaction on the part of the farmer. Adoption does not imply indefinite use of innovation, but the farmer uses the new practice until something else comes up to make him dissatisfied with the innovation. This means that adoption process is that stage when the farmer accepts and integrates the new practice in his farming enterprise and exhibits his sustained decision to practice the technology until otherwise discouraged by new situation. The World Food Summit in a meeting in Rome in 1999 estimated that 790 million people in the developing world do not have enough food to eat (Alamu *et al*., 2005). As a follow up to the summit, Nigeria, one of the 82 Low-Income Food Deficit Countries (LIFDC) requested for assistance under the FAO's National Special Food Security Programme (NSFSP). The National

Special Programme on Food Security (NSPFS) was implemented in a stepwise fashion in Nigeria, starting with pilot activities initially at a few locations, which were progressively scaled up with the aim of gaining pilot experience in all major agro-ecological zones of the country. The pilot phase focused on household and community level food security and livelihood issues, while the first phase tackled these issues at national level so as to open the way for more scaling-up. The first phase was up-scaled into a five-year, nation-wide Special Programme for Food Security (SPFS) between 2002 and 2006, covering the 36 states of the country with a total programme cost of USD 45.2 million exclusively funded by the Federal Government of Nigeria. The nationwide SPFS programme was completed in June 2006 and has already demonstrated very positive impact (Dauda and Ajayi, 2009). Realizing the need to improve small-scale production and sustainable agriculture for food security to reduce hunger rapidly, the government expanded the programme to more sites in each of the 36 states and in Abuja, from 2007 to 2014. At this expansion phase, the programme was renamed National Special Programme on Food Security (NSPFS) in 2007. The implementation of NSPFS in Nigeria was expected to have enhanced adoption of extension recommendations by farmers and improved cassava production in South-East Nigeria, among other objectives. However, the programme with all the laudable objectives ended in 2014, but the level of adoption of its extension recommendations on cassava production is quite unknown, hence this study. Specifically, the study ascertained the level of adoption of NSPFS extension recommendations on cassava production by farmers, and determined the effect of National Special Programme on Food Security on cassava production in the study area.

Methodology

The study was conducted in South-East, Nigeria. The Zone is made up of five states, namely, Abia, Anambra, Ebonyi, Enugu and Imo States. The states in the zone share similar characteristics (NPC, 2006). The zone covers the bulk of the Igbo-speaking ethnic territory or Igboland. The area lies mainly on plains under 200m above sea level. It is bounded on the south by Akwa Ibom and Rivers States, on the east by Cross River State, on the west by River Niger and Delta State, and on the north by Benue State (Monanu, 2000). There were four States that participated in the National Special Programme on Food Security in the zone. Three states namely Ebonyi, Enugu and Imo States were randomly selected from the four States that participated in the programme. Three agricultural zones were purposively selected from each of the selected states. This gave a total of nine agricultural zones. They were Okigwe, Orlu, Owerri in Imo State; Nsukka, Enugu, Awgu in Enugu State; Ebonyi North, Ebonyi Central and Ebonyi South in Ebonyi State. Two blocks were randomly selected from each of the selected agricultural zone; two circles were randomly selected from each of the blocks selected. Five participants of NSPFS were randomly selected from the list of participants in each of the selected circle, while five non-participants were randomly selected from the list of non-participants in the thirty-six selected circles. The lists of farmers were obtained from the respective circle extension agents. A total of Three hundred and sixty respondents were interviewed, comprised 180 NSPFS participants and 180 non-participants. Data were obtained with the aid of structured interview schedule and Focus Group Discussion, and analyzed using descriptive and inferential statistics such as means and Z-test. To determine level of adoption of NSPFS extension recommendations, farmers' responses were categorized into: Never adopted (1point), Adopted and stopped (2 points), Adopted and still using recommendations (3 points). The value assigned to the adoption levels in each technology were calculated thus: 1+2+3 = 6/3 = 2.0. Therefore, a mean score of less than 2.05 is poor/low level of adoption, mean score from 2.05 - 2.5 is moderate level of adoption, while mean score greater than 2.50 is high level of adoption. To determine effect of the NSPFS on cassava production, the null hypothesis that the National Special Programme on Food Security has not significantly increased cassava yield in South-East, Nigeria was tested at 5% level using Z-test. They participants and non-participants indicated their yield per hectare in the last cropping season from cassava production. Mean yield of cassava was computed and used to calculate the Z-test by applying this formula:

$$Z = \frac{\overline{X_1} - \overline{X_2}}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}$$

Where Z = calculated value

$\overline{x_1}$ = Mean yield score of cassava for NSPFS participants
$\overline{x_2}$ = Mean yield score of cassava for non-participants
n_1 = Sample size of NSPFS participants
n_2 = Sample size of non-participants
σ_1^2 = Standard error for NSPFS participants
σ_2^2 = Standard error for non-participants

Results and Discussion

Level of Adoption of NSPFS Extension Recommendations on Cassava by Farmers

The results in Table 1 show the level of adoption of NSPFS extension recommendations for cassava production by farmers. Grand mean score of 2.31 shows that there was moderate level of adoption of NSPFS extension recommendations for cassava production by farmers in South-East, Nigeria.

Table 1: Level of Adoption of NSPFS Extension Recommendations on Cassava by Farmers

	Mean Adoption Scores			
Recommendations	**Imo**	**Enugu**	**Ebonyi**	**Mean ($\bar{x}$)**
Improved Cassava variety production	3.00	2.78	2.78	2.85**
Cassava/Maize/Egusi intercrop	2.73	2. 72	2.80	2.75**
Early planting of cassava	3.00	2.88	2.87	2.92**
Fertilizer application	2.78	2.50	2.35	2.54**
Soil fertility improvement	2.88	2.97	2.95	2.93**
Soil sampling	1.07	1.12	1.07	1.09
Processing	2.95	3.00	3.00	2.98**

Book keeping	1.88	1.37	1.15	1.47
Grand mean	**2.40**	**2.29**	**2.25**	**2.31***

Source: Field Survey, 2016. **High level of adoption, *Moderate level of adoption

Although there was high level of adoption in cassava processing (2.98), soil fertility improvement (2.93), early planting of cassava (2.92), improved cassava variety production (2.85), cassava/maize/egusi intercrop (2.75) and fertilizer application (2.78), while there was low level of adoption of book keeping (1.47), herbicides application (1.25) and soil sampling (1.09) extension recommendations on cassava by farmers. It is expected that high level of adoption of extension recommendations on cassava would lead to increase in cassava production and yield in the study area. This agrees with Agbarevo and Obinne (2009) that there is significant effect of adoption of research and extension recommendations by farmers on the yield of crop.

Effect of NSPFS on Cassava Yield of Farmers

Information in Table 2 shows the effect of NSPFS programme on cassava yield of farmers in South-East, Nigeria. Results show significant difference between cassava yield of participants and non-participants in the zone. The cassava yield of NSPFS participants was 15.69 t/ha, while that of non-participants was 7.50 t/ha. The value of t-calculated is greater than the value of t-tabulated. This implies that the National Special Programme on Food Security increased cassava production in South-East, Nigeria. Hence, the Z-test rejects the null hypothesis that, the National Special Programme on Food security has not significantly increased yield of cassava in the study area, while the alternative hypothesis is accepted at 5% level. This is in agreement with Elemi *et al*. (2015) that the National Special Programme on Food Security increased yield of cassava in Cross River State, Nigeria.

Table 2: Z-test Analysis of Significance of Difference between Cassava Yield of NSPFS Participants and Non-participants

NSPFS	N	Mean	SD	t- tabulated	t-calculated
Participants	180	15.69	2.3069	1.96	1453.61**
Non-participants	180	7.50	1.7158		

Source: Field Survey, 2016. **Significance at 5%

Conclusion

There was moderate level of adoption of NSPFS extension recommendations for cassava production by farmers in South-East, Nigeria. The National Special Programme on Food Security has succeeded in increasing the cassava yield of participants. Hence, it has partly met its mandate of incremental food production, which is geared towards ensuring food security in South-East, Nigeria. The study therefore recommended that farmers should be sensitized and educated by Government on the importance of adoption of extension recommendations for increased food production, income and enhanced standard of living.

Effect of Pesticides and Fertilizers on the Health of Farmers in Akpabuyo Local Government Area, Akwa Ibom State

C.L. Aboh and J.B. Effiong
Department of Agricultural Extension and Rural Sociology, Faculty of Agriculture, Forestry and Wildlife Resources Management, University of Calabar, Cross River State, Nigeria
Corresponding author: johneffiong@yahoo.co.uk.

Abstract
The study assessed the effect of pesticides and fertilizers on the health of farmers in Akpabuyo Local Government Area, Akwa Ibom State, Nigeria. Specifically, the study described the socio-economic characteristics of the respondents, assessed the effect of pesticides and fertilizers on the health of farmers in the study area and identified sources and types of pesticides and fertilizers used on locally grown crops, in the study area. A sample size of 90 respondents was selected through multistage sampling procedure from crop farmers in Akpabuyo Local Government Area. Descriptive statistics such as frequency, percentage, mean scores and rank were used for data analysis. Result of the socio-economic characteristics of the respondents revealed that majority (66.67%) were males. Also, majority had farming experience of 31-40 years (38.89%). Majority (61.11%) assessed land through inheritance, they have 4-5 persons per household (44.44%), cultivated 1-2 hectares of farmland (54.44%) and earned N51,000-80,000 per annum. The results of the effect of pesticides and fertilizers on the health of farmers in the study area showed that fertilizers/pesticides during their application causes headache, dermatitis and conjunctivitis, fever and abdominal pains were ranked (1st, $\bar{X}$ = 4.25), (2nd, $\bar{X}$ = 3.76), (3rd, $\bar{X}$ = 3.50) and (4th, $\bar{X}$= 3.25) respectively, and were The result, also showed that herbicides, insecticides and bactericides ranked (1st, $\bar{X}$ = 3.90), (2nd, $\bar{X}$ = 3.85) and (3rd, $\bar{X}$ = 3.70) respectively, and were the major pesticides available for locally grown crops. The study revealed that poor handling of agro-chemicals during application impacts negatively on the health of farmers by causing headaches, dermatitis/conjunctivitis, fever and abdominal pains. The study recommend that human capacity development should be encourage through the training of farmers on efficient and safe use of agro-chemicals of crop production so as to reduce the undesirable effects/health hazards associated with use of agro-chemicals.
Key words: Effect, pesticides, fertilizers, health and Akpabuyo

Introduction
Agricultural safety and the resulting environmental and health hazards from agro-chemicals are increasingly attracting global attention. Cooper and Dobson (2007), but Effiong and Asikong (2013) and Fleisher (2006) reported that excessive use of chemical fertilizers in developing countries like Nigeria often receive less attention than the use of pesticides. Consequently, its economic and ecological effect can be dramatic and devastating, for instance, Bangladesh today faces severe loss of topsoil fertility from over application of chemical fertilizers and pesticides. Adetunji (2010). Effiong and Effiong (2015) reported that excessive use of certain agro-chemicals has been associated with contamination of ground water with nitrate rendering it unfit for human and livestock consumption by immobilizing some of the haemoglobin in the red blood cells hence reducing the ability to transport oxygen and also causing a problem in the aquatic ecosystem called Eutrophication (a process whereby green algaes develops and grow on the surface of streams, rivers and lakes due to run-off of agricultural fertilizers into them, thus diminishing oxygen content to the detriment of other organisms). It is therefore very important to assess the sources of agro-chemicals used, the perceived effects on production and the level of utilization for sustainable food productivity and security.

Methodology

The study was conducted in Akpabuyo Local Government Area of Cross River State with her headquarters at Ikot Nakanda. Akpabuyo is an agrarian area measuring approximately 28.5km^2 with an estimated population of 360,000 people (NPC, 2006) and its popularly called the "Food Basket" of Cross River State. Akpabuyo has 10 council wards and major languages spoken are Efik and English while the major ethnic groups like Efiks, the Quas and Efuts share a common cultural and ancestral heritage. Akpabuyo is a major producer of cassava, cocoyam, kolanut, coconut, palm produce as well as seafoods. The land is rich in mineral deposits at commercial quantities. A multistage sampling technique was used to select the respondents. At first stage, purposive sampling technique was used to select Akpabuyo as a block. This was because, Akpabuyo is predominantly an agrarian society. The second stage was a random selection of six cells from the block. In the third stage, 15 respondents were randomly selected from each of the selected cells. This produced a sample size of 90 respondents. Data were presented using frequency, percentage, means scores and ranking.

Results and Discussion

Results in Table 1, showed that majority of the respondents (66.67%) were males, while (33.33%) were females. About 27.78% were aged 45-54 years, 44.44% had tertiary education, 77.78% were engaged in mixed farming as a major type of occupation, 38.89% had farming experience of 31-40 years, 54.44% cultivated 1-2 hectares of farmland, 61.11% accessed land by inheritance and 33.33% earned between N51,000-N80,000 per annum. This result corroborates with the findings of Effiong and Asikong (2013) who reported that farmers in Cross River State, Nigeria, accessed land through inheritance and are engaged in mixed farming as a major type of occupation. Table 2 showed the result of sources and types of pesticides and fertilizers used for locally grown crops. The result revealed that herbicides, insecticides and bactericides ranked 1st, $\bar{X}$ = 3.90; 2nd, $\bar{X}$ = 3.85 and 3rd, $\bar{X}$ = 3.70 respectively as the major type of pesticides available for locally grown crops in the study area, while NKP, compost manure and poultry droppings ranked 1st, $\bar{X}$ = 4.11; 2nd, $\bar{X}$ = 3.88 and 3^{rd,} $\bar{\bar{X}}$ = 3.84 respectively as the major type of fertilizers available for locally grown crops. This result corroborates with the findings of Carolyn, (2013) and FAO, (2000) who asserted that application of pesticides and fertilizers increases agricultural productivity and food security hence minimizing hidden hunger phenomenon, malnutrition and malnourishment. Table 3, revealed that headache, dermatitis and fever ranked 1st, $\bar{X}$ = 4.25; 2nd, $\bar{X}$ = 3.76 and 3rd, $\bar{X}$ = 3.50 respectively as the major health hazards caused by pesticide/fertilizers usage by farmers, while allergy to agro-pesticides and fertilizers, dizziness and abdominal pain ranked 6th, $\bar{X}$ = 2.81; 5th, $\bar{X}$ = 3.00 and 4th, $\bar{X}$ = 3.45 respectively and were considered as minor health hazards of pesticide/fertilizer usage by farmers. This result is in line with the findings of Effiong and Effiong (2015) who reported that fertilizer and pesticide application has become a great threat to human health resulting in asthma, and sterility/infertility in couples and environmental degradations.

Conclusion

Farmers in the study area were into mixed farming for about 31-40 years, farm size ranging from 1-2 hectares. Farmers in the study area perceived agrochemicals as being expensive, causes pollution, had adverse effect on human health and environments. The study therefore recommends training and retraining of farmers on efficient and safe use of agrochemicals so as to reduce the likely undesirable effect of agrochemical on famers health.

Abstract
This study was designed to examine determinants of adoption of National Root Crops Research Institute's value added cassava technology by rural farmers in Umuhia North L.G.A. A simple random sampling technique was adopted in selecting 120 rural women farmers. Well-structured questionnaire was used to elicit information from the respondents. The data generated from the survey was analyzed using descriptive statistical tools and lead square (OLS) regression model. The result of the regression analysis showed that variables such as age, household size, years of experience, education, income and membership to cooperative society influenced the adoption of value added cassava technologies. The R^2 was 0.970 meaning that 97% of the variations in adoption in the level of technologies adopted were explained by the included variables. High cost of modern processing facilities was found to be a major factor affecting adoption and it was recommended that government and donor agencies should bring intervention in this area to enhance the livelihood of the rural poor. Also more awareness should be created and credit facilities should be extended to the rural farmers to increase adoption of the cassava value-addition technologies.
Keywords: Adoption, Value addition and Cassava Technology

Introduction
Cassava (*Manihot esculenta*) is acclaimed the most important food crop both in sub-Saharan Africa and the World's at large (Anyiro et al., 2016). Statistics show that Nigeria is the World's largest producer of cassava with an annual production estimated at 39 million metric tons. (NRCRI, 2006). There was a 5 million metric tons growth in the volume of production of cassava between 2003 and 2004. Nigeria has a comparative advantage in cassava production due to her large land mass which supports its production. According to Okogbenin et. al., (2002), About 600 million people in Africa, Asia and Latin America depend majorly on cassava for subsistence probably because it can be processed into many forms. Women engagement in cassava production and processing is very phenomenal. They play major roles starting from planting, weeding, harvesting, processing and marketing. Adebayo, (2009), observed that the uses of cassava keep increasing by the day, for instance it can now be processed into chips, biscuits, alcohol to mention but a few. It is equally an essential raw material to many industries that produce livestock feed, soft drinks, confectionaries etc. Despite the status of cassava as a major staple in the food economy of Nigeria, farmers record huge losses postharvest due to the perishable nature of cassava (Aniedu et al., 2012). This also reduces the shelf life of the crop. Due this development, several technologies aimed at processing and value addition to cassava have been developed and disseminated by research institutions and extension agents (Anyiro, 2016; Nwakor et al., 2011). According to Rogers (2005), adoption is the final stages the innovation diffusion model. It takes place only when the farmers consider the innovation superior to the previous practice or input. According to literature, certain factors such as socioeconomic, demographic and institutional factors influence adoption of value added technologies (). This study therefore seeks to describe the socio-economic characteristics of the respondents and to determine the socioeconomic, demographic and institutional factors that influence the level of adoption of the Cassava value addition technology by the respondents. Finally, it seeks to identify

the constraints to the adoption of the Cassava value addition technology by the respondents in the study area.

Methodology

This study was carried in Umuahia North Local Government Area of Abia State. A multistage sampling technique was employed to select 3 rural communities out of the 35n communities that are aware of the cassava value addition technologies. Secondly, 5 villages were selected from each of the three communities. Finally 8 rural women farmers were randomly selected from the list of women trained by NRCRI, Umudike on value addition to cassava in each of villages selected. This gave a total of 120 respondents in all. Using structured questionnaires, relevant data on determinants of the rural women farmers' adoption of cassava value added technologies were collected from the respondents. Descriptive statistics such as percentages, and frequency distribution and ordinary least square regression model were used to analyze the objectives.

Model Specification

Y = f(X1, X2, X3, X4, X5, X6, X7, X8---e_i)
Where Y= adoption level
X_1= age (Years).
X_2= household size (number of members).
X_3= farming experience (Years).
X_4= education level (Years spent in school).
X_5= level of Income (Naira).
X_6= farm Size (hectares).
X_7= membership to cooperative (1=yes, 0=no).
X_8= access to Credit (1=yes, 0=no)
e_i= stochastic distribution or error term.

Results and Discussion

Socio-Economic characteristics of respondents

The analysis on Table 1 showing the socio-economic characteristics of the rural women cassava farmers, reveal that majority of the respondents (66%) were within 20-39 years of age and 27% of the respondents were 40-59 years of age, while only 3% of the respondents were within 60-82 years of age. This indicates that majority of the respondents were in their active productive age, hence they can effectively engage in manual farm work. This agrees with the findings of Ekong (2003) who noted those young farmers are innovative and can adopt new innovations which increased income of the household. The analysis also reveals that majority of the respondents (79.17%) in the study area were literate with 45.83%, 16.67% and 16.67% of the respondents having received Primary, secondary and tertiary education respectively. However, 20.83% of the rural women cassava farmers did not obtain any formal education. Furthermore, the analysis showed that 50.00% of the respondents had 1-10 years of farming experience, while 37.50%, of the respondents had 11-20 years, of farming experience. It implies that majority of the women farmers were experienced in cassava farming. The experience gained could enable the farmers use their resources prudently and consequently enhance their adoption of value addiction to cassava Nwaru (2004). Table 1.0 further showed that majority (69.20%) of the respondent's belonged to cooperative societies, while 30.80% of the respondents were non-members of the societies. This means that membership to cooperative societies enhanced farmers adoption of the value added cassava technology. It agrees with a-priori expectation. Finally, the analysis revealed that most women farmers depended on household labour more than hired labour as was shown in table 1.0 this could impede production since most of the household members could be unproductive or belong to the dependent group. This agrees with Iheke, (2006).

Table 1: Distribution of Respondents Based on Socio-Economic Characteristics

Variables	Categories	Frequencies	Percentages
Age	20-39	72	60
	40-59	33	27.5

Factors influencing the level of adoption of cassava value added innovations

The OLS regression analysis results for determinants of adoption of NRCRI's value added cassava technologies are shown in Table 2. The double- log functional form was chosen as the lead equation because the R square value was highest at 0.970 indicating that 97% of the observed variations in the resultant output are explained by the included variables. In the model four out of the eight explanatory variables were statistically significant at various levels of probability. The result showed that farming experience (0.078) was positively related to the level of adoption of value-added cassava technologies at 1% level of significance. This implies that level adoption increased with increase in years of experience of the farmers. This agrees with a-priori expectation and was supported by Ironkwe (2010) who opined that increase in years of experience led to increase in the use of new technology. More so, the analysis showed that level education (0.137) had a positive relationship with level of adoption at 1% level of significance. This means that as farmers' level of education increases, the level of adoption also increases. It is in line with a-priori expectation and agrees with the findings of Ironkwe, (2010) and Onuk et al, (2010), which say education enhances adoption. The result also showed that income (2.679E-5) was positively related to the level of adoption of the value- added cassava technologies and was significant at 1% level of probability. This indicates that as income increases, the level of adoption of the innovations will also increase. Again this agrees with a-priori expectation, since most of these value-added technologies are cost intensive. It is also in agreement with Ekong (2003) that confirmed a positive relationship between level of income and adoption of innovations. Furthermore, the result showed that membership to cooperative (1.039) was positively related to the level of adoption of the value- added cassava technologies at 1% level of significance. This implies that as more of the rural women join cooperatives, the more their adoption level increases, this agrees with a prior expectation and agrees with the study of Ekong (2003), who found out that farmers who participated in cooperative tend to adopt agricultural innovation more than those farmers who are not members. According to the result, age (-0.086), had a strong negative relationship with adoption of the value added cassava technologies and was significant at 1% level of probability, which means as the age of the rural women increases, their adoption level decreases. This is in accordance with a-priori expectation but disagrees with the work of Ekumankama (2002) who opined that a direct relationship exists between age the level of adoption of improved agricultural technologies. Table 2 also, revealed that Household size (-0.048) showed a negative relationship with the level of adoption of value added cassava technologies and was significant at 1% level of probability. This implies that as the household size increases, the level of adoption decreases. This also disagrees with the findings of Onuk *et al* (2010) who noted that increase household size, increased adoption. It could be that be that the members of the household fall into the dependent category and so cannot add to the household labour of the farmer.

Table 2: OLS multiple regression estimates of factors that influenced the level of adoption of Cassava Value-added innovations by rural women in Abia State.

Challenges associated with the adoption level of value added innovations

The analysis of the factors that constrain the adoption of value added innovations as shown in Figure , revealed that constraints such as high cost of modern processing facilities (23.08%) was the major problem affecting the level of adoption of value added cassava technologies. This was followed by inadequate storage facilities as indicated by 20.60% of the respondents. Furthermore, 19.35% of the respondents indicated that inadequate capital was the problem that affected their adoption of value added cassava technologies.

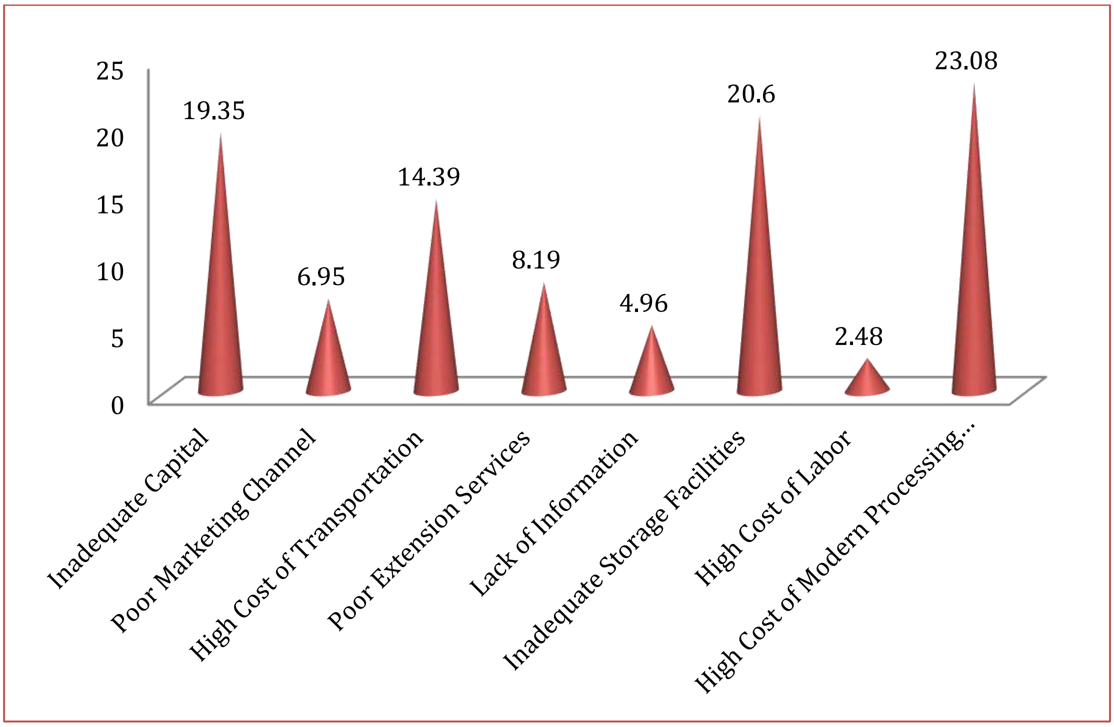

Figure 1: Problems Encountered by Rural Women Farmers in the Adoption of Value added

Conclusion

This study showed that the major determinants of adoption of NRCRI'S value added cassava technology were age, household size, years of experience, education, income and membership to cooperative. The study therefore recommends that more awareness be created in the study area about the technology. The trainings should target mostly the youth to reduce youth restiveness and unemployment. Government should provide sufficient credit to enhance rural farmers' adoption of the technology which require some capital.

Performance of Unified Agricultural Extension System and Policy Implementation for Sustainable Agricultural Development in Owerri Agricultural Zone, Imo State

E.O. Nwachukwu, E.O. Nwoye, C.O. Nwozor, C. Okoli, F.E. Nwarieji, N. Asonye and J.I. Offor
Agricultural Education Department, Alvan Ikoku Federal College of Education, Owerri
e-mail: *ephychuks@yahoo.com*

Abstract
The study investigated the extent of performance of the Unified Agricultural Extension System of the Agricultural Development Programme (ADP) in policy implementation from 2007-2010; for sustainable agricultural development in Owerri Agricultural Zone of Imo State. The study also sought the extent of achievement of the ADP's set targets as well as constraints faced, in its extension delivery service. The respondents which included 53 extension stakeholders were involved in the study. Structured questionnaires, as well as ADP set-target and achievement records were made use of. Data collected were analyzed using simple Percentages, Mean and frequency distribution. Chi – square statistic(x^2) was used to test the hypothesis which stated that there is no significant difference between the ADP's set targets and achievement by the system. This was tested at 0.05 level of significance. The results of the finding showed that there is significant difference between the ADA set targets, and their achievements ($P< 0.05$)..Most of the set-targets were either not achieved, or only partially achieved. It was recommended among other things, that for sustainable agricultural development, relationship between research and extension should be strengthens and for effective extension service delivery and policy implementation. More qualified youths should be employed to strengthen the system, with extended motivational incentives. There should be regular training and retraining programmes for stakeholders to enhance knowledge, with programmes monitored effectively.

Keywords: Performance, Unified Agricultural extension, Policy implementation and Sustainable Agricultural Development

Introduction
The quest for sustainable agricultural development has been a big challenge facing many developing countries mostly in Africa and Asia. It has been observed that for the country to catch up with its food crisis there has to be 4% annual increase in food production level, as against 2.5% annual population increase. Attempts have been made in the past by various governments to enhance food production through intensive agricultural extension service delivery. The overall objective was to ensure adequate food supply for the teeming population, and to achieve a sustained and positive contribution of the agricultural sector to the Gross Domestic Product (GDP). According to Agbamu (2005), Agricultural Extension has been the handmaid of agricultural research. Regrettably, the ability of extension to bring about the much needed increase in agricultural productivity has been in doubt. Asiabaka (2002) posited that Agricultural Extension should aim at teaching rural and urban clientele, how to determine their problems, and be able to rise above such problems using their own resources. The basic goal of training and visit (T& V) system, is to build a professional extension service that is capable of assisting farmers in raising agricultural production, and/or income, and of providing appropriate support to agricultural development (Benor 1987). Agbarevo and Obinne (2010) agreed and stated that this is the mandate of the Agricultural development project, a parastatal of the Federal Ministry of Agriculture. The goal of the Agricultural Transformation Agenda as highlighted by Nwaiwu (2016), is to empower the youth in Nigeria through the full realization of the potential of cassava, rice and sorghum value chains for employment/income generation and food security, especially among some of the country's poorest and most vulnerable population. Adesope

(2007), acknowledged the role of extension in sustainable agricultural and rural development. It contributed that in order to alleviate the poverty situation in many rural areas of Nigeria, there is need to identify the indigent persons through participatory survey, and determining the type of skill that will help the individuals and their communities. Behaviour of farmers can be positively influenced through compulsion, coercion, manipulation, or by providing services. The farmers cannot solve their problems because of their insufficient or limited knowledge, but do so if they are exposed to more knowledge (Nwachukwu and Onuekwusi 2005).

Methodology

The performance of the Unified Agricultural Extension System of the Agricultural Development Programme (ADP) in policy implementation, from 2012-2015 was investigated. This is in view of the impact for sustainable agricultural development in Owerri Agricultural Zone of Imo State, where the study was delimited. The Owerri Agricultural zone is one of the 3 zones in Imo state. Others include Orlu and Okigwe Agricultural zones, under the ADP structure. The Owerri Agricultural Zone consists of 18 blocks in the ADP structure, with Agricultural Extension staff for effective extension delivery to farmers. The zone lies within latitude 50^0 15′N and 50^0 45′N and Longitude 60^0 45′ and 70^0 30′E. The 18 blocks in the zone include: Owerri-Urban North, Owerri-Urban South, Mbaitoli West, Mbaitoli East, Ikeduru East, Ikeduru West, Oguta, Egbema/Agwa, Umuokanne, Obosima, Obibi/Ihiagwa, Umuneke-Ngo, Obokwe, Ahiazu, Aboh-Mbaise, Ezinihitte, Okeuvuru, and Emekuku. Each block has a minimum of six (6) cells/circle, and a maximum of eight (8). An annual rainfall of about 1,600mm is recorded, and the area endowed with fertile soil and undulating topography. The zone is headed by a Zonal Manager, each of the blocks by Block Extension Supervisors (BES), while the cells/circles are manned by Extension Agents (EA). The Block Extension Agents (BEAs) are eighteen (18) in number for women in Agriculture Programmes. The sample size comprised all the fifty three (53) Extension Officers, purposively selected for the study: BESs 12, BEAs 18, EA's 23. Primary data were collected through interviews with officials of ADP, and Extension staff at the zonal office. Secondary data source included available performance record from the zonal office on forth-nightly training (FNT) and Monthly Technology Review Meeting (MTRM) of the extension staff. Data analysis methods include percentage and Chi-square statistics.

Percentage (%) $= \frac{f}{n} \text{ x } \frac{100}{1}$

Where: f = Frequency of response
n = sample size
100 =basis for percentage

Chi-square (X^2) model: $X^2 = \sum_i^n \frac{(o-e)^2}{e}$

Where: o = observed frequency
e = expected/theoretical frequency
n= sample size
$\sum_i$ = summation

This model was used to test the hypothesis that there is no significant difference between the ADP's set objectives and their achievement by the EAs.

Results and Discussion

The data on gender characteristics in Table 1 indicated that 43% of the respondents are males, with the frequency response of 23, while the frequency response for females is 30 (57%). The higher number of female respondents than that of the males shows that men prefer to engage in other businesses with quicker returns. This is a positive development in view of the fact that women play significant roles in national agricultural output, environmental sustenance, and family food security, processing and utilization.

Table 1: Distribution of respondents according to gender

Sex	Frequency	Percentage (%)
Male	23	43
Female	30	57
Total	53	100

Source: Field survey data

The Chi-square (X^2) statistics in Table 2, gave information on the differences between the ADP set targets, and their achievements by the Extension staff, from 2012 to 2015. The hypothesis was tested at 0.05 level of significance.

Table 2: Extension activities in 2012

O	E	Df	X^2-Cal	X^2-tab	Decision
13,468	25,031	6	159.21	12.59	Ho: rejected P<0.05

Source: Field survey data

Table 3: Extension activities in 2013

O	E	Df	X^2-Cal	X^2-tab	Decision
1936	9788	6	1465.73	12.59	Ho: rejected P<0.05

Table 4: Extension Activities in 2014

O	E	Df	X^2-Cal	X^2-tab	Decision
8498	18524	6	1040.5	12.59	Ho: rejected P<0.05

Table 5: Extension Activities 2015

O	E	Df	X^2-Cal	X^2-tab	Decision
19828	26595	6	888.2	12.59	Ho: rejected P<0.05

From the data in the Chi-square Tables 2 to 5, it can be observed that the hypothesis was tested at 0.05 level of significance, using 6 as the degree of freedom (Df), while the critical table value is 12.59. The calculated chi-square values are 159.29, 1465.73, 1040.5, and 888.2 respectively. In all instances, $P<0.05$. Since the critical table values are less than the calculated chi-square values in all the years (2012-2015). The null hypothesis is rejected in all cases. This implies that there is significant difference between the ADPs set targets, and their achievements by the Extension Officers. Most of the targets were not achieved. Some of the performance indicators include: Trainings and re-training of Extension personnel through the fortnightly training (FNT), Monthly Technology Review Meeting (MTRM), field visits, field days, group formation, communication support, etc. The targets of achievements were rarely met in most areas. Paucity of funds, poor facilities, lack of motivation, among other factors, could be attributable to this problem. Chukwunta (2003) is of the opinion that poor funding at the state level, inadequate staffing due to poor remuneration; inadequate input, etc. limit the effectiveness of the system. Venkatesan (2004) recognized the fact that regular training of farmers has positive impact on sustainable agricultural development. He stated that the actualization of training goals and overall success in technology transfer to farmers depends largely on adequacy of extension contacts. Adams (2000) contributed that for an extension worker to be able to carry out his duties diligently, proper education and training is necessary.

Conclusion

The study which covered 2012-2015, focused on the performance of the unified agricultural extension system in policy implementation for sustainable agricultural development in Owerri Agricultural Zone. Fifty three (53) extension officers constituted the sample size, purposively chosen. Interview and available data on extent of achievement of set targets formed the main instruments for collection of data. Simple percentage and Chi-square statistic were the major tools for data analysis. The results obtained showed that there is significant difference between the ADP's set targets and their achievement by the extension officers. This implied that most of the set targets could not be achieved, due to some identified constraints. The inability of the ADP and the extension staff to live up to their responsibilities is a threat to sustainable agricultural development. It should be realized that extension is weak, and can only be effective and strong if the essential ingredients of motivational incentives, input supply, credit, etc are made available. For a sustainable agricultural development, relationship between research and extension should be strengthened. More qualified youths should be employed to strengthen the system. Motivational incentives should be made available to the extension staff, for more input. There should be a mechanism for effective monitoring of extension programmes of activities. For meaningful knowledge enhancement, there should be regular training and retraining programmes for stake-holders in the system.

E-mail:miisrael@yahoo.com

Abstract
The study was carried out in Ikwuano LGA of Abia State on analysis of adoption of NRCRI improved cassava technologies among farmers in Ikwuano LGA, Abia state, Nigeria. A multi-stage random sampling procedure was used to select 120 cassava farmers from 28 communities and purposive sampling method was used to select 4 communities for the study. The data collected were analyzed with descriptive statistical tools such as percentage, mean and frequency distribution for socio economic characteristics and Likert scale for analysis of adoption. The results of technology adoption showed that the farmers accepted all of the given improved technologies. The most important technology accepted was time of harvesting (4.3) which ranked the highest, followed by time of weeding (4.18).
Keywords: Adoption, NRCRI, Improved cassava technologies and farmers

Introduction
Cassava is an important staple in Nigeria and perhaps the most versatile staple in terms of the variety of products derived from it and the uses to which these products can be put. Garri is the major food product derived from cassava. Cassava pellet is an important animal feed, while starch, another derivative is important industrially. Cassava leaves are also consumed as vegetable (Jones, 1959; Fresco, 1986; Dostie *et al*., 1999; Haggblade and Gelson, 2003). Iheke and Nwaru (2013*)* confirmed this fact by their augment that innovation adoption is the key to increasing farm productivity. One of the strategies for poverty reduction through increased agricultural productivity is to promote the production of high yielding crop varieties (Nkonya et al., 2004).

Methodology
This study was conducted in Ikwuano LGA area of Abia State Nigeria. Ikwuano is a local government in Abia State, Nigeria. Its headquarters is in Isiala-Oboro. The coordinates of Ikwuano lies between 5^{o}, 25' N, and 7^{o} 34' E. It has an area of 281 km^{2} and an estimated population of 137,993 (NPC 2006). The study was carried out using purposive and multi-stage random sampling method to select the sample size. Four communities out of the 28 communities were selected thus: Umuariaga, Amawom, Ndoro, and Isiala respectively. These villages were selected because they are predominantly cassava growers in the study area. Two villages were randomly chosen from each community, making eight villages used in the study. 15 cassava farmers were randomly selected, totaling 120 cassava farmers that were used for the study. Primary data were used for this study. The data were generated through a well-structured questionnaire. The data collected were subjected to both descriptive and quantitative analysis. Data were analysed using descriptive statistic tools like frequency tables, means and percentages and Likert rating scale: The levels of adoption by the respondents were measured by using the seven point Likert scale:
Unaware (0), Aware (1), Interest (2), Evaluation (3), Trial (4), Adoption (5),and Rejection (6)
To determine the mean of adoption level $X = \sum x$; the mean score X, of each item was computed by multiplying the frequency of each response pattern with its appropriate nominal value and

dividing the sum with the number of respondents to the items. This can be summarized with the equation thus;

$$X = \frac{\sum fn}{n}$$

Where X = Mean score
∑ = Summation
N = frequency
n = Likert nominal value

$$X = \frac{0 + 1 + 2 + 3 + 4 + 5 + 6}{7} = \frac{21}{7} = 3.0$$

Results and Discussion

The result in Table 1 shows that majority (65.83%) of cassava farmers in the study area were males while 34.17% were females. 8.33% of the farmers were less or equal to 30 years and 35.83% were within the range of 31-40 years. Thirty percent were within the range of 41-50 years of age, 19.16%, within the range of 51-60 years of age while 6.66% were more than 60 years old. According to Bonabanna (2002), there seems to be contention on the direction of the effect of age on adoption. Nwaru, (2004), argues that the ability of a farmer to bear risk and be innovative has been reported to decrease with age. 4.16% of the farmers had no formal education, 10.83% had primary school education 20% had secondary education while 65% had tertiary education. Literate farmers tend to dominant in the study area. Educated farmers are expected to be more receptive to improved farming techniques. Imoh and Essien (2005) opined that educated farmers have more sources of information than their non-educated counterparts and are expected to adopt technologies faster than their non- educated counterparts. 22.5% had farming experience within the range of 1-5years, 41.57%, 6-10years, 20.85%, 11-15years, while 15% had over 15years. Adoption levels, ability to bear risk and the level of confidence a farmer can muster is predicated on his farming experience. 13.33% had a farm size of less than one hectare, 81.67% 1-5 hectares, 3.33% , 6-10; while 1.67% had farm size of more than 15 hectares. Cassava production in the study area is dominated by small-holder cassava farmers with farmlands ranging from 1-5 hectares. 29.17% of respondents in the study area had no contact with extension agents, 51.67% of respondents had contact with extension workers within the range 1-3 times, 14.17% 4-6 times, 3.33% between 7-9 times ; while 1.67% had more than 9 times. 46.67% of the respondents were members of a co-operative society, while 53.33% were not. 74.17% of the respondents had between ₦ 10,000- ₦ 50,000 as farm income, while 17.5% had between N51, 000-N100, 000, 5% had between ₦ 101,000- ₦ 150,000 whereas 3.33% had ₦ 151,000- ₦ 200,000. Increased level of farm income is a precursor in the sustenance of the adoption of improved technologies. 18.3% of the respondents had household size number ranging from 1-3. 55.8% 4-6, 19.17% of the respondents had household size ranging from 7-9, while 6.67% of the respondents had household size of more than 9 respectively. Majority (55.8%) had large household size of 4-6.

Table 2 shows that the farmers in the study area accepted all of the given improved technologies. The most important technology accepted was time of harvesting (4.3) which ranked the highest, followed by time of weeding (4.18). Others are: fertilizer application (4.1), use of improved varieties (4.08), stem preparation (3.93), planting date (3.92), Land preparation (3.89), and planting distance (3.83), with the least accepted technology being: time of herbicide application (3.61).

Table 2: Rating Scale Analyses of adoption of improved cassava technologies in the study area

Farmers' Knowledge of Agrochemicals for Seed Yam Production in Umuahia South Local Government Area of Abia State, Nigeria

B. Ibeawuchi and K.C. Ekwe
Department of Rural Sociology and Extension, Michael Okpara University of Agriculture, Umudike, Nigeria
Corresponding author: kcekwe@yahoo.com

Abstract
The paper examined farmers' knowledge of vital agrochemicals for seed yam production in Umuahia South Local Government Area of Abia State, Nigeria. Two-stage sampling procedure was adopted in selecting respondents for the study which gave rise to a sample size of 120 respondents. Data were generated from the respondents through use of structured questionnaires. The data obtained for the study were then analysed using descriptive statistics. Results of the analysis showed that respondents rated high their knowledge of agrochemicals used in weed control and inorganic fertilizer for seed yam production. Also, farmers perceived use of agrochemicals for seed yam production to be unsafe (dangerous to humans), not readily available and costly. It was therefore recommended that both extension agents and other relevant government agencies should also educate farmers on types and functions of agrochemical as well as their safety measure when in use.
Keywords: Farmers, knowledge, Agrochemicals, and Seed yam

Introduction
Researchers in Nigeria of the National Root Crops Research Institute (NRCRI), Umudike, and IITA, Ibadan, developed the minisett technique to overcome the critical problem of the unavailability of good quality seed yam by improving the rate of multiplication of white yam. With the technique, the multiplication ratio can increase from the traditional 1:5 to 1:30 (Orkwor et al. 2000). The minisett technique involves the cutting of 'mother' seed tubers into small setts (minisetts) of 25-40 g which must possess a reasonable amount of peel (periderm) from which sprouting can occur. The minisetts are treated with chemicals to prevent damage from diseases and pests, planted, and managed to produce small whole seed tubers; these in turn are planted to produce ware tubers for food. The minisett dust which are fungicides, insecticides and nematicides are agrochemical used in the minisett technique for seed yam production and has been reported as not being readily available to farmers hindering the adoption of the technique if famers cannot access the various components. Again, use of agrochemicals (such as minisett dust, herbicides inorganic fertilizer etc) is very prominent and indispensable in the improved technology for seed yam production. This implies that the accessibility of the agrochemicals to farmers enhances the adoption of the technology. Consequently, non-use of agrochemicals in the practice of the minisett technology could compromise the expected seed yam yield and influence rejection of the technology. In view of fore going, farmers' knowledge of agrochemicals may have influenced seedyam production in the study area of Umuahia South Local Government Area. This paper is therefore conceived to examine the farmers socio-economic characteristics as well as their knowledge of vital agrochemicals used for seed yam production in Umuahia South Local Government Area of Abia State.

Methodology
The study was carried out in Umuahia South Local Government Area (LGA) of Abia State, Nigeria. The LGA has a land area of 140km^2 and a population of 138,570 people at 2006 census. Two-stage sampling procedure was adopted in selecting respondents for the study. The first stage was selection of 10 out of 20 communities that make up the study area by simple random sampling

technique. The next stage was random sampling of 20 respondents from each of the 10 sampled communities in the area. These procedures gave a sample size of 120 respondents for the study. Data for the study were generated from the respondents through structured questionnaires. Farmers' knowledge of agrochemical were captured with 4-point Likert type measurement scale. These included 'very much knowledge' assigned the highest scale of 4… graded downwards to 'very little knowledge' with lowest scale of 1. The values of the 4 responses were added and further divided by 4 to obtain 2.50 which was regarded as the benchmark for decision rule. Thus knowledge mean scores below or above the 2.5 benchmark indicated the level of knowledge as either much or little respectively.

Results and Discussion

Socio-economic characteristics of farmers

Results presented in Table 1 shows that 38.3% of the farmers were females and 61.7% were males. Analysis of the respondent's sex revealed that the farming activity in the study area was dominated by males. This was expected since yam farming requires lots of energy and is culturally driven by the men. The results from Table 1 also showed that those within ages of 50-59 years constituted 53.3% of the respondents while the mean age of the respondents was 48.22 years. This means that majority of the farmers were ageing. Table 1 also reveals that most (65.8%) of the farmers in the area were married while 9.2% were single and 20.0% were widowed. The distribution of household size of the respondents gave a mean household size of 5 members per household. It further shows that more than half (57.5%) of the respondents has household size of 6-10 members.

Farmer's educational attainments showed that 15.0% of the farmers had no formal education; while more than half (52.5%) attended primary school. However, Oluwatusin and Shitu (2014) had reported high proportion of illiteracy among yam farmers in Western Nigeria.

Source: Field Survey Data, 2016.

The results further showed that 49.9% of the respondents had farming experience of 11-15 years while 23.3% indicated between 6-10 years' experience in farming. This implied that the farmers in the study area had been engaged in one form of agriculture or the other which means that they must have acquired good farming experience. Also, Table 1 showed the distribution of respondents' based on level of participation in social organizations. Results revealed that 74.2% of the respondents belonged to one farmers' association or the other. One of the roles of the farmer's organizations is to boost knowledge sharing among members. However, not all farmers are aware of the importance of being a member of such organizations. These farmers' organizations are effective channels of communicating information to farmers (Arimi, 2014).

Respondents' knowledge of common agrochemicals used for seed yam production
Table 2 below shows respondents' knowledge of common agrochemical used in seed yam production in the study area. From the results, the mean score value of 2.26 was less than the benchmark of 2.5 thus suggesting that generally farmers have little knowledge of common agrochemicals used in seed yam production. Specifically farmers have much knowledge of common agrochemicals used in weed control (2.68) and inorganic fertilizer (especially NPK) (2.67). This high rating could be attributed to the common practice of weed control as well as the high use of inorganic fertilizer for crops production by farmers in the area. The findings agreed with Nonga *et al.* (2011) who reported that most farmers have knowledge of the type, handling and applications of the agrochemicals which they usually obtain from the agrochemical shop owners. Nevertheless, it could be observed from the results that the farmers had litle knowledge of the common agrochemicals used for insect control (2.35); disease control (1.95) as well as limes (1.75) used to control soil acidity.
Similarly, the results revealed that more than one-third (38.5%) of the respondents had no knowledge of the common agrochemicals used for seed yam production. This raises concern on the farmers' handling of such high risk products without basic knowledge. Nonga et al. (2011) had also reported that majority of the farmers (76%) were unaware of the effects of pesticides to the environment in Uganda.

Table 2: Common knowledge of agrochemicals used for seed yam production

Agrochemicals	So much knowledge	Much	Little	No knowledge	Mean (x)
Agrochemicals for weed control	50	17	19	35	**2.68**
Agrochemicals for insect control	18	47	11	44	**2.35**
Agrochemicals for disease control	7	27	35	50	**1.93**
Limes for acid soil	3	22	38	58	**1.75**
Inorganic fertilizer	18	47	11	44	**2.67**
Mean	**19(16%)**	**32(26.7%)**	**23(19%)**	**46(38.5%)**	**2.26**

Conclusion

Analysis of the respondents' knowledge of common agrochemicals in seed yam production showed high rating for agrochemicals used in weed control and inorganic fertilizer. In order to realise the full potentials of seed yam production and yam minisett technology, the researchers needs to address the issues identified in this study with regards extent of farmers knowledge and perception of farmers about agrochemicals used by the farmers. It is therefore recommended that both extension agents and other relevant government agencies should enhance farmers' knowledge of the agrochemicals for seed yam production by essentially educating them on types and functions of agrochemical as well as their safety measure when in use.

Differentials in Gender Roles among Cassava Processors in Imo State

G. Amadi
National Root Crops Research Institute Umudike, PMB 7006, Umuahia Abia State
okeyamadi2003@yahoo.com

Abstract
This study investigated cassava processing in Imo State with a view to ascertaining, and presenting in a disaggregated manner inherent gender roles. Purposive and multi-stage random sampling techniques were used in the selection of 240 respondents comprising of 120 male and 120 females were involved in this study. Data collection was with a set of structured and pre-tested questionnaire and analyzed using descriptive statistical tools such as means, frequencies and percentages. Results indicate that most of processing operations including peeling, sieving, toasting, fermenting, cooking, pounding and wrapping are carried out mainly by women. Youths and men dominated grating and dewatering because they operated the machines used for these operations while youths assume prominence in washing of peeled roots, and played important part in sieving, toasting garri and pounding fufu. Gender gaps in cassava processing exist in the study area. In order to address these gaps, males in the state should be encouraged to be more involved in cassava processing through the mechanization of the entire process while at same time females should be encouraged through provision of credit facilities to own and access these processing machines.
Keywords:** **Men, Women, Youths, cassava processing, gender roles and socioeconomic characteristics

Introduction
Nigeria is the world's largest producer of cassava; its production is put at about 57.1 million metric tonnes in 2016 (FAOSTAT, 2018). Unfortunately, cassava roots are notorious for their content of varying amounts of potentially toxic cyanogens (Cardoso *et al*., 2005, CIAT 2007); and short shelf-life due to post-harvest physiological deterioration (Yimala *et al*., 2008; Njoku, *et al*., 2014); hence they have to be processed into non-toxic and more stable value added products. Cassava roots can be processed into many primary products like garri, fufu, tapioca chips, pellets, flour, alcohol, starch and cassava cake. Cassava processing is laborious but locally adaptable. It usually includes all or some of the following specific operations: peeling, washing, grating, dewatering, sieving, toasting, fermenting, cooking, pounding, wrapping, slicing, chipping, grinding and drying. Gendered power relations permeate social institutions such that gender is never absent as it deals with the social relationship between men and women and how these relationships are negotiated in the production of goods and services (Ironkwe *et al.,*2007). Such gender relations exist in cassava processing where men and women have different roles, priorities, opportunities and constraints. The cassava value chain reflects gender roles for men and women in value addition activities (Nweke and Tollens, 2002). There is insufficient disaggregated data on gender which could help in understanding gender differences in cassava processing. In addition, there is poor planning, monitoring and evaluation of development programmes targeted at different gender to increase productivity due to scarcity of necessary gender specific data (Ironkwe and Asumugha, 2007). This paucity of empirical disaggregated data on gender necessitated this study on gender roles in cassava root processing in Imo state Nigeria.

Methodology
This study was carried out in Imo State in South Eastern Nigeria. A purposive and multi-stage sampling technique was used in selecting two hundred and forty (240) cassava farmers

consisting of 120 males and 120 females. Instrument for data collection was a set of structured and pre-tested questionnaire. The primary data gathered included socio-economic characteristics of respondents like age, education, marital status, household size, farm size, quantity of roots processed, farming experience and membership of cooperative societies and gender roles in specific processing activities. Descriptive statistics were used to analyze the data generated from the study.

Results and Discussion

Socio-economic Characteristics of Cassava Processors in Imo State

The distribution of male and female cassava processors according to their socioeconomic characteristics is presented in Table 1. It is evident from the table that majority of the males (69.0%) and of females (70.0%) were within the age range of 20 to 49 years showing that respondents were within the active and productive work segment of the population. Age is known to be a primary latent characteristic affecting agricultural production and processing. Being aged (>60 years) is known to reduce the ability of a farmer to effectively withstand the rigours, strain and stress involved in agricultural production (Onyenucheya and Ukoha, 2007). Most (97.0% of males and 95.5% of females) of the respondents were literate at various levels with only a small proportion (3.0% for males and 5.0% for females) having no formal education. Cassava processing can be restrained or improved by the overall level of education of individual members of the household. According to Okoye *et al* (2004), education has the capacity to influence people to accept new technology and change their attitude to the desired technology. Majority (74.0% males and 77.0% females) were married. The preponderance of the married people could create potential for increased labour supply which would contribute positively to cassava processing. Amadi *et al*, (2016) observed that the married class does have access to extra financial, moral and physical supports from their spouses that could go a long way to improve their production activities. The most (83.0% for male and 77.0% for female) frequent household sizes ranged from 4-9 persons. This is in agreement with the report of other authors (Udensi *et al*, 2011). The mean household size of 7 reported in this study suggests availability of family labour in the study area. The availability of substantial family labour may reduce the cost of labour needed for processing. Average quantities of cassava roots processed weekly by male and female respondents were 147.0kg and 183.0kg respectively. More males (27.0%) than females (6.0%) did not process their roots implying that they sold off their roots for cash while women processed probably to feed their family. It appears that the major aim of women producing cassava was to feed their families. This finding and conclusions are corroborated by the report by Butterworth, *et al*., (2008). A sizable proportion (48.0%) of males had between 1-10yrs experience while a similar proportion (46.0%) of females had between 11-20 years of experience in cassava. Though female respondents have slightly more mean farming and processing experience (15.0yrs) compared to males (14.0yrs), both groups of respondents were established and knowledgeable in cassava processing. Farming and processing experience affect farm and processing managerial know-how and decision-making process. Khanna (2001) also noted that higher farming experience attainable through increased years of farming leads to higher rates of adoption of new agricultural innovation.

Gender Roles in Cassava Processing

The distribution of respondents according to their indication of who performs what role in cassava processing is presented in Table 2. Generally, women dominated most processing operations with youths and men playing complimentary roles especially where heavy strength is needed. This finding is in accord with the report of Ezeibe *et al*., (2015). Aminu *et al* (2017) found women to be technically more efficient in processing than men. An analysis of specific processing operations show that both male and female respondents indicated that peeling is carried out mostly by women (50.0% by males, 52.5% by females) and youths (31.0% by males, 40.0% by females) with men (6.0% by males, 3.0% by females) playing a negligible role. This finding is consistent with the report of Aminu *et al*, (2017). Peeling usually the first operation in cassava processing is time consuming and laborious. Men lack the patients to do such work. Youths assume prominence in washing of peeled roots as indicated by 62.0% of male respondents and 58.0% of female respondents. Next to youths in this role are women as indicated by 32.0% of male and 51.0% of female respondents. Men hardly partook in washing peeled roots as indicated by less than 5.0% of both male and female respondents. Grating of peeled cassava roots was carried out by mainly youths and men to a lesser extent as indicated by both male and female respondents. This finding is consistent with the report of Mgbakor and Nwamba (2013). Youths and men operated the grating machines as this was perhaps considered too complex, heavy and risky for women. Men and youths were also the main operators of the pressing or dewatering machines in the study area. However while female respondents indicated that youths (48.0%) were the major operators of the dewatering devices in the study area, female respondents gave it to men (43.0%). This is consistent with a similar finding by Ogunleye *et al*, (2008). Sieving which serves to breakup compressed mash of grated roots and remove un-grated fragments and fibres was carried out mostly by women and youths while men played a negligible role (Table 2). Majority of male respondents (50.0%) gave it to youth while majority of female respondents indicated that women played the dominant part in sieving. Both male and female respondents were in agreement that women played pivotal role in the toasting (frying) of dewatered and sieved cassava mash into garri. This finding is in agreement with other reports (Ogunleye *et al*., 2008; Taiwo and Fasoyiro, 2015) Youths also play a significant part in toasting grated cassava roots to produce garri. Fermenting operation as indicated by both group of respondents were carried out mostly by women and to a lesser extent youths with men playing negligible roles. Perhaps men considered this operation petty and not strength exerting hence they left it for women and youths. Cassava processed into gari undergoes solid state fermentation for about 3 days while fufu is a product of submerged fermentation in which whole roots or pieces of peeled roots are placed in water for 3-5 days. Fermentation process either by solid or sub-merged fermentation reduces the cyanide content of cassava (Imeh and Odibo, 2013). Women dominated cooking, pounding and wrapping of food. These activities as these were within their traditionally assigned roles going by the culture of the people in the study area. However the role of youths in pounding was significant perhaps due to the strong physical exertion involved. The dominant role of women in cooking and related activities have also been previously reported (Taiwo and Fasoyiro, 2015)

Source: Field Survey 2018; Males: 120, Females: 120, *Multiple responses,

Conclusion

This study investigated the gender roles in cassava processing among farmers in Imo State, Nigeria. Men, women and youths played complementary roles in various operations involved in cassava processing. Women dominated most processing operations except mechanized grating and dewatering.

Gender gaps in cassava processing exist in the study area. In order to address these gaps, males in the state should be encouraged to be more involved in cassava processing through the mechanization of the entire process while at same time females should be encouraged through provision of credit facilities to own and access these processing machines.

Abstract
This study was conducted in 2018 and focused on Poverty Profile and Needs Assessment of Women in Kaduna State, Nigeria. The specific objective of the study was to analyze the livelihood status of women groups. The paper utilized primary data using the open data kit (ODK) application technique. The survey instrument was administered to ten women groups, ten respondents were randomly selected from each women group while five women leaders were also interviewed for the study. Descriptive Statistics such as frequency distribution, percentages and mean were used to achieve the stated objectives. Results showed that 42% of the respondents are in the active ages of between 17–31 years, 52% have a household size of between 1-10 members while about 53% of the respondents can read and write. Poverty profile showed that about 74% have no access financial institutions, 36% have access to owned land. Needs assessment revealed that majority, 63% of the women required capital ranging between one thousand to one hundred thousand naira to start their business, The paper argued that, although women contribute greatly in societal growth and development, however, their condition of poverty can be improved upon. It was suggested in conclusion that by providing them with loans; women poverty can be greatly reduced in Kaduna state.
Keywords: Women, poverty and Kaduna State

Introduction
Majority of the population in developing countries live in rural areas where there is myriad of individuals who continue to live in extreme poverty. Identifying the extent and nature of poverty requires a clear definition of poverty be established. In year 2000 the World Bank defined poverty as a 'pronounced deprivation in well-being'.Regardless of the fact that Nigerian economy is paradoxically growing, the proportion of Nigerians living in poverty is increasing every year (NBS, 2012). For instance, aggregate poverty rose from 28.3 % in 1980 to 69.3 % in 1996, declined to 63.3 % in 2004 and increased to 69.0 % in 2010 (Ogwumike and Akinnibosun, 2013). Soludo (2012) while making presentation at the stakeholders meeting on the Nigerian economy stated that "Very high levels of poverty is essentially a northern phenomenon".. The root causes of poverty need to be understood to design efficient measures tailored to the needs and strengths of poor people hence the study objectives include: to describe the socio-economic characteristics of women in the study area, describe the poverty status of women based on their livelihood strategies, and identify the types of intervention that are likely to be most appropriate for the different categories of poor women

Methodology
The Study Area
Kaduna State is located between latitude 09^0N and 11^0Nand between longitude 06^0E and 08^0E of the Greenwich meridian. The State has a population of 6, 113,503 people (NPC, 2006), the estimated projected population in 2017 is 8,645,035 people going by a population growth rate of 3.2% per annum. The State is agrarian with an annual rainfall of 1600mm (NAERLS, 2015). Giwa Local Government vegetation is made of up grasses and shrubs, majority of the people in the area are farmers. They produce both crops (maize, rice, sorghum, cowpea, soybean and vegetables) and livestock. Sabon-Gari Local Government has similar vegetation with Giwa Local Government,

where there is predominance of grasses and shrubs in the area. Crop and livestock production are the major occupation of the people in the area. Women in the two Local Government areas are engaged in processing of farm produce, handcraft and petty trading among others.

Sources of Data and Analytical Technique

The study was conducted among twenty (20) National Agricultural Extension and Research Liaison Services Adopted Villages and Schools Outreach women groups located in Giwa and Sabon Gari Local Government Areas of Kaduna State in 2018. Multi-stage sampling technique was employed in this study. In the first stage, five women groups were selected from each of the two local government areas based on availability of the members, making a total of ten women groups for the study. In the second stage, ten respondents were randomly selected from each women group while five women leaders were interviewed separately, making a total of two hundred and five respondents for this study. Computer assisted personalized interview (CAPI) technique using structured questionnaire was adopted to capture bio- data, poverty profile and the needs assessment of the respondents in the study area. In addition, focus group discussions with key informants were also conducted during the data collection for validation. Descriptive Statistics such as frequency distribution, percentages and mean were used to achieve the stated objectives.

Results and Discussion

Table 1 presents the socioeconomic description of the respondents in the studied areas. The result revealed that 42% of the respondents are between the ages of 17–31 years while, 37% were between 32–46 years of age. Based on the findings, it shows that majority of the women are either in their youth or productive age. Further, the best part of the respondents is married (91%). About half of the respondents (52%) have a household size of between 1-10 members, an indication of existence of nuclear family. Notably, about 84% of the women were spouses of the household head, it is worth mentioning that 1% of respondents were daughter in-laws of the household head. This suggests that the incidence of widowed or divorced women in the areas is nominal. About 53% of the respondents can read and write, grounded on discussion with the women, those that can read have at least JSS III certificate. This implies that women in the study sites can follow simple written instructions and other extension publications for better life. Half of the respondents (50%) own 6–10 children, while 46% had 1-5 children. About 77% of the women send a number of their children to school ranging from 1-5. Among the children in school, respondents reported that majority of them (73%) were attending public or government schools while only 12% had some of their children attending private schools. The implication of this is that there is dire need to further improve the education system in Nigeria to enable the rural poor obtain standard education. About 15% stated that they pay their ward's school fees, whereas 58% testified that their spouses pay the school fees. In other cases, it was a combined effort (14%). This shows that there is still no free access to education for the rural poor even at the primary level. Conversely, about 58% of the respondents have been members of groups for 1–5 years.

Table 1: Socioeconomic Characteristic of Respondents (n=205)

Variable	Frequency	Percentage
Age		
17 – 31 years	87	42.43
32 – 46 years	76	37.07
47 – 61 years	38	18.53

Poverty Profile among Women

The result in Fig. 1 gives the level of poverty of the women groups in the study area.

Own bank account

The result in figure 1 indicated about 74% don't own bank accounts, while only about 26% were found to own bank accounts. This implies that majority of the respondents interviewed were not interacting with financial institutions such as commercial banks and micro finance banks. This may also be due to their financial status which cannot warrant them to have bank account. They further stated that the money in their possession was very meager.

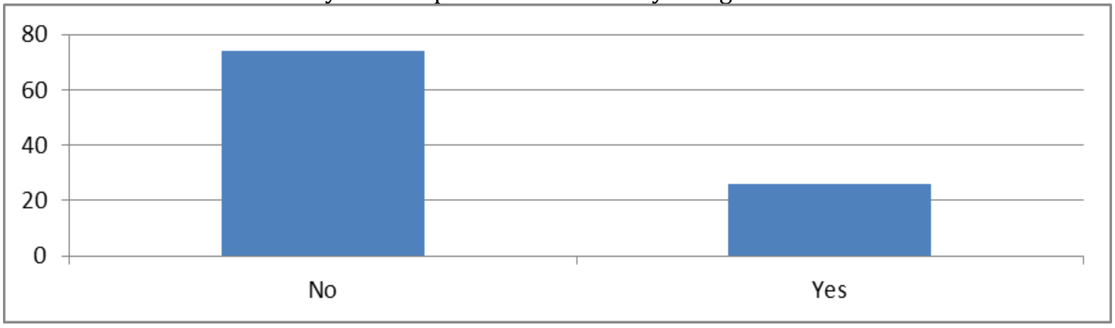

Figure 1: Ownership of Bank Account

Land ownership

The information in figure 2 revealed about 36% owned land through inheritance, about 32% rented the land under their control, 14% reported to have purchased their land. However, 15% of the respondents' land ownership was through other means like gift, lease and others.

Figure 2: Land Ownership Status

Livelihood sources

The following highlighted the various livelihood sources adopted by the women groups. The livelihood sources rest on their major occupations and other income generating activities engaged upon as at the time of investigation.

Figure 3: Major Occupation of women groups

Figure 3 shows that 37% of the women interviewed were traders, 33% were food processors, while only 8% participate in farming activities. Low mobility of women due to religious restrictions may be accountable to their low participation in farming activities.

Needs Assessment and type of Intervention

Table 2: Respondents Capital Requirement to Start Business (n=205)

Capital (N)	Frequency	%
0	59	28.78049
1-100000	129	62.92683
100001-200000	7	3.414634
200001-300000	3	1.463415
400001-500000	5	2.439024
500001-600000	1	0.487805
600001-700000	1	0.487805

Source: Field Survey, 2018

From Table 2, approximately 63% of the total population requires a minimum capital of between 1-100000 naira to start a trade while approximately less than 1% of the population require between 500001-600000 and 600001-7000000 naira respectively. Approximately 3%, 1% and 2% of the population require a minimum capital of between 100001-200000 and 200001-3000000 and 400001 and 500000 naira respectively while 28% requires capital less than 100000 naira.

Conclusion

Based on the findings of this study, it can be concluded that there is poverty and felt needs among rural women groups in the study area. This implies that more intervention projects effort should be geared towards improving the micro variables that will improve the welfares and living standard and reduce poverty level among the women in the study area.

Abstract
This study ascertained and described gender roles in cassava production in Imo State. Purposive and multi-stage random sampling techniques were used to select 240 respondents comprising of 120 male and 120 females involved in this study. Data were collected with a structured and pre-tested questionnaire and analyzed using descriptive statistics. Results from this study showed that while men dominated heavy energy operations such as land clearing and tillage, women dominated other operations like planting, weeding, harvesting and preparing food for farm use. Youths participated in most operations but rarely had access to and control of finances for cassava production. In line with the finding of this study, it is recommended that policy issues targeted at increasing cassava production in the state should advocate for more involvement of the males in especially those roles dominated by women and allowing youth's greater access to and control of finances for cassava production.
Keywords: Gender, Men, Women, Youths, Cassava production and Socioeconomic characteristics

Introduction
In Nigeria, wide adoption of high-yielding cassava varieties, better pest management and value addition technologies have resulted in a sharp rise in its production. In Imo State, it is one of the most important food crop cultivated and consumed widely. In most parts of rural Nigeria, division of labour within the household is gender-specific and according to age. Gender refers to socially constructed role differences between men and women usually for the purpose of allocating powers, duties, status, responsibilities and roles in any given social milieu or context (USAID, 2005). Such gender relations exist in agricultural production where men and women have different roles, priorities, opportunities and constraints. Lack of gender consideration has often led to failure of different popular projects in the past (Chukwu and Nwaiwu, 2012). Men and women perform different functions and roles in cassava production (FAO, 2007). These roles vary widely and are in many instances determined by culture and tradition (Ironkwe and Asumugha, 2007). There is also lack for disaggregated data on gender which could help in understanding gender differences in cassava production. In addition, there are poor planning, monitoring and evaluating development programmes targeted at different gender to increase productivity due to scarcity of necessary gender specific data (Ukeje, 2004; Ironkwe and Asumugha, 2007). This paucity of empirical disaggregated data on gender necessitated this study of gender roles in cassava production in Imo state Nigeria.

Methodology
This study was carried out in Imo State in South Eastern Nigeria. A purposive and multi-stage sampling technique was used in selecting two hundred and forty (240) cassava farmers consisting of 120 males and 120 females. Instrument for data collection was a set of structured and pre-tested questionnaire. The primary data gathered included socio-economic characteristics of respondents like age, education, marital status, household size, farm size, quantity of roots produced, farming experience and membership of cooperative societies.

Descriptive statistics such as mean, percentage, and frequency distribution were used to analyze the data generated from the study.

Results and Discussion

Socio-economic Characteristics of Cassava Producers in Imo State

The distribution of male and female cassava producers in Imo state Nigeria according to their socioeconomic characteristics is presented in Table 1. It is evident from the table that majority of the males(69.0%) and of females(70.0%) were within the age range of 20 to 49 years while 31.0% and 30.0% of them were within the ages of 50 years and above. The mean ages of male and female respondents were 40.6 and 41.3 years respectively. This result indicated that cassava farmers were mostly of middle age (30-59 years) hence, they are within the active and productive work segment of the population. Age is known to be a primary latent characteristic affecting agricultural production. Being aged (>60 years) is known to reduce the ability of a farmer to effectively withstand the rigours, strain and stress involved in agricultural production (Onyenucheya and Ukoha, 2007). Most (97.0% of males and 95.5% of females) of the respondents were literate at various levels with only a small proportion (3.0% for males and 5.0% for females) having no formal education. Cassava production and processing can be restrained or improved by the overall level of education of individual members of the household. According to Okoye *et al* (2004), education has the capacity to influence people to accept new technology and change their attitude to the desired technology.

The most frequent household sizes (83.0% for male and 77.0% for female) ranged from 4-9 persons. This is in agreement with the report of Ezeibe *et al*, (2015). Awoniyi *et al.* (2009) noted that large household sizes assist in providing family labour for cassava farmers, thus leading to a more efficient use of resources and higher output. Many of the respondents (52.0% males and 55.0% females) had farms whose sizes were less than one hectare. This is in agreement with the report of Onumadu and Onuoha (2015) who noted that the sizes of the land cultivated by majority of male and female farmers are in the range of 0.1 - 2.0ha. Ugwumba *et al*, (2010) asserted that small sizes of farms amongst smallholders in south Eastern Nigeria call for some form of land integration policy. The mean quantity of roots produced by males (191.0kg) was slightly higher than their female (182.0 kg) counterparts. This finding is in disagreement with Onumadu and Onuoha, 2015 who reported that in Abia state, female headed households produced more bags of cassava than male headed households. Many (48.0%) of males had between 1-10yrs experience while a similar proportion (46.0%) of females had between 11-20 years of experience in cassava production. Though female respondents have slightly more mean farming experience (15.0 yrs) compared to males (14.0 yrs), both groups of respondents were established and knowledgeable in cassava production. Farming experience affects farm managerial know-how and decision-making process. Khanna (2001) also noted that higher farming experience attainable through increased years of farming leads to higher rates of adoption of new agricultural innovation. Only 20.0% males and 18.0% females belonged to cooperative societies indicating that majority of the respondents did not. This finding is consistent with the report of Onyemauwa, (2012) which showed that about 72.0% of the respondents do not belong to, and take part in, cooperative activities. Since most agricultural technologies are provided to farmers who take part in cooperative activities, their non participation will likely constrain their production and processing activities (Tahirou *et al*., 2015).

Gender Roles in Cassava Production

The distribution of respondents according to their indication of who performs what role in cassava production is presented in Table 2. Data presented show that most of the male (86.0%) and to lesser extent females (77.0%) respondents indicated that men select site for cassava production suggesting that the responsibility lies with men. This finding is in tandem with the land tenure system in the study area which vests ownership and authority over land on men. Majority of male (65.0%) and female (60.0%) respondents indicated that the responsibility for land clearing rests mainly on men with women and youths playing lesser role. Udemezue and Onwuneme (2017) also reported that men did most of land clearing for cassava production in Anyamelu LGA of Anambra state. Both male (42.0%) and female (41.0%) respondents indicated that burning after slashing was carried out mainly by men but with increasing involvement of women and youths. Uzokwe and Ofuoku (2006) also reported the increasing involvement of women in stubble burning in Delta State in the last decade. Men (39.0% by males and 41.0% by females) followed by youths (25.0% by males and 29.0% by females) do most of land tilling and preparation but women (19.0% by males and 22.0% by females) are also involved substantially. This finding is in agreement with similar research report of Ezeibe *et al*., (2015). Tillage is a heavy energy task hence men and their sons with inherent physic do most of the job. Women and to a much lesser extent youths did most of cassava planting operation as indicated by 51.0% and 13.0% of male and 42.0% and 15.0% of female respondents respectively. The trend was similar in weeding as indicated by 60.0% and 20.0% of male and 58.0% and 18.0% of female respondents respectively. These findings are in agreement with many previous reports (Lenis *et al.*2009, Udemezue and Onwueneme, 2017; Atser *et al*., 2017) which found women to be mostly engaged in planting and weeding. Both group of respondents indicated that herbicide application was mainly the prerogative of men and youths with 40.0 and 32.0% respectively from male and 44.0 and 23.0% respectively from female respondents. Harvesting was carried out by all (men women and youths) with women having a slight edge. The trend in response was the same for both male and female respondents. Ezeibe *et al*., (2015) however reported that women dominated the work of harvesting cassava in Abia state.

Table 2: Distribution of male and female respondents according to gender roles in Cassava Production

Gender Roles	**Male**		**Female**	
Site Selection	***Freq.**	**Percent**	***Freq.**	**Percent**

Source: Field survey 2017, N = 120 (Males), 120 (Females) 240 (Pooled), *Multiple responses.

Both male and female respondents are in accord as shown in figure (1) that women play a pivotal role in preparing food and taking it to those engaged at the farm. This finding is in tandem with the traditional role of women in the study area to cook for their families. This is a very important operation usually overlooked when accessing labour input in the farms.

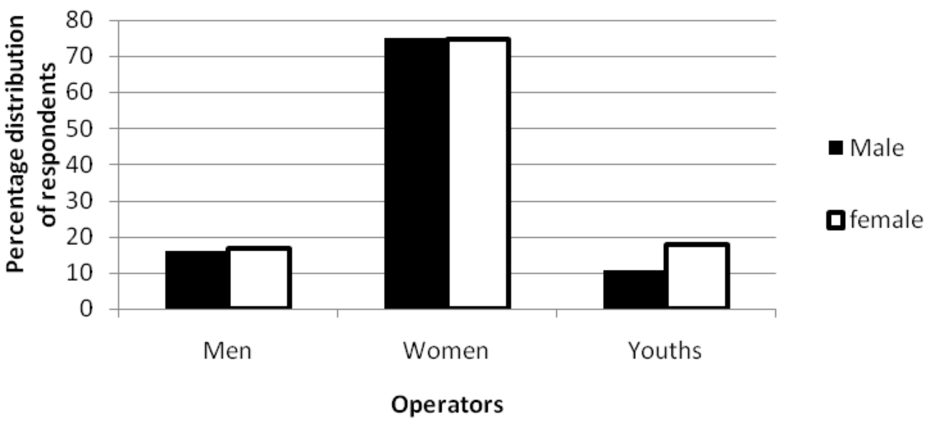

Fig 1: Distribution of Respondents According to Who Prepare food and water for labour in cassava production

Both male and female respondents indicated that men have more access to and control of finance than women and youths (Figures 2 and 3). Youths are the most disadvantaged in these aspects. Butterwort, *et al,* (2008) also reports that men have more access to formal capital because they have collateral in the form of land and houses. Women, who lack ownership of these assets, rarely take formal loans.

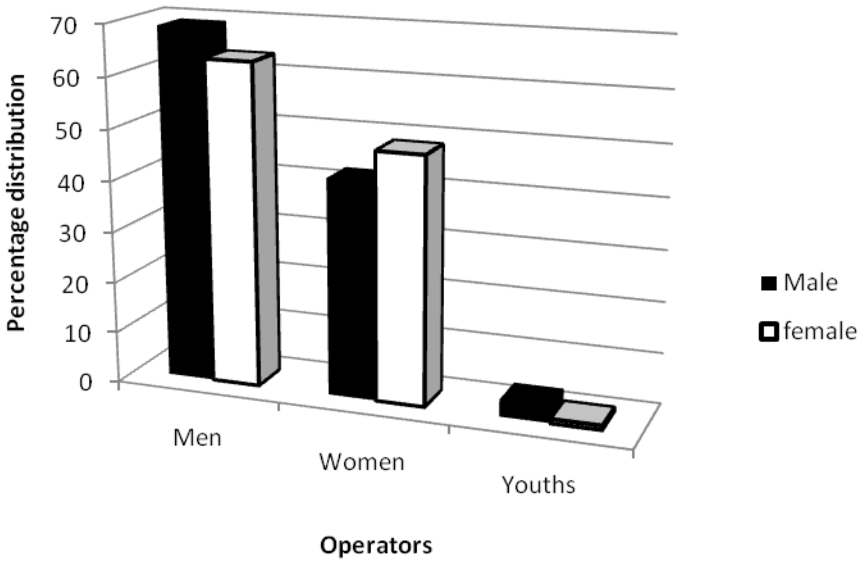

Fig 2: Distribution of Respondents According to their Access to finance

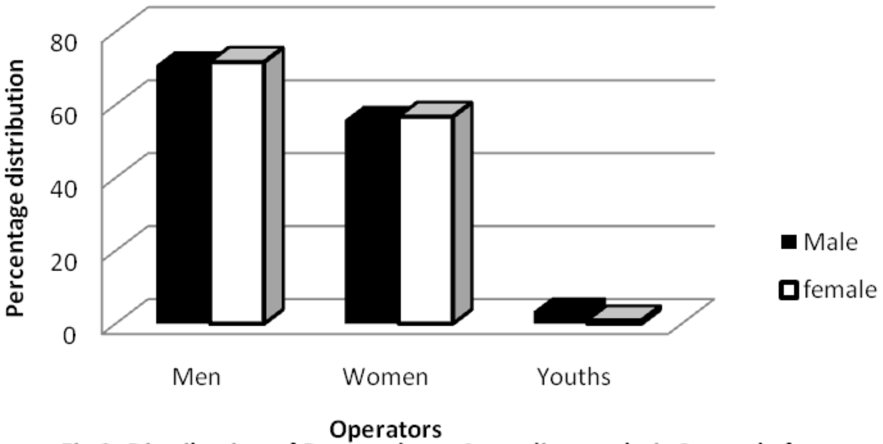

Fig 3: Distribution of Respondents According to their Control of finance

Conclusion

This study investigated gender roles in cassava production in Imo State, Nigeria. Men, women and youths played complementary roles in various operations involved in cassava production. While men dominated in heavy labour operations such as land clearing and tillage, women dominated in other operations like planting, weeding, harvesting and preparing food for farm use. Youths rarely had access to and control of finances for cassava production. In line with the finding of this study, gender gaps in cassava production exist in the study area. In order to address these gaps, male and female cassava farmers in the area should be allowed unrestricted access to productive resources as a way of exploiting their potentials in cassava production through the establishment of gender based cassava development programmes. Policy issues targeted at increasing cassava production in the state should advocate for more involvement of the males in and increased access to and control of finance by youths.

Assessment of Gender Participation in Modern Broiler and Layer Poultry Production Management Practices in Abia State, Nigeria

C.I. Ibeawuchi, C.V. Chinedu-Eze C.N. Azikiwe
Department of Agribusiness and Management, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria
Corresponding Author: *cynthia.ibeawuchi18@gmail.com*

Abstract
This study assessed gender participation in modern broiler and layer poultry production management practices in Abia State, Nigeria. Specifically, the study identified constraints militating against gender participation in modern broiler and layer production management practices in the study area. A two-stage sampling technique was used in selecting sixty (60) poultry enterprises made up of thirty (30) modern broiler enterprises and thirty (30) modern layer poultry enterprises drawn from six (6) Local Government Areas across the three (3) Agricultural Zones of Abia State. Data for the study were collected through primary source using questionnaire, and analyzed with descriptive statistics. The results of the descriptive statistics showed that male participated more in the following poultry management activities: vaccination schedule, provision of light, marketing/sales and carcass disposal, while female participated more in these poultry management practices: drug administration, procurement, disinfection/sanitation, nutrition, brooding and record keeping. The three major constraints militating against gender participation in modern broiler and layer practices in the study area were: inadequate information, high cost of modern poultry equipment and lack of technical know-how. Hence, government through its relevant agencies should enlighten the masses on modern management practices in poultry production, to enhance gender participation.
Keywords: Gender participation, broiler and layer production and management practices

Introduction
The poultry industry plays significant role in the development of Nigeria economy constituting a major source of livelihood, income and helps in bridging the dietary protein deficiency prevailing in the country. (Abimbola *et al.,* 2014). Nigeria poultry industry fulfills a wide range of functions such as the provision of meat and eggs, food for special festivals, chicken for traditional ceremonies a source of pest control and petty cash, while requiring minimal external inputs, minimal human attention and causing minimal disruption to the environment (Adeyemi, *et al.,* 2012). Over the past decades awareness of gender issues in development has steadily increased (Rahman, *et al.,* 2007). There is a large and growing literature concerned with gender-based distributional issues and the economic activities of rural women. In poultry management, there is a growing recognition of the contribution of women in poultry production. Although there are several poultry enterprises in different agricultural zones of Abia State, there is dearth of information on gender participation in modern broiler and layer poultry production management practices in the study area. Hence, this study analyzed gender participation in modern layers and broilers poultry production management practices in Abia State, Nigeria with a view to fostering sustainable strategies for enhancing food security and livelihoods in Nigeria through gender mainstreaming.

Methodology
The study was carried out in Abia State, Nigeria. The state covers an area of about 5,243.7sq.km which is approximately 5.8 percent of the total land area of Nigeria. Its capital is Umuahia and

Aba is its major commercial city. Abia State lies within latitudes 4°40' and 6°14' north, and longitude 7°10' and 8° east. The indigenous ethnic group is Igbo. It has seventeen (17) Local Government Areas. The people of the state are enterprising. Modern poultry is practiced by a good number of people. Other agricultural products produced in the state include: cassava, yam, cocoa, palm oil and vegetables. Two stage sampling technique was used in the study. In the first, two Local Government Areas (LGAs) were purposively selected from each of the three Agricultural Zone of Abia state base on the preponderance of poultry enterprises. In the second stage, five modern broiler and five modern layer poultry enterprises were purposively selected from each of the six selected LGA. This brought the sample size to sixty poultry enterprises comprising thirty modern broiler and thirty modern layer poultry enterprises. Data for the study were sourced primarily using questionnaire. Data collected were analyzed with descriptive statistics such as mean, frequency and percentage.

Results and Discussion

Gender Participation in Management Practices of Modern Broiler and Layer Poultry Enterprises

The result of gender participation in management practices of modern broiler and layer poultry enterprises is as presented in Table 1.

Table 1: Gender participation in management practices of modern broiler and layer poultry enterprises

Management Practices	Male Mean Participation	Female Mean Participation	Remarks
Vaccination	3.71	3.57	Male dominated
Drug administration	3.46	3.83	Female dominated
Chick procurement	3.94	4.17	Female dominated
Provision of light	4.69	4.37	Male dominated
Disinfection/sanitation	3.71	3.94	Female dominated
Nutrition/feeding	4.31	4.93	Female dominated
Marketing/sales	4.00	3.87	Male dominated
Brooding	3.37	3.51	Female dominated
Record keeping	2.80	2.97	Female dominated
Carcass disposal	2.66	2.23	Male dominated

Source: Field Survey Data, 2017

The result on assessment of gender participation in management practices of modern broiler and layer poultry enterprises on Table 1 indicated that there was male dominance in the following poultry management activities: vaccination, provision of light, marketing/sales and carcass disposal while female participated more in these poultry management practices: drug administration, chick procurement, disinfection/sanitation, nutrition/feeding, brooding and record keeping. However, Okoh, Rahman and Ibrahim (2010) observed that males participated more on management activities such as vaccination, administration of drugs, debeaking and chick procurement while females were more engaged in daily routine activities like cleaning of pens, provision of water and sorting of eggs.

Constraints militating against gender participation in modern broiler and layer poultry enterprises in the study area

The result of the descriptive statistics on the constraints militating against gender participation in modern broiler and layer poultry enterprises in the study area is shown in Table 2 below

Table 2: Constraints militating against gender participation in modern broiler and layer poultry enterprises

Constraints	Mean	Rank
Lack of technical know-how	3.81	3rd
Insufficient capital	3.79	4th
Inadequate information on modern poultry management practices	4.70	1st
High cost of modern poultry equipment	3.96	2nd
Low access to credit	3.61	5th

Source: Field Survey Data, 2017

The result on Table 2 above showed that the constraints militating against gender participation in modern broiler and layer poultry enterprises in their descending order of importance were: inadequate information on modern poultry management practices, high cost of modern poultry equipment, lack of technical know-how, insufficient capital and low access to credit.

Conclusion

This study have shown that both male are female participate in modern broiler and layer poultry management practices, though female dominated activities tend to be more than their male counterparts. It is thus recommended that government through its relevant agencies should enlighten the masses on modern management practices in poultry production, to enhance gender participation. Also government should subsidize modern poultry equipment to make it affordable to poultry entrepreneurs.

Abstract
The survey was conducted to ascertain effect of cassava traditional salad sales on the living standards of women farmers in Bende Local Government Area, Abia State towards increasing food production and cassava curb poverty, examine the socio-economic characteristics of farmers engaged in processing and sale of the cassava traditional salad, compare difference between their incomes before and after embarking on the processing business, as well as identifying the constraints of the producers/traders during and after processing and sales of the cassava traditional salad business. The analytical technique used to achieve the objective of the study was Paired Samples Test and descriptive statistics (frequency, percentages and mean). The result showed that the dominant respondents were within the age range of 45 - 55 years which accounted for 42% and 41%. The mean incomes of the cassava traditional salad producers before they started the trading business were ₦74,435.43 while their incomes after the processed cassava traditional salad sales were ₦91,435.43, with a difference of ₦23,435.43. This means that the incomes of the respondents are higher than their incomes before their cassava traditional processing trade. The research study showed that the major constraint of the respondents was inadequate cassava traditional salad value addition facilities, lack of funds and storage facilities, and incessant electricity supply. It was recommended that Government should increase the fund allocation to the National Root Crops Research Institute, Umudike for provision of logistics for Extension Service Programmes, to increase food production and sustainability in rural development. Extension delivery on mechanized processing of cassava into traditional salad should be embarked on by the National Root Crops Research Institute, to encourage more rural women farmers. There is crucial need to train and employ more agricultural engineers in the Agricultural Sectors, including National Root Crops Research Institute to fabricate root and tuber crops processing machines for increased value added products, economic empowerment and to improve the livelihood of the rural women in Nigeria.

Introduction
The level of unemployment, poverty, hunger and hardship, in developing countries is still on the increase despite global advances in agricultural Technologies and entrepreneurial development. The business of processing of cassava into traditional salad for sale is one of the major sources of income of the farmers in Bende Local Government Area of Abia State because the area has a vast and fertile land for cassava production, as well as the cassava traditional salad producers and traders. Agro-business incomes account for progress and development towards poverty reduction in a country. Nigeria is the largest producer of cassava in the world with an annual output of 45 million metric tons, (F.A.O., 2017). Cassava Traditional Salad popularly known as "Agworoagwo Nsisa" in Bende Local Government Area of Abia State is taken as food. Cassava value added product is revenue yielding and provides employment opportunities for the jobless. Also, it enhances foreign exchange earnings in Nigeria (Aniedu, 2014). Cassava is peeled, washed, cut to size, cooked, sliced, fermented, sun-dried and prepared as traditional salad for

eating. The cooked cassava can be manually or mechanically sliced or processed into "Nsisa" used for preparing the traditional salad in Bende Local Government Area, (Oti, 2012). Due to the fact that cassava tuber crop is a vital source of food, rich in vitamins and highly medicinal, it becomes imperative to give adequate attention towards encouraging the cassava traditional salad value addition technologies producers. Majority of the respondents (55%) engaged in sales of cassava processing traditional salad were full-time farmers. The rest were either part-time farmers or combined farming with petty trading. Since the-women farmers in the area depend largely on traditional agriculture for subsistence, any meaningful effort for their effective participation and improved living standards must be directed toward improving their production, processing and storage technology. In order to bring rural women to the limelight of sustainable agricultural development, there is urgent need to encourage the women farmers in the cassava processing business. Therefore, the essence of this research study is to empower the producers on the one hand. and to increase food production as well as food security and sustainability on the other hand.

Methodology

The research study was conducted in four Communities in Bende Local Government Area of Abia State namely: Uzuakoli, Nkpa, Ozuitem and Akoli-Imenyi Communities. Bende is one of the seventeen Local Government Areas in Abia State, South-eastern Zone of Nigeria. There are among the major cassava processing traditional salad communities in Bende Local Government Area of Abia State. A survey on the involvement of women in processing of cassava into traditional salad, as a strategy to boost food production for the new century was conducted among the four communities. All the four communities were purposively selected; and questionnaires were distributed to a total of (20 x 5) 100 respondents as the sample size, from the area under study. The services of Agricultural Development Programme (ADP) Extension Agent employed to supervise each of the selected communities and the list of cassava processing traditional salad traders were obtained. The analytical technique used to achieve the objectives was descriptive statistics (percentages, mean and frequency) and Paired Samples Test.

Results and Discussion

The Socio-economic status and general living standard of the respondents were assessed under the following; age, occupation, marital status, education, income, type of housing, type of building, source of drinking water and source of lighting. The results of the analysis for the socio-economic profile and Paired samples test incomes of the respondents (Before) and their incomes (After) sales of the cassava traditional salad. are presented in the Tables 1 - 3 respectively.

Socio-Economic Status of the Respondents before and after Processing and Sales of Cassava Traditional Salad in the Study Area

Age of respondents

The dominant age range was 46 - 55 years, which accounted for 42% and 41% before and after the sales respectively. The implication is that majority of the respondents belong to the adult aged group that are known for their creativeness, productiveness, mental alertness and effective reasoning more their younger farmers (Amadi,, 2011).

Occupation

Up to 55% were full-time farmers after the business, while their counterparts' part-time farmers represented 53% (before the business). This explains why the part-time farmers tend to be less amenable to income diversification than their full-time counterparts. (Okoye, 2011).

Marital status

Up to 80% of the respondents are married. This implied that majority of the married women dominated this group. This is in line with the proposition that women play vital role in food production, processing and marketing in Nigeria (Asumugha, 2014).

Education

Also, the number of respondents who had secondary education increased from 17% to 21%. According to Okoye (2011), educated farmers are more receptive to changes while farmers with little or no education are conservative to accept changes and innovations. The percentage of respondents with non-formal education (35% and 20%) confirms their perception.

Income The respondents between the age range of 46 – 55 and 56 - 65 years recorded the highest incomes (N500,000 - N690,999 and N600,000 – N790,999) respectively. This showed that cassava traditional salad trade is income generating, profitable and job creating, thereby improved the respondents' livelihood in the study area.

General Living Standard of the Respondents
The variables that recorded the highest scores marked asterisks showed that there were remarkable improvement in the general living standards of the cassava traditional salad women farmers in the study area.

Type of Housing: This showed that 30% and 27% who emerged majority of the respondents lived in flats without water closet, followed by 44% and 42% who lived in flats with water closet before and after the cassava traditional salad sales respectively. It is glaring that there was a clear distinction between the respondents general standard of living after the business in terms of housing , than the type of house they were occupying before they started the agro-business.
Types of Building Materials: Up to 20% and 42% of the respondents lived in buildings constructed with block with/zinc roof while 18% and 25% of the respondents resided in houses with thatched roof. While the minority of the respondents experienced changes in the type of building materials they had; there is no doubt that the cassava traditional salad value addition sales had positive effect on the type of building materials respondents' houses were constructed with.
Sources of Drinking Water: As an important measure of standard of living, source of drinking water was assessed. About 30% of the trainees get drinking water from tap water before the training, while the number increased to 37% after the training. Also, there was an increase in the number of the respondents who use bore-hole from 37% to 40%. The use of well and stream/spring water was drastically reduced. There is obviously marked difference between the respondents source of drinking water both before and after the business..
Health Service Provider: It was observed that the majority of the respondents (35% as against 29%) receive medical treatments from the Clinic/Hospital/Health Centre, followed by healing through prayers by their Churches which recorded 40% as against 9% before the cassava traditional salad sales. There was drastic percentage reduction in patronizing and consulting the traditional healers/native doctors by the respondents from 30% to 11%, to attend to their health needs. Hence there was positive change observed between the respondents health service provider before and after the cassava traditional salad sales.
Source of Lighting: Majority of the respondents which accounted for 30% as against 45%, and 28% as against 33%; have electricity and kerosene lamps as their source of lighting after the sales respectively. Based on observations, it is obvious that the cassava traditional salad sales influenced the living standard of the rural women cassava farmers positively since their living standards registered a remarkable improvement.

Paired Samples Test of Income of Respondents Before and After Commercialization
This showed that the mean incomes of the cassava traditional salad producers before they started the trading business were ₦74,435.43 while their incomes after the processed cassava traditional salad sales were ₦91,435.43, with a difference of ₦23,435.43. This means that the incomes of the respondents are higher than their incomes before their cassava traditional processing trade.

Conclusion

The mean income difference, ₦23,435.43 of the respondents after the processing and sales of the cassava traditional salad indicated that the business is viable. This implies that the income of the women cassava traditional salad producers were higher than their incomes before they embarked on the business. The research study showed that the major constraints of the respondents were lack of funds and inadequate facilities for cassava value added products. It was therefore recommended that both the women cassava farmers and cassava traditional salad producers should be encouraged to enable them access to agricultural information and benefit from agricultural programmes of the government. Government intervention to release more funds to National Root Crops Research Institute, Umudike for training of the rural women on mechanized cassava traditional salad value added products is very imperative. This will enable them to move from the low to high level mechanized production of cassava traditional salad, not only to increase their incomes but also to enhance foreign exchange earnings. More agricultural engineers should be employed and trained in the Agricultural Sectors, including National Root Crops Research Institute to fabricate root and tuber crops processing machines for increased value added products, economic empowerment and to improve the livelihood of the rural women in Nigeria.

Analysis of Gender Differences in Agricultural Inputs Use among Cassava Farmers in Anambra State, Nigeria

[1]Okonkwo, I.I., [1]Okonkwo, G.U., [1]Okoye, B.C. and [1]Anyaegbunam, H.N
National Root Crops Research Institute Umudike
okonkwoannainno@gmail.com

Abstract
This study was designed to estimate and compare the level of the use of agricultural inputs among cassava farmers in Anambra State by gender. The State lies within the $6^{o}13'$ and 7^{o} 9' North and longitudes $7^{o}49'$ and $7^{o}57'$ East and on a plain under 200m above sea level. A multi-Stage random sampling technique was used in selecting 180 farmers (equal number of female and male) from three out of four Agricultural Zones of the State. Primary data were used for this study and were analyzed using descriptive statistics (mean, frequency and percentage) and rated using Likert rating scale. The result of the likert showed that male cassava farmers control and use high level of inputs than their female counterparts. This study therefore recommends a policy that will aim at gender equality in the control and use of inputs for cassava production by gender.

Introduction
The cassava (*Manihot esculenta*) plant is a perennial woody shrub that grows from about one to three meters in height with palmate leaves. It was introduced to Africa by the Portuguese during the late 16^{th} century (Nweke, 1994). The crop is friendly to different environmental conditions and well suitable for integration into the farming systems and socioeconomic conditions of Africa (Nweke, 1996a). The crop's ability to provide a stable food base is a function of its flexibility in terms of planting and harvesting strategies. (Government of Ghana, 1996). According to Onyemauwa (2010), cassava has the potential to increase farm incomes, reduce rural and urban poverty and help close the food gap. As a cash crop, cassava generates cash income for the largest number of households, in comparison with other staples, contributing positively to poverty alleviation (Obisesan, 2012). Reports have shown that a higher proportion of cassava farmers, in Nigeria get a higher income from its production than they get from most other major staple (Ezeibe et al., 2015). Nigeria has remained the global leader in cassava production with an annual production of 35 million metric tonnes (Food and Agriculture Organization, 2011). Nigeria is regarded as the largest producer of cassava but the output per hectare remains one of the lowest in the world principally due to poor technological development and use rudimentary farm inputs. (Ogundari, 2010). However, because of economic diversification towards agriculture, modern agricultural inputs started to emerge. Anaglo, (2014) noted that farmer capacity to employ improved technology and investment depends on their access and use of productive resources. Both men and women contribute significantly to agricultural production yet their access to agricultural resources differ (Deere and Doss, 2006). For instant women face several challenges most importantly cultural restrictions in accessing inputs than men (FAO, 2010). Based on this information therefore, the focus of this paper is to estimate the gender differential access to farm inputs by cassava farmers.

Methodology
Study Area
This study was conducted in Anambra State, in South Eastern Nigeria, which comprises of 21 Local Government Areas (LGAs) with four Agricultural zones (ASADEP, 2003). The area lies within the $6^{o}13'$ and 7^{o} 9' North and longitudes $7^{o}49'$ and $7^{o}57'$ East (Nfor, 2006). The area lies

mainly on plains under 200m above sea level (ASADEP, 2003). It has tropical rain forest vegetation, humid climate and a rainfall of between 152mm- 203mm. The main crops of the State are roots, tubers, cereals and tree crops. The State has comparative resource advantage for production of cassava than most of the Southeastern States (ASADEP, 2003).

Sample Selection

Sample Selection

A multi-stage sampling technique was used in choosing the samples. Three agricultural zones (Aguata, Anambra and Awka) were randomly selected for the study. Secondly from the zones, one extension block each was randomly selected. Thirdly, two circles were randomly selected from each of the blocks. Furthermore, one village was randomly selected from each of the circles. Ten (30) respondents (that is 15 males and 15 females) were randomly selected from each of the villages. Thus a total of 180 cassava farmers were selected for the study.

Data Collection

Preliminary visits were carried out to the three agricultural Zones before the commencement of the actual data collection. The visit was an aid for the familiarization of the researchers with the study locations, resident agricultural extension agents, key informants and field guides. Data were collected using structured questionnaires and interview schedule. Data collection covered the socio-economic characteristics of the farmers, labour, farm size, herbicides application, capital, improved cassava stem, fertilizer application.

Data Analysis

Descriptive statistics (such as mean, frequency, and percentages) was used to derive socio-economic characteristics of the farmers while likert scale on a 3-point with a bench mark of 2 such that high (3), medium (2) and low (1). Note that any technologies rated 2.5 to 3 is regarded as high, from 2 to 2.49 is medium and from 1 to 1.49 is low. The likert-scale is stated as follow:

likert scale model:

$\overline{X}s = \frac{\sum FN}{N_r}$

Where

$\overline{X}s$ = mean score

$\sum$ = summation sign

F = frequency

N = likert nominal value

Nr = number of respondents

Results and Discussion

Socio-Economic Characteristics of the Respondent

The distribution of respondents according to socio-economic characteristics presented in Table1 indicated that the farmers (both male and female) were adults but still active in the business of cassava farming. The result confirmed that adult male farmers were the majority (76.11%) that had access to inputs for cassava production compared with their female (57.78%) counterparts. This is an indication that female farmers are still taking a lead in cassava enterprise than male farmers. The result for the level of education shows that male farmers were more educated than their female counterparts and is an indication that male farmers will have more knowledge on where to source and use the inputs. The female farmers have more experience (mean level of 23 years) on cassava production than the male (20 years). Perhaps female are virtually involved in all the scopes of its production (production, processing and marketing). The mean level of farm size for male farmers (1.8ha) and that of female farmers (1.2ha) is an indication that both of the farmer groups are small scale farmers (Onyebinama, 2004) but yet male farmers control the land more than their female counterparts.

Table1: Distribution of respondents according to socio-economic characteristics

	Male		Female	
Age (Years)	Frequency	Percentage	Frequency	Percentage
18-35	26	14.44	20	11.11
36-53	11	6.11	41	22.78

Table 2: Distribution of respondents according to the level of inputs assessment by gender

	Male Farmers		**Female Farmers**	
Agric. Inputs	**Level Of Usage**	**Rating**	**Level Of Usage**	**Rating**
Herbicide	2.1	Medium	2.8	High
Fertilizer	2.0	Medium	2.9	High
Capital	2.7	High	1.7	low
Labour	2.5	High	1.9	Low
Land	2.6	High	1.5	Low
Improved Cassava Variety	1.7	Low	2.8	High

Source: Survey Data 2017

Table 2 shows the level of inputs assessment by male and female farmers in Anambra State. The result shows that female cassava farmers have high level of use of herbicides than male farmers. Perhaps female farmers use the herbicides as assistance for weed control on cassava farm than the male farmers who predominantly engage in land preparation. This agreed with the finding of Food and Agriculture Organization, (2009) who reported that women specialized on weeding and other farm maintenance. The result also shows that female farmers have high level of use of fertilizer than their male counterparts. Maybe the level of usage would be as a result of experience from training (women empowerment training) that productivity of cassava could be increased with the application of right quantity of fertilizer. This agrees with the report of Nwaru (2004) who noted that experience is knowledge and skill gained by contact with facts and events. Male cassava farmers have high control/use of capital than their female counterparts especially in a household where male farmers are the household head. Perhaps male farmers engage in economic activities that generate them more income than their female counterparts. This agrees with the finding of Eftila et al., (2013) who noted that female farmers are limited with revenues and therefore restrict from investing in new technologies.

Male farmers usually use hired labour for their farming activities than their female counterparts who normally use self-labour and family labour maybe due limited fund female farmers control in their family. This agrees with Mgbakor and Nwamba, (2013) who that the major challenge faced by the women is inadequate labour. The result for the use of land by male and female farmers shows that male farmers have high level of land usage than their female counterpart. This is an indication that female farmers especially in male headed household have less right over the use of land for any economic activity than male perhaps due to the culture. This agrees with FAO, (2010) who stated that globally women scarcely own land due to norms and custom. From the result, female cassava farmers have high level of the use of improved cassava varieties than their male counterparts. This would be perhaps attributed to the early adoption ability by female farmers than their male counterparts who will always adopt crops they think are of economic relevant. This would be attributed to the fact that more than 50% of women are involved in cassava production than men (Mgbakor and Nwamba, 2013).

Conclusion

From the result male farmers have high level of controls/uses over capital, labour and land, medium level over herbicide and fertilizer, and low level over improved cassava variety while female farmers have high level over the controls/uses of herbicides, fertilizer and improved cassava variety and low over the control/use of capital, labour and land. The study concludes that male farmers have high level of inputs control/use in the production of cassava despite that female farmers are much involved in cassava production than male. Therefore this study recommends that all the resources meant for cassava production should be made available to all categories of farmers for sustainability and high productivity of cassava.

Gender Roles in Forest and Tree Products Employment and Poverty Reduction in Rural Areas of Delta State, Nigeria

Nwandu, P. I.
Department of Agricultural Economics and Extension
National Open University of Nigeria Abuja

Abstract
The study was conducted to investigate gender roles in forest and tree products (FTPs) employment and poverty reduction in rural areas of Delta State, Nigeria. Purpose was to attract the attention of policy makers and stakeholders that aside farming there are other sectors of the rural economy that can help address food problems, and poverty when given attention. Multistage sampling techniques were used to select 360 rural household respondents. Data was sourced from primary and secondary sources. Data was analysed using descriptive statistics, t-test distribution and Foster, Greer and Thorbecke model of poverty analysis. FTPs income helped to reduce poverty among the rural households. This is as a result of the fact that when FTPs income was excluded from household total income, incidence, gap, and severity of poverty increased from 0.4870, 0.1522 and 0.0476 respectively to 0.7903, 0.3203 and 0.0810 respectively. Females were more actively involved in FTPs employment than their male counterparts (P<0.05). While adult females and children exploited FTPs for subsistence purpose, the adult males reasons were found to be commercial. Recommendations include integration of FTPs into National Accounting System, allowing women and men to participate in policy formulation and implementations; policies should shift towards participatory approach to FTPs activities and creating an enabling environment in rural areas through the provision of basic amenities.

Keywords** **Gender** **Forest and Tree** **Products** **Poverty

Introduction
Within the framework of off-farm economy in Nigeria, the rural people especially the poor are dependent on forest and tree products (FTPs) for most of their livelihood. Forest and tree products are derived from natural forest, planted forests and trees outside forest. Trees outside forest include isolated trees in landscape, windbreaks, shelter belts, trees along roads and rivers, trees in agricultural systems and trees in urban environment (FAO, 2013). According to Ahmed (2000), FTPs are products from forest and all other parts or produce of trees and plants including climbers, grasses and creepers. They also include produce from animals when found or brought from a forest, peat surface soil and minerals. In this study, FTPs are defined as products derived from natural forest, planted forest (including plantations and orchards) and trees outside forest. FTPs are made up of wood and non-wood products. The wood products are mainly timber, firewood and charcoal. Timber is used mainly as building materials, furniture, matches, utensils, books, newspapers, toilet tissues and fuelwood among others (FAO, 2013). On the other hand non-wood forest products (NWFPs) consist of goods of biological origin (FAO, 2013). They include fruits, nuts, mushrooms, beverage, wine, clean water, medicinal plants, latex, rubber, gums, and resins, cloth, jute fibres, bask fibres, chewing sticks, tooth cleaners, sponges, decorative bead, oil, barks, bark and lac, natural varnish, tanning extracts, fodder, honey, bee wax, milk cocoons and forest games (Nwandu, 2015). For the purpose of this study, the economic and environmental services provided by forest and trees, for example carbon sequestration, soil fertility and soil protection, watershed protection, windbreak uses or general aesthetic and spiritual values are not included. FTPs contribute significantly to rural household consumption, income and employment. FTPs based employment provide opportunities in many rural areas. These FTPs based employments often require low establishment costs and are

characterized by easy and open market access which tend to make them accessible to rural households and the poor (Rahut; Behera and Akhter, 2016). It may be full or seasonal employment. Most of these enterprises are very small and household based enterprises. There is increasing recognition within the field of forestry that gender issues are important. The focus has shifted recently to women and men's access to forest resources, as a means of improving livelihoods for the resource poor and sustainable forest management locally and globally. Men usually focus on the management of timber while many rural women spend many hours each day collecting NTFPs especially fuelwood which they depend on for cooking their meals (Moss and Swan, 2013). It is necessary to explore and develop other sectors of the rural economy aside agriculture. The expectation is to help broaden the choice of policy alternatives in solving food problems, reduce poverty and income inequalities in the rural areas. An important but neglected sector in the rural economy is the FTPs. Apart from the exploitation of FTPs like timber which is well documented, quantified and generally accessible to national statistics and calculations, information on the informal activities of the non-timber FTPs which is engaged in by the vast majority of the rural households are not generally known. If known, they tend to be descriptive rather than quantitative and are discounted in national statistics. Moss and Swan (2013) stated that women contribute to forest management. Yet these contributions have been under-recognised as there are significant income disparities between men and women in forestry performing the same task. Women are supposed to be involved in policy making and management. However, in practice, the reverse is usually the case. When State Department of Forestry (SDF) seek local advice they turn as men to men in the household or village. These knowledge gaps identified are not being targeted but are necessary for policy. This study therefore examined these issues and made some recommendations.

The broad objective of the study is to investigate gender roles in forest and tree products employment and poverty reduction in rural areas of Delta State, Nigeria.

Methodology

The study area was Delta State, Nigeria. The rural population is engaged in one form of farming or the other. However, apart from farming, majority of the rural population were engaged in off-farm, non-agricultural employment.

Sample and Sampling Procedure

A multistage sampling technique was used for the study. The first stage was the purposive selection from the 3 Agricultural Zones, 2 local government areas each giving a total of 6 LGAs used for the study. The second stage was selection through random sampling, 4 rural villages each from the 24 villages. The final stage of the sampling was the selection of 15 rural households each from the 24 villages giving a total of 360 households respondents used for the study.

Data Collection

Data was gathered from both primary and secondary sources. The primary data were generated by use of sets of structured and semi-structured questionnaires. In all 340 questionnaires was successfully completed and was used for the analyses. The semi-structured questionnaire was also used to collect rural household consumption data on the different economic activities of the households. Data were collected on daily basis and collated into weeks, months and finally annually. At the end of the exercise, 179 rural household respondents successfully completed the exercises on income and consumption and were used for analyses. Because of the seasonal availability of FTPs, this exercise was carried out for a year (October 2014 to September 2015).

Data Analysis: Data was analysed by the use of descriptive statistics such as frequency distribution, percentages, means and standard deviations. The economic valuation techniques of market price-based valuation method such as Benefit Transfer (BT) method were also used. Hypotheses were tested using t-test distribution. Poverty was analysed using Foster, Greer and Thorbeck (FGT) Model

Results and Discussion

Demographic characteristics of FTPs-dependent rural households

Table 1 shows the common occupations engaged in by the rural household respondents in the study area. The main occupations were agriculture and FTPs activities. Other occupations engaged in by the rural households include business with the highest proportion of 35.6%. This was followed by agricultural labour and artisans. The public and private occupations were the least sector with 19.4%. Usually, FTPs activities are usually grouped with agriculture but in this study they were separated to find out the contribution of each sector to the rural household economy. While some members of the household engage in farm work others are busy with FTPs activities

Table 1: Demographic characteristics of rural household *(n =340)*

Age (Years)	**Frequency**
20 – 30	19 (5.6) *
31 – 40	90 (26.5)
41 – 50	101(29.7)

Measurement and Analysis of Poverty among FTPs-Dependent Rural Households

Table 3 shows that when relative poverty was measured with FTPs consumption income inclusive, the head count index was 0.4870 depicting that 48.70% of FTPs-dependent rural households were poor. The income-gap ratio or intensity of poverty was 0.1522. That is the poor individuals' income transfer requires about 15.22% to bring them to poverty line. The severity of poverty was 0.0476 which shows that 4.76% of the individuals suffer severe poverty. However, when relative poverty was measured without FTPs consumption income poverty increased tremendously. The head count index increased to 0.7903 throwing about 30.3% more individuals into poverty. The income-gap ratio widened to 0.3202 while the severity of poverty also rose to 0.0810.These findings have therefore revealed that although poverty pervades in rural households, FTPs income is an important source in reducing poverty in rural households as also observed by Muleng, et al (2012).

Table 3: Relative Poverty Indices With and Without FTPs Consumption

	H (α = 0)*	I(α = 1)*	FGT (α = 2)
1.	Poverty indices with FTPs consumption income		
	0.4870	0.1522	0.0476
2.	Poverty indices without FTPs consumption income		
	0.7903	0.3202	0.0810

Source: Field Survey 2014/2015
*H(**α** = 0) = Head count ratio, I(**α** = 1) = Income – gap ratio, FGT (**α** = 2) = severity of poverty.

Rural Household Members FTPs Employment Status

Table 4 Show that 87.6% of the rural household members were engaged in FTPs employment. The result also shows that almost all the members living in the household were involved in FTPs activities. However, the adult females with 96.0% were more involved in FTPs activities, followed by adult male with 93.03%. The children female (84.6%) and children male (83.3%) were also very much engaged in FTPs employment. On gender, the females with 87.85% were more involved in FTPs activities than their male counterparts with 86.3%. These findings were in line with that of Mulenga, Richardson and Tambo, 2012. Moss and Swan (2013) also stated that females are very much engaged in FTPs activities than their male counterparts. That while females are engaged in FTPs production, processing, marketing and management especially NTFPs, men usually focus on the management of timber.

Table 4: Rural household members FTPs employment status

Gender	Total number in sample	Number engaged in FTPs employment	Percentage (%)
Adult male	258	240	93.0
Children male *	593	494	83.3
Total male	**851**	**734**	**86.3**
Adult female	321	308	96.0
Children female *	790	668	84.6
Total female	**1111**	**976**	**87.9**
Total household members	**1962**	**1710**	**87.6**

Source: Field Survey 2014/2015
* Children are members of the household below the age of 17

Employment in FTPs as Affected by Gender

The gender compared was the male and female members of household involved in FTPs employment using the t-test analysis.

Table 9: T-Test Statistics of gender in relation to FTPs employment

	Mean	N	Std deviation	Std Error Mean	t-cal	df	Sig (2) tailed	Remark
Members involved in FTPs employment – Male	4.37	339	1.479	0.080				
Number of household members involved in FTPs employment – Female	5.47	339	1.741	0.095	9.184	338	0.00	S*

Source: Field Survey 2014/2015; * = Significant; Significant level = 0.05

The t-test analysis in table 9 shows a calculated t-value of 9.184 as compared to critical t-value of 1.96 at 0.05 level of significance. This indicates that the difference was significant. That is, there was difference in the male and female members of the household engaged in FTP employment. We can further conclude that the females were more engaged in FTPs employment than their male counterparts in the household. The hypothesis that gender was not affected by the total number of household members engaged in FTP employment was therefore rejected and the alternative accepted.

Conclusion

Results confirmed that poverty generally pervade in the rural areas. However, incomes from FTPs employment were found to help reduce poverty in the rural areas. Policies should shift towards participatory approach to FTPs activities. The present "top to bottom" approaches where policies and regulations about FTPs are passed from government agencies to the rural households usually alienate the rural households who are the end users. The result is a disconnect between the policy makers, policy implementers and end users. The rural household should be involved in any policy or regulation formulation and implementation. This will help them see such policies or regulations as their own and work hand in hand with government agencies to enforce and defend the policies.Similarly, at local levels giving females chance to fully participate in formulation and implementation matters concerning FTPs will improve conservation, extraction and utilization. As revealed by the findings of the study, females constitute majority of rural household members engaged in FTPs employment. Their views are needed to guide the formulation and implementation of FTPs policies and regulations. Education and enlightenment of rural households especially women who constitute majority in FTPs activities will go a long way in improving the quality and value of their products. The enlightenment can be on issues of production, processing, marketing and conservation among others. Methods can be through demonstration, discussions, meetings, exhibitions, television and radio programmes.

Preference of Songs in Disseminating Maternal Health Care Messages among Rural Women in Imo State, Nigeria

Odonze B.N. and Odoemelam L.E.
Federal Department of Agricultural Extension DD-Field Extension Services, Abuja, Nigeria.
Email: gozika2@gmail.com
Department of Rural Sociology and Extension, Michael Okpara University of Agriculture Umudike Abia State, Nigeria.
Email: *lovinasteve@gmail.com*

Abstract
The study assessed why rural women preferred songs as a channel of communicating maternal health messages in rural communities in Orlu Senatorial zone, Imo state, Nigeria. About 180 respondents were selected from villages, they were previously exposed to songs where health issues were incorporated. Data were collected with the help of semi- structured interview schedule. A 4-point Likert type scale was used to generate data and analyzed with mean scores in disseminating maternal health messages shows that non-technological in nature had a mean score of $\overline{(x = 3.42)}$*, messages presented life* $\overline{(x = 4.0)}$*, appealing effect* $\overline{(x = 3.14)}$*, cultural compatibility* $\overline{(x = 3.28)}$*, in built feedback mechanism* $\overline{(x = 3.43)}$*, attract people easily* $\overline{(x = 3.50)}$ *and minimum input* $\overline{(x = 2.67)}$*. Songs as a channel of disseminating maternal health messages was preferred by the women and the study records that policy makers should also incorporate folk media as one of the major channels in reaching rural women.*

Key words: Songs, Rural women and Maternal health

Introduction
Folk media is a broad concept representing a variety of forms that have differing communicative entertainment and educational potential. They vary from place to place, culture to culture and region to region (Mathiyazhagan 2005), but in all these forms the purpose remains the same, that is to inform, educate and entertain the audiences for generating awareness among them about development issues, including health and family welfare, rural development, agriculture and social aspects among others. With this, there exist varied level of acceptance and preference towards folk media, which in turn determine their applicability for development communication in a given development setting. This study is confined to a specific folk media (songs and dance). Poor health status, a wide range of controlled, uncontrolled, preventable and non-preventable diseases and inadequate health care services are considered a major deterrent to human, social and economic development in developing countries (Brass etal, 2007). Anasi (2012) investigated the dissemination and spread of health data in African and demonstrated that numerous African nations use distinctive techniques and channels to disperse health information to most communities. Besides utilizing normal speech, health are also conveyed as melodies, stories and talks (Anasi, 2012). Tsehay (2014) also explored that maternal health information sources of women residing in five villages in Ethiopia. The outcome of the study revealed that lack of knowledge perceived personal risk of health problems, and seeking a healthy life are the main the factors that motivate women to seek for information. Nwagwu and Ajama (2011) examine the health information needs, sources and information seeking behavior of people living in rural Nigeria. The study explained that the respondents relied on traditional sources for health information and visited health services when they are seriously sick. Omogor (2013) also conducted a similar study in Nigeria, the result revealed that town criers, market places, songs, traditional festivals, radio were vehicles of information that were used to set and distribute health information among themselves. A study conducted by Wolf and Bond (2002) affirms that

peer education tends to increase the behavioural change of adults and adolescent due to the similarities that may exist between the educator and the target. In Nigeria, these demographic similarities, along with trends towards the familiar, can be observed in effective communication. In the later parts of the 1940s where health communication to the Nigerian people by the government began, attempts at showing films clips and using innovative technology were not successful. It was only through the utilization of specially designed puppet shows and performance directed to the specific ethnic groups that the expected conduct and awareness level change happened (Onogor, 2013). The best communication strategy for developing countries is based on the idea of integrating with the community. (Ford *et. al.,* 2005) opine that that the adoption of participation, self-determination and the inclusion principle in the information delivery strategy has a fundamental way certain behavior is wrong and also further state that permeating people to deliver input on how health data is going to help them change both talking over different communication channels to be used and setting goals for desired change together provide such responsibilities. The study investigated, Women Preference of Songs in Disseminating Maternal Health Care Services, since that the closer a message is to the culture, expectations and lifestyles of the individual and the more integrated the advert campaign is with such characteristics, the more effective health information can be passed on and behavior change achieved.

Methodology

The study was conducted in Orlu Senatorial zone of Imo state. For the purpose of this study, three villages namely Nwangele, Orlu and Ideato North purposively selected in which traditional media shows (songs related to health issues) were performed regularly in a year previous to the investigation. Using the purposive randomly sampling method, a total of 180 viewers from the selected villages were selected. All the 180 viewers were found to be regular viewers of the traditional media. Data were collected with the help of semi-structured interview schedules. 4-point Likert type scales of strongly agree = 4, agree = 3, strongly disagree = 2 and disagree = 1 was used to generate data for the study. Data generated were analyzed using mean scores.

Results and Discussion

Table 1: Mean Preference of Songs in Communicating Health Care Messages among Rural Women in Imo State

Statement	Mean Score
Non- technological in nature	3.42
Messages are presented life	4.0
Have more appealing effect on target audience	3.14
Cultural compatibility	3.28
In built feedback mechanism	3.43
Minimum input, maximum output	2.67
Attracts people easily	3.50
Grand mean	3.38

Source: Field Survey, 2017

Results on Table 1, shows mean preference of songs in communicating health care services among rural women. From the result, non-technological in nature had a mean score of $(\overline{x} = 3.42)$. The implication is that no special skill is required in disseminating the information but only flexible and culturally rigid. Messages are present life $(\overline{x} = 4.0)$. According to agricultural extension concept, when messages are supported with visual aids it enhances their recollecting ability. Effect on target audience had a mean score of $(\overline{x} = 3.14)$. This is possible because it has been designed to cum entertainment mode so as to make the messages more appropriate, understandable and convincing (Chiovoloni, 2004). Cultural compatibility had a mean score of $(\overline{x} = 3.28)$. This could be possible because of the face to face interaction. Minimum input had a mean score of $(\overline{x} = 2.67)$. Traditional folk media according Motgnty *et. al;* (2011) operate with the motto of minimum input and maximum output. Bringing about changes in the behavior of the target audience. Attracting people had a mean score of $(\overline{x} = 3.50)$, because of the cultural affinity and belief. The songs are more acceptable to the society and their ideas are easily adopted for the behavior change because according to the performances are almost from the same community.

Conclusion

The study investigated the mean preference of songs in disseminating maternal health care messages in rural communities of Imo state. From the results, all the statement had positive and significant outcome, hence communication. Therefore, songs as a vehicle of development messages, including health and family welfare was fully preferred by the respondents because communication was practical in approach and goes to the heart and head of the people. Though advances have been made in electronic media and their reach is quite high, yet people use them for getting information but for putting the information into action, they need channels like interpersonal communication or the media which can help them remove queries where the traditional media (songs) comes into effect.

Land Accessibility among Women Farmers and Effect on *Telferia* Production in Esit Eket Local Government Area, Akwa Ibom State, Nigeria

J.B. Effiong and C.L. Aboh
Department of Agricultural Extension and Rural Sociology, Faculty of Agriculture, Forestry and Wildlife Resources Management, University of Calabar, Cross River State, Nigeria
Corresponding author*:* *johneffiong@yahoo.co.uk*.

Abstract
The study assessed land accessibility among women farmers and effect on Telferia production in Esit Eket Local Government Area, Akwa Ibom State, Nigeria. Specifically, the study described the socio-economic characteristics of the respondents, identified land accessibility pattern by women farmers in the study area and identified factors affecting level of access to land by women for Telferi production. A multistage sampling technique was used to select 100 respondents for the study using a well-structured questionnaire. Data obtained were analysed using descriptive statistics such as frequency, percentage, mean score and rank. The results revealed that majority of the respondents (47%) were married. Majority of the respondents had farm size ranging from 1-4ha (76%) and were engaged in Telferia production for 1-5 years (45%). On land accessibility pattern by women farmers for Telferia production, the result, revealed that land ownership by gift or freewill had the highest percentage (92%), followed by government allocation (90%) and shared cropping (86%). The study therefore recommended that arable land should be made accessible and affordable to women by government and individuals for Telferia production so as to improve their sources of livelihood diversifications and productivity in Esit Eket in particular and Nigeria in general.
Keywords: Land, accessibility, women farmers, Telferia and Esit Eket

Introduction
Agriculture provides man with food for consumption, raw materials for industries, housing and clothing among very many others. Therefore, it importance cannot be overemphasized. Land is a fixed and immobile factor of agricultural production. According to Cotula, Toulmin and Quan (2006), Aboh and Akpabio (2008), land accessibility is a situation whereby people both men and women (individually or collectively) gain rights and opportunities to occupy and utilize arable land. In otherwords, land accessibility is the opportunity to own, hold, use, manage and control land (Akpabio, 2005). *Telferia* is a leafy vegetable that are intensively grown in the southern region of Nigeria containing rich assortments of vitamins, minerals and proteins that augments the nutritive values of staple foods such as rice, maize, cassava and yam hence fighting/mitigating incidences of hidden hunger menace and malnutrition/malnourishment in Nigeria. (Akpabio, 2005; Effiong and Asikong, 2013 and Ekanem, 2018). According to Akpabio (2005) women farmers are generally less privileged and often face discriminations and limited access to rural land because of systemic gender biases in the forms of customs, tradition, cultures and norms that bars women from ownership and active participation in decision-making processes in their respective rural communities/villages hence reducing agricultural activities and productivity since women constitute approximately over 75% of the Nigerian agricultural labour force. In 2004, Asian Vegetable Research Development Centre (AVRDC) stated that vegetables are the most affordable and accessible sources of micronutrients such vitamins, minerals, proteins, sugars and essential oils that increases man's inherent resistance to debilitating diseases such as scurvy, night blindness, diabetes mellitus, diarrhea, ataxia, cardio-vascular disease (CVD), and cancer, and that, its production is recognized as a catalyst for development and as a means of foreign exchange earnings.

Methodology

The study was conducted in Esit Eket Local Government Area, Akwa Ibom State, Nigeria, Esit Eket is located at the Atlantic West-line boundaries of Ibeno, Eket and Nsit Ubium LGA's of the state. It has an estimated population of 63,701 (NPC, 2006) with 23 recognized villages with Ekid as the major dialect. The inhabitants of the area are predominantly farmers, fishermen and traders. Majority of the farmers in the area are engaged in crop and livestock production activities: *Telferia occidentalis* production in the area serves as a major source of livelihood diversification for rural households, but farmers especially women are often constrained by land acquisition patterns for *Telferia* production. Multistage sampling technique was used to select the respondents. At first stage, purposive sampling technique was used to select Esit Eket as a block from Eket Agricultural Zone. This was necessitated by the prevalent of vegetable farmers in the block. The second stage was the purposive selection of 10 cells from the block due to the intensive all year round cultivation of vegetables in the cells. In the third stage, 10 respondents were randomly selected from each of the selected cells. This produced a sample size of 100 respondents used for the study. Primary data were collected with the aid of an interview schedule and a structured questionnaire, while secondary data were obtained from relevant literatures and publications. Descriptive statistics such as frequency distribution, percentage, means scores and rank were used in analyzing the objectives and drawn conclusions.

Results and Discussion

Table 1, showed results of socio-economic characteristics of the respondents, this revealed that majority (33%) were aged 30-40 years, while (27%) were aged between 51-60 years. Also, majority of the respondent (58%) had primary education, (24%) had secondary education and a small number (12%) had no formal education implying that their level of education was relatively high. The result is in line with the findings of Effiong, Ijioma and Effiong, (2016); Effiong and Udo (2015), who asserted that a good level of formal education had direct relationship with higher economic returns, better access to agro-information, innovations, technologies, adoption/utilization and management of economic ventures. Results of household size revealed that (59%) had 1-5 persons per household, majority (76%) had 1-4 hectares of farmland, implying that the higher the number of persons per household /farm size, the higher the *Telferia* productivity (yield) and labour force for production in the rural communities. Table 2, showed land accessibility patterns by women farmers for *Telferia* production. The table revealed that (92%) of the respondents acquired land through gifts/freewill donations, (90%) through government allocations, (86%) through share-cropping and (88%) through leasing system. This result corroborates with the findings of Effiong and Efifong (2015) who reported that renting, leasing, community allocation and gifts are the land patterns predominantly adopted by most women farmers in Nigeria and are used mainly for agricultural production. Results of factors affecting womens' access to land is shown in table 3, the table revealed that high cost of land, inability to transfer land and insecured land tenure policy were ranked 1st ($\bar{X}$ = 2.67), 2nd ($\bar{X}$ = 2.38), and 3rd ($\bar{X}$ = 2.18) respectively, while inadequate land, difficulty in land transaction and limited use of land were minor factors affecting women access to land for *Telferia* production and were ranked (6th, $\bar{X}$ = 2.00), (5th, $\bar{X}$ = 2.12) and (4th, $\bar{X}$ = 2.14) respectively. This result corroborates with the findings of Adamu, (2014) and Odudu, (2015) who stated that high cost of land, inadequate land, unfertile land, land under dispute limited use of land, inability to transfer, and difficulties in land transactions among very many others were the factors affecting women access to land for crop and animal production in our rural communities. This study showed that non-availability of agricultural land negatively affected women's involvement in *Telferia* production in the study area.

Conclusion

The study concluded that majority of the respondents had a good level of formal education, farming experience and high income per annum. They accessed land for production through gifts/freewill donations, government allocations, leasing, share-cropping, community allocations and rents. Based on the findings of the study, the following policy recommendations were proferred.

- Women should be encouraged to access extension service irrespective of their tribe, race, culture, ethnicity and religious inclinations. This would improve on their innovativeness and productivity.
- Agricultural credit facilities should be accessible and affordable to women farmers at very low interest rate, to enhance farm productivity and increase income among women farmers.
- Government should encourage participation of women farmers in *Telferia* production by reducing the cost of land and regulating the process of land transactions in the rural communities.

Rural Women Participation in Cassava Flakes (Abacha) Processing in Umunneochi LGA Abia State

Nwakor, F.N., Azoro A.V., Anyaegbunam, H.N. and Amadi, P.O
National Root Crops Research Institute, Umudike Abia State, Nigeria.
E-mail: ngonwakor@gmail.com

Abstract
The study was conducted among rural women in Umunneochi Local Government Area of Abia State. The people of Umunneochi are well known for cassava flakes production. One community (Isuochi), out of the 3 communities in umunneochi LGA was purposively selected and 54 women were interviewed to assess their levels of participation in the production of cassava flakes popularly known as Ighu in Isuochi or Abacha in Southeast Nigeria. Structured questionnaire and interview schedule were used to elicit the true information about cassava flakes processing among the women. Data collected were analyzed by means of descriptive statistics such as frequency distribution tables, percentages and means. A five point likert scale of strongly agree, agree, undecided strongly disagree and disagree was used to present the level of participation of the respondents. The result shows that majority of the women had the highest level of participation in cassava flakes processing in the following activities with the following mean(x) scores; storage(3.9), slicing/grating (3.8), packaging (3.8), soaking/washing of cassava flakes (3.7). The cost of processing implements used by cassava flakes processors in the study area shows that good number of the respondents (38.9%) made use of pots at the cost of N4500 – ₦9,000 per pot for the processing of cassava flakes which seems to be high. the major constraints in cassava flake production were problem of pests attack (100%), lack of water (96.2%) and climate change impact(94%). It was recommended that modern processing facilities should be made available for cassava flakes production at reduced and affordable price and water bole holes should be made available in the study area by the government.

Keywords: Participation, Rural Women, Cassava flakes (Abacha) and Processing

Introduction
Cassava is one of the major food crops grown in Nigeria as a food security crop. The significant of the crop in tropical agriculture has been recognized in the area of its growth potential human and animal food, its enrichment and fortification, industrial uses, economic of production and genetic improvement (Okereke and Ojuwale, 2005). Cassava has a great processing value it can be processed and eaten as fufu, garri, flour, flakes (abacha) and many other food products(Nwakor and Nwakor, 2012). Diversification of the uses of cassava through indigenous diets promised high capacity for fighting hunger, alleviating poverty as well as enhancing livelihood of many rural farm households. Abacha is a local and indigenous food from cassava products that is popular and highly consumed by people in southeastern Nigeria. Abacha is made from cassava tubers,. It is white and crunchy and can be eaten dry or wet as a snack with coconuts or palm kernel (Adepoju and Nwangwu(2010). Cassava flake is prepared with simple implements like Knife for peeling and cutting the cassava tubers, Bowls for washing the sliced abacha, Pot for boiling, cassava slicer/shredder for slicing the cassava tubers into abacha, big flat baskets/mat for drying them under the sun .This abacha or African salad is the major food used as a sign of acceptance to any visitor that come to the people of Umunneochi especially Isuochi. Today the food is widely eating in every part of Nigeria as a special indigenous diet people who are into abacha restaurant, hotel or even mama put business are making a good living from the business. Abacha is the major source of income among the women of Umunneochi LGA because every household in this area produces cassava flakes to prevent hunger and poverty. This work

was designed to assess the levels of participation of women in abacha processing activities in Umunneochi L.G.A Abia State.

Methodology

The study was conducted among rural women in Umunneochi L.G.A of Abia State out of the three communities in Umunnneochi LGA one community was purposively selected for this study. This is because the community is well known for cassava flakes (Abacha) production. In this community three villages were randomly selected and in each of the villages eighteen (18) women were randomly selected for this study. Well-structured and interview schedule were used to get information from the women about their level of participation in abacha processing activities the instrument and cost for processing this commodity in the study area. Data collected were analyzed by simple descriptive statistics such as frequency distribution tables percentage and mean scores involving likert scales.

Results and Discussion

The results and discussion shows the levels of participation of the women in cassava flakes (abacha) processing activities, costs and quantities of processing instruments and the constraints in abacha processing among respondents.

Table 1:Level of participation of the respondents in cassava flakes (abacha) processing

Activities	Strong participation	Fair participation	Not participation	Total	Mean
Cassava peeling	32	20	04	140	2.5
Cassava washing	28	23	03	133	2.4
Cassava boiling	46	02	06	148	2.7
Cassava slicing/grating	54	22	02	208	3.8
Cassava flake drying before washing	54	16	05	199	3.6
Cassava soaking /washing	52	23	02	204	3.7
Cassava flakes spreading in mat	45	15	01	166	3.0
Cassava flakes sun drying after washing	54	17	03	199	3.6
Routine turning of flakes under sun	51	22	00	197	3.6
Packing of the dry flakes	53	23	04	209	3.3
Storage of the flakes	49	31	05	214	3.9
Marketing of flakes	28	22	21	149	2.7

Source: Field Survey, 2018

Table 1 shows the level of participation of the women in cassava flakes processing activities which include cassava peeling, Cassava washing, Cassava slicing/grating, Cassava flake sun drying before washing Cassava flakes soaking /washing, Cassava flakes spreading on mat, Cassava flakes sun drying after washing, Routine turning of flakes under sun, Packing of the dry flakes, Storage of the flakes, Marketing of flakes. The result shows that majority of the women had the highest level of participation in cassava flakes processing in the following activities with the following mean(x) scores; storage(3.9), grating (3.8), packaging (3.8), soaking/washing of cassava flakes (3.7), drying of cassava flakes 3.6 and 3.6 respectively. There was high participation of the women in cassava flakes (Abacha) processing in the twelve activities considered.

Table 2: Quantity and cost of cassava processing implements used by respondents

Quantity	Pot	Cost	Knife	Cost	Grater	Cost	Basket	Cost	Mat	Cost	Basin	Cost
<2	24	700-3500	0	0	0	0	0	0	0	0	0	0
2-4	21	450-900	36	100-500	45	200-600	39	500-800	0	0	27	3000-3500
5-7	09	400-500	15	250500	03	2507000	15	500-800	03	800-1000	21	3000-5000
8-10	0	0	0	0	03	200-600	06	800-1000	21	1000-1300.	03	2500 -5000
11-13	0		0	0	0	0	0	0	06	1000-1200.	0	0
Above 13	0		03	200-500	03	200-500	0	0	24	700-1200	0	0

Source: Field Survey, 2018

Table 2 shows the cost and quantities of implements used by the women in cassava flakes (Abacha) processing. The result shows that the following instruments/ implements were used in the processing of cassava flakes (Abacha) among rural women in Umunneochi LGA. They were pots, knifes, slicer, baskets, spreading mat, basins. The result shows that good number of the respondents (38.9%) made use of 2-4 pots at the cost of N4500 – ₦9,000 per pot for the processing of cassava flakes. (66.6%) of respondents made use of kitchen knife at the cost of ₦100-N500 per knife, 83.3% made use of grater at the cost of ₦200 – ₦600 per grates.72.2% of the women made use of 2-4 baskets at the cost of ₦500 – ₦800 per basket for cassava flakes processing 44.4% of the respondent used above 13 cassava flakes spreading mat at the cost of N700-₦1,200 per mat. 50% of the women made use of 2-4 basins at the cost of N3000- ₦3500 per basin for cassava flakes (Abacha) processing. This analysis of cost of implements of Abacha processing show that most of the processing implements were affordable, but expensive.

Table 3: Distribution according to the Constraints in cassava flakes production

Constraints	Frequency	Percentage
Lack of land	09	16.6
Lack of fertilizer	48	88.8
Unavailability of finance	48	88.8
Lack of herbicides	27	50
Poor yield	21	38.8
No access to modern processing technologies	42	77.7
High labour cost	48	88.8
High cost of processing equip	42	77.7
Pests incidence	54	100
Climate change	51	94.4
Storage problems	18	33.3
Marketing	06	11.1
Theft	0	
Lack of storage facilities	12	22.2
Fragmentation of land	09	16.6
No access to credit	42	77.7
Lack of water	52	96.2

Source: Field Survey, 2018

The result in table 3 shows that the major constraints in cassava flake production were problem of pest attack (100%), lack of water (96.2%) and climate change (94%). Others were high cost of labour (88.8%) lack of fertilizer and lack of money (88.8%) and poor access to credit (77.7%) and no access to modern processing implements (77.7%). Many other problems constraints cassava flakes processing in Umunneochi LGA. But due to improvement in technological development some of these problems are becoming reduced.

Conclusion

The level of participation of rural women in cassava flakes production was very high. In all the activities involved in the processing of cassava root into flakes the women were highly involved. These women used this occupation to fight against food in security, hunger and poverty among the people. Both the young, middle aged to elderly women in this area were involved in the production of Abacha . These women have their challenges in the production or processing of cassava flakes (abacha) which include pest attack, climate change, lack of money, high cost of labour, lack of fertilizer for cassava production and lack of water for washing of cassava flake. Modern processing implements should be made available for cassava flakes production. Government should encourage industrial production of cassava flakes by establishing a processing plant in the area. Modern water facilities such as tap water should be provided by the government for increased production. A survey on the levels of participation of men in this activity is also recommended.

Food Insecurity and Coping Strategies among Rural Households in Yobe State, Nigeria: A Gender Perspective

J.D. Moses[1], and S.A. Okpachu[2]
[1]Department of Agricultural Economics, Adamawa State University, Mubi
[2]Department of Agricultural Education, Federal College of Education (T), Potiskum

Abstract
Food insecurity has remained a recurring decimal in the development of Nigeria despite the several efforts to tackle it. Most of the previous food insecurity studies focused on rural farming communities without regard to gender issues. Focus on gender differentials in the knowledge of technologies for coping with food security has not yet been properly addressed. The study evaluated the food security and coping strategies of farming households in Fika and Potiskum Local Government Areas of Yobe State. Data were collected with structured questionnaire and observation technique from 100 farming household and analysed using descriptive, food poverty line, and coping strategies use index it was observed that male headed household were more food secured than their female headed counterparts in the study area. The major coping strategy are planting food crops on a small scale of land, occupation diversification and harvesting food crops from the farm.
Keywords: Food security, Gender, Coping strategies, rural household and Yobe State

Introduction
During the 1996 World Food Summit of November, held in Rome, all heads of Government or their representatives at the summit pledged their support and commitments to achieving global food security and alleviation of hunger with the aim of halving the population of undernourished persons by the year 2015 (FAO, 1996). Despite this unprecedented effort by international institutions, the population of the undernourished people in the world still constitutes a major problem in most parts of the world. Food is no doubt, the most basic of all human survival needs, its availability (via production and distribution) and accessibility (i.e. affordability) remains a major challenge in developing economies. Although, so many efforts have been sunk in improving the quality as well as production of world food supplies, food insecurity remains prevalent in Nigeria. Nigeria have an energy intake of 1730Kcal and an average protein supply of 64g capita per day far below the 2500 – 3400Kcal minimum recommended daily intake per day This shows that Nigeria is facing the challenge of unbalanced diet leading to various deficiency symptoms.
Similar to other developing countries, there is a strong gender dimension to food insecurity and malnutrition in Nigeria. Women in developing countries play significant roles in maintaining the three pillars of food security- food production, economic access to available food, and nutritional security. But they play these roles in the face of enormous social, cultural and economic constraints. However, the place of gender as a fundamental issue in assuring food security both at national, household and individual levels cannot be overemphasized. Food security refers to a situation whereby individuals have access at all times to quality and sufficient food resources to maintain a healthy and active life (World Bank, 1986). On the other hand, food insecurity exists when there is constrained physical and economic access to secure sufficient quantities of nutritionally adequate food to allow individuals sustain an active and healthy living (Ifeoma and Agwu, 2014). Food insecurity comes with unpleasant conditions with consequences detrimental to human health, well-being and productivity. Consequently, when faced with food insecurity, households device strategies to minimize the impact of food insecurity and as well as to stabilize their food access. Generally, households employ different coping strategies in the early stages of

food insecurity, which however vary based on cultural and geographical differences (Maxwell, 2008) and as well as their social and economic resource endowment (Liwenga, 2003). Literature have identified that households are significantly more inclined to adopting multiple coping strategies when hit with food crisis However, the contexts that compel households to apply multiple coping strategies, are not particularly well defined. This paper is therefore an attempt to examine the coping behaviours of households and factors influencing the number of coping strategies employed. Understanding the implemented coping strategies at the household level is critical for formulating and implementing appropriate policy and design programs related to addressing the problem of food insecurity. This study was undertaken to complement the current understanding of different coping strategies pertaining to food insecurity from a gender perspective in Yobe State.

Methodology

Study area

The study area for this research is Yobe State which is located in the North – East geopolitical zone in Nigeria while the target population is all the households in the area. A multistage sampling technique was employed for this study. Two Local Government Areas (Fika and Potiskum) were purposively selected from the state. Ten communities popular for farming activities were selected across each of the two LGA's. Fifty respondents were randomly selected and interviewed across communities for each LGA making overall total respondents of one hundred. The study used primary data collected with the aid of well-structured questionnaires. Open discussions, interviews and physical observation were also employed to complement. A multistage sampling technique was employed for this study. Two Local Government Areas (Fika and Potiskum) were purposively selected from the state. Ten communities popular for farming activities were selected across each of the two LGA's. Fifty respondents were randomly selected and interviewed across communities for each LGA making overall total respondents of one hundred.

Analytical techniques

Construction of Food Poverty Line

This was done to categorise the respondents into food secure and non food secure group using the two-third mean per-capita food consumption expenditure (Oluwatayo, 2005) as the benchmark. Households whose mean consumption expenditure falls below the food poverty line are regarded as being food insecure while those with their expenditure above the benchmark are food secure. Per-capita Food Consumption Expenditure (PCFEXP) = Food Consumption Expenditure/Household Size

Total Per-capita Food Consumption Expenditure (TPCFEXP) = Summation of PCFEXP

Mean TPCEXP (MTPCEXP) = TPCEXP/ Total Number of Households

Food Poverty Line (FPL) = 2/3 * MTPCEXP

Coping strategy index (CSI)

In analysing the extent of use of the coping strategies by these households, a coping strategy index (CSI) was developed and was ranked with the weighted mean score. The CSI gives a quantitative score for each household and is an accumulative measure of the level of coping (Orewa and Iyangbe, 2010). The extent of use of the coping strategies was expressed using a four-point scale with the scoring order 3, 2, 1, 0 for frequently, occasionally, rarely and never used respectively. The formula used to obtain the CSI score was adapted from Adebo and Falowo (2015) as follows:

$CSI = N_3 X_3 + N_2 X_2 + N X_1 + N_0 X_0$-- eqn (1)

Where:

CSI = Coping strategies use index

N_3 = Number of households using a particular coping strategy frequently

N_2 = Number of households using a particular coping strategy occasionally

N_1 = Number of households using a particular coping strategy rarely

N_0 = Number of households not using any of the coping strategies.

X_4 = Scoring order for everyday

X_3 = Scoring order for frequently

X_2 = Scoring order for occasionally

X_1 = Scoring order for rarely
X_0 = Scoring order for not using any
The CSI was used in rank order to reflect the relative position of each of the coping strategy in terms of their use.

Results and Discussion

Socioeconomic Characteristics of the Respondents

The socioeconomic characteristics of the respondents are presented in Table 1. The results reveal that majority of the respondents (60%) are in the 20 – 40 years age bracket and could be classified as youth and it is expected that they are more likely to play crucial roles as care takers of household's food and nutrition security. Household heads distribution by gender reveals that there are more female-headed households (56%) than male-headed households (44%) showing that the majority of the household were headed by female. This could be as a result of the prevailing security insurgency in the study area. The educational status of the respondents shows that majority of the respondents (50%) lack formal education. This is because the state is regarded as an educationally disadvantaged state. This is similar to the findings of Shuaibu, Abdullahi, Ango, Yusuf, Sulaiman and Bello (2015). Household sizes were grouped into the range of 1-5, 6-10, 11-15, 16 -20 and more than 20.The distribution shows that 38% of the respondents fell into the range of 1-5, 34% fell into the range of 6-10, and 18% of the respondents fell into the range of 11-15, 5% fell into the range of 16 -20, while 5% of the respondents fell the range above 20. This shows that the households' size is fairly large and can contribute to the rise in household consumption especially when the household members are jobless. Farm size land holdings of the respondents reveal that majority (88%) of the respondents own between 1 -2 hectares of land. This indicates that they are small scale subsistence farmer and may not produce enough for food security. This is similar to the conclusion of Agada and Igbokwe (2014).

Table 1: Socio economic characteristics of the respondents

Variable	Frequency	Percentage
Age

Estimates of the Food Poverty Line

The estimate of the food poverty line of the respondents is presented in Table 2. Findings in the study area shows that male households are more food secure (30%) than female households (16%) in the study areas. The findings agree with the findings of Adepoju, Ogunniyi and Agbedeyi (2015).

Table 2: Distribution of respondents by Food Poverty status and Gender.

Ranking of Food Insecurity Coping Strategies

The coping strategies to household food insecurity were measured on a four point scale; frequently, occasionally, rarely and never used and is shown in Table 3. The ranking was carried out with the aid of a four-point likert scale to score households' responses. These scores are 3, 2, 1 and zero for frequently used, occasionally used, rarely used and not used respectively. Generally, about 13 different coping strategies were very prominent among the available strategies employed. The study indicates that planting food crops on a small scale of land, occupation diversification and harvesting food crops from the farm were ranked first, second and third respectively. This agrees with the findings of Adebo and Falowo (2015). Other strategies adopted in descending order were reduce the number of times to eat, reduce the quantity of meals taken, cut down expenditure on food items, borrow money from friends/relatives, purchase food on credit, sale of asset such as land ,jewelries, engage children in hawking, rely on help from relatives or friends outside household, skip whole day without eating and withdraw children from school . The strategies are similar to what (Orewa and Iyangbe, 2010; Quaye, 2008) found in their studies in Nigeria and Ghana respectively. This may be because of traditional and cultural similarities between the study areas.

Table 3: Ranking of Food Insecurity Coping Strategies by coping strategy adopted

Strategy	Frequently Used(3)	Occasionally Used(2)	Rarely Used(1)	Not Used(0)	CSUI	Weighted mean	Rank
Reduce the quantity of meals taken	33	23	35	9	180	1.80	5
Reduce the number of times to eat	40	37	15	8	209	2.09	4
Sale of asset such as land ,jewelries	19	36	26	19	155	1.5.5	9
Borrow money from friends/relatives	15	45	23	14	167	1.67	7
Cut down expenditure on food items	13	54	26	7	173	1.73	6
Withdraw children from School	14	20	18	48	100	1.00	13
Engage children in hawking	20	20	38	22	138	1.38	10
Purchase food on credit	29	25	25	21	162	1.62	8
Rely on help from relatives or friends outside household	22	17	28	33	134	1.34	11
harvesting of food crops from the farm	44	36	14	6	218	2.18	3
Occupation diversification	50	30	17	13	227	2.2.7	2
Planting of food crops in a small scale of land.	52	32	11	5	231	2.31	1
Skip whole day without eating	10	40	8	42	118	1.18	12

Source: Field Survey, 2018

Conclusion

Based on the findings of the study, it could be concluded that households in the study area are food insecure and they actively adopt various strategies to improve their situation. Also, male-headed households are more food secure than female-headed households. It is therefore recommended that women should be enlightened about birth control measures to reduce household size hence, enhance food security. Also, they should be encouraged to participate in income generating activities to boost their household food security. Women literacy should be encouraged as women with formal education are more likely to adopt new technologies and increase productivity in their chosen career and invariably improve the food security of their households. Because women are the majority of the world's agricultural producers, Policies should be made to favour women and compete considerably with men in the field of Agriculture. Women should be encouraged to access productive resources like land, farm inputs and Finances.

Abstract

A large proportion of agricultural workforce in Nigeria are women, yet they control less than 2 percent of resources and contribute more than 50 percent of agricultural produce. Women invest income in food, nutrition and education of children and sometimes pay back family debts to improve family welfare. This study examines access to and ownership of resources by gender, determine gender roles and gender relations among respondents and the constraints faced by men and women in Nigeria. A sample of 200 respondents participated in the study which was conducted in Calabar Metropolis Cross River State Nigeria. Data collection technique used three large drawings of a man, woman and a couple. A set of cards showing various resources and possessions owned by members of the communities were presented to respondents who were asked to assign ownership of each item to either man, woman or both. The result shows that 82.40% of the resources were owned and controlled by men. The findings also reveal that women played a very significant role in agricultural development by contributing 78.60% but do not have equal opportunities with men in the society. Recommendations are made for a need for gender mainstreaming in agriculture and strengthening of women-in agriculture, constitute an all–women group for group activities. The contributions of women in agricultural development should not be overlooked to enhance food security and livelihoods in Nigeria.

Keywords: Access, control, gender, and resources

Introduction

There is always a potential controversy surrounding gender analysis. Women play a significant role in agricultural development, but their contribution is often overlooked (Maunder, 1972). An extension educator must understand women's special needs and constraints. Gender unlike sex which is determine biologically is a social construct that points to relations between and among sexes, with regards to their roles and can change over time while the social expectations of tasks, responsibilities and behaviors that are considered appropriate for people of a particular sex is termed gender roles. But the manner in which people of the same or different genders interact with one another is gender relations (Manfre et al., 2012). Gender analysis is therefore "the systematic gathering and analysis of information on gender differences and social relations to identify and understand the different roles, divisions of labor, resources, constraints, needs, opportunities, and interests of various groups, including men and women, girls and boys, and transgendered persons, in a given context" (Manfre et al., 2013). In agriculture, women suffer a lot of discrimination and have an image that is very much undervalued. For example, according to Rebouché, (2006) women's farm work is often on an informal basis and it is regarded as part of their family obligations to be available to work on the farm while having no control of resources At most times, when the men have emigrated or are off working as day labourers on other farms or in other sectors, the women take care of day-to-day work on the family farm in addition to their traditional role of looking after the children and the house. The work that Women performed both on the land and in the home have been underestimated and predominantly informal and unpaid, perhaps where a wage is paid it is always lower than for men (Rebouché, 2006). Nevertheless, it is generally considered that women do 60%-80% of the farm work in developing countries (World Bank, FAO and IFAD, 2009). In other words, women are generally overworked and very little attention paid to their plights. According to ENPARD (2016), these deficiencies in the treatment of women result in limited access to social welfare benefits such as maternity leave, sick leave, pensions and social security. Forty-three percent of the agricultural workforce is women, and it can go up to 70 percent in certain regions (Doss, 2011). They control 2 percent of resources and contribute more than 50 percent of global agricultural produce. They invest income in food or nutrition, education of children and paying back debts, which together contribute to family welfare. Data from several studies point to the fact that women have very few land tenure rights as a result of the patriarchal nature of many traditional rural societies which consequently prevents women from holding or using land or makes it a herculean tasks for them to do so (FAO, 2011). Those problems are compounded by similar difficulties with access to credit and to business promotion activities. Almost in every spheres of life women are at a disadvantage in comparison with their male counterparts, suffering higher levels of un-employment, discrimination in access to land and other assets, and other socio-cultural limitations. The consequence is that in recent years we have seen a high proportion of women become internal migrants, sometimes even higher than for men due to lack of access and control over domestic and community resources (FAO, 2016). Hence, the major objective of this gender analysis in the agricultural extension context is to clarify how gender roles and relations create opportunities for and/or obstacles to achieving development objectives. Specifically,

Methodology

This study was conducted in Calabar Metropolis of Cross River State, Nigeria. Visual tools were found to be very effective in getting both men and women to focus on gender without any sense of challenge or threat and as such were used for this study (Suvedi and Kaplowitz, 2016). The tools provides insights into how access to and control of domestic and community resources vary according to gender. As the community goes through the process, it raises the awareness of community members about how assets are owned and distributed within the community. Similarly, another approach to learning about gender roles used was asking about who does some particular tasks. Who do they do it with? The technique uses three large drawings of a man, a woman and a couple (Suvedi and Kaplowitz, 2016). A set of cards show various resources and possessions owned by people in the community. Participants were shown each of the above items and asked to assign ownership of each item to either man, woman or both. The question asked is not who uses them but who owns them. The list arrived at showed the pattern of ownership and whether men or women differ in ownership. The result also shows whether women have equal power with men in the society

Results and Discussion

The result of Table 1 shows that male dominated access and ownership of resources in the study area. This was clearly shown in the predominant ownership of 14 resources out of 17 representing 82.40% of resources while the female own only 4 (17.65) out of the 18 resources listed confirming the findings of (Rebouché, 2006) women's farm work is often on an informal basis and it is regarded as part of their family obligations to be available to work on the farm while having no control of resources. For example, women had zero land title as earlier reports (FAO, 2011) suggested. On the other hand, male and female only shared 2 resources equally, that is cell phone and currency at 50% respectively.

Table 1: Access to resources

Resources	Male		Female

They care for the elderly and the very young	20	10%	180	90%

Source: Field survey, 2017

Table 2 result indicate that out of a total of fourteen (14) tasks, female predominantly performed eleven (11) of such tasks representing 78.60% while the male performed the remaining 21.4%. More so, both male and female performed three (3) tasks equally which are field preparation, grains processing and care for animals thereby corroborating the findings of (World Bank, FAO, IFAD, 2009 and Doss, 2011) that women contribute 60%-80% of the farm work in developing countries. Hence, women lack access and control over domestic and community resources (FAO, 2016).Gender mainstreaming is the way forward for gender equity and development in agriculture to enhance food security and livelihoods in Nigeria.

Assessment of Constraints Militating Against Agribusiness Enterprises in Ikwuano Local Government Area of Abia State

B. O. Okpara, B.A. Ahamefule and W. Gracious
Department of Agricultural Economics, Michael Okpara University of Agriculture, Umudike, PMB 7267 Umuahia, Abia State, Nigeria
beatriceokpara@gmail.com

Abstract
The study assessed the constraints and socioeconomic attributes of agribusiness entrepreneurs in Ikwuano LGA in Abia State. A well-structured questionnaire was used to collect data from the respondents. Data analyses were carried out using descriptive analytical tools such as means, frequencies, percentages and likert scale. Results showed that the mean age of the respondents was 42.5 years. Majority (71.7%) of the farmers in the study area were married while 23.3 % of them were single. majority (90%) had formal education while 10.0% of them had no formal education. On average, the farming household has spent about 12 years in farming. Inadequate capital (4.40), was the most important constraint militating against agribusiness enterprises in the study area. This was followed by lack of appropriate technology (4.33), and high transportation cost, poor policy articulation, inadequate infrastructure, inadequate market information and no incentives with means of 3.63, 3.50, 3.83 and 3.25 respectively. The results therefore call for policies aimed at addressing these constraints for enhanced participation in agribusiness enterprises in the study area.
Keywords: Assessment, Socioeconomic, Attributes, Constraints, and Entrepreneurs

Introduction
Agribusiness is considered essential in achieving sustainable economic growth and significant level of food security in an under developed country like Nigeria. Its importance in accelerating the pace of economic growth cannot be over emphasized given its usefulness in determining the efficiency and effective capacity of the nation's production system (Oyeranti, 2008; Nto and Mbanasor, 2008). NIPC (2008) observed that productivity in agribusiness sector is critically important if output is to increase at a sufficient level to meet escalating demand for food. This is true following empirical data which revealed that while food output increased at 2.5%, food demand increased at a rate more than 3.5% due to high rate of population growth of 3.18% (FOS, 1996; ABSEEDS, 2005; FRN 2009). Efforts by government to ensure that the deficit is augmented will turn to naught if a critical and fundamental review of the determinants of productivity in the subsector is not examined (Ojo, 2003; Prasada-Rao et al., 2004; NIPC, 2008). Improving the production system and capacity of agribusiness firm in emerging economy like Nigeria through increase productivity is an important policy goal especially now that agribusiness represents an important sector in agricultural commercialization of the economy. Block (1995) asserted that within the context of growth in food and poverty alleviation, emphasis should be placed on productivity increase arising from output maximization at constant or decreasing input. By extension, indices on productivity increase should be predicated upon maximization of output at minimum input (Nto and Mbanasor, 2008). This becomes necessary following the 29% productivity decline in individual agribusiness firms and 2.5% average annual decrease contrary to the targeted average annual productivity increase of 6% (Vallano et al. 2005; FARA, 2006 and Prasada-Rao et al. 2004)

Methodology
The study was carried out in Ikwuano Local Government Area of Abia State, Nigeria. Ikwuano is approximately 14km away from the state capital, Umuahia town. Ikwuano lies between latitude 5.5 N and longitude 7.5 E. Ikwuano is made up of four major historic clans: Ibere, Oloko, Ariam and Oboro, from which the existing autonomous communities and villages come from. In the first stage,

two of the historic clans namely Ariam and Oboro were randomly selected from the Local Government Area. In the second stage, three autonomous communities from each clan's communities were randomly selected. In the third stage, 2 villages were selected from the selected autonomous communities respectively. Finally, from the selected autonomous communities, five agribusiness entrepreneurs were randomly selected from each village, given a total of 60 respondents for the study. Primary data was obtained using a well-structured questionnaire. Descriptive statistics like frequency, percentages and means were used for data analysis

Results and Discussion

The age distribution of the farmers in Ikwuano Local Government Area is shown in Table 1. The results show that 6.67% of the respondents were below 21yrs old and between 41-50 and 51-60yrs each. About 38.3% and 31.7% were within the age ranges of 21-30 and 31-40yrs respectively. The mean age of the respondents was 42.5 years. This is an indication that the farmers in the study area were mostly middle aged within the active productive work force. This has implication on agricultural production because of the ability of this segment of the population to effectively withstand the rigors, strain and stress involved in agricultural production. This is in line with the findings of Onyenucheya (2007). The table shows that majority (71.7%) of the farmers in the study area were married while 23.3 % of them were single. Also, 3.3% and 5.0% of them were widowed and divorced respectively. This therefore implies that the married were more involved in farming because of the need to supplement the family's means of livelihood (Adegboye *et al*, 2008). A mean was 4 persons was obtained for household. The economic implication is that it will provide the agribusiness enterprises with family labour and reduce cost of production, marketing and increase their revenue. This corroborates Adegbite and Oluwalana (2004), that a relatively large household size may likely enhance family labour supply. The Table revealed that majority (90%) of the farmers had formal school education while 10.0% of them had no formal education. Possession of literacy (ability to read and write) would enable the farmers to better utilize effectively and efficiently whatever available resources in the area and curtail frivolous spending. As expected, higher education would enhance improved technology adoption hence increased farm income (Njoku and Odii 1991; Ezeh, 2007). On average the farming household spent about 12years in farming. The result has some positive implications on increased output of the farmers because according to Nwaru (2004), as the number of years a farmer has spent in farming business may give an indication of the practical knowledge he has acquired on how he can overcome certain inherent farm production problems. Also it has been noted that farmers would count more on their farming experience for increased productivity rather than educational attainment. (Olomola 1988; Obasi, 1991 and Nwaru 1993).

Table 1: Distribution of the Respondents according to Socio-economics characteristics

Age (years)	Frequency	Percentage
Less than 21	4	6.7

Source: Field survey data 2018

Analyses of constraints faced by the respondents are shown in Table 2. A 5 point likert scale was used to analyze the respondents' opinions on the selected constraints of agribusiness enterprises. An average rate of 3.00 was used to indicate that the constraints are important. Results show that inadequate capital (4.40) on the average was the most important constraint militating against agribusinesses in the study area. Inadequate capital has been a hindrance for participation in agribusinesses among the entrepreneurs in the study area. As a result of the problems bedeviling credit assessment, entrepreneurs found it difficult to obtain credit from commercial banks for investment. This was followed by lack of appropriate technology (4.33), high transportation cost, poor policy articulation, inadequate infrastructure, inadequate market information and no incentives with rating means of 3.63, 3.50, 3.83 and 3.25 respectively. These indicates that they were all important factors militating against agribusinesses in the study area

Table 3: Constraints Militating against Agribusiness Enterprises in the Study Area

CONSTRAINTS	SA	A	D	SD	UD	N	MEAN	REMARK
Poor Policy Articulation:	20	16	11	8	5	60	3.63	Accepted
Inadequate Working Capital:	32	22	4	2	0	60	4.40	Accepted
Lack of Appropriate Technology:	31	22	3	4	0	60	4.33	Accepted
Inadequate Infrastructure:	15	14	20	8	3	60	3.50	Accepted
High transportation cost	32	14	4	6	4	60	4.07	Accepted
Inadequate market information	22	22	3	10	3	60	3.83	Accepted
No incentives	10	15	21	10	4	60	3.25	Accepted

Source: Survey Data, 2018

Conclusion

The study investigated the constraints and socioeconomic attributes of agribusiness entrepreneurs in Ikwuano LGA, Abia state. The result shows majority of the entrepreneurs were still young and active, married, educated with large household sizes and long years of agribusiness experience. The most important constraint militating against agribusinesses in the study area was inadequate capital, followed by lack of appropriate technology, high transportation cost, poor policy articulation, inadequate infrastructure, inadequate market information and no incentives. The results therefore call for policies aimed access to credit at little or no interest rates, provision of infrastructure especially good road networks to reduce transactions cost and access to market information especially prices. These will enhance participation and investment in agribusinesses in the study area.

Abstract
The study analysed the comparative analysis of the economics of Rainy and Dry Seasons' fluted pumpkin production in Bende local government of Abia State, Nigeria. A two-stage sampling technique was employed to select 60 farmers who produce fluted pumpkin during rainy and dry seasons in the study area. Data were analyzed using frequency counts, percentages, means and budgetary technique. The result of the socioeconomic characteristics showed that majority of the farmers were females, whom were married and educated with a mean age of 39.8 years, household size of about 6 persons and farm size of 1.01 hectares. Also, majority (75%) of the fluted pumpkin farmers had no access to credit, while 58.3% were members of different cooperative societies with mean farming experience of 13.8 years. The results of the costs and returns of the fluted pumpkin farmers gave net profit of ₦24894.2 and ₦38010.84 for rainy and dry season fluted pumpkin respectively. The benefit cost ratio per 0.5 hectare of fluted pumpkin production were ₦1.69 and ₦1.95 for rainy and dry season respectively which indicates that for every ₦1 invested in fluted pumpkin production, the farmer realizes ₦1.69 and ₦1.95for rainy and dry season respectively. The major constraints to fluted pumpkin production during the rainy season were lack of storage facilities, poor price, insufficient land and post-harvest losses due to perishable nature of the produce while lack of irrigation facilities, poor weather, high cost of labour, pest infestation and poor access to credit were the major constraints militating against dry season fluted pumpkin production in the study area. The study recommends that massive dry season fluted pumpkin production should be intensified through provision of low-cost irrigation facilities to women farmers in order to increase production and income.
Keywords: Dry and Rainy Season, Fluted Pumpkin, Cost and Returns

Introduction
Telfairia occidentalis commonly called fluted pumpkin is a tropical vine grown in the rain forest zone of West Africa. It is mainly cultivated as a leafy fluted pumpkin and it is used primarily in soups and herbal medicines or pot herbs. The consumption of fresh, green and yellow fluted pumpkins is generally inadequate. FAO (2009) reported that some 60% of the households in less developed countries derive more than 80% of the calories from cereals, starchy, root and sugar, implying that some 60% of households in these part of the World live on diets which are inadequate in nutritional quality, but fluted pumpkins are rich in vitamins and minerals, they also add to the bulk of the diet and help the body to achieve smooth digestion of food. Its production is increasingly recognized as a means of increasing foreign earning, (AVRDC, 2004). Apart from the income generating potential of fluted pumpkin production, it equally plays crucial role in off-setting the food budget of households involved. It provides an effective use of marginal lands and is crucial towards hunger reduction, poverty alleviation and promotion of growth and development. In spite of the lofty potential of the fluted pumpkin, its supply can barely match the growing consumption of the Nigeria populace. Per capita fluted pumpkins and fruits intake in Nigeria is still less than the 400g per day recommended by the World Health Organization as the minimum requirement for the growth and development of the body (Mirmiran, 2009). Moreover, farmers who depend on fluted pumpkin as a source of livelihood still live on low and unstable incomes. In Nigeria, there are two distinct seasons for fluted pumpkin production, the peak and the lean seasons. During the lean (dry) season, fluted pumpkins are produced in low quantities, scarce and expensive to get. In the peak (peak) season, it is produced in large quantities much more

than what the local populace can consume (Farinde, *et al.,* 2009). However, despite the favorable features of rainy season fluted pumpkin production there have not been established clear cut evidence as to whether the highest income is being made in this season or during the dry season. The knowledge of when the highest production is made in this area is important to take care of the patterning of fluted pumpkin production, bearing in mind the lean and peak period that will serve as a base for policy making. From the above deduction this study estimated the costs and returns associated with dry and rainy season fluted pumpkins production in the study area and identified factors militating against dry and rainy season fluted pumpkin production in the study area

Methodology

The study was conducted in Bende Local Government Area (L.G.A) of Abia state. Bende Local Government is composed of thirteen (13) communities, namely: Alayi, Bende, Ezukwu, Igbere, Item, Itumbuzo, Nkpa, Ntalakwu, Ozuitem, Ugwueke, Umu-imenyi, Umuhu-Ezechi, and Uzuakoli. The population of Bende LGA according to the 2006 population census was 192,621 persons (NPC, 2006). Bende L.G.A has agric-climatic conditions typically of the tropics. Bende is bounded in the north by Cross River State, Afikpo and Ohaozara, and in the South by Arochukwu and Ohafia, while in the East and West by Ikwuano L.G.A. and Umuahia L.G.A respectively. Agriculture is widely the occupation of the people and it a major fluted pumpkin producing area in Abia state.

Two-stage sampling techniques were used in selecting the respondents used for the study. In the first stage, 3 communities namely; Bende, Umu-imenyi, and Umuhu-Ezechi were randomly selected. The second stage involved listing of all the fluted pumpkin farmers from the 3 communities which formed the sampling frame from which 20 fluted pumpkin farmers were randomly selected in each chosen community to give a sample size of 60 respondents.

Data were collected by the use of structured questionnaire administered to the respondents and interview schedules and relates to the 2017 cropping season. Data were analyzed using frequency counts, percentages, means and budgetary technique. The models are specified as follows:

$$\text{Net Profit} = \pi = TR - (TFC + TVC) \quad (1)$$

Where π	=	profit
TR	=	Total revenue
TFC	=	Total fixed cost
TVC	=	Total variable cost

$$\text{Return on Investment} = \frac{Revenue}{Total\ Cost} \quad (2)$$

Results and Discussion

Socio-economic Characteristics of Respondents in the Study Area

The socio-economic profile of dry and rainy season fluted pumpkin farmers is shown in Table 1. The analysis of the socio-economic characteristics of fluted pumpkin farmers in the study area show that majority (76.7%) of the farmers were females, while 23.3% where males. These indicate that female seem to dominate fluted pumpkin farming in the study area. The distribution of the respondents based on age showed that 50% of the farmers were between the age ranges of 36-45 years, 33.3% were between the age range of 26-35 years while 10% and 6.7% were between the age range of 46-55 and 56-65 respectively. The mean age of the farmers was 39.8 years indicating that fluted pumpkin farmers in the study area were young and still in their productive age. The distribution of the respondents based on their marital status showed that majority (70%) of the fluted pumpkin farmers were married while 18.3% and 11.7% were single and widowed respectively. The distribution of the respondents based on their level of education showed that 46.7% of the farmers had secondary education, 26.7% had primary education while 21.7% had tertiary education. Five percent of the farmers had no formal education in the study area. The mean years spent in school of the farmers was 12.8 years indicating that majority of the farmers were literate and that level of education may have helped them the choice of cultivating fluted pumpkin both in dry and rainy season.

Table: 1: Socio-economic Characteristics of respondents in the study Area

Variable	Dry and Rainy Season Fluted pumpkin Production		
	Frequency	Percentage	Mean
Sex (HH Head)

Source: Field Survey, 2017

This result is in line with (Ironkwe *et al.,* 2007 and Adekunmi *et al.,* 2017) who separately asserted that education increases the ability of the farmers to understand and evaluate new production techniques. The distribution of the respondents based on their household size showed that 40% of the fluted pumpkin farmers had a household size of between 4-6 persons, 33.3% had between 7-9 persons while 26.7% had between 1-3 persons. The mean household size was about 6 persons indicating that the farmers in the study area had a moderate household size that could help in supplying the needed labour for both dry and rainy fluted pumpkin farming. This might have implication for available family labor force. The distribution of the respondents based on their farm size showed that 50% of the farmers farmed between 0.1-0.5 hectare of land for both dry and rainy season fluted pumpkins, 33.3% farmed between 0.6-1.0 hectare of land, while 16.7% farmed between 1.1-1.5 hectares of land for both dry and rainy season fluted pumpkins in the study area. The mean farm size was 1.01 hectares. The distribution of the respondents based on their access to credit showed that majority (75%) of the fluted pumpkin farmers had no access to credit while 25% had access to credit. The distribution of the respondents based on their membership of cooperative society showed that majority (58.3%) of the fluted pumpkin farmers were members of cooperative society why 41.7% were non- members of cooperative societies in the study area. The distribution of the respondents based on their farming experience showed that 41.7% had between 10-16 years' experience in fluted pumpkin farming, 35% had between 4-9 years' experience in fluted pumpkin farming while 23.3% had between 17-22 years' experience in fluted pumpkin farming in the study area. The mean farming experience was 13.8 years, which implies that the farmers had gotten considerable farming experience. Farmers experience is expected to have a considerable effect on farmer's productive efficiency

Cost and returns Analyses of 0.5 hectare dry and rainy season fluted pumpkin (Telferia) production

The cost and returns analyses of dry and rainy season fluted pumpkin production in the study area is presented in Table 2

Table 2 Costs and Return Analysis of Dry and Rainy Season Fluted pumpkin Production in Ikwuano LGA

Item/Operation	Rainy Season Fluted pumpkin			Dry Season Fluted pumpkin		
	Quantity	Price	Value	Quantity	Price	Value

Return on Investment			1.69			1.95

Source: Field Survey, 2018.

To realize profitability of fluted pumpkin production, a specific unit of land (0.5 hectare) was used to compute cost and returns of fluted pumpkin production among the farmers in both rainy and dry seasons for 2017 cropping season. The variables considered and used for comparison in both rainy and dry season fluted pumpkin production were yield, revenue, variable cost, net profit and benefit-cost ratio (BCR). Table 2 showed that the total revenue per 0.5 hectare of land for dry and rainy season fluted pumpkin production were ₦78100 and ₦61100 respectively. The revenue was gotten from the sale of an average of 71 bundles of fluted pumpkin at the rate of ₦1100 per bundle during the dry season while the sale of average of 94 bundles at the cost of ₦650 per bundle during the rainy season. The figures indicate that the revenue generated from fluted pumpkin production during the dry season is higher than that obtained during rainy season, although higher yield is obtained during rainy season. This implies that fluted pumpkin production attracts high income in both season but higher price in dry season. The findings are consistent with Bamire and Oke (2003) and Nwalieji *et al.,* (2015) who observed that okra yield was higher during the rainy season, while higher total revenue was obtained under dry season conditions. The total mean variable cost for fluted pumpkin production during rainy season cropping was ₦27114.65 while that of dry season was ₦30751.36. This implies that the cost incurred by farmers in fluted pumpkin production in 0.5 hectare during dry season cropping is higher than that of rainy season; the high variable cost during the dry season is attributed to the cost of irrigation that is not applied during the rainy season. The mean total fixed cost for fluted pumpkin production per 0.5 hectare of the farmers during the rainy and dry seasons were ₦9091.15 and ₦9337.8 respectively while the total cost were ₦36205.8 and ₦40089.16 for rainy and dry season fluted pumpkins respectively. The result of the net profit for fluted pumpkin production per 0.5 hectare showed a net profit of ₦24894.2and ₦38010.84 for rainy and dry season fluted pumpkin respectively. The benefit cost ratio of fluted pumpkin production were ₦1.69 and ₦1.95 for rainy and dry season respectively which indicates that for every ₦1 invested in fluted pumpkin production, the farmer realizes ₦1.69 and ₦1.95for rainy and dry season respectively. This implies that fluted pumpkin production during the dry season is though cost ineffective but attract high market price than the rainy season fluted pumpkin production, hence the reasons for engaging in the production as it can serve to supplement farm income during the off-season. This is in agreement with Alimi (2005) and Nwalieji *et al.,* (2015) which observed that mono-cropped okra production was profitable in both seasons, but profits were higher in the dry season. Also, in line with this, Edet and Etim (2010) indicated from profit analysis carried out that okra production is profitable with an average profit of N35, 781.7 per hectare; and commends a high market price in Nigeria markets because it features daily in the diets of most Nigerians.

Constraints Militating Against Dry and Rainy Season Fluted Pumpkin Production in Bende LGA

The constraints militating against dry and rainy season fluted pumpkin production is presented in Table 3.

Table 3: Distribution of respondents on the basis of constraint encountered in different season

Constraints	*Rainy Season	*Dry Season
Lack of Storage Facilities	45 (75)	3 (5)
Disease infestation	18 (30)	3 (5)
Pest infestation	6 (10)	21 (35)
High cost of labour	10 (16.7)	24 (40)
Poor price	30 (50)	0 (00)
Poor Weather	6 (10)	25 (41.7)
Insufficient land	26 (43.3)	8 (13.3)
Post-harvest losses due to perishable nature of produce	22 (36.7)	2 (3.3)
Poor access to credit	21 (35)	21 (35)
Poor extension contact	15 (25)	15 (25)
Lack of Irrigation Facilities	0 (00)	48 (80)

Source: Field Survey, 2018, *Multiple response Note, figures in parenthesis are percentages

Table 3 shows the percentage distribution of the identified constraints militating against dry and rainy season fluted pumpkin production in the study area. The result showed that lack of storage facilities, poor price, insufficient land; post-harvest losses due to perishable nature of the produce and poor access to credit were the major constraints militating against rainy season fluted pumpkin production in the study area, while lack of irrigation facilities, poor weather, high cost of labour, pest infestation and poor access to credit were the major constraints militating against dry season fluted pumpkin production in the study area The findings on constraints facing fluted pumpkin farmers are in line with Onuk *et al.,* (2010) who stated that farmers are generally faced with constraints that can limit production. Also, Edet and Etim (2010) identified insect and disease attack, lack of storage facilities, lack of improved varieties of seeds, insufficient capital, lack of extension agents' visit and lack of government assistant as major constraints that affect okra production. The implication of this according to Farinde, Owolarafe and Ogungbemi (2009) is that production of fluted pumpkin will remain stagnant due to the many identified constraints.

Conclusion

Women highly engaged in both rainy and dry season fluted pumpkin production enterprises as major source of income. Also, the results of the profitability analysis for fluted pumpkin production per 0.5 hectare of the farmers during 2017 rainy and dry season cropping showed that fluted pumpkin production in both seasons is profitable and lucrative, but more in dry season. Lack of irrigation facilities, poor weather, high cost of labour, pest infestation and poor access to credit were the major constraints militating against dry season fluted pumpkin production in the study area while lack of storage facilities, poor price, insufficient land, post-harvest losses due to perishable nature of the produce and poor access to credit were the major constraints militating against rainy season fluted pumpkin production in the study area. It is recommended that efforts be geared toward making fluted pumpkin production more viable and lucrative in the study area.

This could be done by educating women farmers on how to increase their productivity, income and sales through extension services. Also massive dry season fluted pumpkin production should be intensified through provision of low-cost irrigation facilities to women fluted pumpkin farmers in order to increase production and income. There is also the need for women to have good access to loan facilities with low interest rate in order to motivate them into practicing commercialized fluted pumpkin farming. This should be made available to them by stakeholders such as governments, CBN, donor agencies, etc. through formation of viable co-operatives.

Effect of Different Mulch Materials (*Azardirachta indica*, *Gmelina arborea* and *Chromolaena odorata*) on the Yield of Sweet Potato (*Ipomoea batatas*)

R. B. Balogun, H. Terdoo, and A. Emegha
Federal College of Agriculture, Ishiagu; Ebonyi State
Corresponding author e-mail: balogunrb@gmail.com

Abstract
A field study was conducted at the research site of Federal College of Agriculture, Ishiagu in 2017 with the objective of comparing the effect of three different source of mulch materials (Azardirachta indica, Gmelina arborea Chromlaena odorata) on the yield of sweet potato (Ipomoea batatas). The mulch materials were T_1 - Azardirachta indica, T_2 - Gmelina arborea, T_3 - Chromolaena odorata and T_4 - control. The treatments were replicated four times each using Randomized Complete Block Design (RCBD). The research work lasted for a period of four months. The analysis of variance indicated that there were significant difference ($P<0.05$) among the treatments and between the parameters measured. Treatment 1 and 3 indicated an improved yield than control and treatment 2. It was recommended that mulching materials should be used in crop production since it significantly improve yield.
Keywords: mulching, yield, and sweet potato

Introduction
Sweet Potato is among the world most cultivated food crop, it is socially accepted across the globe without any cultural or religious inhibition, easy to cultivate and mature within a space of time unlike other staple crops (FAOSTAT, 2010). The sweet potato's biggest draw is its impressive concentration of caroteniods, which are colourful pigments that our bodies can convert into the important antioxidant vitamin A. It is a source of manganese which plays a major role in metabolism of carbohydrate that supports healthy blood sugar level. It also contains much fibre which helps to prevent constipation. It is also rich in vitamin C and E which potent antioxidant vitamins that play an important role in disease prevention and longevity (Collins, 1993, Cabanilla, 1996; Jasson, and Kanan, 1991). Most often poor soil nutrient hamper good yield and effort to intensify the use of synthetic fertilizers and agrochemical is being discourage because of their toxicity to the ecosystem and the consuming public. Production effort globally is tending toward sustainable agriculture which emphasizes among others the use of organic sources of soil amendment and as pesticides. Towards this end, this study would be focusing on the effect of different source of mulch materials on the yield of sweet potato so as to determine the best mulch materials that can be recommended to farmers who engage in sweet potato production.

Materials and Method
Study Area
The research farm of Federal College of Agriculture, Ishiagu lies within latitude $05^{o}56^{1}$N and longitude $07^{o}41^{1}$E in the derived savanna zone of Southeastern Nigeria. The area has a tropical wet and dry climate with a mean temperature and rainfall of 30^{o}C and 1539mm.
Experimental Materials
The experimental material includes the test crop: Sweet potato (*Ipomoea batatas*) vines from National Root Crops Research Institute (NRCRI), Umudike.
T_1-Neem leaves (*Azardirachta indica*), T_2 - Gmelina leaves (*Gmelina arborea*)
T_3 - Siam weed (*Chromolaena odorata*), T_4 - Control
Experimental design used was Randomized Complete Block Design (RCBD) with the treatment replicated four times.

Agronomic Practices
The project site was cleared with cutlass, the debris removed with rake and the land was tiled with West African hoe to the required measurements. The manure was incorporated on the beds and allowed to cure for one week as a basal application on the 16 beds. The mulch materials were also incorporated on the beds at the rate of 12kg per bed in a Randomized Complete Block Design (RCBD). The potato vines were planted one week after the incorporation of the treatments (mulch materials); *Azardirachta indica*, *Gmelina arborea* and *chromolaena odorata*. The potato vines were planted at a planting distance of 50cm by 50cm. Weed control was done with the aid of weeding hoe with frequent inspection of the project site. Pest and disease was controlled biologically. Harvest was done manually with hand.

Parameters to be measured
Data were collected on the following:

- Vine length at 2, 3, 4, 5, 6, 7 and 8 Weeks after Planting (WAP).
- Number of leaves at 2, 3, 4, 5, 6, 7 and 8 Weeks after Planting (WAP).
- Weight of tubers at harvest (kg).

Data Analysis
Data collected were subjected to statistical analysis using analysis of variance ANOVA, according to the procedure for the RCBD as described by GENSTAT 37.2 edition. The significant means were separated using LSD at 5% level of significance or 0.05 probability level or 0.05%.

Results and Discussion

Mean Number of Leaves of Sweet Potato
Table 1 shows the effect of the treatments on the mean number of leaves of sweet potato at 2, 3, 4, 5, 6, 7 and 8 weeks after planting. The analysis of variance also indicated that there were significant difference ($P<0.05$) among the treatments.

Table 1: The Effect of the Treatments on the Mean Number of Leaves of Sweet Potato

	Treatment				
Weeks	T1	T2	T3	T4	LSD
2 WAP	23.63	8.81	7.88	7.13	5.16
3 WAP	28.06	16.75	14.88	13.00	2.63**
4 WAP	36.38	25.50	23.44	13.00	2.34***

Mean Weight of Tubers at Harvest (kg)
Table 3 shows the effect of the treatments on the mean weight of tubers of sweet potato. The analysis of variance also indicated that there were significant difference ($P<0.05$) among the

treatments. This result is in line with similar study from Nunez, (2013), Maduakor *et al*., (1984) and Collins, (1994).

Table 3: The Effect of the Treatments on the Mean Weight of Tubers (kg)

Treatment	Mean
T1	8.68
T2	4.60
T3	6.55
T4	2.98
LSD	1.57***

Conclusion

Azardirachta indica mulch (T_1) gave the highest mean weight of 8.68kg, followed by *Chromolaena odorata* mulch (T_3) with 6.55kg followed by *Gmelina arborea* mulch (T_2) with 4.60kg. The control (T_4) gave the least mean weight of 2.98kg. The results of this study indicated that mulching materials are useful in improving the soil fertility and subsequently crop yield. Based on the finding of this study, it is recommended that mulching materials should be used in crop production since it significantly improve crop yield.

Abstract
A field experiment was carried out to evaluate the effect of five levels of potassium (0, 15, 30, 45, and 60 kg K/ha) on the vegetative, yield parameters and protein contents of soybean. The experiment was a 3 x 5 factorial experiment arranged in a randomized completed block design and replicated three times; the factors are five levels of potassium using muriate of potash and the three cultivars of soybean (TGX1987-62F, TGX1835-10E and TGX1910-14F). The results showed that the highest plant height (37.1 cm) and highest number of leaves (29.2) obtained at 8 weeks after planting (WAP) when 30 kg K/ha was applied were not significantly different from other means. The highest mean pod weight (1827 kg/ha) was obtained when 30 kg K/ha was applied. The highest nitrogen content (6.6%) and potassium content (2.1%) was obtained when 15 kg K/ha was applied while the highest calcium content was obtained when 0 and 60 kg K/ha was applied. Potassium application at 15 kg K/ha gave the highest percentage of protein content of 41.4%. In conclusion, TGX1910-14F treated with 15 kg K/ha in the trial location maximized the productivity and nutritional quality of soybean.

Introduction
Constraint analyses have indicated that unbalanced soil nutrition is one of the most important reasons of low productivity (Sharma *et al.,* 1996; Tiwari, 2001). Soybean meal is preferred livestock feed because of its high protein content and low fiber content. Oil from soybean is mainly used by food processors in baked and fried food products or bottled into cooking oil (US soybean Export Council, 2008). Young seedlings of soybean do not use K, but the rate of uptake climbs to a peak during the period of rapid growth. The K in vegetative parts is transferred to seed during pod fill process. The matured soybean seed contains nearly 60% of the total K in plant (Hoeft *et al.,* 2000). The K concentration in soybean plants decreases near maturity and any deficit of K during the late vegetative and reproduction stages is going to reflect on yield of soybean. The uptake of nutrients by crop per unit weight of soil and the dry matter produced may be affected by climatic factors. For example, K uptake in the seedlings will be greater with the higher water supply, the proportional (%) increase differing with the nutrient (19–77%) in the general order Ca > K, Mg > P > N. (Beaton and Speer, 2006). Also, the potential yield will be reduced by either low temperatures which restrict vegetative growth or by high temperatures which prevent flower production (Menzel *et al*., 1998). Thus, the objectives of this research are; to determine how five different rates of potassium fertilizer applied on the three soybean cultivars will influence the vegetative growth, yield and most importantly their N, K and Ca contents.

Materials and Methods
The experiment was carried out at the Teaching and research Farm of the Faculty of Agricultural Sciences, Ladoke Akintola University of Technology, Ogbomoso, Oyo state, Nigeria during the cropping season in 2016. Ogbomoso lies on the longitude 8° 10′ N and latitude 4° 10′ E and the temperature in the area ranges from 28°C to 33°C with relative humidity of about 74% all year found except in January when the dry wind blows from the north. The annual rainfall is about 1000

mm and is bimodal in pattern (Okotete, 2008; Oni *et al.,* 2015). The experiment was a 3 x 5 factorial experiment arranged in a randomized completed block design and replicated three times The factors are three cultivars of soybean (V1 – TGx 1987-62F medium maturing, V2 – TGx 1835-10E early maturing and V3 – TGx 1910-14F late maturing) sourced from the International Institute of Tropical Agriculture (IITA), Ibadan, and five rates of potassium application (0, 15, 30, 45 and 60 kg K/ha). Beds of 3 m by 2 m were made for each treatment plot and 15 treatment plots per replicate. Each treatment plot has 50 cm inter row spacing and 25 cm intra row spacing giving a total of 65 stands per treatment plot. Five plants were randomly selected from the net plot in each plot and tagged for the growth and yield data that were taken which include; number of leaves, plant height, dry pod weight, seed weight and shelling %. Nitrogen, Potassium and Calcium contents of the matured seeds for each variety were determined. Daily temperature and precipitation for the planting period were also recorded using the HOBO-Automatic weather station located about 100 m away from the experimental plot.Data collected were subjected to the analysis of variance (ANOVA) and means were separated using Least Significant Difference at 5% probability level.

Results and Discussion

Effect of level of potassium on growth parameters of soybean cultivar

Soybean variety and levels of potassium applied had no significant effect on the plant height (Table 1). Plant height at 0 kg K/ha was not significantly different compared with all others for the same cultivar. However, there was significant interaction between potassium level of K and variety on plant height. For instance at 8 WAP, the tallest plant height obtained from TGX 1987-62F (37.2 cm), TGX 1835-10E (42.1cm) and TGX 1910-1 (43.1 cm) were obtained when 30, 15, and 45 kg K/ha respectively were applied. The number of leaves data followed similar trend. This is in agreement with observation of Hungria and Franchini, (2000) that plant height of soybean responded to potassium application level. Also, Priyadharsh and Seran, (2009) who reported that 30 kg K/ha had the highest number of leaves for soybean.

Effect of potassium application on yield and yield parameters of soybean cultivars

The yield performance of TGX 1910-14F was significantly better than others. It produced the highest pod (2,984.9) and seed (1,542.9) weight per hectare (Table 2). The least production was obtained from TGX 1987-62F soybean cultivar treated with control (0 kg K/ha). The result presented in Table 3, showed that nitrogen (N) contents of soybean seed at different potassium rates were not significantly different from each other. The highest N content (6.6%) was obtained when 15 kg K/ha was applied while 60 kg K/ha gave the lowest N content (6.1%). The calcium (Ca) contents of soybean seed at different potassium rates were not significantly different from each other. The highest Ca content (3.1%) was obtained at 0 and 60 kg K/ha while 30 kg K/ha gave the lowest Ca content (2.7%). Also, the potassium rates had no significant effect on potassium (K) contents of soybean seed. The highest K content (2.1 %) was obtained at 0, 15 and 30 kg K/ha which were not significantly different from other treatments.

Climatic parameters of the experimental site in 2016

Daily record of solar radiation (SRAD), maximum temperature (Tmax), minimum temperature (Tmin) and rainfall during the 2016 growing season were recorded (Table 4). The result shows the average monthly record for each data. The seed received enough irradiation for germination (May) and there was no water stress during the flowering (June) seedling (July) periods.

Conclusion

In conclusion, each cultivar of soybean responded differently to levels of potassium tried. Planting of TGX1910-14F with application of 15 kg K/ha in the trial location maximized the productivity and nutritional quality of soybean.
